## 9. Child health

Overall, 84 individual studies examined the effect of pesticide exposure on child health outcomes (median sample size: 267; IQR 119-811), contributing 821 separate analyses in the data extraction database. More than 120 health-related outcomes were assessed with a large proportion focusing on congenital malformations and developmental parameters including but not restricting to somatometrics (Table 10). As seen with other outcomes, the diversity of the exposure definition is remarkable and poses special challenges to data synthesis. Only 38 out of the 84 were prospective cohort studies and other 5 were nested case-controls; the majority of evidence comes from retrospective case-control analyses, which are prone to recall bias in exposure measurement. The sample size in the reported analyses was often small; it ranged between 23 and 183,313 participants (median 267) and the largest studies in the domain are smaller than the largest studies assessed in the cancer field. Here, we observed no large clusters of publications coming from large, well-known studies in the field, such as the Agricultural Health Study (AHS), while 26 studies assessed occupational exposures. In addition, the presence of studies with information on biomarkers of exposure was more prominent here (n=49, 58%) while 3 studies assessed occupational exposure through JEM. The different outcome categories examined are presented in Table 10 along with the number of studies contributing to each outcome category and a decision on quantitative synthesis (Table 11). Due to heterogeneity of data and small number of studies identified, statistical synthesis of the data (meta-analysis) was only performed for urological malformations only.

## 9.1. Prematurity

Fifteen studies assessed the association between pesticide exposure during pregnancy and prematurity with a median sample size of 193 (IQR 87-469), contributing 54 separate extracted comparisons in the database. More than half of the studies were retrospective and in more than three-fourths of the studies, the exposure was assessed through a biomarker. A large variety of individual pesticides were assessed with DDT metabolites being assessed more frequently (8 studies). Nevertheless no single pesticide and related biomarker was assessed in more than 4 studies using the same comparison unit, thus a quantitative synthesis was not performed. The largest prospective study (ID CH 091) assessed a Dutch population of greenhouse workers and reported a decreased risk of preterm birth among male greenhouse workers (OR= 0.47; 95%CI= 0.35–0.65) while the observed increased risk in women was not statistically significant (OR= 1.14, 95%CI= 0.57–2.31). The remaining studies reported statistically non-significant results with effect estimates pointing towards a positive association. Moreover, no meta-analysis of published studies was identified. Based on these data, there is no recent evidence to suggest a robust, clinically significant association between pesticide exposure and prematurity in general.

#### 9.2. Restricted fetal growth

Twelve studies assessed the association between pesticide exposure during pregnancy and restricted fetal growth and/or small for gestational age neonates with a median sample size of 422 (IQR 178-1,630), contributing 44 separate extracted comparisons in the database. Sixty percent of the studies were prospective, three assessed occupational exposure and in more than two-thirds of the studies, the exposure was assessed through a biomarker. A large variety of individual pesticides were assessed with DDT metabolites being assessed more frequently (4 studies). Nevertheless no single pesticide and related biomarker was assessed in more than 4 studies using the same comparison unit, thus a

EFSA supporting publication 2013:EN-497

The present document has been produced and adopted by the bodies identified above as author(s). This task has been carried out exclusively by the author(s) in the context of a contract between the European Food Safety Authority and the author(s), awarded following a tender procedure. The present document is published complying with the transparency principle to which the Authority is subject. It may not be considered as an output adopted by the Authority. The European Food Safety Authority reserves its rights, view and position as regards the issues addressed and the conclusions reached in the present document, without prejudice to the rights of the authors.

quantitative synthesis was not performed. The largest study (ID RPD 26) assessed in a retrospective cohort whether atrazine in drinking water is associated with increased prevalence of small-for-gestational age and preterm birth. The authors reported that atrazine in drinking water during the third trimester and the entire pregnancy was associated with a significant increase in the prevalence of SGA (Small for Gestational Age); atrazine in drinking water > 0.1 µg/L during the third trimester resulted in a 17–19% increase in the prevalence of SGA compared with the control group (< 0.1 µg/L). All the remaining studies reported statistically non-significant results without a consistent pattern regarding the effect direction of the effect magnitude. Moreover, no meta-analysis of published studies was identified. Based on these data, there is no recent evidence to suggest a robust, clinically significant association between pesticide exposure and prematurity in general.

## **9.3.** Somatometrics (Body size metrics)

Numerous studies examined the association between pesticide exposure and growth.

# 9.3.1. Birth length / Height

Length at birth and height was assessed in 13 and 8 studies, respectively, contributing 78 separate comparisons in the database. In the vast majority of the studies, the exposure was assessed through a biomarker. A large variety of individual pesticides were assessed with DDT metabolites being assessed more frequently; nevertheless no single pesticide and related biomarker was assessed in more than 4 studies, thus a quantitative synthesis was not performed.

The largest prospective study (ID CH 073) assessing a North American population born before 1980, reported that only the highest prenatal concentrations of p,p'-DDE (>60 mg/l), as compared with the lowest (<15 mg/l), were statistically significantly associated with decreased height at age 7 years [adjusted coefficient (SE) -2.21 cm (0.67)]. The remaining studies reported conflicting results without a consistent pattern either towards the effect direction or the effect magnitude. Moreover, no meta-analysis was identified. Given the large number of analyses these results need cautious interpretation and, based on these data, there is no recent evidence to suggest a robust, clinically significant association between pesticide exposure and birth length or height in general.

# 9.3.2. Body weight

Twenty-six studies assessed the association between pesticide exposure during pregnancy and birth weight, contributing 134 separate extracted comparisons in the database. Another 5 studies assessed the association between pesticide and ponderal index. In a large number of comparisons, the exposure was assessed through a biomarker. A large variety of individual pesticides were assessed with DDT metabolites being assessed more frequently (11 studies). Nevertheless no single pesticide and related biomarker was assessed in more than 4 studies using the same comparison unit, thus a quantitative synthesis was not performed. The largest prospective study (ID CH 014) was a Agricultural Health Study (AHS) publication and reported that first-trimester pesticide-related tasks were not associated with birth weight and that, after multiple analyses, ever use of the pesticide carbaryl was associated with decreased birth weight (-82 g, 95% CI = -132, -31). The remaining studies reported conflicting results without a consistent pattern either towards the effect direction or the effect magnitude. Moreover, no meta-analysis of published studies was identified. We identified though a meta-analysis of individual participants data from European cohorts which reported that a  $1-\mu g/L$  increase in p,p'-

EFSA supporting publication 2013:EN-497

The present document has been produced and adopted by the bodies identified above as author(s). This task has been carried out exclusively by the author(s) in the context of a contract between the European Food Safety Authority and the author(s), awarded following a tender procedure. The present document is published complying with the transparency principle to which the Authority is subject. It may not be considered as an output adopted by the Authority. DDE was associated with a 7-g decrease in birth weight (95% CI= -18, 4 g) (Govarts E 2012). Given the large number of analyses these results need cautious interpretation and, based on these data, there is no recent evidence to suggest a robust, clinically significant association between pesticide exposure and birth weight in general.

Twenty-six studies assessed the association between pesticide exposure and body weight at various time-points after birth, contributing 68 separate extracted comparisons in the database. In almost 85% of the assessed comparisons, the exposure was assessed through a biomarker. A large variety of individual pesticides were assessed with DDT metabolites being assessed more frequently (10 studies). Nevertheless no single pesticide and related biomarker was assessed in more than 4 studies using the same outcome definition, the same time-point for the outcome assessment, the same pesticide, and the same comparison unit, thus a quantitative synthesis was not performed. The largest study (ID CH 074) assessing DDT exposure in a Mexican population of boys born in 2002 and 2003, reported that, overall, associations between prenatal DDE level and Body Mass Index (BMI) at any given age were not observed and that the predicted values showed that children with the highest exposure (DDE: 49.00 mg/g) compared to those least exposed (DDE: <3.01 mg/g) grew similarly and they had a BMI similar to the referent group. The remaining studies reported conflicting results without a consistent pattern either towards the effect direction or the effect magnitude. Moreover, no meta-analysis was identified. Given the large number of analyses these results need cautious interpretation and, based on these data, there is no recent evidence to suggest a robust, clinically significant association between pesticide exposure and body weight in general.

# 9.3.3. Head circumference

Fourteen and three studies assessed the association between pesticide exposure during pregnancy and head circumference at birth and after birth, respectively, contributing 85 separate extracted comparisons in the database. In more than two-thirds of the comparisons, the exposure was assessed through a biomarker. A large variety of individual pesticides were assessed for birth head circumference, with DDT metabolites being assessed more frequently (7 studies). Nevertheless no single pesticide and related biomarker was assessed in more than 4 studies using the same comparison unit, thus a quantitative synthesis was not performed. The largest prospective study (ID CH 026) was a Generation R study publication which explored associations between maternal occupational exposure to various chemicals and fetal growth in 4,680 pregnant women participating in this population-based prospective cohort study in the Netherlands (2002-2006). For fetal head circumference, only maternal occupational exposure to alkylphenolic compounds showed a statistically significant lower growth rate (-0.01752 SD per gestational week) compared with nonexposed mothers, adjusted for potential confounders. The remaining studies reported conflicting results without a consistent pattern either towards the effect direction or the effect magnitude. Moreover, no meta-analysis of published studies was identified. Given the large number of analyses the reported study results need cautious interpretation and, based on these data, there is no recent evidence to suggest a robust, clinically significant association between pesticide exposure and head circumference in general.

# 9.3.4. Congenital malformations

Five studies examined the association between pesticide exposure and congenital malformations in general. The largest study (ID CH 002) assessed a Canadian farm population, reported 146 potential associations, did not yield statistically significant results in the primary analysis and proposed that pre-

conception exposure to cyanazine (OR = 4.99, 95% CI: 1.63-15.27) and dicamba (OR = 2.42, 95% CI: 1.06-5.53) were associated with increased risk of birth defects in male offspring. Nevertheless, given the number of the available comparisons and the self-reported nature of the exposure and outcomes in this study, the present findings should be considered with caution. The remaining four retrospective studies reported conflicting results (ID CH 043, occupational exposure (father), OR: 3.42, 95% CI: 1.97-5.92; ID CH 035, at least one parent exposed, OR = 1.3, 95%CI = 0.4 - 3.9; ID CH 008, HR for maternal urine metolachor, 95% 0.4-1.4). Given the large number of analyses these results need cautious interpretation and, based on these data, there is no recent evidence to suggest association between pesticide exposure and congenital malformations in general.

# 9.3.5. Neural tube defects

Identified studies examined associations between pesticide exposure and neural tube defects (N=4 studies), including an encephaly and spina bifida and providing a very large number of reported analyses between different pesticides and neural tube defects, anencephaly and spina bifida with no adjustments for multiple testing (average 27 analyses per paper). Out of the 134 extracted analyses, 43 were statistically significantly positively associated with the outcome (of which 14 borderline significant) but need to be interpreted with caution due to high false positive probability. The range of different pesticides analysed by each of the 5 studies as well as the varying definitions of pesticide exposure do not allow for a meaningful quantitative synthesis of the results even using the "any pesticide" exposure definition since there is also considerable heterogeneity between studies regarding the exposure period as well as the parent analysed; three studies assessed maternal exposure, one study assessed paternal exposure and one study both. Previous meta-analyses on neural tube defects and pesticide exposure have not been identified. Overall, the evidence for pesticides and neural tube defects is limited and the current state of the most recent literature does not support a robust association. Of note, the largest study in the field (ID CH 044) investigated whether maternal residential proximity to applications of specific pesticides or physicochemical groups of pesticides during early gestation increases the risk of these malformations, included 731 cases and 940 controls and after reporting 107 different analyses for individual pesticides, pesticide physicochemical categories and any exposure, no exposure and multiple exposure definitions yielded 15 statistically significant results without correction for multiple testing and without a particular pattern with regards to a pesticide category or an additive effect.

#### 9.3.6. Urogenital malformations

Overall, 19 studies examined urogenital malformations, namely cryptorchidism (n=9) and hypospadias (n=9).

Cryptorchidism was assessed in nine mostly retrospective studies, of a median sample size of 199 (IQR 136-710). Four studies assessed DDT levels; hexachorobenzene (HCB) and chrordane were assessed in one study each, while general pesticide exposure was assessed in 2 studies. When we attempted to investigate the association between exposure to any pesticide and cryptorchidism across all assessed studies, the observed effect was not statistically significant (OR 1.19, 95% CI 0.96 – 1.49, I<sup>2</sup> 24%) (Figure 23). Moreover, when we assessed the potential association between DDT exposure and cryptorchism, we again observed a statistically non-significant association (OR 1.47, 95% CI 0.98- 2.2, I<sup>2</sup> 51%) (Figure 24). Given the large number of analyses, these results need cautious interpretation and, based on these data, there is no recent evidence to suggest a robust, clinically significant association between any pesticide exposure and cryptorchidism.

EFSA supporting publication 2013:EN-497

The present document has been produced and adopted by the bodies identified above as author(s). This task has been carried out exclusively by the author(s) in the context of a contract between the European Food Safety Authority and the author(s), awarded following a tender procedure. The present document is published complying with the transparency principle to which the Authority is subject. It may not be considered as an output adopted by the Authority. The European Food Safety Authority reserves its rights, view and position as regards the issues addressed and the conclusions reached in the present document, without prejudice to the rights of the authors.

Hypospadias was assessed in 9 mostly retrospective studies, of a median sample size of 784 (IQR 200 - 861). Two studies assessed DDT levels, while general pesticide exposure was assessed in 6 studies. When we attempted to investigate the association between maternal exposure to any pesticide (during preconception and pregnancy) and hypospadias across all assessed studies, the observed effect was not statistically significant (OR 1.02, 95% CI 0.74 – 1.39,  $I^2$  72%) (Figure 25). When we included in the analysis the three studies that assessed a specific pesticide (DDT, n=2; chrordane, n=1), we again observed a statistically non-significant association (OR 1.00, 95% CI 0.84- 1.16, I<sup>2</sup> 66%) (Figure 26). Our systematic review retrieved one meta-analysis including original research published in English and indexed in PubMed from January 1966 through March 2008 (Rocheleau CM, 2009). Nine studies published before 2007 met all study inclusion criteria and the authors reported that elevated but marginally significant risks of hypospadias were associated with maternal occupational exposure (PRR of 1.36, CI=1.04-1.77), and paternal occupational exposure (PRR of 1.19, CI=1.00-1.41). Due to the different time-periods for the literature assessment and the resulting minimal overlap between our review and the published meta-analysis, we were able to synthesize the two efforts and again we retrieved a statistically non-significant result (OR 1.14, 95% CI 0.84 - 1.55, I<sup>2</sup> 73%). Thus, there is no recent evidence to suggest a robust, clinically significant association between any pesticide exposure and cryptorchidism.

#### 9.4. Child health outcomes with few studies

For all the assessed outcomes not included in Table 10, too few studies are available to allow synthesis of evidence for each outcome alone; these outcomes comprise a vast variety of captured information ranging from well-defined clinical entities yet with too few studies, such as gastroschisis, cardiac birth defects, diaphragmatic hernia, and esophageal atresia, as well as a large numbers of metrics pertaining to broad clinical entities but with a prominent lack of harmonization and standardization in the outcome definition. For example, outcomes related to neurodevelopment were assessed extensively; nevertheless the metrics used, ranging from IQ measurement to perceptual reasoning, deemed any further attempt towards a quantitative synthesis impossible. Our systematic review did not identify any previously published meta-analyses on these outcomes to allow for comparisons with previously published evidence (prior to 2006). Generally the results on these outcomes were of small effect and not statistically significant with few exceptions. Given the large number of analyses these results need cautious interpretation and, based on these data, there is no evidence to suggest association between pesticide exposure and these outcomes.

The present document has been produced and adopted by the bodies identified above as author(s). This task has been carried out exclusively by the author(s) in the context of a contract between the European Food Safety Authority and the author(s), awarded following a tender procedure. The present document is published complying with the transparency principle to which the Authority is subject. It may not be considered as an output adopted by the Authority. The European Food Safety Authority reserves its rights, view and position as regards the issues addressed and the conclusions reached in the present document, without prejudice to the rights of the authors.

Pesticide epidemiology

## Table 10: Assessed outcomes in the field of child health as defined by eligible studies

Health outcome		
Abnormal urogenital distance	Body mass index (BMI) Z-score	Increased serum prolactin levels
Abnormal body mass index (BMI)	Body fat percentages (log transformed)	Increased serum total testosterone level
Abnormal bone age	Chordee	IQ
Abnormal breast size	Coarctation of the aorta	LH dysregulation
Abnormal change of body mass index	Congenital diaphragmatic hernia (CDH)	Low annual height velocity
Abnormal change of height	Congenital heart defects	Major congenital anomalies
Abnormal chest circumference	Congenital malformations	Male genital malformations
Abnormal gestational age	Cretinism	Maternal age
Abnormal head circumference-for-age	Crown-Heel Length	Maternal weight gain
Abnormal height	Cryptorchidism	Miscarriage or stillbirth
Abnormal hip circumference	Decreased inhibin B levels	Musculoskeletal defects
Abnormal length	Decreased serum FSH levels	Neural tube defects
Abnormal ovarian measurements	Decreased serum inhibin B levels	Obesity
Abnormal penis length (stretched)	Decreased serum SHBG levels	Oestradiol dysregulation
Abnormal penis width	Decreased testicular volume	Perceptual Reasoning
Abnormal serum DHT levels	Decreased testosterone levels	Performance IQ
Abnormal sitting height	Decresed serum LH levels	Ventricular septal defect
Abnormal standing height	Duration of lactation	Placental weight
Abnormal Tanner stage	Esophageal atresia	Placental weight
Abnormal upper arm circumference	Fetal death	Ponderal Index
Abnormal upper arm fold circumference	Fetal head circumference	Ponderal index
Abnormal uterine measurements	Fetal length	Precocious puberty
Abnormal waist circumference	Fetal weight	Preeclampsia
Abnormal weight	FGR	Premature breast development
Abnormal weight-for-length	Freedom from distractability	Premature oestradiol secretion
Affected breast development	FSH dysregulation	Premature puberty onset (pubic hair)
Anal position index	Gastroschisis	Prematurity
Androstendione dysregulation	Gestational age	Processing speed
Anencephaly	Gynecomastia	Rapid infant weight gain
Anti-mullerian hormone dysregulation	Head Circumference	SGA
APGAR 1-minute score	Hypospadias	SHC
APGAR 5-minute score	Idiopathic precocious puberty	Spina bifida
Atrioventricular septal defect	Increased FSH levels	Sum of four skin folds
Birth head circumference	Increased levels of SHBG	Testosterone dysregulation

#### **10. Reproductive diseases**

Overall, 63 publications examined the effect of pesticide exposure on child health outcomes (median sample size: 299; IQR 111-544), contributing 578 separate analyses in the data extraction database. More than one third of the analyses (n=217, 38%) assess the sperm/semen quality, whereas other cluster of studies/analyses examine among others reproductive related hormones, infertily and spontaneous abortion As seen with other outcomes, the diversity of the exposure definition is remarkable and poses special challenges to data synthesis. Only 4 out of the 64 were prospective cohort studies whereas the vast majority of the studies were cross sectional (n=45, 70%). The sample size in the reported analyses was rather small; it ranged between 41 and 29,649 participants (median 161) and the largest studies in the domain are smaller than the largest studies assessed in the cancer field. Here, we observed a cluster of publications coming from INUENDO (INUit-ENDOcrine) research group (n=8), a project that has been established in three European countries together with a population of Inuits from Greenland and aims to enlighten the impact of Persistent Organic Pollutants (POPs) on human reproductive function. Almost 2/3 of the studies were conducted in Europe and America (n=22 and 20 respectively). Twenty-two studies assessed occupational exposures and, in addition, more than half of the studies had information on biomarkers of exposure (n=38, 59%), 3 studies assessed occupational exposure through Job Exposure Matrix (JEM), whereas 2 studies used both questionnaires and biomarkers. The different outcome categories examined are presented in Table 12 along with the number of studies contributing to each outcome category and a decision on quantitative synthesis. Due to heterogeneity of data, statistical synthesis of the data (meta-analysis) was only performed for abortion.

## **10.1.** Impaired sperm parameters

Twenty-five studies (median 189: IQR 87-336) assessed the association of pesticides on sperm/semen quality using a variety of outcomes. The total analyses conducted for these outcomes are 217 and the sample size of the conducted analyses is small ranging from 41 to 763. The largest study is a European cross-sectional study from INDUENDO research group (ID RPD 009) and assess the impact of p,p'-DDE to sperm concentration, sperm motility and sperm morphology and showed that the sperm motility was negatively associated with p,p'-DDE across the four populations under study. Another large study from the same group (ID RPD 012) did not provide evidence that Persistent Organic Pollutants (POPs) may interfere with male reproductive function. Even though a large number analyses have been conducted no single pesticide and related biomarker was assessed in more than 4 studies using the same comparison unit and analysis, thus a quantitative synthesis was not performed.

# **10.2.** Fecundability disorders

Eight studies including 30 different analyses assess the effect of pesticides on low fecundability. The sample sizes are rather small ranging from 41 to 2,365 participants. Different effect sizes and analyses are used for the assessment of potential associations therefore the synthesis of the results through meta-analysis is not feasible. The largest study (ID RPD 038) that examined pesticide exposure of female greenhouse farm workers reported a reduced fecundability (OR=0.68, 95% CI=0.49-0.94). However the second largest study in the field (ID RPD 034) on female greenhouse farm workers did not shown a significant association (OR=1.11, 95%CI=0.96-1.29). Fourteen additional analyses did not report significant findings; therefore the evidence is contradictory in the field.

EFSA supporting publication 2013:EN-497

The present document has been produced and adopted by the bodies identified above as author(s). This task has been carried out exclusively by the author(s) in the context of a contract between the European Food Safety Authority and the author(s), awarded following a tender procedure. The present document is published complying with the transparency principle to which the Authority is subject. It may not be considered as an output adopted by the Authority. The European Food Safety Authority reserves its rights, view and position as regards the issues addressed and the conclusions reached in the present document, without prejudice to the rights of the authors.

#### **10.3.** Spontaneous abortion

Ten studies of spontaneous abortion focused on occupational exposure. We were able to synthesize data from six studies that provided an effect estimate and a metric of its variation. The summary OR was 1.52 (95%: 1.09-2.13) using random effects models and large heterogeneity was observed ( $I^2=63\%$ ) (Figure 27). However, the largest cross-sectional study on this outcome conducted by the INUENDO research group (ID RPD 003) did not shown any statistical effect (OR=1) between p,p'-DDE and abortion. One more study compared full-time vs. part time farming and did not report a significant association (p-value=0.99). Three other studies did not provide adequate information for their inclusion in the meta-analysis.

#### **10.4.** Reproductive hormones

Nineteen studies (median sample size 257: IQR 97-322) contributing with 250 analyses for various reproductive hormones were identified in this systematic review. The studies were comparable to the other large group of impaired sperm parameters sample size-wise; their range was from 62 to 887. The largest study is a European cross-sectional study that assess the effect of hexachlorobenzene on the levels of testosterone and estradiol. Hormonal status of 14- to 15- year-old male adolescents was studies in relation to internal exposure to pollutants. The study shows that the exposure is associated with substantial differences in hormone concentrations. Different patterns were observed in study conducted by the INUENDO research group where the overall analysis between DDE and reproductive related hormones did not reveal any significant results. However in center-specific analysis, gonadotropin levels and sex-hormone-binding globulin seem to be affected by exposure on p,p'-DDE supporting substantial variations between different populations. The large variety of outcomes and pesticides assessed did not allow for any quantitative synthesis of the data.

#### **10.5.** Reproductive outcomes with few studies

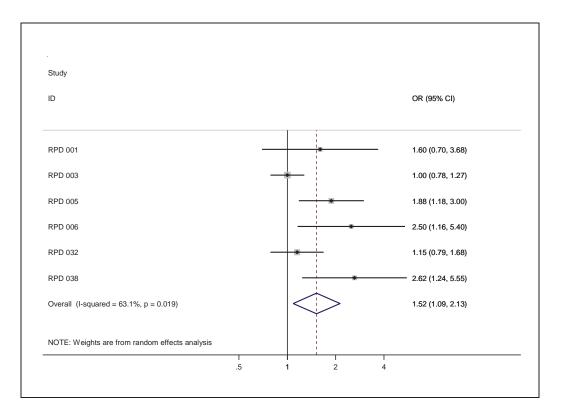

For all the assessed outcomes not included in Table 12, assessment of menstrual cycles cannot allow synthesis of the available evidence. Our systematic review did not identify any previously published meta-analyses on these outcomes to allow for comparisons with previously published evidence (prior to 2006). Results on different menstrual outcomes showed that it is unlikely that exposure to DDE is a main cause of menstrual disturbances.

#### 11. Neurological diseases

Overall, 60 publications examined the effect of pesticide exposure on neurological outcomes (median sample size: 390; IQR 246-781), contributing 573 separate analyses in the data extraction database. More than thirty health-related outcomes were assessed with the largest proportion focusing on Parkinson's disease with 32 studies (Table 13). As seen with other outcomes, the diversity of the exposure definition is remarkable and poses special challenges to data synthesis. Only 8 out of the 60 were prospective cohort studies and other 2 were nested case-controls; the majority of evidence comes from retrospective case-control analyses, which are prone to recall bias in exposure measurement. The sample size in the reported analyses was often small; it ranged between 46 and 143,325 participants (median 390) and the largest studies in the domain are smaller than the largest studies assessed in the cancer field. Here, we also observed large clusters of publications coming from large, well-known studies in the field, such as the Agricultural Health Study (AHS), while 43 studies assessed occupational exposures. In addition, the presence of studies with information on biomarkers of exposure was far less prominent here (n=7, 12%). The different outcome categories examined are presented in Table 13; due to the small number of studies identified per assessed outcome, statistical synthesis of the data (meta-analysis) was only performed for Parkinson's disease and amyotrophic lateral sclerosis.

# 11.1. Parkinson's disease

Thirty-two studies assessed the association between pesticide exposure and Parkinson's disease with a median sample size of 399 (IQR 286-711), contributing 266 separate extracted comparisons in the database. Eighty percent of the retrieved studies assessed occupational exposures, only 10% were prospective and the exposure was assessed through a biomarker in a small number of studies (10%). A large variety of individual pesticides were assessed with the following pesticides being assessed more frequently: general pesticide (28 studies), as well as DDT (5 studies), paraquat (9 studies).

We initially assessed the association between general pesticide use and Parkinson's disease. The observed effect indicated a statistically significant association with the presence of considerable heterogeneity (random-effects OR 1.58, 95% CI 1.35 - 2.85, I<sup>2</sup> 61%) (Figure 28). With the exception of four studies where specific pesticides were assessed (e.g. paraquat), all the other studies assessed mainly occupational general pesticide use in mainly a retrospective fashion via a questionnaire. The results of the meta-analysis are in accordance with the largest studies on that research question.

We then proceeded to assess the association between DDT exposure and Parkinson's disease. The observed effect indicated a non-statistically significant association without the presence of heterogeneity (random-effects OR=1.01, 95% CI=0.78–1.30,  $I^2=0\%$ ) (Figure 29). Finally, we assessed the association between paraquat exposure and Parkinson's disease. The observed effect indicated a statistically significant association with the presence of moderate heterogeneity (random-effects OR=1.32, 95% CI=1.10–1.60,  $I^2=34\%$ ) (Figure 30). The results of the meta-analysis are in accordance with the largest studies on these research questions.

Our literature search yielded 7 systematic reviews and/or meta-analyses on the association between pesticide exposure and Parkinson's disease published from 2000 to 2013 (Pezzoli 2013, Van-Maele Fabry 2012, van der Mark 2012, Dick 2006, Priyadarshi 2001, Priyadarshi 2000, Allen 2013). Despite the considerable time interval between the oldest and most recent research synthesis effort and the different methodologies endorsed (prospective studies only assessed, methodological assessment of

EFSA supporting publication 2013:EN-497

The present document has been produced and adopted by the bodies identified above as author(s). This task has been carried out exclusively by the author(s) in the context of a contract between the European Food Safety Authority and the author(s), awarded following a tender procedure. The present document is published complying with the transparency principle to which the Authority is subject. It may not be considered as an output adopted by the Authority. the included studies, etc.), the results are consistent across the meta-analyses and are also consistent with the present effort spanning from 2006 (Table 14).

## **11.2.** Amyotrophic lateral sclerosis (ALS)

Seven studies assessed the association between pesticide exposure and amyotrophic lateral sclerosis with a median sample size of 356 (IQR 201-1156), contributing 11 separate extracted comparisons in the database. All the retrieved studies assessed occupational exposures, while 4 also assessed residential exposure. Only one study was prospective and the exposure was assessed through a questionnaire in most of the studies (n=6).

We assessed the association between general pesticide use and ALS. The observed effect indicated a statistically significant association with the presence of small heterogeneity (fixed-effects OR=1.58, 95% CI=1.31 – 1.90, I<sup>2</sup> 10%) (Figure 31) and the results of the meta-analysis are in accordance with the largest studies on that research question.

Our literature search yielded 2 systematic reviews and/or meta-analyses on the association between pesticide exposure and ALS published in 2012 (Kamel 2012, Malek 2012). Regarding these efforts, the results are consistent with our findings and the authors' report of evidence on an association of exposure to pesticides and risk of ALS in male cases compared to controls (OR=1.88, 95% CI: 1.36-2.61), although the chemical or class of pesticide was not specified by the majority of studies.

## **11.3.** Neurological outcomes with few studies

With the exception of Parkinson's disease and amyotrophic lateral sclerosis, for all the remaining neurological outcomes, too few studies are available after 2006 to allow synthesis of evidence for each outcome alone; these outcomes comprise a vast variety of captured information ranging from well-defined clinical entities yet with too few studies, such as hearing loss or diabetic neuropathy, as well as a large number of metrics pertaining to neurological endophenotypes but with a prominent lack of harmonization and standardization in the outcome definition. Our systematic review did not identify any previously published meta-analyses on these outcomes to allow for comparisons with previously published evidence (prior to 2006). Generally the results on these outcomes were of small effect and not statistically significant with few exceptions. Given the large number of analyses these results need cautious interpretation and, based on these data, there is no evidence to suggest association between pesticide exposure and these outcomes.

#### 12. Endocrine diseases

Overall, 35 publications examined the effect of pesticide exposure on thyroid hormone dysregulation (median sample size: 226; IQR 130-453), contributing 343 separate analyses in the data extraction database. The main outcomes assessed were thyroxin (T4), triiodothyronine (T3) and thyroid stimulating hormone (TSH) levels. Only 3 prospective cohort studies were conducted in the field; the majority of evidence comes from retrospective case-control or cross-sectional analyses, which are prone to recall bias in exposure measurement. The sample size in the reported analyses was often small; it ranged between 27 and 16,529 participants (median 341). Here, we observed no large clusters of publications coming from large, well-known studies in the field, while the vast majority of the studies assessed environmental exposures (n=28, 80%). However, the presence of studies with information on biomarkers of exposure was more prominent here (n=29, 83%). Even though hypothyroidism, hyperthyroidism and other thyroid diseases contribute with more than 1/3 of the total analyses (n=123) the available evidence derives from Agricultural Health Study (AHS) which apparently is the largest in the field and examines the association between pesticide use and thyroid diseases in females. The study found an association between hypothyroidism and ever use of organochlorine insecticides (OR=1.2, 95% CI= 1.0-16) and fungicides (OR=1.4, 95% CI= 1.1-1.8). However, the results should be interpreted with caution due to borderline significance levels and absence of type-I error corrections due to multiple comparisons. Other studies in the field assessing several thyroid hormone levels are quite smaller and provide contradictory results. As seen with other outcomes, the diversity of the exposure definition is remarkable and poses special challenges to data synthesis. Due to heterogeneity of data and different analyses, effect sizes and metrics provided, statistical synthesis of the data (meta-analysis) was not performed.

The present document has been produced and adopted by the bodies identified above as author(s). This task has been carried out exclusively by the author(s) in the context of a contract between the European Food Safety Authority and the author(s), awarded following a tender procedure. The present document is published complying with the transparency principle to which the Authority is subject. It may not be considered as an output adopted by the Authority. The European Food Safety Authority reserves its rights, view and position as regards the issues addressed and the conclusions reached in the present document, without prejudice to the rights of the authors.

## **13.** Mental and psychomotor development outcomes

Overall, 32 publications examined the effect of pesticide exposure on mental and psychomotor development outcomes in pediatric populations (median sample size: 238, IQR 109-305), contributing 462 separate analyses in the *data extraction database*. Only one study was performed in a population of non-European (Asian) ancestry, while seventeen health-related outcomes were assessed with a large proportion focusing on attention-deficit hyperactivity disorder (ADHD, 6 studies, 102 analyses). As seen with other outcomes, the diversity of the exposure definition is considerable and poses special challenges to data synthesis. A large majority of the studies (23 publications, 72%) referred to prospective cohort studies, while the sample size in the reported analyses was often small; it ranged between 25 and 7,440 participants with the largest study assessing retrospectively maternal residence near agricultural pesticide applications and autism spectrum disorders among children in the California Central Valley. Here, we also observed clusters of publications coming from large, well-known studies in the field, such as the CHAMACOS (The Center for Health Assessment of Mothers and Children of Salinas) (5 publications), while 84% of the studies assessed environmental exposures. In addition, the presence of studies with information on biomarkers of exposure was prominent here (n=28, 88%). The different outcome categories examined are presented in Table 15 along with the number of studies contributing to each outcome category and a decision on quantitative synthesis. Due to heterogeneity of data and small number of studies identified, no statistical synthesis of the data (meta-analysis) was performed for any outcome.

## 13.1. Mental and psychomotor development outcomes with few studies

With the exception of mental and psychomotor development and Attention-deficit hyperactivity disorder (ADHD), for all the remaining assessed outcomes included in Table 15, too few studies are available to allow synthesis of evidence for each outcome alone; these outcomes comprise a variety of captured information ranging from well-defined clinical entities yet with too few studies, such as autism, or pervasive developmental disorder, as well as a vast number of outcomes representing neurodevelopmental endo-phenotypes such as communication, fine and gross motor development or expressive language development. Our systematic review did not identify any previously published meta-analyses on these outcomes to allow for comparisons with previously published evidence (prior to 2006). Generally the results on these outcomes were of small effect and not statistically significant with few exceptions. Given the large number of analyses and the small number of studies and sample sizes, these results need cautious interpretation and, based on these outcomes.

# **13.2.** Attention-deficit hyperactivity disorder (ADHD)

Six studies assessed the association between pesticide exposure and ADHD with a sample size ranging from 278 to 2,539 participants, contributing 102 separate extracted comparisons in the database. Three studies were cohorts, all assessed environmental exposure and in all the exposure was assessed through a biomarker. General organophosphate exposure was assessed in three studies, DDT exposure in two studies, while trans-nonachlor, hexachlorobenzene, and 2,4,6-Trichlorophenol (TCP) were assessed in one study each. Thus, no single pesticide and related biomarker was assessed in more than 4 studies using comparable outcome definitions or the same comparison unit, thus a quantitative synthesis was not performed. The largest study in the field is a National Health and Nutrition Examination Survey (NHANES) report (ID 17) used data from the 1999-2004 NHANES to evaluate the association between urinary trichlorophenols (TCPs) and parent-reported ADHD among 2546 children aged 6-15 years. The authors report that children with low levels (<3.58 mg/g) and high levels

EFSA supporting publication 2013:EN-497

The present document has been produced and adopted by the bodies identified above as author(s). This task has been carried out exclusively by the author(s) in the context of a contract between the European Food Safety Authority and the author(s), awarded following a tender procedure. The present document is published complying with the transparency principle to which the Authority is subject. It may not be considered as an output adopted by the Authority. The European Food Safety Authority reserves its rights, view and position as regards the issues addressed and the conclusions reached in the present document, without prejudice to the rights of the authors.

(>3.58 mg/g) of urinary 2,4,6-Trichlorophenol (TCP) had a higher risk of parent-reported ADHD compared to children with levels below the limit of detection (OR 1.54, 95% CI 0.97 to 2.43 and OR 1.77, 95% CI 1.18 to 2.66, respectively; p for trend=0.006) after adjusting for covariates.

Our systematic review did not identify any previously published meta-analyses on ADHD to allow for comparisons with previously published evidence (prior to 2006). Generally the results on ADHD were of small effect and not statistically significant with few exceptions. Thus, given the large number of analyses these results need cautious interpretation and, based on these data, there is no evidence to suggest association between pesticide exposure and ADHD.

# **13.3.** Neurodevelopment

Thirty-one studies assessed the association between pesticide exposure and aspects of neurodevelopment with a sample size ranging from 25 to 1,041 contributing 325 separate extracted comparisons in the database. Only one study assessed neurodevelopmental aspects in Asian children; all the rest pertained to populations of European ancestry. Seventy-four percent of the studies were cohort studies and, in 27 studies the exposure was assessed through a biomarker. A large variety of individual pesticides were assessed with the general category of organophosphate pesticides being assessed more frequently (Table 16). No single pesticide and related biomarker was assessed in more than 4 studies using comparable outcome definitions or the same comparison unit, thus a quantitative synthesis was not performed. Actually, the assessment of neurodevelopment, as seen for cognitive function, is another typical example of a general outcome category where the multiplicity and complexity of the 35 tools and sub-tools used (Table 17) renders the attempt to systematically and quantitatively synthesize the results of the published literature fruitless.

The largest study in the field is a Collaborative Perinatal Project report (ID MPD 029) assessing inutero exposure to dichlorodiphenyltrichloroethane and cognitive development among infants and school-aged children. The authors report that although levels of DDT and DDE were relatively high in this population (median DDT concentration, 8.9 g/L; DDE, 24.5 g/L), neither were related to Mental or Psychomotor Development scores on the Bayley Scales nor to Full-Scale Intelligence Quotient at 7 years of age.

Our systematic review did not identify any previously published meta-analyses on these outcomes to allow for comparisons with previously published evidence (prior to 2006). Generally the results on neurodevelopmental outcomes were of small effect and not statistically significant with few exceptions. Thus, given the large number of analyses these results need cautious interpretation and, based on these data, there is no evidence to suggest association between pesticide exposure and these outcomes.

## 14. Respiratory diseases

Overall, 29 publications examined the effect of pesticide exposure on respiratory outcomes (median sample size: 249, IQR 126-1728), contributing 399 separate analyses in the *data extraction database*. Sixty-seven percent came from Europe and America, while ten health-related outcomes were assessed with a large proportion focusing on asthma (N=9). As seen with other outcomes, the diversity of the exposure definition is considerable and poses special challenges to data synthesis. Only 6 out of the 29 publications referred to prospective cohort studies and 12 were cross-sectional studies. The sample size in the reported analyses was often small; it ranged between 35 and 47,756 participants with the largest study being the Singapore Chinese Health Study. Here, we also observed large clusters of publications coming from large, well-known studies in the field, such as the AHS (6 publications), while 17 studies (68%) assessed occupational exposures. In addition, the presence of studies with information on biomarkers of exposure was less prominent here (N=8, 34%) while 1 study assessed occupational exposure through JEM. The different outcome categories examined are presented in Table 18 along with the number of studies contributing to each outcome category and a decision on quantitative synthesis. Due to heterogeneity of data and small number of studies identified, statistical synthesis of the data (meta-analysis) was only performed for asthma.

# 14.1. **Respiratory outcomes with few studies**

With the exception of asthma, for all the remaining assessed outcomes included in Table 18, too few studies are available to allow synthesis of evidence for each outcome alone; these outcomes comprise a variety of captured information ranging from well-defined clinical entities yet with too few studies, such as idiopathic pulmonary fibrosis, or sarcoidosis, as well as a numbers of biomarkers such as forced expiratory volume (FEV). Our systematic review did not identify any previously published meta-analyses on these outcomes to allow for comparisons with previously published evidence (prior to 2006). Generally the results on these outcomes were of small effect and not statistically significant with few exceptions. Given the large number of analyses and the fact that most of the results come from the Agricultural Health Study (AHS), these results need cautious interpretation and, based on these data, there is no evidence to suggest a robust association between pesticide exposure and these outcomes.

# 14.2. Asthma

Nine studies assessed the association between pesticide exposure and asthma with a median sample size of 402 (IQR 127-724), contributing 196 separate extracted comparisons in the database. More than half of the studies were cross-sectional and in more than two-thirds of the studies, the exposure was assessed through a questionnaire. A large variety of individual pesticides were assessed with DDT, paraquat and chlorpyrifos being assessed more frequently. With the exception of DDT, chlorpyrifos and paraquat (Table 19), no other single pesticide and related biomarker was assessed in more than 4 studies using the same comparison unit, thus a quantitative synthesis was not performed.

When we attempted to investigate the association between exposure to DDT and asthma across the 5 available studies, the observed effect was statistically significant without indications of heterogeneity (OR 1.29, 95% CI 1.14 – 1.45,  $I^2$  0%) (Figure 32). We then attempted to investigate the association between exposure to paraquat and asthma across the 6 available studies and the observed effect was not statistically significant with indications of heterogeneity (OR=1.40, 95%CI=0.95–2.06,  $I^2$ =53%) (Figure 33). We finally attempted to investigate the association between exposure to chlorpyrifos and

EFSA supporting publication 2013:EN-497

asthma across the 5 available studies and the observed effect was not statistically significant without indications of heterogeneity (OR= 1.03, 95% CI= 0.82-1.28, I<sup>2</sup>=0%) (Figure 34). We caution that the meta-analyses results are largely driven by the AHS; in the meta-analyses 4 entries belong to the AHS as the results were separately reported for men and women and for allergic and non-allergic asthma. We also acknowledge that the results of the meta-analyses are restricted to data published after 2006. We thus conclude that for DDT, but not for chlorpyrifos and paraquat, there is recent evidence to suggest a statistically significant, moderate association between exposure to this pesticides and asthma.

### 15. Neuropsychiatric diseases

Overall, 15 publications examined the effect of pesticide exposure on neuropsychiatric outcomes in adult populations (median sample size: 596, IQR 158-12,263), contributing 358 separate analyses in the data extraction database. Three-quarters came from Europe and America, while 17 health-related outcomes were assessed with a large proportion focusing on cognitive function (9 studies, 246 analyses). As seen with other outcomes, the diversity of the exposure definition is considerable and poses special challenges to data synthesis. Only 2 out of the 15 publications referred to prospective cohort studies and 60% of the publications were cross-sectional studies. The sample size in the reported analyses was often small; it ranged between 66 and 112,683 participants with the largest study being a retrospective American study. Here, we also observed clusters of publications coming from large, well-known studies in the field, such as the Agricultural Health Study (AHS) (4 publications), while all but one study assessed occupational exposures. In addition, the presence of studies with information on biomarkers of exposure was far less prominent here (n=2, 13%). The different outcome categories examined are presented in Table 20, along with the number of studies contributing to each outcome category and a decision on quantitative synthesis. Due to heterogeneity of data and small number of studies identified, no statistical synthesis of the data (meta-analysis) was performed for any outcome.

# **15.1.** Cognitive function

Nine studies assessed the association between pesticide exposure and cognitive function with a median sample size of 80 (IQR 141-205), contributing 246 separate extracted comparisons in the database. All but one of the studies were cross-sectional and, in seven studies the exposure was assessed through a questionnaire. A large variety of individual pesticides were assessed with the general category of organophosphate pesticides being assessed more frequently. No single pesticide and related biomarker was assessed in more than 4 studies using comparable outcome definitions or the same comparison unit, thus a quantitative synthesis was not performed. Actually, the assessment of cognitive function is a typical example of a general outcome category where the multiplicity and complexity of the 62 tools and sub-tools used in the 15 available studies (Table 21) renders the attempt to systematically and quantitatively synthesize the results of the published literature fruitless.

The largest study in the field is an AHS report (ID NPD 014) assessing potential associations between long-term pesticide use and neurobehavioral function, with relevant tests administered to licensed pesticide applicators. The authors report that "test performance was associated with lifetime days of use of some pesticides". Ethoprop was significantly associated with reduced performance on a test of motor speed and visual scanning. Malathion was significantly associated with poor performance on a test of visual scanning and processing. Conversely, we observed significantly better test performance for five organophosphate pesticides. Specifically, chlorpyrifos, coumaphos, parathion, phorate, and tetrachlorvinphos were associated with better verbal learning and memory; coumaphos was associated with better performance on a test of motor speed and visual scanning; and parathion was associated with better performance on a test of sustained attention. Overall, we found no consistent evidence of an association between organophosphate pesticide use and adverse test performance among this older sample of pesticide applicators. Potential reasons for these mostly null results include a true absence of effect as well as possible selective participation by healthier applicators.

Our systematic review did not identify any previously published meta-analyses on these outcomes to allow for comparisons with previously published evidence (prior to 2006). Generally the results on neuropsychiatric outcomes were of small effect and not statistically significant with few exceptions.

EFSA supporting publication 2013:EN-497

The present document has been produced and adopted by the bodies identified above as author(s). This task has been carried out exclusively by the author(s) in the context of a contract between the European Food Safety Authority and the author(s), awarded following a tender procedure. The present document is published complying with the transparency principle to which the Authority is subject. It may not be considered as an output adopted by the Authority. The European Food Safety Authority reserves its rights, view and position as regards the issues addressed and the conclusions reached in the present document, without prejudice to the rights of the authors.

Thus, given the large number of analyses these results need cautious interpretation and, based on these data, there is no evidence to suggest association between pesticide exposure and these outcomes.

### **15.2.** Neuropsychiatric outcomes with few studies

With the exception of cognitive function, for all the remaining assessed outcomes included in Table 20, too few studies are available to allow synthesis of evidence for each outcome alone; these outcomes comprise a variety of captured information ranging from well-defined clinical entities yet with too few studies, such as depression, or obsessive-compulsive disorder, as well as a numbers of outcomes representing neuropsychiatric endo-phenotypes such as hostility or orientation disorders. Our systematic review did not identify any previously published meta-analyses on these outcomes to allow for comparisons with previously published evidence (prior to 2006). Generally the results on these outcomes were of small effect and not statistically significant with few exceptions. Given the large number of analyses and the fact that a number of the results come from the AHS, these results need cautious interpretation and, based on these data, there is no evidence to suggest a robust association between pesticide exposure and these outcomes.

#### 16. Diabetes

Overall, 23 publications examined the effect of pesticide exposure on diabetes related outcomes (median sample size: 430; IQR 192-1721), contributing 125 separate analyses in the *data extraction* database. Four health-related outcomes were assessed with a large proportion focusing on type 1 diabetes (n=93, 74%) whereas 18 analyses focused on type 2 diabetes. The rest of the outcomes assessed was prediabetes (n=10), gestational diabetes (n=2) and other glucose and insulin related outcomes (n=2). Only one prospective cohort study was performed; the large majority was crosssectional designs (n=15), whereas 3 studies were case-controls and 4 studies used a nested casecontrols. The large majority of the studies was conducted in America (n=15, 65%) whereas 7 studies where Europeans and only one Asian. Here, we did not observe large clusters of publications coming from large, well-known studies in the field, such as the AHS. Only three study assessed occupational exposures the rest examined environmental exposures (n=19) or both (n=1). In addition, the presence of studies with information on biomarkers of exposure was limited to 9 studies, whereas 10 studies included information both on questionnaire and biomarkers. The different outcome categories examined are presented in Table 22 along with the number of studies contributing to each outcome category. For the pesticides accessed meta-analysis was feasible for DDE and DDT exposure and type 1 diabetes and DDE exposure and type 2 diabetes.

### 16.1. Type 1 diabetes

Thirtheen studies assessed the effect of pesticides on type 1 diabetes (median sample size: 309, IQR: 159-398) and a meta-analysis of ORs was feasible for DDE and DDT exposure. For DDE, 9 studies contributed a median sample size of 202, IQR=142-334. We were not able to include a prospective study that reported a (significant) Incidence Rate Ratio (IRR) of 7.1 and compared the highest vs. the lowest tertile of exposure with DDE. The computed summary OR was 1.90 (95% CI: 1.25-2.86) for the DDE exposure using random effects models. Moderate heterogeneity was observed (I<sup>2</sup>=49%). For DDT, 6 studies had available data for synthesis (median sample size: 577, IQR: 272-2163) providing a summary effect of 1.76 (95% CI: 1.20-2.59) with very large heterogeneity observed ((I<sup>2</sup>=76%)). Main source of heterogeneity is the different exposure levels used for the calculations of the effect estimates. Even though there is evidence from the random effects meta-analysis that an increased risk for type 1 diabetes exists, however the findings should be interpreted with caution due to the heterogeneity that was observed.

### 16.2. Type 2 diabetes

Four studies were eligible for the assessment of the DDE exposure and risk for type 2 diabetes (median sample size: 471, IQR=292-642). The summary OR derived from those studies was 1.30 (95% CI: 1.13-1.48). No heterogeneity was observed, however the summary results is driven by a case-control study that reported an effect size OR=1.30 (95% CI=1.11-1.52). Even though, there is evidence suggesting that DDE exposure is a risk factor for developing type 2 diabetes, this is based on small studies.

### 17. Cardiovascular diseases

This section includes hard cardiovascular outcomes (myocardial infraction, stroke etc.), cardiovascular risk factors (lipids, blood pressure) and other cardiometabolic outcomes (metabolic syndrome and obesity). No previous meta-analysis has been identified for any of these traits. The evidence collected in this systematic review provides weak suggestions of associations in particular regarding cardiometabolic risk factors and organochlorines; however, other classes of pesticides were not studied and even results on organochlorines were limited and require prospective replication.

## 17.1. Hard cardiovascular outcomes

Five studies examined hard cardiovascular outcomes including myocardial infarction (ID CVD 005, ID CVD 006), peripheral arterial disease (PAD) (ID CVD 007), stroke (ID CVD 008), and composite cardiovascular disease (ID CVD 009). The Agricultural Health Study (AHS) contributed two prospective analyses (ID CVD 005, ID CVD 006) and National Health and Nutrition Examination Survey (NHANES) other two cross-sectional analyses (ID CVD 007, ID CVD 009). Studies on myocardial infarction (ID CVD 005, ID CVD 006) showed no evidence of an association between having used pesticides, individually or by class, and myocardial infarction mortality among men in the AHS. Similarly, among women of AHS, no overall association with pesticide use and myocardial infarction was seen. Six of 27 individual pesticides evaluated were significantly associated with nonfatal myocardial infarction among women (ID CVD 006), including chlorpyrifos, coumaphos, carbofuran, metalaxyl, pendimethalin, and trifluralin, which all had relatively high odds ratios (>1.7) but also high probability of false positive due to multiple testing.

Another prospective study (8) examined 21 persistent organic pollutants (POPs) in relation to stroke. After adjusting for known stroke risk factors, most polychlorinated biphenyls (PCBs) with 4, 5, or 6 chlorine atoms, p,p'-DDE, trans-nonachlor, and octachlorodibenzo-p-dioxin significantly predicted the risk of stroke. Nonetheless, results need replication from future studies. Peripheral arterial disease (PAD) and composite cardiovascular disease were studied in the cross-sectional NHANES cohort in relation to POPs. Compared with subjects without PAD, those with PAD had significantly higher concentrations of organochlorine pesticides but associations were not seen among non-obese participants. For composite cardiovascular disease, significant associations were observed for chlordane only. These findings need to be carefully interpreted because of the cross-sectional design and use of self-reported cardiovascular disease.

Overall, evidence for associations between pesticide exposure and cardiovascular outcomes is weak and mainly concentrated on organochlorine pesticides.

# 17.2. Cardiovascular risk factors

# 17.2.1. Blood pressure

Five studies examined associations between pesticides and blood pressure (ID CVD 002, ID CVD 003, ID CVD 004, ID CVD 010, ID CVD 011). All but one study (ID CVD 011) had cross-sectional

EFSA supporting publication 2013:EN-497

The present document has been produced and adopted by the bodies identified above as author(s). This task has been carried out exclusively by the author(s) in the context of a contract between the European Food Safety Authority and the author(s), awarded following a tender procedure. The present document is published complying with the transparency principle to which the Authority is subject. It may not be considered as an output adopted by the Authority. The European Food Safety Authority reserves its rights, view and position as regards the issues addressed and the conclusions reached in the present document, without prejudice to the rights of the authors.

designs. All effect sizes were very small and not suggestive of an association between pesticide exposure and blood pressure.

# 17.2.2. Metabolic syndrome components

Nine studies examined components of metabolic syndrome in relation to pesticide exposure including lipids levels, glucose and insulin levels. All but one study examined exposure to organochlorine pesticides and significant associations for some classes and lipid levels or glucose levels were observed. Highest quality evidence comes from the prospective Coronary Artery Risk Development in Young Adults (CARDIA) Study (ID CVD 016). In CARDIA, p,p'-DDE most consistently predicted higher triglycerides, and homeostasis model assessment value for insulin resistance (HOMA–IR) and lower High Density Lipoprotein (HDL)-cholesterol at year 20 after adjusting for various confounders. Oxychlordane, trans-nonachlor, and hexachlorobenzene also significantly predicted higher triglycerides. Finally, a case-control study in China, examined differences in glucose regulation in participants highly exposed to pyrethroids (occupational exposure). An indication of increased risk for abnormal glucose regulation was noted for exposure to pyrethroids (OR = 1.48, 95%CI = 1.24–1.77) (ID CVD 021). However, these results need external replication in other populations as the study is retrospective and residual confounding cannot be excluded.

# 17.2.3. Subclinical atherosclerosis

The population-based Prospective Investigation of the Vasculature in Uppsala Seniors examined in a cross-sectional study, whether POP levels were related to subclinical atherosclerosis. Circulating levels of PCBs were associated with atherosclerotic plaques and echogenicity of the intima-media complex independent of cardiovascular risk factors, but associations need to be confirmed in prospective studies.

# 17.3. Metabolic syndrome and obesity

Three studies (ID CVD 010, ID CVD 011) examined associations between organochlorine exposure and prevalence of metabolic syndrome. In National Health and Nutrition Examination Survey (NHANES) (ID CVD 010) significant association between organochlorine exposure and prevalence of Metabolic Syndrome was reported with ORs of 1.0, 1.5, 2.3 and 5.3 across organochlorine pesticide quartiles (p for trend <0.01). In the other case-control study (ID CVD 011) significant associations were noted for heptachlor only.

Overall, 12 cross-sectional studies examined associations between pesticide exposure and measures of body fatness or obesity. Also, 10 out of 12 studies examined associations between organochlorines and obesity or body fatness; evidence around other pesticide classes was scarce. Three studies (ID CVD 012, ID CVD 013, ID CVD 014) only presented correlation analysis with measures of body fatness. The remaining studies have shown some significant associations between waist circumference, Body Mass Index (BMI) and organochlorines (DDT and chlordane) but the evidence is limited to cross-sectional analysis and results are only suggestive of an association.

EFSA supporting publication 2013:EN-497

The present document has been produced and adopted by the bodies identified above as author(s). This task has been carried out exclusively by the author(s) in the context of a contract between the European Food Safety Authority and the author(s), awarded following a tender procedure. The present document is published complying with the transparency principle to which the Authority is subject. It may not be considered as an output adopted by the Authority. The European Food Safety Authority reserves its rights, view and position as regards the issues addressed and the conclusions reached in the present document, without prejudice to the rights of the authors.

# 18. Mortality

Overall, 11 publications examined the effect of pesticide exposure on mortality (median sample size: 1,986), contributing 318 separate analyses in the *data extraction database*. This section consists of a heterogeneous group of publications, which assessed associations between pesticides and all cause mortality of major mortality outcomes. Despite the fact that these studies were large, they were of modest quality and they are not very informative as they test a wide range of diseases simultaneously without corrections for multiple testing. The results do not show any apparent trend of pesticide exposure with overall mortality.

EFSA supporting publication 2013:EN-497

The present document has been produced and adopted by the bodies identified above as author(s). This task has been carried out exclusively by the author(s) in the context of a contract between the European Food Safety Authority and the author(s), awarded following a tender procedure. ### **19.** Immune/ Autoimmune diseases

Overall, 10 publications examined the effect of pesticide exposure on immune disorders (median sample size: 196, IQR 81-476), contributing 67 separate analyses in the *data extraction database*. Sixty studies were conducted in America, 3 in Europe and one study was Asian. Various health related outcomes including arthritis, osteoarthritis, rheumatoid arthritis and an extensive list of various antibodies, cytokines etc. as summarized in Table 23. Seven out of the 10 publications referred to prospective cohort studies whereas 2 studies were cross-sectional and only one was case-control. The sample size in the reported analyses was rather small; it ranged between 19 and 532 participants with the largest study being the Carolina Lupus Study. Half of the studies assess occupational exposures and information on biomarkers of exposure was available in 2 studies whereas 4 studies used both biomarkers and questionnaires. As seen with other outcomes, the diversity of the exposure definition and the outcomes assessed are extensive and poses special challenges to data synthesis. No single outcome was assessed in more than two studies therefore synthesis of the data was not feasible for the field of immune disorders.

Health outcome	
Antinuclear antibodies	Interleukin-4 (IL-4)
Arthritis	Interleukin-13 (IL-13)
Complement components C3, C4	Immunologic effects
Eosinophils	Leucocyte counts
Erythrocyte counts	Lymphocyte levels
Glycoproteins	Neutrophils
Hematocrit/Hemoglobin	Natural Killers (NK) cells
Interferon-γ (IFN-γ)	Osteoarthritis
Immunoglobulin 1 (lgG1)	Rheumatoid arthritis
Immunoglobulin 4 (IgG4)	Systematic Lupus
Immunoglobulin M (IgM)	

 Table 23:
 Health outcomes assessed in the field of immune disorders

EFSA supporting publication 2013:EN-497

The present document has been produced and adopted by the bodies identified above as author(s). This task has been carried out exclusively by the author(s) in the context of a contract between the European Food Safety Authority and the author(s), awarded following a tender procedure. The European Food Safety Authority reserves its rights, view and position as regards the issues addressed and the conclusions reached in the present document, without prejudice to the rights of the authors.

#### 20. Allergic diseases

Nine studies from eight different populations reported associations between pesticide exposure and allergic disorders. Seven studies examined occupational exposure whereas two studies examined environmental exposure. Eight studies were cross-sectional investigations and therefore conclusions are prone to reverse causality and other biases. In terms of outcomes examined, five studies examined self-reported allergic rhinitis, one examined self-reported asthma and the remaining 3 examined selfreported skin irritation, contact dermatitis, food allergy, hay fever and fragrance allergies. Statistically significant results were reported by four studies on allergic rhinitis (ID ALL 003, ID ALL 004, ID ALL 005, ID ALL 006). These studies reported significant association between various pesticide classes and allergic rhinitis. In particular, the Agricultural Health Study (AHS) reported significant association between allergic rhinitis and exposure to the herbicides 2,4-Dichlorophenoxyacetic acid (2,4-D) glyphosate and petroleum oil, the insecticide diazinon and the fungicide benomyl. However, the study has many limitations and results need cautious interpretation and require replication by future prospective studies. The study is limited by its ability to distinguish allergic from non-allergic symptoms of rhinitis and to establish temporality between exposure and symptoms due to its crosssectional design. One study with low overall quality reported high effect sizes (OR, 12.50; 95% CI, 2.00-78.05) for allergic rhinitis in greenhouse flower and ornamental plant growers with pesticide application by hand pump vs. without (ID ALL 006). Again, the study has low overall quality, concerns a heavily exposed population with definition of exposure related to the method of application rather than a chemical class. Overall, the evidence around allergic disorders and pesticide exposure is weak.

The present document has been produced and adopted by the bodies identified above as author(s). This task has been carried out exclusively by the author(s) in the context of a contract between the European Food Safety Authority and the author(s), awarded following a tender procedure. The present document is published complying with the transparency principle to which the Authority is subject. It may not be considered as an output adopted by the Authority. The European Food Safety Authority reserves its rights, view and position as regards the issues addressed and the conclusions reached in the present document, without prejudice to the rights of the authors.

### 21. Haematological diseases

## 21.1. Aplastic anaemia

Three studies examined associations between pesticide exposure and aplastic anaemia; a rare hematologic condition. All studies were case-control designs and had small sample sizes (range 9-310). Two studies reported significant associations with large effect sizes but it is difficult to draw firm conclusions due to the small number of studies available and the limitations of these studies (Table 24). The other case control study (ID APL\_002) did not report effect sizes but only the p value of association, which was non-significant. Further evidence is required to throw light into these suggestive results.

 Table 24:
 Summary of results between pesticide exposure and aplastic anemia in 2 case-control studies that reported effect sizes

Study ID	Pesticide assessed	Comparison	OR	Lower 95% Cl	Higher 95% Cl	N cases	N controls
APL_001	Organophosphates	yes/no	2.1	1.1	4.2	21	32
APL_001	DDT	yes/no	6.7	1.5	30	5	4
APL_001	Carbamates	yes/no	7.4	1.7	31	8	3
APL_001	Paraquat	yes/no	2.3	1	5.1	12	24
APL_001	Other occupational pesticides	yes/no	1	0.4	2.2	11	32
APL_001	Any household pesticides	yes/no	1.3	0.9	1.9	64	238
APL_001	Organophosphates	yes/no	2.1	1	4.4	17	26
APL_001	Paraquat	yes/no	1.9	0.7	4.9	7	20
APL_001	Other occupational pesticides	yes/no	1.1	0.4	2.7	9	24
APL_003	Agricultural use of pesticides	yes/no	2.2	1.1	4.7	12	23
APL_003	Home use of pesticides	yes/no	1.3	0.9	1.9	70	240
APL_003	Organophosphorates	highest tertile of exposure/no exposure	3	0.9	10.1	5	7
APL_003	Pyrenthroids	highest tertile of exposure/no exposure	1.8	1	3.1	23	57
APL_003	Herbicides	yes/no	2.4	0.9	6	8	15

# 21.2. Haematological and biochemical alterations

Fourteen studies examined various haematological and biochemical alterations in relation to pesticide exposure. Main alterations studied were basic haematology and vitamin levels. The sample size ranged between 51 and 1,275. The quality of these studies was modest to low. Most studies reported unadjusted correlation statistics or means between haematological parameters and pesticide exposure and no effect sizes beyond the p values were reported. All studies provided cross-sectional evidence. Despite the fact than many of the reported analyses were statistically significant, results should not be interpreted at this stage due the limited evidence and modest quality associated with these data.

EFSA supporting publication 2013:EN-497

The present document has been produced and adopted by the bodies identified above as author(s). This task has been carried out exclusively by the author(s) in the context of a contract between the European Food Safety Authority and the author(s), awarded following a tender procedure. The present document is published complying with the transparency principle to which the Authority is subject. It may not be considered as an output adopted by the Authority. The European Food Safety Authority reserves its rights, view and position as regards the issues addressed and the conclusions reached in the present document, without prejudice to the rights of the authors.

### 22. Other outcomes

Overall, 30 publications examined the effect of pesticide exposure on other outcomes. Based on our criteria for data synthesis no meta-analysis was performed for those outcomes.

## 22.1. Bone diseases

Three studies examined the effect of pesticide exposure on osteoporosis including 13 different analyses. We identified two European cross-sectional studies and one Asian cohort (median sample size: 176, IQR: 153-908). All studies assess environmental exposure with information on biomarkers of exposure and all studies examined exposure to organochlorines only. Osteoporosis was assessed via ultrasound measurements and bone mineral density. The largest study of 908 women showed that p,p'-DDE was positively associated with bone mineral density, the association remained after adjustment for confounders, but the effect was weak.

## 22.2. Skin diseases

Six studies examined the effect of pesticide exposure on skin lesion (median sample size: 356, IQR 262-2203) including 11 analyses. Four studies used cross-sectional design. Environmental exposure was assessed in 3 studies. The definition of outcome was often skin rash or eczema. The resulst were largely not statistical significant. One prospective study (ID SKD 004) on 5,042 men from the Health Effects of Arsenic Longitudinal Study in Araihazar reported highly significant effect sizes for skin lesions and pesticide use but study also evaluated arsenic exposure and it is difficult to differentiate between the effect of each exposure.

### 22.3. Dental diseases

One study cross-sectional study from America including 496 participants assessed two outcomes. The study assessed environmental exposure with information of biomarkers (ID PER 001). In this study, organochlorine (OC) pesticides were strongly associated with periodontal disease.

### 22.4. Metabolic diseases

One European cross-sectional study assessed the effect of pesticides on metabolic diseases and specifically on levels of various prorfyrins including 8 analyses but no significant results were reported. Environmental exposure was studied using biomarkers for the assessment of exposure.

### 22.5. Men health

One case-control study reported association between pesticide exposure and erectile dysfunction. The study focused on organochlorine pesticides and compared 101 cases with erectile dysfunction to 234 comparable control subjects. The results were no statistically significant and do not provide evidence of an association.

EFSA supporting publication 2013:EN-497

The present document has been produced and adopted by the bodies identified above as author(s). This task has been carried out exclusively by the author(s) in the context of a contract between the European Food Safety Authority and the author(s), awarded following a tender procedure. The present document is published complying with the transparency principle to which the Authority is subject. It may not be considered as an output adopted by the Authority. The European Food Safety Authority reserves its rights, view and position as regards the issues addressed and the conclusions reached in the present document, without prejudice to the rights of the authors.

### 22.6. Gynaecological diseases

In this group we included gynaecological outcomes not included in the previous outcome categories. Four studies are included in this group, three examined endometriosis and one the timing of menopause. The three studies on endometriosis (ID GYN 001, ID GYN 002, ID GYN 003) were all cross-sectional and all examined organochlorines. One out of 12 separate analyses on endometriosis and organochlorines was statistically significant; the highest tertile of aromatic fungicide was associated with a fivefold risk of endometriosis (OR = 5.3; 95% CI, 1.2-23.6) compared to the lowest tertile. This effect size is large and requires independent replication in other prospective studies.

Data from the Agricultural Health Study (AHS) was used to study associations between exposure to pesticides and age at menopause in a prospective investigation of pre-menopausal women. After control for age, smoking status, and past use of oral contraceptives, the median time to menopause increased by approximately 3 months for women who used pesticides (HR 0.87, 95% CI: 0.78, 0.97) and by approximately 5 months for women who used hormonally active pesticides (HR 0.77, 95% CI: 0.65, 0.92). Pesticide use may be associated with a later age at menopause based on these results; however results are prone to false positive bias and independent replication is needed.

# 22.7. Symptoms and general health

Five studies examined general health symptoms such as nausea, fatigue, dizziness, and shortness of breath. The definition of these outcomes is very hard and associated with large measurement errors. Studies were of modest to low quality and all concerned occupational exposures. Some statistically significant results were observed but are far form conclusive at this stage due to heterogeneity of data reported and the limitations associated with these studies.

# 22.8. Kidney diseases

Three studies examined kidney diseases including chronic kidney disease and gallstone disease. One study reported statistically significant results between DDE and DDT residues and gallstone disease.

# 22.9. Benign tumours

One a population-based case-control study on acoustic neuroma found no link between pesticide exposure and acoustic neuroma.

# 22.10. Gastrointestinal diseases

Seven studies examining associations between pesticide exposure and liver enzymes were identified. All studies were cross-sectional or case-control. One study, the National Health and Nutrition Examination Survey (NHANES), examined organochlorines, another one examined exposure to 2,4-dichlorophenoxyacetic acid (2,4-D) and paraquat and the remaining studies examined broadly defined pesticide categories. The studies were of modest and low quality and presented only the means of enzymes in exposed and unexposed participants often without adjustments. Almost all studies reported statistically significant results with higher level of liver enzymes (e.g. Gamma-glutamyltransferase (GGT), Alanine aminotransferase (ALT), Aspartate aminotransferase (AST)) in participants exposed to pesticides. However, due to the low quality of the data and the limited number of studies firm conclusions cannot be drawn and data is only suggestive of associations at this stage.

### CONCLUSIONS

After an exhaustive and comprehensive search of almost 46,000 scientific publications we identified 602 publications, which examine epidemiologic associations between pesticide exposure and diverse health outcomes. The entire spectrum of health outcomes related to pesticide exposure has not been studied before. Our results show a very wide spectrum including 24 major disease categories. Few environmental exposures have been associated with such a wide range of outcomes. The most prevalent outcomes are cancers and mother and child health outcomes. But other disease categories have received considerable attention such as neurological conditions and reproductive diseases. Despite the large volume of available data and the large number (>6,000) of analyses available, firm conclusions cannot be made for the majority of the outcomes studied. This observation is disappointing especially when one accounts for the large volume of research in the area. However, this observation is in line with previous studies on environmental epidemiology and in particular on pesticides which all acknowledge that such epidemiological studies suffer from many limitations and that the heterogeneity of data is such that does not allows firm conclusions to de made.

The range of categories of pesticide studied is wide but studies very often concentrate on a broadly defined pesticide category, and it is hard to understand which pesticide the population is exposed to. Studies often examine pesticides that have already been banned in western populations and the European Union. The use of biomarkers as means of exposure assessment is infrequent but still available in almost half of the studies. In addition, cohort studies represent a minority of this literature with case control and cross-sectional studies representing an approximately equal proportion of eligible articles. Case-control and cross-sectional evidence does not allow the study of temporal relations and thus are unable to provide support regarding the causality of associations. The assessment of exposure is perhaps the most important methodological limitation of the studies. Studies used different methods for exposure assessment and assignment. Most studies were based on selfreported exposure to pesticides, defined as ever versus never use or as regular versus non-regular use. Such methods suffer from high misclassification rates and especially in the case of retrospective studies where misclassification would be differential with higher exposures reported in participants with disease (recall bias). Above all, such questionnaires might be capable of differentiating subjects with very high and very low exposure levels but are not capable of valid exposure classification across an exposure gradient thus not allowing the study of dose-response relationships. Also, the accuracy of exposure might be high for broad categories of pesticides and commonly used pesticides, but not for specific pesticides. It is important that questionnaires used for exposure assessment are validated. However, studies largely used "home- made" versions of questionnaires, sometimes not giving the information on the actual questions used to assess exposure. In addition, exposure simultaneously in multiple agents is common which may introduce further bias in the results. For example, occupational exposure to pesticides is likely to coexist with exposure to benzene, heavy metals, solvents, suspended particulate matter etc. all of which have adverse health outcomes. It is essential to account for confounding from exposure to multiple agents in order to delineate true associations but this has not been possible in the overwhelming majority of evidence assessed herein.

In addition, the evidence collected and appraised herein is likely to suffer from selective reporting and multiple testing. The studies reported a very wide range of analyses; 602 publications resulted in 6000 analyses. The amount of multiple hypothesis testing is enormous. These analyses need to be adjusted for multiple hypothesis testing else the results suffer from high false positive rate. Even when studies present only one analysis, selective reporting is always a possibility as has been shown in other epidemiological fields as well. In addition, when interpreting results one should also take into account that, especially for certain outcomes (e.g. cancers), the majority of evidence comes from single study populations and the AHS in particular.

Beyond definition of exposure, the definition of clinical outcomes displayed large variability in eligible epidemiological studies, which can further cause the variability in results. Perhaps most important in this setting is the use of surrogate outcomes examined. Here we observed a great number of surrogate outcomes. Surrogate outcomes are biomarkers or physical measures that are generally accepted as substitutes for or predictors of specific clinical outcomes. However, many times these surrogate outcomes are unvalidated and do not meet the strict definitions of surrogate outcomes. Such outcomes can be defined as possible predictors of clinical outcomes but do not fulfil the criteria for a surrogate outcome. It is essential that the evidence around unvalidated surrogate outcomes are appraised taking into account the implicit assumptions of unvalidated surrogate outcomes.

Acknowledging these limitations we attempted to summarise the evidence retrieved in this report. An added important limitation here is the fact that this review is limited to publications after 2006. This allows us only to review recent evidence and any meta-analysis needs very cautious interpretation, as it does not include all available evidence. Results might be biased if data published after 2006 are different from earlier evidence. To this end, we also provided updated meta-analysis for major outcomes and for those that a relevant meta-analysis published after 2006 was identified. This has only been possible for childhood leukaemia and for Parkinson's disease. For both these outcomes we found significant associations between pesticide exposure and disease in line with previous evidence. Significant summary estimates have also been reported for other outcomes as summarised in Table 25 below. However, as they represent studies form 2006 onwards results should be regarded as suggestive of associations only and limitations especially regarding the heterogeneity of exposure should always been take into consideration.

### RECOMMENDATIONS

As discussed above, the extensive evidence gathered for this report highlights that there is immense amount of information available on pesticide exposure and health outcomes from epidemiological studies. Nonetheless, the quality of this evidence is usually low and many biases are likely to affect the results to an extent that firm conclusions cannot be made. Childhood cancers and Parkinson's disease are the two outcomes for which a corresponding meta-analysis after 2006 was found and for which data are consistent to show an increased risk associated with pesticide exposure. Nonetheless, the exposure needs to be studies further in order to disentangle the effect of specific pesticide classes or even individual pesticides. Effects on other outcomes, such as endocrine disorders, asthma and allergies, diabetes and obesity, are showing increased risk and should be explored further. This report concentrated on examining separately health outcomes. An alternative approach would be to look for pesticide classes, subclasses or even individual pesticides across a range of outcomes. These approaches could highlight whether a pesticide class has a particular detrimental effect across a variety of disease endpoints. Finally, exposure epidemiology has long suffered from exposure measurement and definition and in particular for pesticides this has always been exceptionally difficult to assess and define. Technological advances now enable us to measure in a large scale and agnostic way biomarkers of exposure using high throughput technologies of omics. For example, metabolomic analysis offers a way to capture a whole range of environmental exposures with minimal measurement error and ability to specify the exposure. These approaches are now being developed and are likely to offer much clearer view on the associations between environmental exposures, including dietary exposures, and health outcomes.

# APPENDIX II. EXPLANATIONS TO THE DATA EXTRACTION DATABASE

Study ID	This is the unique ID of the study given sequentially for each
	study major outcome
PUBMED_ID	This is the PUBMED ID of the study (if not available ID in
	EMBASE was provided and when this was not available the
	title of the study was provided)
First author	First author's last name
Journal	Journal in which the study was published
Year	Year of publication
Country	Country where the study was conducted
Location (continent)	Continent where the study was conducted
Recruitment period	Period during which the study participants were recruited
Exposure Period (preconception,	Growth period in which the pesticide exposure occurred
infancy, childhood, adulthood,	(preconception, pregnancy, infancy, childhood, adolescence,
pregnancy)	adulthood)
Follow-up period	Follow-up calendar period for prospective/ retrospective studies
Follow-up duration (maximum)	Maximum follow-up period in years for prospective/
	retrospective studies
Follow-up duration (years)	Mean or median follow-up period in years for prospective/
(median/mean)	retrospective studies
Study type (cohort, nested case-	The epidemiological study design: cohort, nested case-control,
control, case-control, cross-	case-control, cross-sectional
sectional)	The name of the enviolenced study
Cohort name	The name of the epidemiological study
Age (years) (range/mean/median)	The age of the population studied (preference is to provide the mean or meadian age, when not available the range is
	given). Data is presented in years unless otherwise stated.
Gender (% male)	Percentage of males in study population
Active substance assessed	Pesticide assessed in the study as defined/named in the study
Active substance category	Chemical or functional pesticide category in which the
	pesticide is classified
Authorisation status	Pesticide active substances authorized within EU
	(06/09/2013). Yes/No/NA (NA=not applicable)
Biomarker name	The name of the biomarker of exposure to pesticide (if
	measured)
Control definition	Definition of the control group in case-control studies
Pesticide co-exposure (measured)	Did the study provided information on other co-exposed pesticides? (yes, no)
Population characteristics	Description of the population examined (gender, location,
	disease status)
Type of exposure (occupational,	What is the source of exposure to pesticides: occupational (if
environmental, both)	the exposure is related to a specific occupational activity);
	environmental (if the exposure is not related to any

Pesticide epidemiology

	occupational activity (e.g. domestic use of pesticides, use of
	pesticides in gardening, exposure related to gardening etc.); both (when both occupation and environmental exposure is
	present).
Type of exposure assessment (direct	Means of measuring pesticide exposure: direct exposure
exposure questionnaire/ biomarker/residential	questionnaire (interview or self-administered); measurement of biomarker in biological fluids; residential history;
history/occupational history/ JEM/	occupational history; Job Exposure Matrix (JEM)
expert evaluation/ environmental	
odeling)	
Exposure definition	Definition of exposure as described in the study
Questionnaire type	Questionnaire type (interview or self administrated) (for
	studies which assessed exposure through questionnaires, else state n/a)
Measurement of biomarker (whole	Body fluid or tissue in which the biomarker was measured
blood, plasma, urine, breast milk,	(whole blood, plasma, urine, breast milk, placenta, nails, hair,
placenta, nails, hair, saliva, adipose	saliva, adipose tissue etc.)
tissue)	Tupo of biochomical accounted for biomarker measurement
Assay type Exposure duration	Type of biochemical assay used for biomarker measurement Duration of exposure to pesticides in years (when available)
Pediatric exposure type (mother,	For studies on child outcomes, describe means of exposure
father, child, combinations)	through self-exposure or parental exposure (mother, father,
	child, combinations)
Pediatric exposure time	For studies on child outcomes, was parental exposure during
(preconception, pregnancy,	preconception, pregnancy or combinations?
combination)	
Health outcome	Health outcome as described in the study
Outcome definition	Health outcome definition used in the study
Disease category Effect estimate type (RR, OR, HR,	Disease category Type of effect estimate for the assessment of pesticide and
beta, MD, SMD)	health outcome relationship (RR, OR, HR, beta, MD, SMD)
Effect (binary, continuous)	Effect estimated on a binary or continuous manner (binary,
× 5. ,	continuous)
Comparison unit (yes/no, unit	The definition of comparison for the calculation of the effect
increase,)	size (yes/no, unit increase etc.)
Effect estimate	Value of effect estimate
SE/SD effect stimate	Standard error/Standard deviation of effect estimate
Lower 95% CI	Lower 95% confidence interval of the effect estimate
Higher 95% Cl	Higher 95% confidence interval of the effect estimate
Adjustment for	Confounders/ variables for which the effect estimate was adjusted for
Controls matched for	Variables for which controls were matched to cases (case
	control studies only)
Sample size	Total number of participants
N cases	Number of cases

Ntzani EE, Chondrogiorgi M, Ntritsos G, Evangelou E, Tzoulaki I

Pesticide epidemiology

N controls	Number of controls
Statistical method	Statistical method used to calculate the effect size
Study design (prospective, retrospective, mixed, cross- sectional)	Prospective or retrospective type of study design (prospective, retrospective, mixed, cross-sectional)
Inclusion/exclusion criteria clearly stated (yes, partially, no) Authors mention power calculations (yes, no) Level of detail in describing exposure (high, medium, low) Robust measurement of exposure. (biomarker (yes); small area ecological measures, job titles, questionnaire (partial); was based on large area ecological measures (no)	Was the description of study participants (population) inclusion and exclusion criteria detailed? (yes/partially/no) Do the authors mention power calculations in the manuscript preceding or proceeding their statistical analysis (yes/no) Level of detail in which the definition of exposure to pesticides is provided (high/medium/low) Was the measurement of exposure robust: biomarker (yes); small area ecological measures, job titles, questionnaire (partial); was based on large area ecological measures (no)
Were measures of exposure specific? Yes; based on broader, chemically-related groups (partial); based on broad groupings of diverse chemical and toxicological properties (no)	Were measures of exposure specific? (yes); based on broader, chemically-related groups (partial); based on broad groupings of diverse chemical and toxicological properties (no)
Attempt to balance the allocation between the groups (e.g., through stratification, matching) Adjustment performed for	Was an attempt to balance the allocation between the groups in case-control studies either through stratification or matching (yes/no)? Was the effect size adjusted for potential confounders (yes,
potential confounders (yes, some, no)	some, no)?
Assessors blinded to exposure status (for cohort studies)	Were the assessors blinded to exposure status in cohort studies (yes/no/;n/a:not available or not applicable when studies are not cohorts)?
Outcomes assessed using valid and reliable measures, implemented consistently across all study participants?	Were the outcomes assessed using valid and reliable measures implemented consistently across all study participants (yes/no)
Sample size (top [991], middle, bottom quartiles[104])	The size of the sample
Was source of funding acknowledged	Do the authors acknowledge any possible source of funding (yes/no)
Rough quality assessment	Rough quality assessment taking into account the data in all other columns of the quality assessment of data extraction form
COMMENTS	Any comments related to the study that help interpretation of the data extracted

#### **GLOSSARY AND ABBREVIATIONS**

AHS: Agricultural Health Study

Beta estimate: coefficient of linear regression

Bias: A systemic inaccuracy in data due to the characteristics of the process employed in the creation, collection, manipulation and presentation of the data or due to faulty sample design of the estimating technique

Biomarker: A measurable substance or characteristic in the human body that can be used to monitor the presence of a chemical in the body, biological responses, or adverse health effects. Biomarkers of exposure are used to assess the amount of a chemical that is present within the body.

Blinded outcome assessment: Individuals who assess the exposure are blinded to the health outcome status of the participants.

CARDIA: The "Coronary Artery Risk Development In Young Adults" study, a multi-center, population-based study.

Case-control study: A type of observational study in which two existing groups differing in outcome are identified and compared on the basis of some supposed causal attribute. Case-control studies are retrospective, as the exposure status is assessed retrospectively.

Case reports: Detailed reports of the symptoms, signs, diagnosis, treatment, and follow-up of individual patients.

Case series: descriptive study that tracks patients with a known exposure given similar treatment or examines their medical records for exposure and outcome. These studies lack control groups.

Center-specific analysis: Analysis per centre in studies, which have participants, recruited from more than one centre.

CHAMACOS: The Center for the Health Assessment of Mothers and Children of Salinas (CHAMACOS). A prospective birth cohort aimed at studying the association of pesticides and other environmental agents on the health of pregnant women and their children living in the Salinas Valley, California.

#### CI: Confidence Interval

Cohort study: A longitudinal/prospective study, which analyses risk factors and follows a group of people who do not have the disease until participants develop the disease(s) of interest

Confounders: Extraneous variables in a statistical model that correlate (positively or negatively) with both the dependent variable (exposure) and the independent variable (outcome)

Cross-sectional study: A study that involves observation of all of participants at one specific point in time, exposure and outcome are measured in the same time point.

Ecological study: Studies in which the unit of observation is the population or community. Disease rates and exposures are measured in each of a series of populations and their relation is examined.

EFSA supporting publication 2013:EN-497

157

The present document has been produced and adopted by the bodies identified above as author(s). This task has been carried out exclusively by the author(s) in the context of a contract between the European Food Safety Authority and the author(s), awarded following a tender procedure. The present document is published complying with the transparency principle to which the Authority is subject. It may not be considered as an output adopted by the Authority. The European Food Safety Authority reserves its rights, view and position as regards the issues addressed and the conclusions reached in the present document, without prejudice to the rights of the authors.

Effect (binary/continuous): Outcome is binary (dichotomous, e.g. cancer (yes/no)) or continuous (e.g. systolic blood pressure (120mmHg)).

Effect estimate/ size: A measure of the strength of association

ESCALE: The "Etude sur les cancers de l'enfant" study, a national registry-based case-control study

Funnel plots: graph designed to check the existence of publication bias in systematic reviews and meta-analyses

Heterogeneity: meta-analysis is used to estimate a combined effect from a group of similar studies. However, the individual estimates of treatment effect will vary by chance; some variation is expected. The question is whether there is more variation than would be expected by chance alone. When this excessive variation occurs, it is called heterogeneity

#### HR: Hazard Ratio

 $I^2$ : measure of the consistency between trials in a meta-analysis, it is a measurement of heterogeneity and takes values form 0 (no heterogeneity) to 1 (extreme heterogeneity)

INUENDO: "INUENDO—Biopersistent organochlorines in diet and human fertility" Epidemiological studies of time to pregnancy and semen quality in Inuit and European populations", a European project on fertility that was supported by the European Commission to the 5th Framework Programme Quality of Life and Management of Living Resources, Key Action 4 on Environment and Health (Contract no. QLK4-CT-2001-00202) (http://www.inuendo.dk).

IRR: Incidence rate ratio

IQR: Interquartile Range

JEM :Job Exposure Matrix

MD: Mean Difference

Meta-analysis: The process or technique of synthesizing research results by using various statistical methods to retrieve, select, and combine results from previous separate but related studies.

Multiple testing: Testing many hypotheses, which are not a priori defined or based on a priori hypothesis.

Misclassification: Bias in an estimate arising from measurement error

Multivariable models: Statistical models with more than one dependent variable. These models typically adjust for a number of confounders the analysis of interest.

Nested case-control study: In a nested case-control study, cases of a disease that occur in a defined cohort are identified and, for each, a specified number of matched controls is selected from among those in the cohort who have not developed the disease by the time of disease occurrence in the case

NHANES: National Health and Nutrition Examination Survey

EFSA supporting publication 2013:EN-497

The present document has been produced and adopted by the bodies identified above as author(s). This task has been carried out exclusively by the author(s) in the context of a contract between the European Food Safety Authority and the author(s), awarded following a tender procedure. The present document is published complying with the transparency principle to which the Authority is subject. It may not be considered as an output adopted by the Authority. The European Food Safety Authority reserves its rights, view and position as regards the issues addressed and the conclusions reached in the present document, without prejudice to the rights of the authors.

Observational study: an observational study draws inferences about the possible effect of a treatment on subjects, where the assignment of subjects into a treated group versus a control group is outside the control of the investigator

OR: Odds ratio

Pooled effect estimate: Summary effect estimate of the meta-analysis, the result of meta-analysis

POPs: Persistent Organic Pollutants

Prospective study: An epidemiologic study in which the groups of individuals (cohorts) are selected on the bases of factors that are to be examined for possible effects on some outcome

Publication bias: Bias arisen from the tendency for <u>researchers</u>, editors, and pharmaceutical companies to handle the reporting of experimental results that are *positive* (i.e. showing a <u>significant</u> finding) differently from results that are <u>negative</u> (i.e. supporting the <u>null hypothesis</u>) or inconclusive.

Recall bias: Systematic errors due to differences in accuracy or completeness of recall to memory of past events or experiences.

Residual confounding: Residual confounding occurs when a confounder has not been adequately adjusted for in the analysis (usually because the confounder is not known)

Retrospective study: an epidemiologic study in which participating individuals are classified as either having some outcome (cases) or lacking it (controls); the outcome may be a specific disease, and the persons' histories are examined for specific factors that might be associated with that outcome

Reverse causality: Reverse causality refers to the direction of cause-and-effect, it is not known whether the exposure has led to the outcome or the outcome has led to the exposure.

RR: Relative Risk

Narrative review: An article written to consider the critical points of current knowledge including substantive findings, as well as theoretical and methodological contributions to a particular topic

SD: Standard Deviation

SE: Standard Error

Surrogate outcome: A laboratory measurement or physical sign that is used in trials as a substitute for a clinically meaningful endpoint that is a direct measure of how a patient feels, functions, or survives and is expected to predict the effect of the exposure

Systematic reviews: Reviews of the evidence on a clearly formulated question that use systematic and explicit methods to identify, select and critically appraise relevant primary research, and to extract and analyse data from the studies that are included in the review

Type-I error: The incorrect rejection of a true null hypothesis

UFW: United Farm Workers

## 農薬ばく露と健康影響に関連する疫学研究に関する文献レビュー<sup>1</sup>

Evangelia E Ntzani, Chondrogiorgi M, Ntritsos G, Evangelou E, Tzoulaki I

Department of Hygiene and Epidemiology, University of Ioannina Medical School, Ioannina,

Grecce

#### 概要

我々は、2006 年以降に発表された農薬ばく露と健康影響との関連を調査した疫学研究の系統的かつ 広範な文献レビューを行った。43,259 件の引用文献を検索し、非常に多様な影響を調査した 603 件の 論文を同定し、6,000 件以上の農薬ばく露と健康影響との間の分析結果を提示した。さまざまな影響を 23 の主要な疾患カテゴリーに分類した。研究の中で最も多いのは、発がん影響(N=164)と子どもの健 康に関連した影響(N=84)であった。研究の大部分は症例対照研究と横断研究(N=222)で、農薬への 職業ばく露(N=329)を調査したものであった。さまざまな農薬の定義を用いて研究が行われ、広範囲 かつ多様な農薬が研究されていたため、これらの情報を研究間で調和させることは非常に難しい。利 用可能なデータの量が多く、分析の数も多い(6,000以上)にもかかわらず、研究された結果の大部分 について確固たる結論を出すことはできなかった。これは、この分野の研究量の多さを考慮すると、特 に残念な結果である。しかし、この結果は環境疫学、特に農薬に関するこれまでの研究と一致してお り、疫学研究には多くの限界があり、データの不均一性があるために確固たる結論を出すことができ ないことを認めている。我々はまた、主要な影響及び2006年以降に発表された関連するメタアナリシ スが確認されたものについて、更新されたメタアナリシスを実施した。これは小児白血病とパーキン ソン病についてのみ可能である。これらの影響については、以前のエビデンスに沿って、農薬ばく露と 疾患との間に有意な関連があることが分かった。

### 背景と参考文献

ここ数年の間に、農薬ばく露とヒトへの有害健康影響との関連を調査する疫学研究が豊富に行われ るようになった。これらの研究では、例えば、吸入、経口、経皮及び経胎盤による農薬ばく露が、様々 な臓器や組織のがん、小児の神経発達障害、アレルギー、生殖能力の低下(男性と女性)、先天異常、 パーキンソン病などの原因となる、あるいはその可能性が示唆されていることが立証されている。

しかし、農薬ばく露に起因する多くの有害健康影響については、矛盾した、あるいは曖昧な研究も存 在する。研究は一般的にデザイン(例:症例対照研究とコホート研究)、サンプルサイズ、そして多く の場合、ばく露量は実際の測定値ではなく、むしろ推定値または想定値である。

2006年1月1日から2012年3月31日までの関連出版物を網羅した包括的な最新の文献収集とレビューを実施し、これらの研究の質も評価すべきである。

今回の調達手続きによる契約の目的は以下の通りである。

目的1:農薬ばく露とヒトへの有害健康影響との関連が調査された科学的出版物を収集・集積する。

目的2:収集された各研究の質的側面(調査のコーナーポイントなど)をレビューし、評価する。

目的3:疫学研究のデータベースと報告書の提供。

本契約は、EFSAが次の者に授与した。イオアニナ大学医学部衛生・疫学部(Ioannina, Grecce) 契約者: イオアニナ医科大学衛生・疫学部、イオアニナ大学、(Ioannina, Grecce)。 契約タイトル: 農薬へのばく露と健康影響を関連付ける疫学研究の文献調査 契約番号: CFT/EFSA/PRAS/2012/04 - CT 01

### 序文と目的

本プロジェクトは、すでに確立されている、あるいは示唆されているヒトにおける有害影響との関 連についての理解を深めるために、農薬ばく露と健康関連影響との関連を調査するために実施された 疫学研究を体系的に収集し、レビューし、評価することを目的としている。このレビューでは、特に食 い違いの原因を調査することに焦点を当て、職業を通じた、あるいは一般集団におけるすべてのばく 露タイプに焦点を当てている。特に、農薬ばく露とヒトへの有害健康影響との関連が調査された科学 的出版物を収集した。利用可能なエビデンスは、その質的側面に関してレビューと評価が行われてい る。最後に、農薬の有害健康影響を調査した研究のデータベースを作成した。

最終報告書は、健康影響カテゴリーを中心に構成され、データ抽出データベースとリンクしている。 方法のセクションでは、文献レビューと研究の選択プロセスで使用した検索基準と検索戦略の詳細な 文書を提供している。このセクションでは、選択されたばく露とばく露指標及び検討された代用及び 臨床影響に関する詳細な文書を用いた分析的枠組みについても記述している。対象となる研究の完全 なリストとデータ抽出データベースの内容を含めた文献検索の結果を提示する。また、検討した影響 と農薬の結果及び文献レビューの結果に基づく結論を提示する。

#### 背景と目的

農薬は、昆虫、真菌、野鼠、不快生物、雑草などの作物にダメージを与えることができる有害生物に 対して広く使用されており、長年にわたり、損失を防止または削減し、作物の品質を向上させるために 使用されている。2006年と2007年には、世界で約52億ポンドの農薬が使用された。しかし、農薬は広範 囲に使用されており、それに関連して農薬の使用による利益があるにもかかわらず、これらの化学物 質は対象生物に有害影響を及ぼすように設計されているため、ヒトへの有害健康影響が懸念されてい る。実際、農薬の使用とがん、神経変性疾患、先天異常などの健康有害影響との間にはエビデンスがあ るが、これまでのところ結果には一貫性がなく、いくつかの農薬について確固たる結論を出すことは できていない。

本レビューの目的は、農薬ばく露と健康関連影響との関連を調査するために実施された疫学研究を 体系的に収集し、レビューし、評価することである。このレビューでは、特に食い違いの原因を調査す ることに重点を置いて、職業を通じた、または一般集団におけるすべてのばく露タイプを対象として いる。特に、農薬ばく露とヒトへの有害健康影響との関連が調査された科学的出版物を収集し、まとめ た。利用可能なエビデンスは質的側面に関してレビューされ評価され、妥当な研究からデータが抽出 されている。最後に、結果の継続的な更新を容易にする目的で、農薬の有害健康影響を調査した研究の データベースを作成した。

前述の目的は、特に環境疫学と農薬ばく露の方法論的課題と、膨大な量の査読付き文献のため、刺激的な課題を構成している。

### 材料と方法

### 1. 検索戦略

包括的な文献検索を実施し、農薬ばく露と健康影響に関する査読付きの原著研究を対象とした。検 索戦略は、2006年1月1日から2012年9月30日までに発表された観察疫学研究で、重要なばく露期間(妊 娠前、妊娠期、小児期、成人期)における農薬ばく露と健康関連影響との関係を調査したものを特定す るように設計された。検索戦略は、主にMEDLINE(1950年から現在まで)、EMBASE(Excerpta Medica Database、1980年から現在まで)データベースを使用し、TOXNET(Toxicology Data Network、U.S. National Library of Medicine 2012)、OpenSigle(2012)及びProQuest Digital Dissertations and Theseses(2012)を補足検索として使用した。

### 2. MEDLINE 及び EMBASE における原著論文の検索アルゴリズム

本システマティックレビューは、農薬へのばく露と関連した臨床影響または臨床影響の代用となる 有効なバイオマーカーを調査した研究を特定することを目的とした。最大限の感度を得るために、我々 が開発した検索アルゴリズムには影響に関連する検索用語は含まれていない。検索アルゴリズムの構 築にあたっては、MEDLINEMESHの用語とEMBASEの農薬分類ツリーを用いて同定された農薬関連の用語に 集中した。MEDLINEでは、農薬と農薬(薬理作用)のMESH用語を調べた。同様に、EMBASE Entreeインデ ックスの農薬用語を調べた。農薬のカテゴリー(例えば、殺虫剤、除草剤、殺菌剤など)と、文献に記 載されている特定の農薬名、または薬理学的用語(例えば、DDTまたはジクロロジフェニルトリクロロ エタン)を網羅的に調べた。また、過去10年間の農薬ばく露に関する出版されたシステマティックレビ ューで使用された検索用語を調べ、追加の用語を調べた。

最初に構築したアルゴリズムは、前述のすべての用語を含む長いものであった。異なる検索を試験 的に行い、精度への影響を最小限に抑えながらアルゴリズムの感度を向上させるために検索を短縮し た。すべての検索はヒトに限定し、2006年1月1日以降の出版日に限定した。

農薬薬理学的名称のMESHデータベースから提供された農薬名の長いリストは、MEDLINEの農薬関連 語検索(pesticid\* OR pesticides"[MeSH Terms] OR "pesticides"[All Fields] OR "pesticide"[All Fields] OR "pesticides"[Pharmacological Action])の上位2,270件の引用のみを提供していた。そ のうち2,270件の引用のうち200件を調査したところ、疫学研究は含まれておらず、農薬の物性や化学 構造に関する化学的研究を参照していることが判明した。そこで、一般用語を含む検索アルゴリズム を採用した。アルゴリズムは、データベースがMEDLINEとEMBASEを同時に検索する機能を提供している ため、EMBASEで構築した(下記のテキストボックスを参照)。以下のようなアルゴリズムを構築した。

### 表 1: EMBASE 及び MEDLINE の検索アルゴリズム

pesticid\* OR 'pesticide'/exp OR 'chemical pest control'/exp OR fungicid\* OR 'fungicide'/exp OR herbicid\* OR 'herbicide'/exp OR insecticid\* OR 'insecticide'/exp OR molluscacid\* OR'molluscacide'/exp OR molluscicid\* OR 'molluscacide'/exp OR rodenticid\* OR 'rodenticide'/exp OR carbamat\* OR 'carbamate'/exp OR pyrethroid\* OR 'pyrethroid'/exp OR 'chlorinated hydrocarbon'/exp OR 'agricultural chemical'/exp AND [humans]/lim AND [2006-2013]/py

このアルゴリズムにより、EMBASE と MEDLINE を合わせて 43,259 件の引用が行われた。そのうち 14,539 件は EMBASE に固有のものであった。このアルゴリズムには、分割オプションを使用して Emtree エン トリとして、またテキストワードとして使用された農薬関連の用語とサブカテゴリがすべて含まれて いる。分割オプションを使用すると、用語が Emtree のシソーラス内でより具体的な、またはより狭い インデックス用語を持つ場合、それらも検索の一部として自動的に検索される。有機塩素、グリホサー ト、パラコート、マネブなどの用語は、分割オプションの農薬ツリーの一部であり、検索されるため、 除外された。これらの用語を含めると、同じ結果が得られる。以下の図 1 は、EMBASE で検索された用 語のインデックスツリーの例を示している。

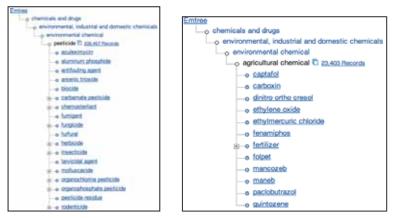

図 1: Emtree の分類ツリーの例

### 3. 補足検索

また、毒性学、有害化学物質、環境衛生、有害物質排出に関するデータベースを掲載しているTOXNET のデータベースを検索し、MEDLINEやEMBASEでの前回の検索で見逃した情報を特定した。生物医学文献 (Toxicology Literature Online (TOXLINE)及びDevelopmental Toxicology Literature (DART))の 文献を検索するデータベースのみを使用した。残りのTOXNETデータベースは、化学物質ごとの化学的 データ、毒物学的データ、環境データのサマリーを提供しており、今回の検索には関係なかった。 TOXLINEとDARTについては、「Pesticide OR Pesticides」という一般的な用語を使用したが、農薬のサ ブカテゴリを含む検索アルゴリズムが長くなっても、同定された参考文献の数にわずかな影響しかな かったためである。検索は2006年以降の出版日に限定し、MEDLINEで同定された文献は除外した。検索 語の化学物質の同義語を特定する機能を有効にした。全体では、TOXLINEから893件、DARTから34件の文 献が検索された。

また、ヨーロッパで出された灰色文献[非商業出版物](論文)の書誌的参考文献700,000件を収録したSystem for Information on Grey Literature in Europe (OpenSigle)も調べた。2006年以降に出

版された農薬(検索語pesticid\*)に関する書誌的文献はなかった。

また、ProQuest Digital Dissertations and Thesesデータベースを検索するための検索アルゴリズ ムを構築した。MEDLINEやEMBASEで検索した結果、学術雑誌に掲載された論文は検索対象から除外した。 検索語を"pesticide\* AND health "とし、特定の主題(環境科学 OR 公衆衛生 OR 環境保健 OR 疫学 OR 農薬 OR 栄養 OR 労働衛生)と、2006年から2012年までの出版日に限定して検索を行った。この検 索戦略の結果、1,713件の検索結果が得られた。主題制限が行われていない場合(12,135)、または「健 康」という用語が最初のアルゴリズムから除外されている場合(18,195)には、多くの検索結果が得ら れた。

最後に、特定されたすべての妥当な研究とシステマティックレビューの参考文献リストをデータ抽 出の際にスキャンして追加の参考文献を探した。

#### 4. 文献システマティックレビューとメタアナリシスの検索

また、特定の健康影響に関連したシステマティックレビューやメタアナリシスを対象とした検索を 行った。MEDLINEでは、4件以上の研究が確認された健康影響を対象としたレビューに限定し、健康影響 名と「システマティックレビュー OR メタアナリシス」というキーワードを用いて、論文のタイトル または要約に限定して検索を行った。

#### 5. 本報告書の構成

本報告書は、健康影響のカテゴリーを中心に構成されており、各健康影響のグループの結果を個別 に提供している。最後に一般的な結論のセクションが提示されている。また、各健康影響のセクション の最後には、読みやすいように表と図を掲載している。また、本文中では各対象論文の ID 番号を参 照している。これらは、本報告書に別ファイルとして提供されているデータ抽出データベースの各健 康影響グループの ID に対応している。IDは、特定の健康影響の略語と研究番号で定義されている。

# 表2:検索されたリソース、検索語及び特定された参照先の概要

データ			
ベース	検索条件	Limits	文献数
MEDLINE	pesticid* OR 'pesticide'/exp OR 'chemical pest control'/exp OR fungicid* OR 'fungicide'/exp OR herbicid* OR 'herbicide'/exp OR insecticid* OR 'insecticide'/exp OR molluscacid* OR 'molluscacide'/exp OR molluscicid* OR 'molluscicide'/exp OR rodenticid* OR 'rodenticide'/exp OR carbamat* OR 'carbamate'/exp OR pyrethroid* OR 'pyrethroid'/exp OR 'chlorinated hydrocarbon'/exp OR 'agricultural chemical'/exp pesticid* OR 'pesticide'/exp OR 'chemical pest control'/exp OR fungicid* OR 'fungicide'/exp OR herbicid* OR 'herbicide'/exp OR insecticid* OR 'insecticide'/exp OR molluscacid* OR 'molluscicide'/exp OR molluscacid* OR 'molluscicide'/exp OR rodenticid* OR 'rodenticide'/exp OR carbamat* OR 'rodenticide'/exp OR pyrethroid* OR 'molluscicide'/exp OR carbamat* OR 'rodenticide'/exp OR carbamat* OR 'rodenticide'/exp OR pyrethroid* OR 'pyrethroid'/exp OR pyrethroid* OR 'pyrethroid'/exp OR pyrethroid* OR	ヒト, 公開日: 2006~2012 ヒト, 公開日: 2006~2012 ELINE で確認された文献は無	28, 729

#### 6. 研究の選択

様々なデータベースの文献検索で特定されたすべてのタイトルをスクリーニングし、農薬と代替健 康影響を含む健康影響との関連を評価した研究を特定した。次に、選択したタイトルのすべての要約 を重複してスクリーニングし、農薬ばく露と代替健康影響を含むあらゆる健康影響との関連を評価す る疫学研究を特定した。主要研究とシステマティックレビューまたはメタアナリシスの両方を選択す る。要約審査の段階で妥当性基準を満たす可能性のある論文を検索し、全文論文を重複して審査して 妥当性を確認した。すべての全文論文の却下理由は記録されている。

#### 6.1. 全文論文の妥当性基準

農薬ばく露と健康関連影響との関連を評価する観察研究を対象とした。コホート研究、横断研究、症 例対照研究を対象とした。2006 年 1 月 1 日から 2012 年 9 月 30 日までに発表されたヒトを対象 とした研究を対象とした。動物を対象とした研究及びヒトの細胞を対象とした研究は除外した。言語、 集団、地理的制限はなかった。エビデンスの全体性を高めるために、すべての種類の農薬を考慮した。 農薬へのばく露は、研究参加者による農薬の使用報告、または政府登録データ(自己管理質問紙、面接 官管理質問紙、職業ばく露マトリックス (JEM))、居住状況(農薬ばく露への近接性)、農薬ばく露 に関連するバイオマーカーの検出、または各研究で定義されたその他の手段によって定義されたもの とした。妥当な健康関連影響は、腫瘍形成やパーキンソン病などの「主要な」臨床影響、神経認知スケ ールなどの臨床代替健康影響、肝酵素などの臨床影響との関連が確立されている代用実験的影響とし た。

ナラティブレビュー、症例集積、症例報告(対照集団のない研究)は除外した。また、農薬中毒また は不慮の高用量農薬ばく露による健康関連の影響を評価する研究も除外した。論文で報告された十分 な量的情報(効果推定値など)が入手できない研究は除外し、効果量や関連の尺度を計算できるように した。異なる追跡期間で同じ研究に関連する報告があり、同じ結果を調査している場合は、データの重 複を避けるために、追跡期間が長い方の研究を保持した。また、肥料に言及した研究(アルゴリズム用 語「農薬」から分解)や、抗凝固剤のワルファリンや疥癬の治療に用いられる薬剤など、様々な病状の 治療に用いられる物質の副作用に言及した研究も除外した。農薬・除草剤に含まれる溶剤などの非有 効成分は対象外とした。化学戦経験者に対するオレンジ剤の様々な影響を調査した研究は、極高用量 ばく露の事例であるため除外した。最後に、ばく露とばく露のバイオマーカーとの関連を調査した研 究も、健康への影響を調査していないため、対象外とした。最後に、EFSAとの協議により、ヒ素、アル ファ及びベータへキサクロロシクロへキサン(HCH)、鉛、ポリ塩化ビフェニル(PCB)を含むダイオキ シン類などの農薬へのばく露を調査した研究/分析は、本プロジェクトには関係がないと考えられる ため除外した。

システマティックレビュー及びメタアナリシスについては、評価された農薬、ばく露域、影響にかか わらず、健康関連影響に対する農薬ばく露の影響をシステマティックに評価したすべてのシステマテ ィックレビュー及びメタアナリシスを調査した。系統的アプローチ(系統的文献検索、対象とした研究 の方法論的特徴の評価、メタアナリシスが実施された場合には重み付け要約推定値の使用や不均一性 の形式的評価を含む標準的な分析ツールの使用)が承認されているすべての出版物を対象とした。ナ ラティブレビューは除外する。

### 6.2. 品質管理対策

パイロット文献検索はすべて重複して実施した。さらに、すべてのタイトル検索の最初の500件の結 果は重複して行い、研究者間で結果を比較し、高いレベルの一致を示した。同意度のカッパ統計量は 0.78であった。2人の独立した研究グループのメンバーが、要約スクリーニング、全文スクリーニング、 データ抽出を重複して行った。すべての不一致は、合意または第三者の判定によって解決した。

### 6.3. データ抽出データベース

全工程を通じて実行されたデータ抽出項目と品質評価項目を用いて、データ抽出データベースの構 築及び確認を行った。データ抽出データベースは7つのドメイン:参考文献、期間、試験特性、ばく露 評価、影響、統計分析、品質評価(別々のファイル)で構成されている。最初の 6 つの領域は、対象 となる研究の全文から直接抽出された情報に関連しており、主に定量的統合のための研究を選択し、 定量的統合を支援するために使用される。研究は、調査された各影響と調査された各ばく露について、 データベースの一行を提供している。研究が様々なばく露の定義を提示している場合には、最も包括 的なばく露の定義をデータ抽出のために選択し、それに続いてサンプルサイズが最も大きいものを選 択する。しかし、同じ化学物質の同定に使用される異なるバイオマーカーの定量的情報を含む研究、例 えばジクロロジフェニルトリクロロエタン (DDT)の p,p'-DDT と p,p'-DDE のように、それらはすべ て別々の行で報告されている。研究がサブグループでデータを提示している場合(例:男性と女性) は、データがサブグループでのみ提示されている場合は複合論争が提示されている場合を除き、主分 析(グループ全体)のみを抽出している。異なる農薬クラスと異なる健康影響に関する分析は、個別に 抽出されている。付録IIでは、データ抽出データベースで使用されたすべての項目を説明している。

データ抽出フォームは、妥当で体系的な手順を経て検証された。具体的には、データベースから無作 為に選択された研究の情報を抽出するブラインドループの後、様々なバージョンのフォームを検証し た。データベースの網羅性を維持しつつ、最大の一致度が得られるものを選択した。各項目について は、2名の研究者がそれぞれ独立して抽出し、不一致は議論によって解決している。

#### 6.4. 品質評価

データ抽出データベースの最後の部分は、対象となる各論文の方法論的評価に関するものである。 ここでは、研究デザイン、研究集団、ばく露の定義の詳細度、ばく露測定の方法、測定の特異性などに 焦点を当てている。これらはばく露評価の疫学において問われる重要な問題である。我々はまた、マッ チングモデルや多変量モデル、盲検化されたばく露評価、十分に定義された有効な影響評価によって 交絡因子を考慮するための努力にも焦点を当ててきた。また、資金源が認められているかどうかにも 注目した。方法論的評価の要素は RTI 項目バンクから調査した。RTI 項目バンクは、システマティッ ク・エビデンスレビューに含まれる介入またはばく露の観察研究のバイアスのリスクと精度を評価す るための実用的で妥当性のある項目バンクである。質問はばく露評価を反映するように適応されてい る。質的評価の質問では、質的評価への回答を一貫して緑、オレンジ、赤で色分けし、緑はバイアスの リスクが低く、赤はバイアスのリスクが高いことを表している。以下の表 3 は、それぞれどの回答が 低リスク、高リスクと考えられたかを説明したものである。しかし、品質評価の質問は、各研究に関連 するバイアスのリスクを示唆しているに過ぎないので、注意して解釈する必要がある。この品質評価 のスコアが高くても、バイアスのリスクが高い研究もあれば、その逆もあるかもしれない。最後の列 は、研究の全体的な質を低、中、高で評価するために作成された。この分類は、表3で説明した方法論 的評価の質問に対する回答に基づいている。

### 表3:対象研究の方法論的評価

省間	高リスク	低リスク
研究デザイン(有望、回顧的、混合、断面的)	回顧的、混合、該 当なし	有望
除外基準が明確に記載されている(はい、部分的に、いいえ)	いいえ	はい
著者は電力計算について言及しています(はい、いいえ)		はい
暴露の記述の詳細レベル(高、中、低)	低	高
暴露のロパストな測定(パイオマーカー(有):小面積生態学的尺度、 職種、アンケート(部分的):大面積生態学的尺度(無)に基づいてい る。)	いいえ	はい
曝露の尺度は特定のものだったか?はい:より広範な化学的に関連したグループに基づいて(部分的)、多様な化学的および毒性学的特性の 広範なグループに基づいて(いいえ)。	いいえ	はい

ラフな品質評価	6 以上の回答で高リ	6 以上の回答で低リス
	スク	ク

### 6.5. 定量的な統合

結果の定量的な統合は、調査された影響ごとに4件以上の研究があり、発表されたエビデンス間に実 質的な不均一性がない場合にのみ試みられた。不均一性の存在と程度は、I2(0%から100%の範囲)で 評価した(Ioannidis 2007)。固定効果モデルとランダム効果モデルを用いて、RR/ORの推定値をまと めた(Lau 1997)。固定効果モデルでは、共通の基礎となる効果が存在し、観察された変動は偶然のみ に起因すると想定している。不均一でない場合、固定効果モデルとランダム効果モデルでは同じ結果 が得られる。出版バイアスは、ファンネルプロットと結果の視覚的精査を用いて評価した。

5件以上の妥当研究がある各影響について、定量的な統合を試みた。比較するグループが相互に排他 的でない場合には、同じメタアナリシスにおいて、同じコホート研究からのデータはなかった。4件以 上の研究がある各影響については、結果を比較し、以前の研究の背景の中で我々の知見を解釈するた めに、以前に発表されたメタアナリシスも探した。メタアナリシスは、a)文献レビューで同定されたシ ステマティックレビュー及びメタアナリシス及びb)調査対象の各影響について公表されているメタア ナリシスを同定するために、PUBMDBDでの標的検索によって発見された。メタアナリシスのa) 2006年ま でに発表された研究が含まれており、b)影響及びばく露の定義が本報告書で使用されている定義と同 等である場合には、以前に発表されたメタアナリシスを我々の結果で更新するよう試みた。最後に、10 件以上の研究がメタアナリシスに含まれている場合に非対称性を視覚的精査するためにファンネルプ ロットをプロットした。 結果

#### 7. 全体の結果

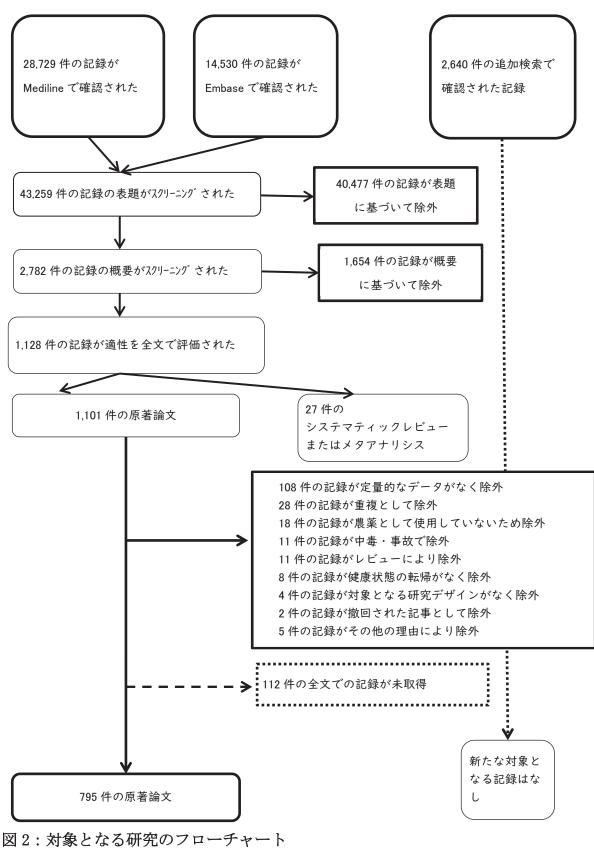

このセクションでは、スクリーニングされ、妥当と判断された研究の数、除外された研究の数とそれ に対応する理由を示すフローチャートを含む文献レビューの結果に焦点を当てている。また、同定さ れた研究とその主な特徴の概要についても説明する。

#### 7.1. 個々の研究の選択プロセス

検索された43,259件の引用のうち、40,477件がタイトルのスクリーニングレベルで除外された。残 りの2,782タイトルのうち、さらに1,654タイトルが要約スクリーニングで除外された。その結果、1,128 件の引用文献のうち、1,101件が原著論文であり、27件がシステマティックレビューまたはメタアナリ シスであることが判明した。1,101 本の原著論文のうち 184 本が除外された(図 2)。また、全文(ま たは学会発表のための要約)がオンラインで見つからない出版物(101 件)については、著者への手紙 や蔵書からの調査により全文を検索したが、要約のみから情報を抽出した58研究については、これが 不可能であった。

全文レベルで除外した主な理由は次の通りである:定量的な情報/データがない(これらは主に、農薬と健康影響との関連に関する定量的な情報を提示していない要約発表またはコメント/論説であった、n=108);記録の重複(n=28)、農薬の使用が示唆されていない(n=18)、中毒または不慮の極高 用量ばく露に関する研究(n=11)、主要データのないレビュー(n=11)、健康影響に関するデータがない(n=8)。補足検索では、大量の政策文書、助成金申請書、研究が既に検索されたため、追加の参考 文献を提供することはできなかった。識別された研究の参照リスト、特に識別されたシステマティッ クレビューの参照リストからの補足検索は、データ抽出の間も継続され、新たに識別された研究は、現 在の妥当な研究リストに追加される。全文スクリーニングとデータ抽出の際に、さらに301研究が除外 された。除外の主な理由は、ポリ塩化ビフェニル(PCB)などの妥当な農薬がなかったことであった(図 2)。全体として、602の個別の出版物が本レビューに含めることができた。これらの602の出版物は、 6,479の異なる分析に対応しており、データ抽出データベースにも存在する。

### 7.2. エビデンスマップ表と調査した影響

我々は、幅広い病態生理をカバーする多種多様な評価された影響を調査した。このデータベースに は、評価された臨床研究上の質問にアプローチするために承認された様々な方法論を反映して、「ハー ド」な臨床影響と多くの代替健康影響が存在している。我々は、異なる影響を23の主要な疾患カテゴリ ーに分類した(表4及び図3)。研究の中で最も多いのは、発がん(N=164)と小児の健康に関連する影 響(N=84)である。表4はエビデンスマップ表に対応し、2006 年から 2012 年の間に農薬ばく露に関 連したすべての影響とその頻度を記述したプロジェクトの影響マッピングを示したものである。

#### 7.3. 対象となる研究の特徴

対象となる研究は 2006 年から 2012 年までに発表されたものである。対象研究の発表年の分布を 見ると、過去 5 年間でほぼ均等に分布していることがわかる(図 4)。特筆すべきは、現場で実施さ れた今日までの観察研究の中で最大のものである Agricultural Health Study (AHS)の様々な報告書 の結果がかなりの割合で存在することである。実際、AHSの出版物 (n=42) は、含まれている研究の7% を占めている。その他の22件の研究は、国民健康・栄養調査 (NHANES) コホートの横断研究である。

研究の大部分は症例対照研究(N=222)と横断研究(図5)であり、農薬への職業ばく露(N=329)を 調査していた。研究のほぼ半数(N=285)はアメリカを拠点とした研究であった(図6)。農薬の評価方 法は、バイオマーカーの測定、または自記式質問紙の使用が最も多かった(図7)。約半数(N=261)の 研究が方法論的評価で「高」に分類された。

広範囲で多様な農薬が研究されており、様々な農薬の定義を用いた研究が行われている。また、公表 されている文献のかなりの割合が、欧州連合(EU)や先進国のほとんどで使用が承認されていない農薬 に焦点を当てていることも予想される。このような研究は、農薬の長期残留の根拠や、開発途上国での 継続的な農薬使用の根拠に関わるものであることを認識している。例えば、DDTとその代謝物のみに焦 点を当てた研究は、対象となる研究のほぼ10%を占めている。

### 8. 発がん

全体では164の出版物が農薬ばく露の発がんへの影響を調査し、2,000以上の個別の分析に貢献した。 他の影響に見られるように、ばく露の定義の多様性は驚くべきものであり、データ統合に特別な問題 をもたらしている。164件のうち36件のみが前向きコホート研究であり、他の13件はコホート内症例対 照研究であった。エビデンスの圧倒的多数は後ろ向き症例対照分析から来ており、ばく露測定におい てリコールバイアスがかかりやすい。また、49の前向き分析のうち、30(61%)は同じ前向き研究であ るAgricultural Health Study (AHS)からのものであり、この前向きコホートを超えたエビデンスは 限られている。これは重要な観察であり、前向きな関連のエビデンスの60%は単一の集団から得られ ているという事実を強調している。分析のサンプルサイズはしばしば小さく、参加者数は24~82,596 人(中央値301人)であった。さらに、33の研究ではばく露のバイオマーカーに関する情報が得られて おり、職業ばく露マトリックス(JEM)を用いて職業ばく露を評価したのは7件のみであった。研究に共 通する制限事項としては、サンプルサイズが小さいこと、ばく露が自己申告であること、多重検定によ る高い偽陽性率の可能性(多重検定を調整せずに複数の仮説を検定しているため、結果が偽陽性にな る可能性がある)及び後ろ向きなデザインなどが挙げられる。多くの研究で有機塩素系殺虫剤を調査 しており、多種多様な農薬が評価された。

調査されたさまざまながんのカテゴリーを、各影響カテゴリーに寄与した研究の数及び定量的統合 の推奨事項とともに表6に示す。データの不均一性と同定された研究数が少ないため、データの統計的 統合(メタアナリシス)は一部のがんサブグループについてのみ実施された。

### 8.1. 造血器新生物

### 8.1.1. 白血病

全体では、26件の研究(及び2件の要約)が農薬ばく露と様々な形態の自血病との関連を調査した。 これら26件の研究のうち14件はAHSからの報告であり、結果が重複していたり、異なる農薬群の調査が 行われていたりした。DDEに関する2件の研究(ID CAN\_063、ID CAN\_064)のみが住居ばく露を調査して おり、残りの研究はすべて農薬への職業ばく露を調査したものである。99の異なる分析のうち12の研 究は、6.1と0.2の間にあるすべての研究の効果量で統計的に有意であった。統計的に有意な結果が得 られたのは7つの研究であり、AHSを除くすべての研究の品質は中等度から低度であった。表7 は、同 じ農薬クラスに関する情報を報告した研究の結果をまとめたものである。結果の大部分は、有意では なく、効果量が小さいものであった。図8は、ランダム効果メタアナリシスを示しており、各研究で最 大のサンプルサイズで分析を行っている。このメタアナリシスでは、有意ではない統合効果(OR 1.26、 95% CI 0.93、1.71)が得られ、中等度の不均一性を有していた。農薬への職業ばく露と自血病に関す る以前のメタアナリシスは、2008年と2007年に発表されている(Merhi 2007, Van Maele-Fabry 2008)。 以前のメタアナリシスからの全体的な要約効果推定値は、農薬への職業ばく露とすべての造血器がん との間には、弱いながらも有意に明確な関連があることを示唆していた。しかし、両報告とも、ばく露 情報や造血器腫瘍の他のリスク因子に関する十分なデータが不足していること、ばく露の定義や白血 病型の定義が不明確であることなど、幅広い限界があることを認めている。

#### 8.1.2. ホジキンリンパ腫

7件の研究が農薬ばく露とホジキンリンパ腫との関連を調査した。すべての研究は質問紙を用いてば く露を評価しており、1件の研究はサンプル数が多く、すべての研究は後ろ向きであった。広範囲の農 薬クラスが調査されたが、結果の意味のある統合はできなかった。75の個別分析のうち12の分析が統 計的に有意であり、すべての分析において効果量は8.4から0.4の範囲であった。我々は、最大のサンプ ルサイズを持つAgricultural Health Study (AHS)分析のみを残して、ランダム効果メタアナリシス を試みた。その結果は統計的に有意ではなく、各研究で調査された農薬クラスが異なることに起因す る可能性がある高い不均一性を有していた(図9)。

### 8.1.3. その他のリンパ腫

ホジキンリンパ腫以外のリンパ腫については、非常に多様な定義が44件の研究で使用されており、 そのうち21件は農業健康調査(Agricultural Health Study: AHS)からの報告で、2件はBC(ブリティ ッシュコロンビア州)製材所の労働者コホート研究からの報告であった。研究ではリンパ腫及びリン パ増殖性症候群(ID CAN\_047、ID CAN\_049、ID CAN\_074)の広範な定義が調査され、他の研究では濾胞 性リンパ腫、びまん性大細胞リンパ腫及び末梢性T細胞リンパ腫のより具体的な定義が調査された。21 件の研究では、農薬ばく露と非ホジキンリンパ腫の幅広い定義との間の効果量が報告された。これら の研究のうち5件は前向き(ID CAN\_063、ID CAN\_064、ID CAN\_067、ID CAN\_118、ID CAN\_121)であり、 7件はばく露のバイオマーカーとの関連を調査した(ID CAN\_056、ID CAN\_057、ID CAN\_064、ID CAN\_065、 ID CAN\_067、ID CAN\_060、ID CAN\_052)。しかし、それ以降の分析はすべて有機塩素系農薬に関するも のであり、関連を示す確固たるエビデンスがないまま、有意な結果が得られたのはわずかであった(全 35 回の分析のうち 6 回の分析)。AHSでは、ブチル酸塩の使用と非ホジキンリンパ腫との間に大きな 有意な効果量が観察された(RR 2.94、95% 1.49~5.96、p=0.002;高ばく露と非ばく露との間に有意な 効果量が観察された)。しかし、同じ出版物のAHSは10種類の異なる影響を調査しており、結果は複数 の試験のための調整が必要であることを繰り返している。

#### 8.1.4. 多発性骨髄腫

また、11件の研究では、農薬と多発性骨髄腫、骨髄異形成症候群及び意義不明の単クローン性免疫グ ロブリン血症との関連が調査された。これらの研究は全般的に異質であり、定量的な統合は示唆され なかった。全体的に、いくつかの分析は統計的に有意であったが、それらは主にフランスの症例対照研 究(ID CAN\_049)からのものであり、147の個別の分析が行われており、結果にバイアスがかかりやす い。AHSはまた、ペルメトリン、ディルドリン、四塩化炭素/二硫化炭素の混合物、クロルタロニルとの 間の有意な関連を報告しているが、これらは他の52分析の中に含まれており、慎重な解釈が必要であ る。ある研究では、骨髄異形成症候群(ID CAN\_070)に対して7.3という非常に高い有意な効果量が報 告されているが、研究の質が悪く、共変量の調整が非常に限られており、同じ表現型の他の研究で結果 が再現されていなかった。

#### 8.2. 前立腺がん

全体では、39件の研究(260件の分析)で農薬ばく露が前立腺がんに及ぼす影響が調査された。その うちの1件は学会発表の要約であり、その結果を評価するための方法論に関するデータがほとんど提供 されていなかった(ID CAN\_107)。また、これら39件の研究のうち25件はAHS集団を対象とした研究で あり、いくつかの結果が重複していた。例えば、2つの研究(ID CAN\_022、ID CAN\_106)では、農薬ば く露と前立腺がんとの関連における遺伝子変異との相互作用が調査されていた。これらのAHS研究では、 農薬ばく露の主な効果は同じであったが、効果はほとんど無効であり、もしあるとすれば、カルバリ ル、クロルデン、メタクロルなどでは有意な逆効果が認められた。残りのAHS研究では、特定の農薬間

の関連を調査したが、いずれの農薬と前立腺がんとの間にも統計的に有意な関連は認められなかった が、ブチル酸塩へのばく露と前立腺がんとの間には弱い有意な影響が認められた。残りのエビデンス は、小規模で質の低い後ろ向き研究から得られたものである。ほとんどの研究(ID CAN\_103、ID CAN\_101、 ID CAN\_100、ID CAN\_094、ID CAN\_143、ID CAN\_142)では、有機塩素の影響を調査したが、ほとんどが 小規模で有意ではない結果であった。2件の研究(ID CAN\_099、ID CAN\_095)では、農薬ばく露と前立 腺がんに関連した高く有意に増加したリスクが示されたが、いずれの研究も質が低く、ばく露の定義 が非常に広く、結果は慎重な解釈が必要であり、適切に実施された大規模な前向き研究(AHSなど)で 報告されたものとは一致しない。特筆すべきは、ばく露量の多い地域で行われた1件の集団ベースの症 例対照研究(ID CAN 104)では、臭化メチルへのばく露と前立腺がんリスクとの間に強い関連が認めら れたが、この研究ではばく露反応関係を示すエビデンスは観察されなかった。まとめると、農薬ばく露 に関連した前立腺がんリスクに関するほとんどのエビデンスは有機塩素の影響に関係しており、研究 では有意ではない弱い影響が示されている。農薬への職業ばく露と前立腺がんに関するメタアナリシ ス (Maele-Fabry 2003) も発表されている。22の疫学研究に基づく統合効果推定値は1.13 (95%CI 1.04 ~1.22)であり、研究間でかなりの不均一性があった。さらに、レビューされた研究には、農薬の影響 を他の職業的、環境的、生活習慣的要因と区別するためのばく露に関する質的及び量的情報が不十分 であった(Maele-Fabry 2003)。全体として、農薬ばく露と前立腺がんとの関連を支持するエビデンス はない。

### 8.3. 肺がん

30件の研究が45の分析を行っており、農薬ばく露と肺がんとの関連を調べているが、これまでに発 表されたメタアナリシスは確認されなかった。ここでも、公表された30件の研究のうち23件、45件の分 析のうち30件がAHSの分析であった。AHSの50種類の分析のうち、統計的に有意な結果が観察されたの は1件のみであった。3つの研究では、ばく露としての農薬の定義が広く(ID CAN\_080、ID CAN\_082、ID CAN\_083)、1つの研究では蚊取り線香の火傷を調査し(ID CAN\_081)、残りの研究では有機塩素系殺虫 剤に重点を置いて様々な農薬を調査していた。殺虫剤のカテゴリーが多様であること、半数以上の研 究で同じコホート集団(AHS)を繰り返し使用していることから、定量的な統合はできなかった。特筆 すべきは、蚊取り線香の火傷と肺がんとの関連は、大きな効果量(3.78(1.55、6.90);使用あり vs 使用なし)で統計的に有意であったが、この研究は相対的に小規模であり、交絡因子の調査が限られた 後ろ向きであり、全体的に質は中等度であった。2件の症例対照研究(ID CAN\_082、ID CAN\_082)では、 農薬への職業ばく露による肺がんリスクの2倍以上の増加が報告されているが、個々の農薬については 調査されていない。別の症例対照研究(ID CAN\_080)では、農薬ばく露と肺がん死亡率との間のこれら の観察を再現することはできなかった。全体として、農薬ばく露と肺がんに関するエビデンスは限ら れており、結論は出ていない。

### 8.4. 小児がん

### 8.4.1. 小児の造血器新生物

全体として、農薬ばく露に関連して小児の造血器新生物を調査した17件の研究(及び1件の要約)が 同定された。17件の研究はすべて小児白血病を対象としており、そのうち4件には他の造血器新生物も 含まれていた。

小児白血病に関するこれまでのメタアナリシスは、農薬への住居内ばく露のみを対象とした研究に 集中していた。メタアナリシスに含まれ、2006年以降に発表されたすべての研究が我々の検索で同定 され、利用可能なすべてのエビデンスが同定されたことを確認した。特定された研究は、国の登録ベー スの症例対照研究ESCALE (Etude sur les cancers de l'enfant) (ID CAN\_073) とNorthern Region Young Persons' Malignant Disease Registry (ID CAN\_120) の2つの研究を除いて、一般的に小規模な ものであった。これらの研究の結果は、サンプルサイズが大きいにもかかわらず、調査された仮説の数 が多い(偽陽性率が高い)ため、慎重に解釈されるべきである。各研究はそれぞれ42件、64件の個別の 分析結果を報告している。すべての研究は症例対照研究であり、大多数は住居内ばく露を調査してお り、職業ばく露に関する研究はほとんど見出されなかった。ほとんどの研究では、農薬または農薬のサ ブグループ(殺虫剤、除草剤、殺菌剤)の使用またはばく露を評価していたが、一部の研究では特定の 農薬に関する情報の収集を試みており(ID CAN\_031、ID CAN\_032)、1つの研究(ID CAN\_032)ではバ イオマーカーレベルを評価していた。農薬の使用頻度や使用期間に関するデータはほとんどなく、ほ とんどの研究では、対象となる農薬の「今までに使用したことがあるかないか」「使用したことがある かないか」のみを報告している。小児の造血器新生物のリスク因子がほとんど確立されていないため、 交絡因子の評価は困難であるが、ほとんどの研究では、少なくとも様々な社会人口統計学的及び母性 の特性を調査または調整している。ほとんどすべての研究では、農薬ばく露を妊娠前、妊娠期、小児期 に分けて評価している。非常に質が低く、統計分析の結果が不完全であった1件の研究では、すべての ばく露期間を調査し、他の2件(ID CAN\_073, ID CAN\_044)では、妊娠前と妊娠期を合わせて調査している。

研究 ID CAN\_040 はCI が不足していたため除外され、研究 ID CAN\_030 はNorthern California Childhood Leukemia Studyのデータが重複していたため(ID CAN\_031と重複)、研究 ID CAN\_037 は研 究集団が特殊であったため(ダウン症患者のみ)、3つの研究が定量分析から除外された。結果の定量 的統合を期間(ばく露の時間域)ごとに分けた。

#### 8.4.1.1 妊娠期のばく露

7件の研究では妊娠期の農薬ばく露に関する情報が得られた。86件中11件の分析で統計的に有意な結 果が得られたのは5件であり、すべての研究で急性白血病を対象とした結果であった。最大の効果推定 値は、国の登録ベースの症例対照研究ESCALE (Etude sur les cancers de l'enfant) から報告されて いる。本研究では、妊娠期の殺虫剤使用は小児急性白血病と有意に関連し(OR = 2.1;95%CI, 1.7-2.5)、父方の住居での殺虫剤使用も急性白血病と関連し(OR = 1.5; 95%CI, 1.2-1.8)、また、父方 の住居での殺虫剤使用も急性白血病と関連した(OR = 1.5; 95%CI, 1.2-1.8)。結果の一連の定量的 統合を行った。まず、各発表報告書の中で最大のサンプルサイズを持つ分析を選択し、結果を統合した (図 10)。この分析は、各研究でばく露評価(農薬の種類と親のばく露経路)が異なり、影響評価に ばらつきがあったため、大きな不均一性(I2>80%)と関連していた。図10の残りのメタアナリシスは、 「住居用農薬と小児白血病」に関する以前に発表されたメタアナリシス(Turner 2010)と結果を調和 させるために、調査した農薬のクラスに基づいた統合または結果を示している。我々は、この系統的レ ビューで確認された殺虫剤及び農薬に関するすべての研究を定量的に統合し、その後、住居ばく露を 評価した研究のみを残して、以前に発表されたメタアナリシスを更新した。全体的に、結果は研究間で 中等度の不均一性を示しており、これは農薬ばく露の定義、影響の定義、ばく露時間域の定義などにば らつきがあることに起因していると考えられる。しかし、メタアナリシスでは、特定されていない農薬 及び殺虫剤へのばく露に関連した小児白血病のリスクの一貫した増加を示した(要約0R=1.69; 96% CI=1.35, 2.11)。我々の更新されたメタアナリシスでは、2010年に発表されたメタアナリシスと比較 して、より保守的な結果となったが、妊娠期の農薬へのばく露と小児白血病との関連は依然として支 持されている。しかし、元のメタアナリシスでは出版バイアスの懸念があったこと、研究の規模が一般 的に小さいこと、ばく露は誤分類されやすい検証されていない自記式質問紙で測定されていることな どから、エビデンスは慎重に解釈する必要がある。ファンネルプロットは、小規模な研究を中心とした 相対的な対称性を示している。住居用殺虫剤への出生前ばく露を減らすことに公衆衛生上のメリット があるかどうかを確認するためには、過去のばく露の有効なバイオマーカーを用いた大規模研究から のさらなるエビデンスが必要である。

## 8.4.1.2. 妊娠前

4つの研究では、ばく露の時期として妊娠前を調査したが(ID CAN\_032、ID CAN\_043、ID CAN\_073、 ID CAN\_120)、いずれも統計的に有意な結果の報告ではなかった。

## 8.4.1.3. 小児期

小児期のばく露に関する情報を有する7件の研究が確認された(ID CAN\_031、ID CAN\_032、ID CAN\_035、 ID CAN\_036、ID CAN\_041、ID CAN\_043、ID CAN\_133)。1件の研究では、現在使用されていないエンド スルファンを調査したが、その研究は非常に質が低く、これ以上の調査は行われなかった。これらの研 究のメタアナリシスを以下の図14に示す。2つの分析が提示されており、A)各報告書の最大サンプルサ イズの分析に基づいて2006年以降に同定された研究(任意の農薬)についての分析と、B)小児期及び 小児白血病における農薬ばく露に関する2010年のメタアナリシスについての更新である。あらゆる農 薬に関するメタアナリシスでは中等度の不均一性があったのに対し、更新されたメタアナリシスでは、 住居ばく露と殺虫剤/特定されていない農薬のみに限定されており、結果に不均一性は見られなかった。 更新されたメタアナリシスの結果は、元のメタアナリシスよりも保守的であるが、それでも2010年に 報告された統合推定値に非常に近いものであった(図14)。ファンネルプロットでは、結果にかなりの 対称性があることが示されている。全体的には、小児期の農薬ばく露と小児白血病との間には関連を 示すいくつかのエビデンスがあるが、これは妊娠期のばく露よりも弱く、確固とした結論を出すため には、適切に実施された大規模な出生コホートからのより多くのエビデンスが必要である。

#### 8.4.2. リンパ腫

白血病以外の小児の造血器新生物に関するエビデンスは3件の研究から得られているのみであり、その中には非ホジキンリンパ腫とホジキンリンパ腫に関する分析を含む多くの分析が報告されている(ID: CAN\_073、ID: CAN\_120、ID: CAN\_133)。すべての分析は統計的に有意ではなく、効果推定値も弱いものであった。

## 8.4.3. その他の小児がん

その他の小児がんに関する研究が7件同定された。4件の研究では脳腫瘍(ID CAN\_006、ID CAN\_011、 ID CAN\_089、ID CAN\_133)、1件の小児生殖細胞腫瘍(ID CAN\_114)、2件の研究では様々な小児がん (ID CAN\_120、ID CAN\_133)が調査された。有意な関連が観察されたのは脳腫瘍のみであったが、これ らは多くの分析のごく一部のサブセットに関連しており、現段階では情報を得ることはできない。

#### 8.5. 大腸がん

全体では、26件の研究で農薬ばく露と大腸がんとの関連性が 207 件の分析で調査された。大腸がん と直腸がんについては、それぞれ24件と11件の研究で別々の分析が行われた。非常に多くのエビデン スがAHS研究から得られている。この研究では、50種類の農薬を用いた大腸がんに関する207の分析の うち194の分析で、これら 3 つの影響発現事象すべてとの関連性が調査されており、多重試験の調整 は行われていない。これら194の分析のうち、影響発現事象と統計的に有意に関連したのは7つの分析 のみであった(カルバリル、アルジカルブ、トキサフェン、ペンディメタリン、ジプロピルチオカルバ ミン酸 S-エチル (EPTC)、イマゼタピル、フォノフォス)が、偽陽性確率が高いため、解釈には注意 が必要である。27の研究が発表されているにもかかわらず、全体的には7つの異なる集団からのエビデ ンスしか得られていない。この事実は、大腸がんに関連してこれらの研究のそれぞれで分析された異 なる農薬の範囲とともに、結果の意味のある定量的な統合を可能にするものではない。表8は、複数の 論文における1つのコホートからの重複データの公表の程度を示しており、結果の一貫性が良好である ことを示している。大腸がんと農薬ばく露に関するこれまでのメタアナリシスは確認されていない。 全体的に、農薬と大腸がんに関するエビデンスは非常に限られており、現在の文献の状態では、農薬と 大腸がんの関連性を支持するものではない。

## 8.6. 皮膚がん

17件の研究では、メラノーマと農薬ばく露との関連が調査された。大半の研究は有機塩素系農薬を 対象としたものであった。ここでも、メラノーマに関する17件の研究のうち14件がAHSの結果であり、 各論文では異なる農薬のカテゴリーやばく露の定義が異なっており、いくつかの結果が提示されてい た。AHSの26の異なる分析のうち、8つは統計的に有意であり、すべて同じ出版物(ID CAN\_085)に由来 するもので、50種類の農薬と皮膚メラノーマとの量反応関係が報告されている。この研究では、皮膚メ ラノーマとmaneb/mancozeb(63日以上のばく露日数:OR = 2.4;95%CI、1.2-4.9;トレンドp = 0.006)、 parathion(56日以上のばく露日数:OR = 2.4;95%CI、1.3-4.4;トレンドp = 0.003)及びcarbary1 (56日以上のばく露日数:OR = 1.7;95%CI、1.1-2.5;トレンドp = 0.013)との間の有意な関連が報 告されている(155)。他の研究では、これらの農薬に関して再現性を調査できるような結果を報告し ていない。1件の症例対照研究では、屋内での農薬ばく露とメラノーマとの間に統計的に有意なリスク の増加が示されたが、同じ研究では屋外での農薬ばく露はメラノーマとは関連していなかった(106)。 有機塩素系農薬に関する残りの研究では、統計的に有意な結果がほとんど得られない不均質な結果が 得られており(ヘキサクロロベンゼン(HCB)、マイレックス)、これらの農薬とメラノーマとの関連 を示すエビデンスは得られてない。

## 8.7. 乳がん

全体では、2006年以降の14件の研究(うち3件は要約)が農薬ばく露と乳がんとの関係を調査した。 大半の研究と分析は有機塩素系農薬に焦点を当てており、バイオマーカー分析によって評価されてい る。乳がんとDDTばく露に関する2つの過去のメタアナリシスが発表されている(Khanjani 2007, López-Cervantes 2004)。全体的に、以前のメタアナリシスでは、ヘプタクロルを除き、シクロジエン系化学 物質と乳がんとの間に有意な関連は示されなかったが、それはわずか2件の研究に基づくものであった。 ジクロロジフェニルジクロロエチレン(DDE)と乳がんに関するシステマティックレビューで同定され た研究(5研究)のメタアナリシスでも、関連を示すエビデンスは示されなかった。我々はまた、乳が んに関する同定されたすべての研究でメタアナリシスを実施し、サンプルサイズが最も大きい各研究 内の分析を毎回選択した。研究ID CAN\_019とID CAN\_023は、統合を可能にする効果量と信頼区間が提 供されていなかったため、統合から除外された。また、研究ID CAN\_022は、誤って報告されたとは想定 されていない非常に狭い信頼区間を報告していたため除外された。ここでの統合には、多くの異なる 農薬の定義とバイオマーカー(DDE、リンデン、広義の農薬定義)の統合効果が含まれており、解釈が 難しい。統合効果は統計的に有意な乳がんリスクの増加(1.07(0.87~1.31))を示したが、この結果 は慎重な解釈が必要である。メタアナリシスでは、非常に異なるカテゴリーの農薬を組み合わせてお り、主に1つの研究(ID CAN\_022)が占めているが、これは住居用農薬の自己申告による農薬ばく露を 評価したもので、バイオマーカーを介して農薬を評価した他の研究に比べて質が低いものである。

## 8.8. 膀胱がん

農薬ばく露に関連して膀胱がんを調査した16件の研究が同定されたが、13件は他の発がん影響について以前に観察されたのと同様にAHSの同じ集団からの研究であった。25の異なる分析結果のうち、AHSにおけるイマゼタピルへの職業ばく露について統計的に有意な結果を示したのは1件のみであった。しかし、複数の試験を行っているため、結果は慎重に解釈する必要があり、報告書で調査されたエビデンスに基づいても、農薬ばく露と膀胱がんとの関連は示唆されていない。

### 8.9. 腎臓がん

10件の研究が農薬ばく露に関連して腎臓がんを調査したが、データはAHSとBC(ブリティッシュコロ ンビア州)製材所労働者コホート研究の2つの集団からのみであった。BC州製材所労働者コホート研究 (ID CAN\_129及びID CAN\_125)の結果は、いずれもペンタクロロフェノール及びテトラクロロフェノ ールへの職業ばく露に関するものであったが、統計分析のアプローチが異なっていた。AHSの結果は、 異なる農薬クラスに関するものであった。全体的に、統計的に有意な結果は観察されず、寄与した集団 の数が限られているため(n=2)、これ以上の定量的な統合はできなかった。

#### 8.10. 膵臓がん

農薬ばく露に関連して膵臓がんを調査した研究は7件、AHSからの報告は4件であった。分析の圧倒的 多数は有機塩素系農薬を対象としたものであった。質の低い小規模な症例対照研究では、ヘキサクロ ロベンゼン(HCB)、クロルデンの和及びポリ臭化ジフェニルエーテル(PBDE)の濃度が健常対照者と 比較して膵臓がん症例で有意に上昇していた(ID CAN\_090)。AHSでは、46種類の分析のうち、 PendimethalinとS-Ethyl dipropylthiocarbamate (EPTC)について有意な関連が報告されている。ペン ディメタリンの生涯使用量の上位半分の散布者は、非使用者と比較して3.0倍(95%CI 1.3-7.2、pトレ ンド5 0.01)のリスクを有し、EPTCの生涯使用量の上位半分の散布者は、非使用者と比較して2.56倍 (95%CI 5 1.1-5.4、pトレンド=0.01)のリスクを有していた。有機塩素系薬剤は、AHSにおける膵臓 がんの過剰リスクとは関連していなかった。これらの知見は、除草剤が膵臓がんと関連している可能 性を示唆しているが、これらはすべて単一の集団から得られたものであり、多重検定調整を行ってい ないため、今後の研究で反復する必要がある。

#### 8.11. 精巣がん

全体では8件の研究で精巣がんが調査された。2件の研究では精上皮腫への影響も報告された。1件を 除くすべての研究がバイオマーカーレベルを評価し、有機塩素系殺虫剤に集中しており、さまざまな バイオマーカーが評価され、精巣がんとの関連には弱い影響を示した研究もあった。しかし、p-p'DDE のみについては4件以上の研究の情報が得られ、定量的統合では有意ではない効果と適度な不均一性が 示された(図20)。各研究で評価されたバイオマーカーの不均一性のため、どの農薬についても定量的 統合は行われなかった。全体的に、ここで調査されたエビデンスに基づいて、農薬ばく露と精巣がんと の関連を支持するエビデンスはない。

#### 8.12. 胃がん

6件の研究で、農薬ばく露と胃がんとの関連が調査された。すべての研究は農薬への職業ばく露を調 査したもので、農薬のクラスは多岐にわたっていた;2件の研究は前向きデザインであったが、すべて の研究でサンプルサイズは中等度から低度であった。農家に関する以前のメタアナリシス(Saphir 1998)と一致するように、研究は不十分で、主に有意でない結果を報告していた。United Farm Workers of America (UFW) コホートにおける胃がんのコホート内症例対照研究(ID CAN\_028)では、有意な関 連が報告された。フェノキシ酢酸除草剤2,4-ジクロロフェノキシ酢酸(2,4-D)の使用量が多い地域で 働くことは、胃がんと関連していた(OR 1.85;95%CI 1.05-3.25)。有機塩素系殺虫剤クロルデンの 使用もこの疾患と関連していた(OR 2.96;95%CI 1.48-5.94)。胃がんは、殺ダニ剤プロパルギトの 使用と関連していた(OR 2.86;95%CI 1.56-5.23)。にもかかわらず、評価が生態学的なものであっ たため、この研究は症例数と対照数が比較的少ないこと、多重検定及びばく露の誤分類によって制限 されている。AHSでは、15例のばく露例に基づいて、胃がんリスクは臭化メチルの使用量の増加ととも に単調に増加した(RR = 3.13;95%CI、非使用と比較して高頻度使用では1.25-7.80;トレンドのp = 0.02)。しかし、この研究では他のすべてのがんのサブタイプが臭化メチル使用と関連していたため、 やはり多重検定の問題がある(ID CAN\_147)。最大のサンプルサイズで分析を選択したメタアナリシス は図21に示されているが、結果は慎重に調査する必要がある。統計的に有意な統合された大きな効果 量にもかかわらず、この結果は、欧州連合で承認されていない2つの化合物であるペンタクロロフェノ ールと臭化メチルを調査している2つの研究(ID CAN\_125, ID CAN\_147)の影響が大きい。

## 8.13. 肝臓がん

5件の研究(11件の個別の分析を含む)と1件の学会発表の要約で、農薬ばく露と肝臓がんとの関連が 調査された。分析の大部分は有機塩素系農薬へのばく露を対象としており、すべての研究は農薬への 職業ばく露を対象としていた。DDTに関する両研究(ID: CAN\_076及びID: CAN\_079)では、肝がんとの 統計的に有意な関連が報告されたが、残りの分析では統計的に有意ではなかった。これら2つの研究が 肝臓がんに関するメタアナリシスの大部分を占めており、統合された結果は統計学的に有意であり、 主にDDT研究に牽引されている。

## 8.14. 研究数が少ないがんサブグループ

表6に示されているように、多数のがんについては、各がんサブグループのエビデンスを総合的に判 断できる研究は非常に限られている。我々のシステマティックレビューでは、過去に発表されたエビ デンス(2006年以前)との比較を可能にするために、これらのがんサブタイプに関する過去に発表され たメタアナリシスを確認しなかった。一般的に、これらのがんサブタイプに関する結果では影響は小 さく、職業ばく露のみに関する少数の例外を除いて統計的に有意ではなかった。各研究内の分析数が 多いことを考えると、これらの結果は慎重に解釈する必要があり、これらのデータに基づいて、農薬ば く露とこれらのがんサブタイプとの間の関連を示唆するエビデンスはない。

また、農薬に関連してすべてのがん(複合発がん影響)を調査した研究も多数あった。がんは非常に 異質な疾患群であり、すべてのがんサブタイプを同時に調査すると、関連にバイアスがかかる可能性 がある。全体では、「すべてのがん」を対象とした30の分析が同定されたが、そのうち28の分析は同じ コホート(AHS)を対象としたものであり、結果をさらに統合することはできなかった。31件のうち統 計的に有意な結果が得られたのは4件のみで、質の低い研究と関連していたため、現段階では解釈に値 しない。

# 表 6: がんサブグループごとに同定された調査対象研究の要約

がん	研究数	メタアナリシス推奨	以前のメタアナリシス
造血器新生物	88	Yes	Yes
前立腺がん	39	No	Yes

#### **9.** 小児の健康

全体では 84 件の個別研究が農薬ばく露の小児への健康影響を調査し(サンプルサイズ中央値:267、 IQR 119-811)、データ抽出データベースでは 821 件の分析が行われた。120 以上の健康関連影響が 評価されており、その大部分は先天性奇形と身体測定を含むがそれに限定されない発生パラメータに 焦点を当てている(表 10)。他の影響に見られるように、ばく露の定義の多様性には目を見張るもの があり、データ統合に特別な問題を与えている。84 件のうち 38 件のみが前向きコホート研究であり、 他の 5 件はコホート内症例対照研究であった。エビデンスの大部分は後ろ向き症例対照分析に由来し ており、これはばく露量測定においてリコールバイアスがかかりやすい。報告された分析におけるサ ンプルサイズはしばしば小さく、23~183,313人(中央値267人)であり、この領域の最大の研究は、が ん分野で評価された最大の研究よりも小さい。ここでは、農業健康調査(Agricultural Health Study: AHS)のような、この分野の大規模でよく知られた研究に由来する多数の出版物まとまっては観察され なかったが、26件の研究が職業ばく露を評価していた。さらに、ばく露のバイオマーカーに関する情報 を有する研究の存在は、ここではより多かった(n=49,58%)が、3つの研究はJEMによる職業ばく露を 評価した。調査した異なるカテゴリーに属する影響を、各カテゴリーに寄与した研究数が少なかったため、デ ータの統計的統合(メタアナリシス)は泌尿器の奇形のみを対象に実施した。

## 9.1. 未熟児

妊娠期の農薬ばく露と未熟児との関連を評価した研究は 15 件あり、サンプルサイズの中央値は 193 件(IQR 87-469)で、データベースには 54 件の比較が抽出されている。半数以上の研究が後ろ 向きで、4分の3以上の研究ではバイオマーカーを用いてばく露が評価されていた。個々の農薬の評価 は多種多様で、DDT代謝物の評価がより頻繁に行われていた(8件の研究)。それにもかかわらず、同じ 比較単位を使用した 4 件以上の研究では、単一の農薬と関連するバイオマーカーの評価は行われず、 定量的な統合は行われなかった。最大の前向き研究(ID CH 091)では、オランダの温室労働者を対象 とし、温室労働者の男性における早産リスクの減少(OR= 0.47; 95%CI= 0.35-0.65)が報告されたが、 女性におけるリスクの増加は統計的に有意ではなかった(OR= 1.14, 95%CI= 0.57-2.31)。残りの研 究では、正の関連を示す推定効果が得られたが、統計的に有意な結果はなかった。さらに、発表された 研究のメタアナリシスは確認されなかった。これらのデータに基づいて、農薬ばく露と未熟児との間 に臨床的に有意な関連を示唆する最近のエビデンスはない。

## 9.2. 胎児の発育制限

12の研究では、妊娠期の農薬ばく露と胎児の発育制限及び/または在胎不当過小児との関連を評価し ており、サンプルサイズの中央値は422(IQR 178-1,630)で、データベースには44件の個別の比較が抽 出されていた。研究の60%は前向きで、3つの研究では職業ばく露を評価し、3分の2以上の研究ではバ イオマーカーを用いてばく露を評価している。個々の農薬の評価は多種多様で、DDT代謝物の評価がよ り頻繁に行われていた(4件の研究)。それにもかかわらず、同じ比較単位を使用した 4 件以上の研 究では、単一の農薬と関連するバイオマーカーの評価は行われず、定量的な統合は行われなかった。最 大の研究(ID RPD 26)では、後ろ向きコホートを対象に、飲料水中のアトラジンが在胎不当過小(SGA) 及び早産の罹患率の増加と関連しているかどうかを評価した。著者らの報告によると、妊娠第3 期及 び全妊娠期間の飲料水中のアトラジンは、SGA(Small for Gestational Age)の罹患率の有意な増加 と関連しており、妊娠第3期に飲料水中のアトラジンが0.1 µg/Lを超えると、対照群(0.1 µg/L 未満)と比較して SGA の罹患率が17~19%増加した。残りのすべての研究では、効果量の方向性に 関する一貫したパターンがなく、統計的に有意ではない結果が報告された。さらに、発表された研究の メタアナリシスは確認されなかった。これらのデータに基づいて、農薬ばく露と未熟児との間に臨床 的に有意な関連を示唆する最近のエビデンスはない。

## 9.3. 身体測定(体格計測)

農薬ばく露と発育の関連を調査した研究は数多くある。

## 9.3.1. 出生時の体長/身長

出生時の体長と身長はそれぞれ13件と8件の研究で評価され、データベースでは78件の比較が行われた。大半の研究では、バイオマーカーを用いてばく露が評価されている。個々の農薬の評価は多種多様で、DDT代謝物の評価がより頻繁に行われていたが、4件以上の研究では単一の農薬と関連するバイオマーカーの評価は行われておらず、定量的な統合は行われていない。

1980 年以前に生まれた北米の集団を対象とした最大の前向き研究(ID CH 073)では、出生前の p,p'-DDE の最高濃度(>60 mg/1)のみが、最低濃度(<15 mg/1)と比較して、7 歳時の身長低下と統 計的に有意に関連していることが報告された[調整係数(SE) -2.21 cm (0.67)]。残りの研究では、 効果の方向性または効果量に一貫したパターンがなく、相反する結果が報告された。さらに、メタアナ リシスは確認されなかった。多数の分析を考慮すると、これらの結果は慎重に解釈する必要があり、こ れらのデータに基づいて、農薬ばく露と出生時の体長または身長の間に、妥当で臨床的に有意な関連 を示唆する最近のエビデンスはない。

#### 9.3.2. 体重

妊娠期の農薬ばく露と出生時体重との関連を評価した研究は 26 件あり、データベースには 134 件 の個別抽出比較が掲載されている。他の 5 件の研究では、農薬とポンデラル指数との関連を評価した。 多くの比較では、バイオマーカーを用いてばく露が評価された。個々の農薬の評価は多種多様で、DDT の代謝物の評価がより頻繁に行われた(11 研究)。しかし、同じ比較単位を使用した 4 件以上の研 究では、単一の農薬と関連するバイオマーカーの評価は行われず、定量的な統合は行われなかった。最 大の前向き研究(ID CH 014)は農業健康研究(Agricultural Health Study: AHS)の論文で、妊娠3ヶ 月までの農薬関連作業は出生時体重とは関連しておらず、複数回の分析の結果、カルバリル農薬の使 用があった場合は出生時体重の減少と関連していた(-82 g、95% CI = -132, -31)と報告された。残 りの研究では、効果の方向性や効果量に一貫したパターンがなく、相反する結果が報告された。さら に、発表された研究のメタアナリシスは確認されなかった。しかし、我々はp,p<sup>-</sup>-DDEの1µg/Lの増加は 出生時体重の7gの減少(95% CI = -18, 4g)と関連していた(Govarts E 2012)ことを報告したヨーロ ッパのコホートの個々の参加者のデータのメタアナリシスを同定した。分析の数が多いことを考える と、これらの結果は慎重な解釈が必要であり、これらのデータに基づくと、農薬ばく露と出生体重との 間の妥当で臨床的に有意な関連を示唆する最近のエビデンスはない。 26件の研究が、出生後の様々な時点での農薬ばく露と体重との関連を評価しており、データベース には68件の個別の比較が抽出された。評価された比較のほぼ85%では、バイオマーカーを介してばく 露が評価された。個々の農薬の評価は多岐にわたり、DDT代謝物の評価がより頻繁に行われた(10研究)。 しかし、同じ定義の影響、同じタイムポイントでの影響評価、同じ農薬、同じ比較単位を使用した4件 以上の研究において評価された単一の農薬とそれに関連するバイオマーカーはなく、定量的な統合は 行われなかった。2002年と2003年に生まれたメキシコの男子集団におけるDDTばく露を評価した 最大の研究(ID CH 074)では、全体的に、出生前のDDEレベルと任意の年齢におけるBMI (Body Mass Index)との間の関連は観察されず、予測値は、最も高いばく露量(DDE:49.00 mg/g)の小児と最も低 いばく露量(DDE:<3.01 mg/g)の小児とでは発育が似通っており、BMI は参照グループと同程度であ ったことを示した。残りの研究では、効果の方向性や効果量に一貫したパターンがなく、相反する結果 が報告された。さらに、メタアナリシスは確認されなかった。分析数が多いことから、これらの結果は 慎重な解釈が必要であり、これらのデータに基づいて、農薬ばく露と体重との間に臨床的に有意な関 連を示唆する最近のエビデンスはない。

#### 9.3.3. 頭囲

妊娠期の農薬ばく露と出生時及び出生後の頭囲との関連を評価した研究はそれぞれ 14 件と 3 件 あり、データベースには 85 件の個別比較が抽出されている。3 分の 2 以上の比較では、バイオマー カーを用いてばく露が評価されていた。出生時の頭囲については、多種多様な農薬が評価されており、 中でも DDT 代謝物がより頻繁に評価されていた(7 研究)。それにもかかわらず、同じ比較単位を用 いた 4 件以上の研究では、単一の農薬と関連するバイオマーカーの評価は行われず、定量的な統合は 行われていない。最大の前向き研究(ID CH 026)は、オランダの集団ベースの前向きコホート研究 (2002-2006)に参加した 4,680 人の妊婦を対象に、様々な化学物質への母親の職業ばく露と胎児の 発育との関連を調査したジェネレーション R 研究の出版物である。胎児頭囲については、アルキルフ ェノール化合物への母親の職業ばく露のみが、潜在的な交絡因子を調整した上でばく露していない母 親と比較して統計的に有意に低い成長率(妊娠週あたり-0.01752 SD)を示した。残りの研究では、効 果の方向性や効果量に一貫したパターンがなく、相反する結果が報告されている。さらに、発表された 研究のメタアナリシスは確認されなかった。分析数が多いことを考えると、報告された研究結果は慎 重に解釈する必要があり、これらのデータに基づいて、農薬ばく露と頭囲との間に臨床的に有意な関 連を示唆する最近のエビデンスはない。

## 9.3.4. 先天性奇形

5件の研究では、農薬ばく露と先天性奇形全般との関連が調査された。最大の研究(ID CH 002)はカ ナダの農場の集団を評価し、146の潜在的な関連を報告したが、主要分析では統計的に有意な結果は得 られず、シアナジン(OR = 4.99、95%CI:1.63-15.27)及びジカンバ(OR = 2.42、95%CI:1.06-5.53) への妊娠前のばく露が、男児の先天性奇形のリスクの増加と関連していることが提案された。それに もかかわらず、利用可能な比較研究の数及び本研究におけるばく露と影響が自己報告であることを考 慮すると、今回の知見は慎重に調査されるべきである。残りの4件の後ろ向き研究では、相反する結果 が報告された(ID CH 043、職業ばく露(父親)、OR: 3.42、95% CI: 1.97-5.92; ID CH 035、少な くとも片方の親の職業ばく露、OR = 1.3、95%CI = 0.4-3.9; ID CH 008、母体の尿中メトラクロルの HR、95% 0.4-1.4)。)多数の分析を考慮すると、これらの結果は慎重な解釈が必要であり、これらの データに基づいて、農薬ばく露と先天性奇形との関連を示唆する最近のエビデンスはない。

### 9.3.5. 神経管閉鎖障害

同定された研究では、農薬ばく露と無脳症や二分脊椎を含む神経管閉鎖障害との関連を調査してお り(N=4研究)、種々の農薬と神経管閉鎖障害、無脳症、二分脊椎との間の分析が非常に多く報告され ており、多重検定の調整は行われていない(1論文あたり平均27分析)。抽出された134の分析のうち、 43の分析は結果と統計的に有意に関連していたが(うち14の分析は境界線上で有意であった)、偽陽性 の確率が高いので注意して解釈する必要がある。5つの研究のそれぞれで分析された農薬の種類の多さ と、農薬ばく露の定義の違いにより、ばく露期間や対象とした親に関しても研究間でかなりの不均一 性があるため、「何らかの農薬」ばく露の定義を用いても、結果の意味のある定量的な統合を行うこと はできない。神経管閉鎖障害と農薬ばく露に関するこれまでのメタアナリシスは確認されていない。 全体的に、農薬と神経管閉鎖障害に関するエビデンスは限られており、最新の文献の現状では、妥当な 関連を支持するものではない。注目すべきは、この分野で最大の研究(ID CH 044)では、妊娠初期に 特定の農薬または農薬の物理化学的グループの使用に母親が居住している場所に近いことが、これら の奇形のリスクを増加させるかどうかが調査され、731例と940例の対照が含まれ、個々の農薬、農薬の 物理化学的カテゴリー、任意のばく露、ばく露なし、多重ばく露の定義について107の異なる分析を報 告した後、多重試験の補正なしで、農薬のカテゴリーまたは相加効果に関して特定のパターンを持た ない15の統計的に有意な結果が得られたことである。

#### 9.3.6. 泌尿生殖器の奇形

全体では、19件の研究で泌尿生殖器の奇形、すなわち停留精巣(n=9)と尿道下裂(n=9)が調査された。

停留精巣は9件の研究で評価されたが、そのうちの9件はほとんどが後ろ向き研究であり、サンプルサ イズの中央値は199件(IQR 136-710)であった。4件の研究ではDDTレベルが評価され、ヘキサクロロベ ンゼン(HCB)とクロルデンはそれぞれ1件ずつ評価され、一般的な農薬ばく露は2件の研究で評価され た。評価したすべての研究で、いずれかの農薬へのばく露と停留精巣との関連を調査しようとしたと ころ、観察された影響は統計的に有意ではなかった(OR 1.19、95%CI 0.96~1.49、I2 24%)(図 23)。 さらに、DDTばく露と停留精巣との間の潜在的な関連を評価したところ、再び統計的に有意ではない関 連が観察された(OR 1.47、95% CI 0.98-2.2、I2 51%)(図 24)。多数の分析を考慮すると、これら の結果は慎重に解釈する必要があり、これらのデータに基づいて、あらゆる農薬ばく露と停留精巣と の間に、臨床的に有意な関連を示唆する最近のエビデンスはない。

尿道下裂は主に9件の後ろ向き研究で評価され、サンプルサイズの中央値は784人(IQR 200 - 861) であった。2件の研究ではDDTレベルが評価され、6件の研究では農薬ばく露一般が評価された。評価さ れたすべての研究において、何らかの農薬への母親のばく露(妊娠前及び妊娠期)と尿道下裂との関連 を調査しようとしたところ、観察された影響は統計的に有意ではなかった(OR 1.02、95%CI 0.74-1.39、I2 72%)(図25)。特定の農薬を評価した 3 つの研究(DDT、n=2; クロルデン、n=1)を分析 に含めると、再び統計的に有意でない関連が観察された(OR 1.00、95% CI 0.84-1.16、I2 66%)(図 26)。我々のシステマティックレビューでは、1966年1月から2008年3月までに英語で出版され、PubMed に索引付けされたオリジナルの研究を含む1つのメタアナリシスを検索した(Rocheleau CM, 2009)。 2007年以前に発表された9件の研究がすべての研究の包含基準を満たしており、著者らは、尿道下裂の リスクの上昇は、母親の職業ばく露 (PRR1.36、CI=1.04-1.77)及び父親の職業ばく露 (PRR1.19、CI=1.00-1.41)と関連していたが、わずかに有意であったと報告している。異なる期間に文献評価した結果とし て、我々のレビューと発表されたメタアナリシスとの重複が最小限であったために、我々は2つの成果 を統合することができ、再び我々は統計的に有意ではない結果を取得した (OR 1.14、95%CI 0.84 -1.55、I2 73%)。このように、いかなる農薬ばく露と停留精巣との間に、妥当で臨床的に有意な関連 を示唆する最近のエビデンスはない。

## 9.4. 研究が少ない小児健康影響

Table 10にはない健康影響には、個々の健康影響のエビデンスの統合には研究数が少なすぎるもの がある。すなわち、これらの健康影響には、腹壁裂、心臓先天異常、横隔膜ヘルニア、食道閉鎖症など のような明確に定義されてはいるが研究数が少ない臨床所見から、広範な臨床所見に関連する多数の 指標からなるが健康影響の定義の一致と標準化が著しく欠如しているものまで、多種多様な情報が収 集されている。例えば、神経発達に関連した健康影響は広範囲に評価されているが、IQ測定から知覚推 論に至るまで使用されている指標は、定量的な統合を目指したさらなる試みは不可能であると考えら れた。我々のシステマティックレビューでは、以前に発表されたエビデンス(2006年以前)との比較を 可能にするために、これらの健康影響に関する以前に発表されたメタアナリシスは確認されなかった。 一般的に、これらの健康影響に関する結果は効果量が小さく、統計的に有意ではなかった(少数の例外 を除く)。分析数が多いことを考えると、これらの結果は慎重に解釈する必要があり、これらのデータ に基づいて、農薬ばく露とこれらの影響との関連を示唆するエビデンスはない。

## 表10:対象となる研究で定義された小児健康分野で評価された影響

健康影響		
尿路性器距離の異常	体格指数 (BMI) Z スコア	血清プロラクチン値の上昇
異常なボディマス指数 (BMI)	体脂肪率(対数変換)	血清トータルテストステロン値の上
		昇
骨年齢の異常	尿道索	IQ
胸の大きさの異常	大動脈の動脈硬化	LH 調節障害
肥満度指数の異常変化	先天性横隔膜ヘルニア (CDH)	年間の高さ速度が低い
身長の異常な変化	先天性心疾患	重篤な先天性異常
胸囲の異常	先天性奇形	男性性器奇形
在胎月齢の異常	クレチン症	母体年齢
年齢に応じた頭囲の異常	頭踵長	母体の体重増加
異常な高さ	停留精巣	流産・死産
股関節周囲の異常	インヒビン B 値の低下	筋骨格系の欠陥
身長の異常	血清 FSH 値の低下	神経管障害
卵巣の異常測定	血清インヒビン B 値の低下	肥満
ペニスの長さの異常(伸びる)	血清 SHBG 値の低下	エストラジオールの調節障害
ペニスの幅の異常	精巣容積の減少	知覚推論
血清 DHT 値の異常	テストステロン値の低下	パフォーマンス IQ
異常な座高	血清 LH 値の低下	心室中隔欠損
異常な立位の高さ	授乳期間	胎盤重量
異常なタナー段階	食道閉鎖症	胎盤重量
上腕囲の異常	胎児の死亡	ポンデラルインデックス
屈曲上腕囲の異常	胎児頭囲	ポンデラルインデックス
子宮の測定値の異常	胎児の長さ	思春期早発
ウエスト周りの異常	胎児の体重	子癇前症
異常な体重	FGR	早熟な乳房の発達
長さに対する重量の異常	注意散漫でない	早期エストラジオール分泌
乳房の発達への影響	FSHの調節障害	思春期早発症(陰毛)
Anal position index	腹壁裂	未熟児
アンドロステンジオンの調節障害	在胎月齡	処理速度
無脳症	女性化乳房	乳幼児の急激な体重増加
抗ミュラーホルモンの調節障害	頭囲	SGA
APGAR 1分間のスコア	尿道下裂	SHC
APGAR 5分間のスコア	特発性早熟性思春期	二分脊椎
房室中隔欠損症	FSH 値の上昇	皮下脂肪計測
出生時の頭囲	SHBG の増加	テストステロンの調節障害
出生時の体長	LH/テストステロン比率の増加	ファロー四徴症

## Ntzani EE, Chondrogiorgi M, Ntritsos G, Evangelou E, Tzoulaki I Pesticide epidemiology

出生時体重	血清 AMH 値の上昇	大動脈の転換
出生時体重、在胎月齢で調整	血清アンドロステンジオン値	言語理解
	の上昇	
BMI	血清 DHEAS 値の上昇	言語性 IQ
出産時の BMI	血清遊離テストステロン値の	ワーキングメモリ
	上昇	
妊娠前の BMI

## 10. 生殖疾患

全体では、63の論文が農薬ばく露の小児健康影響を調査しており(サンプルサイズ中央値:299、IQR 111-544)、データ抽出データベースには578の個別の分析が含まれていた。分析の3分の1以上(n=217、 38%)が精子/精液の質を評価しているのに対し、他の研究/分析では生殖関連ホルモン、不妊、自然流産などを評価している。他の影響に見られるように、ばく露の定義の多様性は顕著であり、データ統合に特別な問題を与えている。64件のうち4件のみが前向きコホート研究であり、大多数の研究は横断研究であった(n=45、70%)。報告されている分析のサンプルサイズはかなり小さく、41人から29,649人の範囲であった(中央値161)。この領域での最大の研究は、がん分野で評価された最大の研究よりも小規模である。ここでは、グリーンランドのイヌイットの集団とともにヨーロッパ3カ国で設立されたプロジェクトであるINUEND0(INUit-ENDOcrine)研究グループ(n=8)からの出版物を調査した。研究のほぼ3分の2がヨーロッパとアメリカで実施された(それぞれn=22と20)。22件の研究が職業ばく露を 評価し、さらに半数以上の研究がばく露のバイオマーカーに関する情報を有し(n=38, 59%)、3件の研究が職業ばく露を職業ばく露マトリックス(JEM)で評価し、2件の研究が質問紙とバイオマーカーの両方を使用した。調査した異なる影響カテゴリーを、各カテゴリーに寄与した研究の数と定量的統合の決定とともに表12に示した。データの不均一性のため、データの統計的統合(メタアナリシス)は流産についてのみ実施された。

## 10.1 障害のある精子パラメータ

25件の研究(中央値 189件: IQR 87-336)が、様々な影響を用いて農薬と精子/精液の質との関連を 評価した。これらの結果について実施された分析の総数は217件で、実施された分析のサンプルサイズ は41~763件と小規模である。最大の研究はINDUENDO研究グループによるヨーロッパの横断研究(ID RPD 009)で、p,p'-DDEの精子濃度、精子運動性、精子形態への影響を評価し、精子運動性は研究対象 の4つの集団においてp,p'-DDEと負の関係があることが示された。同じグループによる別の大規模研 究(ID RPD 012)では、残留性有機汚染物質(POPs)が男性の生殖機能を阻害する可能性のエビデンス は示されていない。多数の分析が行われたにもかかわらず、同じ比較単位と分析を用いた 4 件以上の 研究では、単一の農薬と関連するバイオマーカーは評価されていないため、定量的な統合は行われな かった。

## 10.2 生殖能障害

30種類の分析を含む 8件の研究が、低生殖能に対する農薬の影響を評価している。サンプルサイズ は 41 から2,365 人とかなり小さい。潜在的な関連の評価には異なる効果量と分析が使用されている ため、メタアナリシスによる結果の統合は不可能である。温室栽培農場の女性労働者の農薬ばく露を 調査した最大規模の研究(ID: RPD 038)では、生殖能の低下が報告された(OR=0.68、95% CI=0.49-0.94)。しかし、温室栽培農場の女性労働者を対象とした2番目に大きなフィールド研究(ID RPD 034) では、有意な関連は示されなかった(OR=1.11、95%CI=0.96-1.29)。14の追加分析では有意な結果は報 告されなかったため、フィールド調査ではエビデンスが矛盾している。

## 10.3. 自然流産

自然流産に関する10件の研究では、職業ばく露に焦点が当てられていた。効果推定値とその変動の 指標を提供した6件の研究からデータを統合することができた。ランダム効果モデルを用いた要約0Rは 1.52 (95%:1.09-2.13)であり、大きな不均一性が観察された(I2=63%)(図27)。しかし、INUENDO 研究グループが実施したこの影響に関する最大の横断研究(ID RPD 003)では、p,p'-DDEの農業労働 と流産との間に統計的効果(OR=1)は示されなかった。さらに1つの研究では、フルタイムとパート タイムを比較したが、有意な関連は報告されていない(p値=0.99)。他の3つの研究では、メタア ナリシスに含めるのに十分な情報が得られなかった。

## 10.4 生殖ホルモン

このシステマティックレビューでは、様々な生殖ホルモンについて250の分析を行った19の研究(サ ンプルサイズ中央値257:IQR 97-322)が同定された。これらの研究は、精子障害パラメータに関する 他の大規模なグループのサンプルサイズに匹敵するものであり、その範囲は62から887までであった。 最大の研究は、テストステロンとエストラジオールのレベルに対するヘキサクロロベンゼンの影響を 評価したヨーロッパの横断研究である。14~15歳の男性青年のホルモン状態は、汚染物質への内部ば く露に関連して研究された。この研究では、ばく露はホルモン濃度の大きな差異と関連していること が示された。INUENDO研究グループが行った研究では、DDEと生殖関連ホルモンの全体的な分析では有 意な結果は得られなかったが、異なるパターンが観察された。しかし、センターごとの分析では、ゴナ ドトロピン濃度と性ホルモン結合グロブリンはp,p'-DDEばく露の影響を受けているようであり、母集 団間に大きなばらつきがあることが示唆された。評価された結果と農薬の種類が多いため、データの 定量的な統合はできなかった。

## 10.5. 研究数が少ない生殖影響

表12に含まれていないすべての影響については、月経周期の評価では利用可能なエビデンスを統合 することができない。我々のシステマティックレビューでは、過去に発表されたエビデンス(2006年以 前)との比較を可能にするために、これらの影響に関する過去に発表されたメタアナリシスは確認し なかった。異なる月経影響に関する結果から、DDEへのばく露が月経障害の主な原因であるとは考えに くいことが示された。 表 12:4 件以上の研究がある影響サブグループごとに同定された研究の要約(NA: 利用不可)

影響	研究数	メタアナリシス実施	前回のメタアナリシス結果
精子障害パラメータ	25	No	NA
生殖能障害	8	No	NA
流産	10	Yes	NA
生殖ホルモン	19	No	NA

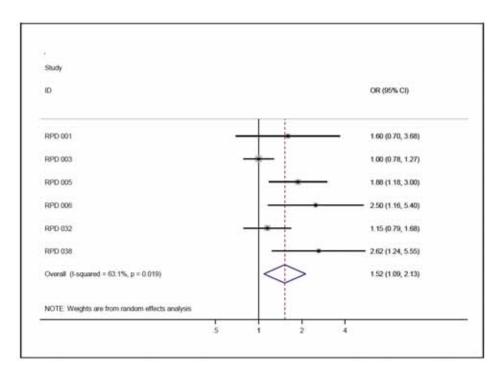

図27:農薬ばく露に関する情報と流産リスクのランダム効果メタアナリシス

### 11. 神経疾患

全体では 60 の論文が農薬ばく露の神経学的影響に及ぼす効果を調査しており(サンプルサイズ中央 値:390、IQR 246-781)、データ抽出データベースでは 573 件の個別分析が行われた。30 以上の健康 関連影響が評価されており、パーキンソン病に焦点を当てた研究が最も多く 32 件あった(表 13)。他 の影響に見られるように、ばく露の定義の多様性には目を見張るものがあり、データ統合に特別な問 題を与えている。60 件のうち 8 件のみが前向きコホート研究で、残りの 2 件はコホート内症例対照研 究であった。報告された分析におけるサンプルサイズはしばしば小さく、参加者数は 46~143,325 人 (中央値 390 人)であり、この領域における最大の研究は、がん分野で評価された最大の研究よりも 小規模であった。ここでは、農業健康調査(Agricultural Health Study: AHS)のようなこの分野の大 規模でよく知られた研究からの多くの出版物のまとまりも観察されたが、一方で 43 件の研究が職業ば く露を評価していた。さらに、ばく露のバイオマーカーに関する情報を持つ研究の存在は、ここではあ まり目立たなかった(n=7、12%)。評価された影響カテゴリーを表 13 に示す。評価された影響ごとに 同定された研究の数が少ないため、データの統計的統合(メタアナリシス)はパーキンソン病と筋萎縮 性側索硬化症についてのみ実施された。

## 11.1 パーキンソン病

農薬ばく露とパーキンソン病との関連を調査した研究は32件あり、サンプルサイズの中央値は399件 (IQR 286-711)で、データベースには266件の比較が抽出されている。検索された研究の80%は職業ば く露を評価していたが、前向き研究はわずか10%で、ばく露をバイオマーカーを介して評価した研究 は少数であった(10%)。個々の農薬の評価は多岐にわたったが、一般的な農薬(28件)、DDT(5件)、 パラコート(9件)などの農薬がより頻繁に評価されていた。

まず、一般的な農薬の使用とパーキンソン病との関連を評価した。観察された効果は、かなりの不均 一性が存在し、統計的に有意な関連を示した(ランダム効果OR 1.58、95%CI 1.35~2.85、I2 61%) (図 28)。特定の農薬を評価した 4 つの研究(例:パラコート)を除いて、他のすべての研究では、 主に質問紙による後ろ向きな方法で、主に職業上の一般的な農薬使用を評価している。メタアナリシ スの結果は、この研究の課題に関する最大の研究と一致している。

次に、DDTばく露とパーキンソン病との関連を評価した。観察された効果は、不均一性の存在なしに 統計学的に有意ではないことが示された(ランダム効果OR=1.01、95%CI=0.78-1.30、I2=0%)(図29)。 最後に、パラコートばく露とパーキンソン病との関連を評価した。観察された効果は、中等度の不均一 性の存在下で統計的に有意な関連を示した(ランダム効果OR=1.32、95%CI=1.10-1.60、I2=34%)(図 30)。メタアナリシスの結果は、これらの研究課題に関する最大規模の研究と一致している。

我々の文献検索では、2000年から2013年までに発表された農薬ばく露とパーキンソン病との関連に 関する7つのシステマティックレビュー及び/またはメタアナリシスが得られた (Pezzoli 2013, Van-Maele Fabry 2012, van der Mark 2012, Dick 2006, Priyadarshi 2001, Priyadarshi 2000, Allen 2013)。研究統合の最も古い取り組みと最新の取り組みとのかなりの時間的間隔、また、方法論(前向 き研究のみの評価、対象研究の方法論的評価など)の違いにもかかわらず、結果はメタアナリシス全体 で一貫しており、2006年からの現在の取り組みとも一致している(表14)。

## 11.2. 筋萎縮性側索硬化症(ALS)

7件の研究が農薬ばく露と筋萎縮性側索硬化症との関連を評価しており、サンプルサイズの中央値は 356 (IQR 201-1156) で、データベースには11件の個別の比較が抽出されている。検索されたすべての 研究は職業ばく露を評価しており、4つの研究は住居ばく露も評価していた。前向き研究は1件のみで、 ほとんどの研究では質問紙を用いてばく露を評価していた(n=6)。

我々は一般的な農薬使用とALSとの関連を評価した。観察された効果は、小さな不均一性(固定効果 OR=1.58、95%CI=1.31~1.90、I2 10%)の存在とともに統計的に有意な関連を示し(図31)、メタア ナリシスの結果は、その研究課題に関する最大の研究に沿ったものであった。

文献検索を行った結果、2012 年に発表された農薬ばく露と ALS の関連に関する 2 つのシステマティックレビュー及び/またはメタアナリシスが得られた(Kamel 2012, Malek 2012)。これらの結果によれば、大多数の研究では農薬の化学物質やクラスが特定されていなかったが、我々の知見や男性で対照と比較して農薬へのばく露とALSの関連を示すエビデンス(OR=1.88、95% CI: 1.36-2.61)についての著者らの報告と一致していた。

## 11.3. 研究数の少ない神経学的影響

パーキンソン病と筋萎縮性側索硬化症を除いて、残りのすべての神経学的影響については、2006年 以降の研究が少なすぎて、それぞれの影響だけでエビデンスを統合することができない。我々のシス テマティックレビューでは、2006年以前に発表されたエビデンスとの比較を可能にするために、これ らの影響に関する以前に発表されたメタアナリシスは確認されなかった。一般的に、これらの影響に 関する結果は効果が小さく、統計的に有意ではなかったが、少数の例外を除いては有意であった。分析 数が多いことを考えると、これらの結果は慎重に解釈する必要があり、これらのデータに基づいて、農 薬ばく露とこれらの影響との関連を示唆するエビデンスはない。

# 表13:神経学分野で評価された影響

健康影響		
手の交代運動の異常	アルツハイマー病	カタプレキシーを伴うナルコレプシー
足首反射の異常	筋萎縮性側索硬化症	神経症状
遠位運動振幅の異常	原因不明の多発神経障害	パーキンソン病
遠位運動潜時の異常	握力の低下	パーキンソン症候群

## 12. 内分泌疾患

全体では、35の出版物で農薬ばく露が甲状腺ホルモン調節障害に及ぼす影響が調査され(中央値サ ンプルサイズ226; IQR 130-453)、データ抽出データベースでは343の個別の分析が行われた。評価さ れた主な影響は、サイロキシン(T4)、トリヨードサイロニン(T3)、甲状腺刺激ホルモン(TSH)レ ベルであった。この分野で実施された前向きコホート研究は3件のみであり、エビデンスの大部分は後 ろ向き症例対照または横断分析によるものであるが、これらはばく露測定においてリコールバイアス がかかりやすい。報告されている分析におけるサンプルサイズはしばしば小さく、参加者数は27~ 16,529人(中央値341人)であった。ここでは、この分野でよく知られた大規模な研究からの出版物の 大きなクラスタは観察されず、大多数の研究は環境ばく露を評価していた(n=28、80%)。しかし、ば く露のバイオマーカーに関する情報を有する研究の存在は、ここではより多数であった(n=29、83%)。 甲状腺機能低下症、甲状腺機能亢進症、その他の甲状腺疾患が分析全体の1/3以上を占めているにもか かわらず(n=123)、利用可能なエビデンスは、この分野では明らかに最大規模で農薬使用と女性の甲 状腺疾患との関連を調査している農業健康調査(Agricultural Health Study: AHS)に由来している。 この研究では、甲状腺機能低下症と有機塩素系殺虫剤(0R=1.2、95% CI=1.0-16)及び殺菌剤(0R=1.4、 95% CI=1.1-1.8)の使用歴との間に関連があることが明らかになった。しかし、この結果は、有意水準 の境界線上であったことと多重比較によるタイプIの誤差補正がないため、注意して解釈されるべきで ある。この分野でいくつかの甲状腺ホルモンレベルを評価している他の研究は非常に小規模であり、 矛盾する結果を示している。他の影響に見られるように、まちまちなばく露の定義に注目すべきであ り、データ統合に特別な問題を及ぼしている。データの不均一性と異なる分析、効果量及び指標の使用 のために、データの統計的統合(メタアナリシス)は行われていない。

### 13. 精神及び精神運動発達影響

全体では、32の出版物が小児集団における精神及び精神運動発達影響に対する農薬ばく露の影響を調 査しており(サンプルサイズ中央値:238、IQR 109-305)、データ抽出データベースでは462の個別の 分析が行われた。非ヨーロッパ系(アジア系)の集団を対象とした研究は1件のみであり、注意欠陥多 動性障害(ADHD、6件、102件の分析)を中心に17件の健康関連影響が評価されていた。他の影響に見ら れるように、ばく露の定義はかなりまちまちであり、データ統合に特別な問題をもたらしている。大多 数の研究(23の論文、72%)は前向きコホート研究を参考にしているが、報告されている分析における サンプルサイズはしばしば小さく、25~7,440人の範囲で、最大のものはカリフォルニア・セントラル バレーの小児における農薬散布付近の母親の居住と自閉症スペクトラム障害の後ろ向き研究であった。 ここで、我々はまた、CHAMACOS(サリナスの母と小児の健康評価センター)(5出版物)などの大規模 な、この分野でよく知られた研究から来ている出版物のクラスタを観察したが、研究の84%が環境ば く露を評価していた。さらに、ばく露のバイオマーカーに関する情報を有する研究の存在がここでは 多数であった(n=28、88%)。調査したさまざまな影響カテゴリーを、各カテゴリーに寄与した研究の 数と定量的統合の決定とともに表15に示す。データの不均一性と同定された研究数が少なかったため、 どの影響についてもデータの統計的統合(メタアナリシス)は行われなかった。

### 13.1. 研究が少ない精神及び精神運動発達影響

精神及び精神運動発達影響と注意欠陥多動性障害(ADHD)を除いて、表15に記載の影響はすべて、そ れぞれの影響だけでエビデンスを総合的に判断するには、利用可能な研究が少なすぎる。これらの影 響は、自閉症や広汎性発達障害のように研究数が少ないが適切に定義された臨床所見から、コミュニ ケーション、微細及び粗大な運動発達、または表現的言語発達などの神経発達の中間形質を表す多数 の影響まで収集されたさまざまな情報で構成されている。我々のシステマティックレビューでは、2006 年以前に発表されたエビデンスとの比較を可能にするために、これらの影響に関する以前に発表され たメタアナリシスは確認しなかった。一般的に、これらの影響に関する結果は影響が小さく、統計的に 有意ではなかったが、少数の例外はあった。分析数が多く、研究数やサンプル数が少ないことを考える と、これらの結果は慎重に解釈する必要があり、これらのデータに基づいて、農薬ばく露とこれらの影 響との間に妥当な関連を示唆するエビデンスはない。

### 13.2. 注意欠陥多動性障害(ADHD)

6件の研究では、278人から2,539人の参加者のサンプルサイズで農薬ばく露とADHDとの関連を評価し、 データベースに102件の別個に抽出された比較を提供した。3つの研究はコホートであり、すべての研 究は環境ばく露を評価し、すべての研究でばく露はバイオマーカーを介して評価された。一般的な有 機リン剤へのばく露は3つの研究で、DDTへのばく露は2つの研究で評価され、trans-ノナクロル、ヘキ サクロロベンゼン、2,4,6-トリクロロフェノール(TCP)はそれぞれ1つの研究で評価された。このよう に、同等の影響の定義または同一の比較単位を用いた4つ以上の研究では、単一の農薬と関連するバ イオマーカーは評価されておらず、定量的な統合は行われなかった。この分野で最大の研究は、国民健 康・栄養調査(NHANES)の報告書(ID 17)で、1999年から2004年のNHANESのデータを使用して、6歳か ら15歳の小児2546人の間で尿中トリクロロフェノール(TCPs)と親が報告したADHDとの関連を評価し ている。著者らの報告によると、尿中の2,4,6-トリクロロフェノール(TCP)の濃度が低値(3.58 mg/g 未満)及び高値(3.58 mg/g以上)の小児は、検出限界値未満の小児に比べて、親に報告されたADHDの リスクが高かった(OR 1.54、95%CI 0.97~2.43、OR 1.77、95%CI 1.18~2.66、それぞれpはトレン ド=0.006)。

我々のシステマティックレビューでは、以前に発表されたエビデンス(2006年以前)との比較を可能 にするために、ADHDに関する以前に発表されたメタアナリシスは確認しなかった。一般的にADHDに関 する結果は効果が小さく、少数の例外を除いて統計的に有意ではなかった。したがって、多数の分析を 考慮すると、これらの結果は慎重な解釈が必要であり、これらのデータに基づいて、農薬ばく露とADHD との関連を示唆するエビデンスはない。

### 13.3. 神経発達

31件の研究が農薬ばく露と神経発達の関連を評価しており、サンプルサイズは25~1,041で、データ ベースには325件の個別比較が掲載されている。アジア系の小児の神経発達を評価した研究は1件のみ であり、その他の研究はすべてヨーロッパ系の集団を対象としたものであった。研究の74%はコホー ト研究で、27の研究ではバイオマーカーを用いてばく露が評価されていた。個々の農薬の評価は多種 多様で、有機リン系農薬一般というカテゴリーがより頻繁に評価されている(表16)。比較可能な影響 の定義または同一の比較単位を用いた 4 件以上の研究では、単一の農薬と関連するバイオマーカーの 評価は行われていないため、定量的な統合は行われていない。実際、神経発達の評価は、認知機能に見 られるように一般的な影響カテゴリーのもう一つの典型的な例であり、使用されている 35 のツール とサブツールの多様性と複雑性(表 17)は、公表されている文献の結果を体系的かつ定量的に統合し ようとする試みを無意味なものにしている。

この分野で最大の研究は、Collaborative Perinatal Projectの報告書(ID MPD 029)であり、ジク ロロジフェニルトリクロロエタンへの胎内ばく露と乳児及び学童期の小児の認知発達を評価している。 著者らの報告によると、この集団では DDT と DDE の濃度は比較的高かったが(DDT 濃度中央値 8.9 g/L、DDE 24.5 g/L)、7歳時のベイリー尺度の精神・精神運動発達スコアやフルスケール知能指数のい ずれにも関連していなかった。

我々のシステマティックレビューでは、2006年以前に発表されたエビデンスとの比較を可能にする ために、これらの結果に関する過去に発表されたメタアナリシスは確認しなかった。一般的に、神経発 達の影響に関する結果は、ほとんどの例外を除いて効果が小さく、統計的に有意ではなかった。したが って、多くの分析が行われたことを考えると、これらの結果は慎重に解釈する必要があり、これらのデ ータに基づいて、農薬ばく露とこれらの影響との関連を示唆するエビデンスはない。

### 14. 呼吸器疾患

全体では、29の出版物が呼吸器影響に対する農薬ばく露の効果を調査しており(サンプルサイズ中 央値:249、IQR 126-1728)、データ抽出データベースでは399の個別の分析が行われた。そのうち67% はヨーロッパとアメリカからのもので、10の健康関連影響が評価されており、その中でも特に喘息に 焦点を当てた影響が多かった(N=9)。他の影響に見られるように、ばく露の定義はかなりまちまちで あり、データ統合に特別な問題をもたらしている。29の出版物のうち、前向きコホート研究に言及して いるのは6件のみで、12件は横断研究であった。報告された分析におけるサンプルサイズはしばしば小 さく、35~47,756人の範囲であり、最大の研究はSingapore Chinese Health Studyであった。ここで は、AHS (6件)のようなこの分野でよく知られた大規模な研究からの出版物の大規模なクラスタも観察 され、17件(68%)の研究が職業的ばく露を評価していた。さらに、ばく露のバイオマーカーに関する 情報を持つ研究の存在は、ここではあまり目立たなかった(N=8、34%)が、1件の研究ではJEMによる 職業的ばく露を評価していた。調査したさまざまな影響カテゴリーを、各カテゴリーに寄与した研究 の数と定量的統合の決定とともに表 18 に示した。データの不均一性と同定された研究数が少ないた め、データの統計的統合(メタアナリシス)は喘息についてのみ実施した。

### 14.1. 研究数が少ない呼吸器影響

これらの影響は、特発性肺線維症やサルコイドーシス、努力性呼気量(FEV)などの多数のバイオマ ーカーに加えて、研究数が少なすぎるが、明確に定義された臨床所見まで、様々な情報を収集したもの で構成されている。我々のシステマティックレビューでは、以前に発表されたエビデンス(2006年以 前)との比較を可能にするために、これらの影響に関する以前に発表されたメタアナリシスは確認し なかった。一般的に、これらの影響に関する結果は効果が小さく、統計的に有意ではなかったが、少数 の例外を除いては有意であった。分析数が多く、結果のほとんどが農業健康調査(Agricultural Health Study: AHS)からのものであることを考えると、これらの結果は慎重に解釈する必要があり、これらの データに基づいて、農薬ばく露とこれらの結果との間に妥当な関連を示唆するエビデンスはない。

#### 14.2. 喘息

9件の研究が農薬ばく露と喘息との関連を評価しており、サンプルサイズの中央値は402(IQR 127-724)で、データベースには196件の比較が抽出されている。半数以上の研究が横断的に行われ、3分の 2以上の研究ではばく露は質問紙で評価されていた。個々の農薬の評価は多岐にわたり、DDT、パラコー ト、クロルピリホスがより頻繁に評価されている。DDT、クロルピリホス、パラコートを除いて(表 19)、 同じ比較単位を用いた 4 件以上の研究では、他の単一の農薬と関連するバイオマーカーは評価されて おらず、定量的な統合は行われていない。

利用可能な 5 つの研究で DDT へのばく露と喘息との関連を調査しようとしたところ、観察された 影響は不均一性を示すことなく統計的に有意であった (OR 1.29、95%CI 1.14~1.45、I2 0%) (図 32)。 次に、利用可能な6つの研究について、パラコートへのばく露と喘息との関連を調査しようとしたが、 観察された効果は、不均一性を示すもので統計的に有意ではなかった (OR=1.40, 95%CI=0.95-2.06, I2=53%) (図33)。最後に、利用可能な5つの研究でクロルピリホスへのばく露と喘息との関連を調査 しようとしたが、観察された効果は、不均一性を示し統計的に有意ではなかった (OR=1.03、95% CI=0.82-1.28、I2=0%) (図34)。メタアナリシスの結果は主にAHSによるものであること、また、男 女別、アレルギー性・非アレルギー性喘息別に報告されているため、4つがAHSに属していることに注 意が必要である。また、メタアナリシスの結果は2006年以降に発表されたデータに限定されているこ とも認めている。したがって、DDTについては、これらの農薬へのばく露と喘息との間に統計的に有意 な中等度の関連を示唆する最近のエビデンスがあると結論付けたが、クロルピリホスとパラコートに ついてはそうではない。

# 表18:呼吸器医学の研究と影響のまとめ(N/A:なし)

影響	研究数	メタアナリシス実施	以前に発表されたメタア ナリシス
咳	2	No	N/A
息苦しさ	1	No	N/A

図34: クロルピリホスばく露に関する情報と喘息のリスクの固定効果メタアナリシ ス(研究6と10は農業健康研究の出版物を参照)

#### 15. 神経精神疾患

全体では、15の出版物が成人集団の神経精神影響に対する農薬ばく露の影響を調査しており(サン プルサイズ中央値:596、IQR158-12263)、データ抽出データベースでは358の個別の分析が行われてい る。4分の3はヨーロッパとアメリカの研究者であり、17の健康関連影響が評価され、大部分が認知機能 に焦点を当てていた(9研究、246の分析)。他の影響に見られるように、ばく露の定義はかなりまちま ちであり、データ統合に特別な問題を与えている。15の出版物のうち、前向きコホート研究に言及して いるのは2件のみで、出版物の60%は横断研究であった。報告された分析におけるサンプルサイズはし ばしば小さく、66~112,683人の範囲であり、最大の研究は米国の後ろ向き研究であった。ここでは、 農業健康調査(Agricultural Health Study、AHS)(4件)のようなこの分野でよく知られた大規模な 研究からの出版物のクラスタも観察されたが、1件を除いてすべての研究が職業ばく露を評価していた。 さらに、ばく露のバイオマーカーに関する情報を有する研究の存在は、ここではあまり目立たなかっ た(n=2、13%)。調査したさまざまな影響カテゴリーを、各カテゴリーに寄与した研究の数と定量的 統合の決定とともに表20に示した。データの不均一性と同定された研究数が少ないため、どの影響に ついてもデータの統計的統合(メタアナリシス)は行われていない。

#### 15.1. 認知機能

9件の研究が農薬ばく露と認知機能との関連を評価しており、サンプルサイズの中央値は80(IQR 141-205)で、データベースには246件の比較が抽出されている。1件を除くすべての研究が横断的で、 7件の研究では質問紙でばく露が評価されていた。個々の農薬の評価は多種多様で、有機リン系農薬の 一般的なカテゴリーがより頻繁に評価されていた。比較可能な影響の定義や同じ比較単位を用いた4件 以上の研究では、単一の農薬と関連するバイオマーカーの評価は行われておらず、定量的な統合は行 われていない。実際、認知機能の評価は一般的な影響カテゴリーの典型的な例であり、利用可能な 15 の研究(表21)で使用された62のツールとサブツールの多様性と複雑性のため、公表されている文献の 結果を体系的かつ定量的に統合する試みは実りのないものとなっている。

この分野で最大の研究は、農薬の長期使用と神経行動機能との間の潜在的な関連を評価したAHSの報告書(ID NPD 014)であり、農薬散布者にこれらに関連する検査を行っている。著者らは、「検査結果は一部の農薬の生涯使用日数と関連していた」と報告している。エトプロプは、運動速度と視覚走査のテストのパフォーマンス低下と有意に関連していた。マラチオンは、視覚的走査と処理のテストのパフォーマンス低下と有意に関連していた。逆に、5種類の有機リン系農薬では、検査結果の有意な改善が観察された。具体的には、クロルピリホス、クマホス、パラチオン、ホレート、テトラクロルビンホスは言語学習と記憶力の向上と関連しており、クマホスは運動速度と視覚走査のテストの成績向上と関連しており、パラチオンは持続注意力のテストの成績向上と関連していました。全体的に、有機リン系農薬の使用とテスト成績低下との間には、この高齢の農薬使用者のサンプルでは一貫した関連のエビデンスは見られなかった。これらのほとんどが無効な結果となった理由としては、真の効果がないことや、より健康的な農薬使用者が選択的に参加している可能性が考えられる。

我々のシステマティックレビューでは、以前に発表されたエビデンス(2006年以前)との比較を可能 にするために、これらの結果に関する以前に発表されたメタアナリシスは確認しなかった。一般的に、 神経精神影響に関する結果は効果が小さく、統計的に有意ではなかったが、いくつかの例外を除いて は有意であった。

したがって、多数の分析を考慮すると、これらの結果は慎重に解釈する必要があり、これらのデータ に基づいて、農薬ばく露とこれらの影響との関連を示唆するエビデンスはない。

# 15.2. 研究数が少ない神経精神影響

これらの影響は、うつや強迫性障害のような明確に定義されているが研究数が少なすぎる臨床所見 から、また敵意や見当識障害のような神経精神医学的な中間形質を表す影響も多数含まれている。我々 のシステマティックレビューでは、以前に発表されたエビデンス(2006 年以前)との比較を可能にす るために、これらの影響に関する以前に発表されたメタアナリシスは確認しなかった。一般的に、これ らの影響に関する結果は効果が小さく、統計的に有意ではなかった(少数の例外を除く)。分析の数が 多く、結果の多くが AHS からのものであることを考えると、これらの結果は慎重に解釈する必要があ り、これらのデータに基づいて、農薬ばく露とこれらの結果との間の妥当な関連を示唆するエビデン スはない。

影響	研究数
不安	3
注意力・計算障害	1
認知機能	9

#### 16. 糖尿病

全体として、糖尿病関連影響に対する農薬ばく露の効果を調査した論文は23編(サンプルサイズ中 央値:430、IQR 192-1721)で、データ抽出データベースには125の個別の分析結果が掲載されていた。 4つの健康関連影響が評価されており、1型糖尿病(n=93、74%)に大きな割合を占めていたのに対し、 18の分析では2型糖尿病に焦点が当てられていた。評価されたその他の影響は、前糖尿病(n=10)、妊 娠糖尿病(n=2)、その他のグルコース及びインスリン関連影響(n=2)であった。前向きコホート研究 は1件のみで、大多数は横断的デザイン(n=15)であったが、3件は症例対照、4件はコホート内症例対 照を使用した研究であった。大多数の研究はアメリカで行われており(n=15、65%)、7研究はヨーロ ッパ人であり、アジア人は1研究のみであった。ここでは、AHSのような分野でよく知られた大規模な研 究からの出版物の大規模なクラスターは観察されなかった。3つの研究のみが職業ばく露を評価し、残 りは環境ばく露(n=19)またはその両方(n=1)を調査した。さらに、ばく露のバイオマーカーに関す る情報がある研究は9件に限られていたが、10件の研究では質問紙とバイオマーカーの両方の情報が含 まれていた。調査した異なる影響カテゴリーを、各カテゴリーに寄与した研究の数とともに表 22 に 示す。DDE と DDT ばく露と 1 型糖尿病、DDE ばく露と 2 型糖尿病についてはメタアナリシスが可能 であった。

### 16.1.1型糖尿病

1型糖尿病に対する農薬の影響を評価した研究は 3 件あり(サンプルサイズ中央値 309、IQR:159-398)、DDE と DDT ばく露については OR のメタアナリシスが可能であった。DDEについては、9件の 研究がサンプルサイズ中央値202、IQR=142-334であった。我々は、(有意な)罹患率比(IRR)7.1を示 し、DDE被曝の最上位層と最下位層を比較した前向き研究を含めることができなかった。計算された要 約ORは、ランダム効果モデルを用いたDDEばく露で1.90(95%CI:1.25-2.86)であった。中等度の不均 一性が観察された(I2=49%)。DDTに関しては、6件の研究が統合に利用可能なデータを持っていた(サ ンプルサイズ中央値:577、IQR:27-2-2163)ため、1.76(95%CI:1.20-2.59)の要約効果が得られ、 非常に大きな不均一性が観察された(I2=76%)。不均一性の主な原因は、効果推定値の計算に使用さ れた異なるばく露レベルである。ランダム効果メタアナリシスでは、1型糖尿病リスクの増加が存在す るというエビデンスがあるとはいえ、観察された不均一性のため、この結果は慎重に解釈されるべき である。

### 16.2.2型糖尿病

DDEばく露と2型糖尿病リスクを評価するために4件の研究が対象となった(サンプルサイズ中央値: 471、IQR=292-642)。これらの研究から得られた要約0Rは1.30(95%CI:1.13-1.48)であった。不均 一性は観察されなかったが、要約結果は、効果量0R=1.30(95%CI=1.11-1.52)を報告した症例対照研 究に牽引されている。DDEばく露が2型糖尿病発症のリスク因子であることを示唆するエビデンスはあ るが、これは小規模な研究に基づくものである。

# 表 22:4 研究以上のサブグループごとに確認された研究の概要(NA:利用不可)

影響	研究数	メタアナリシス実施	前回のメタアナリシス結果
1型糖尿病	13	Yes	NA
2型糖尿病	6	Yes	NA
妊娠糖尿病	2	No	NA
インスリン・グルコース耐性	2	No	NA

図36:DDTばく露と1型糖尿病との関連のサマリーオッズ比(OR)

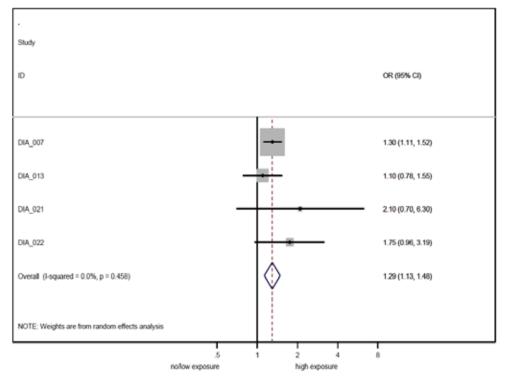

図37:DDEばく露と2型糖尿病との関連のサマリーオッズ比(OR)

### 17. 循環器疾患

重篤な心血管影響(心筋梗塞、脳卒中など)、心血管リスク因子(脂質、血圧)、その他の心血管影響(メタボリックシンドローム、肥満)を含む。これらのいずれについても、これまでのメタアナリシスは同定されていない。この系統的レビューで収集されたエビデンスは、特に心血管リスク因子と有機塩素に関する関連を弱く示唆しているが、他のクラスの農薬は研究されておらず、有機塩素に関する結果でさえ限られており、前向き研究の反復が必要である。

## 17.1. 重篤な心血管影響

心筋梗塞(ID CVD 005、ID CVD 006)、末梢動脈疾患(PAD)(ID CVD 007)、脳卒中(ID CVD 008)、 複合心血管疾患(ID CVD 009)を含む5つの研究が重篤な心血管影響を調査した。Agricultural Health Study(AHS)は2つの前向き分析(ID CVD 005、ID CVD 006)、National Health and Nutrition Examination Survey(NHANES)は他の2つの横断分析(ID CVD 007、ID CVD 009)を提供している。心筋梗塞に関す る研究(ID CVD 005、ID CVD 006)では、AHSの男性の心筋梗塞死亡率と農薬使用(個人またはクラス 別)との関連を示すエビデンスは示されなかった。同様に、AHSの女性では、農薬の使用と心筋梗塞と の全体的な関連は認められなかった。評価された27種類の農薬のうち、クロルピリホス、クマホス、カ ルボフラン、メタラキシル、ペンディメタリン、トリフラリンを含む6種類の農薬が女性の非致死的心 筋梗塞と有意に関連し(ID CVD 006)、いずれも比較的高いオッズ比(1.7以上)を示したが、複数回 の検査による偽陽性の確率も高かった。

別の前向き研究(8)では、脳卒中との関連で21種類の残留性有機汚染物質(POPs)を調査した。既 知の脳卒中リスク因子を調整した後、塩素原子が4、5、または6個のポリ塩化ビフェニル(PCB)、p、 p'-DDE、トランスノナクロル及びオクタクロロジベンゾ-p-ジオキシンのほとんどが脳卒中のリスク を有意に予測した。にもかかわらず、結果は今後の研究で再現する必要がある。末梢動脈疾患(PAD) 及び複合心血管疾患が、横断的なNHANESコホートでPOPsとの関連で研究された。PADのない被験者と比 較して、PADのある被験者では有機塩素系殺虫剤の濃度が有意に高かったが、肥満でない被験者では関 連は認められなかった。複合心血管疾患については、クロルデンのみに有意な関連が観察された。横断 的なデザインと自己申告による心血管疾患のため、これらの所見は慎重に解釈する必要がある。

全体的に、農薬ばく露と心血管影響との間の関連エビデンスは弱く、主に有機塩素系農薬に集中している。

### 17.2. 心血管リスク因子

## 17.2.1. 血圧

5件の研究で農薬と血圧の関連が調査された(ID CVD 002、ID CVD 003、ID CVD 004、ID CVD 010、 ID CVD 011)。1件の研究(ID CVD 011)では、横断的な研究が行われていた。 すべての効果量は非常に小さく、農薬ばく露と血圧との関連を示唆するものではなかった。

### 17.2.2. メタボリックシンドロームの構成要素

9件の研究では、脂質レベル、グルコース、インスリンレベルを含む農薬ばく露に関連したメタボリ ックシンドロームの構成要素が調査された。1件を除くすべての研究で有機塩素系農薬へのばく露が調 査され、いくつかのクラスと脂質レベルまたはグルコースレベルとの有意な関連が観察された。最も 質の高いエビデンスは、前向きCARDIA(Coronary Artery Risk Development in Young Adults)研究 (ID CVD 016)から得られている。CARDIAでは、様々な交絡因子を調整した後、20年目にp,p'-DDEが 最も一貫してトリグリセリド、インスリン抵抗性のホメオスタシスモデル評価値(HOMA-IR)及び高密 度リポ蛋白(HDL)コレステロールの低下を予測していた。また、オキシクロルデン、トランスノナク ロル、ヘキサクロロベンゼンもトリグリセリドの上昇を有意に予測した。最後に、中国で行われた症例 対照研究では、ピレスロイド(職業ばく露)に高度にばく露された参加者のグルコース調節の違いが調 査された。その結果、ピレスロイドにばく露されると異常なグルコース調節のリスクが高まることが 示された(OR = 1.48、95%CI = 1.24-1.77) (ID CVD 021)。しかし、この研究は後ろ向きであり、 残留交絡因子を除外できないため、これらの結果は他の集団で外部で再現の必要がある。

#### 17.2.3. 無症候性アテローム性動脈硬化症

集団ベースの Prospective Investigation of the Vasculature in Uppsala Seniors (ウプサラ高 齢者の血管系に関する前向き調査)では、POPのレベルが無症候性アテローム性動脈硬化症と関連して いるかどうかを横断研究で調査した。循環中のPCBレベルは、心血管リスク因子とは無関係に、アテロ ーム性動脈硬化性斑点と内膜複合体の超音波反射性と関連していたが、関連は前向き研究で確認する 必要がある。

#### 17.3. メタボリックシンドロームと肥満

3件の研究(ID CVD 010、ID CVD 011)で有機塩素ばく露とメタボリックシンドローム罹患率との関 連を調査した。国民健康・栄養調査(NHANES)(ID CVD 010)では、有機塩素系農薬の四分位間のORが 1.0、1.5、2.3、5.3であり、有機塩素ばく露とメタボリックシンドロームの罹患率との間に有意な関連 が報告された(傾向<0.01の場合はp)。他の症例対照研究(ID CVD 011)では、ヘプタクロルのみで 有意な関連が認められた。

全体として、12件の横断研究で農薬ばく露と体脂肪率または肥満度の測定値との関連が調査された。 また、12件中10件の研究では有機塩素系農薬と肥満または体脂肪率との関連が調査されていたが、他 のクラスの農薬についてはエビデンスが乏しかった。3件の研究(ID CVD 012、ID CVD 013、ID CVD 014)では、体脂肪率の測定値との相関分析のみが示された。残りの研究では、ウエスト周囲長、体格 指数(BMI)、有機塩素系農薬(DDTとクロルデン)との間に何らかの有意な関連が示されているが、エ ビデンスは横断的な分析に限られており、結果は関連を示唆するものに過ぎない。

## 18. 死亡率

全体では 11 の論文が農薬ばく露の死亡率への影響を調査し(サンプルサイズ中央値:1,986)、デ ータ抽出データベースでは 318 の個別分析が行われた。このセクションは、農薬と主要な死因との関 連を評価した異種の出版物群で構成されている。これらの研究は大規模なものであったにもかかわら ず、質は中等度であり、多重検定の補正を行わずに種々の疾患を同時に検定しているため、あまり有益 ではなかった。結果は、農薬ばく露と死亡との明らかな傾向を示していない。

## 19. 免疫疾患/自己免疫疾患

全体では、農薬ばく露が免疫障害に及ぼす影響を調査した論文は 10 (サンプルサイズ中央値 196、 IQR 81-476) で、データ抽出データベースでは 67 の個別の分析が行われた。60の研究はアメリカで 実施され、3つの研究はヨーロッパで実施され、1つの研究はアジアで実施された。関節炎、変形性関節 炎、関節リウマチ、様々な抗体、サイトカインなどの広範なリストを含む様々な健康関連影響が表 23 にまとめられている。10の出版物のうち7つは前向きコホート研究に言及していたが、2つの研究は横 断的であり、1つだけが症例対照であった。報告されている分析のサンプル数はかなり少なく、19~532 人で、最大の研究はCarolina Lupus Studyであった。研究の半分は職業ばく露を評価しており、ばく 露のバイオマーカーに関する情報は2つの研究で得られたが、4つの研究ではバイオマーカーと質問紙 の両方を使用していた。他の影響に見られるように、ばく露の定義と評価された影響はまちまちであ り、データ統合に特別な問題をもたらしている。2件以上の研究で単一の影響が評価されたものはなく、 免疫障害の分野ではデータの統合は不可能であった。

健康影響	
抗核抗体	インターロイキン-4(IL-4
関節炎	インターロイキン13(IL-13
補体成分 C3、C4	免疫学的効果
好酸球	白血球数
赤血球数	リンパ球レベル
糖タンパク質	好中球
ヘマトクリット/ヘモグロビン	ナチュラルキラー (NK) 細胞
インターフェロン γ	変形性関節症
免疫グロブリン1(IgG1)	関節リウマチ
免疫グロブリン4(IgG4)	全身性エリテマトーデス
免疫グロブリン M (IgM)	

## 表23:免疫障害の分野で評価された健康影響

## 20. アレルギー疾患

8つの異なる集団における9つの研究が、農薬ばく露とアレルギー性障害との関連を報告した。7件の 研究では職業ばく露が調査され、2件の研究では環境ばく露が調査された。8件の研究は横断的な調査 であったため、結論は逆因果関係やその他のバイアスがかかりやすい。結果については、5件の研究が 自己申告によるアレルギー性鼻炎、1件の研究が自己申告による喘息、残りの3件の研究が自己申告に よる皮膚刺激、接触性皮膚炎、食物アレルギー、花粉症、香料アレルギーを調査した。アレルギー性鼻 炎に関する4件の研究 (ID ALL\_003、ID ALL\_004、ID ALL\_005、ID ALL\_006) で統計学的に有意な結果 が報告された。これらの研究では、様々な農薬クラスとアレルギー性鼻炎との間に有意な関連が報告 されている。特に、Agricultural Health Study (AHS) では、アレルギー性鼻炎と除草剤である2,4-ジ クロロフェノキシ酢酸(2,4-D)グリホサート及び石油油、殺虫剤であるジアジノン及び殺菌剤である ベノミルへのばく露との間に有意な関連が報告されている。しかし、この研究には多くの限界があり、 結果は慎重な解釈が必要であり、将来の前向き研究での再現が必要である。この研究は、アレルギー性 鼻炎と非アレルギー性鼻炎の症状を区別できているか、また、横断的なデザインのためにばく露と症 状の間の時系列を示せるかという点で制限されている。全体的に質の低い1件の研究では、温室内の花 卉及び観賞用植物の栽培者におけるアレルギー性鼻炎について、手押しポンプによる農薬散布と農薬 散布なしの比較で高い効果量(OR、12.50;95%CI、2.00-78.05)が報告されている(ID ALL\_006)。 ここでも、この研究は全体的に質が低く、化学物質の種類ではなく散布方法に関連して定義された高 濃度ばく露集団に関係している。全体的に、アレルギー性障害と農薬ばく露に関するエビデンスは弱 1

## 21. 血液疾患

## 21.1. 再生不良性貧血

3件の研究では、農薬ばく露と再生不良性貧血(まれな血液疾患)との関連が調査された。すべての 研究は症例対照デザインであり、サンプルサイズは小さい(9~310の範囲)。2件の研究では、大きな 効果量で有意な関連が報告されたが、利用可能な研究の数が少ないことと、これらの研究の限界があ るため、確実な結論を出すことは難しい(表24)。もう1件の症例対照研究(ID APL\_002)では、効果 量は報告されていないが、関連のp値のみが報告されており、有意ではなかった。これらの示唆に富む 結果を明らかにするためには、さらなるエビデンスが必要である。

# 表 24: 効果量を報告した 2 つの症例対照研究における農薬ばく露と再生不良性貧 血の結果のまとめ

Study ID	  調査した農薬	比較	OR	下位 95% CI	上位 95% CI	ケース数	コントロ ール数

# 21.2. 血液学的及び生化学的変化

14の研究では、農薬ばく露に関連した様々な血液学的及び生化学的変化を調べた。主に一般血液検 査とビタミンレベルであった。サンプル数は51~1,275人であった。これらの研究の質は中等度から低 度であった。ほとんどの研究では、血液学的パラメータと農薬ばく露との間の無補正相関統計値また は平均値が報告されており、p値以外に効果量は報告されていない。すべての研究は横断的なエビデン スを提供している。報告された分析の多くが統計的に有意であったにもかかわらず、これらのデータ に関連するエビデンスが限られており、質も中等度であるため、現段階では結果を解釈すべきではな い。

#### 22. その他の影響

全体では 30 の論文がその他の影響に対する農薬ばく露の効果を調査した。データ統合のための 我々の基準に基づき、これらの影響に対するメタアナリシスは実施されなかった。

### 21.1. 骨疾患

農薬ばく露が骨粗鬆症に及ぼす影響を調査した研究は3件あり、13の異なる分析を行った。我々は2 つのヨーロッパの横断研究と1つのアジアのコホート研究を同定した(サンプルサイズ中央値:176、 IQR:153-908)。すべての研究は、ばく露のバイオマーカーに関する情報とともに環境ばく露を評価し ており、すべての研究は有機塩素へのばく露のみを調査している。骨粗鬆症は超音波測定と骨密度に よって評価された。908名の女性を対象とした最大の研究では、p,p'-DDEが骨密度と明確な関連を示 し、交絡因子を調整した後も関連は維持されたが、効果は弱いことが示された。

#### 22.2. 皮膚疾患

11件の分析のうち農薬ばく露が皮膚病変に及ぼす影響を調査した研究は6件(サンプルサイズ中央値 356、IQR 26-2203)であった。4件の研究では横断的デザインが用いられていた。環境ばく露は3件の研 究で評価された。影響の定義は多くの場合、発疹や湿疹であった。結果はほとんど統計的に有意ではな かった。1つの前向き研究(ID SKD 004)では、男性5,042人を対象としたAraihazarのヒ素の健康影響 縦断研究から、皮膚病変と農薬使用について非常に有意な効果量が報告されているが、この研究では ヒ素ばく露も評価されており、それぞれのばく露の効果を区別することは困難であった。

#### 22.3. 歯科疾患

アメリカで行われた1つの横断研究では、496人の参加者が2つの影響で評価された。この研究では、 バイオマーカー(ID PER 001)の情報を用いて環境ばく露を評価した。この研究では、有機塩素系(0C) 農薬は歯周病と強く関連していた。

#### 22.4. 代謝性疾患

ヨーロッパで行われた横断研究では、農薬が代謝性疾患、特に様々なprorfyrins(誤植?)のレベル に及ぼす影響を評価し、8つの分析を行ったが、有意な結果は報告されていない。環境ばく露は、ばく 露評価のためのバイオマーカーを用いて研究された。

#### 22.5. 男性機能疾患

1件の症例対照研究では、農薬ばく露と勃起不全との関連が報告されている。この研究では有機塩素 系農薬に焦点を当て、勃起不全の症例101例を234例の同等の対照群と比較した。結果は統計的に有意 ではなく、関連を示すエビデンスとはならなかった。

## 22.6. 婦人科疾患

このグループには、上述の影響カテゴリーには含まれていない婦人科学的影響が含まれている。こ のグループには4件の研究が含まれており、3件は子宮内膜症、1件は閉経のタイミングを調査した。子 宮内膜症に関する3件の研究(ID GYN 001、ID GYN 002、ID GYN 003)はすべて横断的であり、すべて 有機塩素を調査していた。子宮内膜症と有機塩素に関する12の個別分析のうち1つは統計学的に有意で あった;芳香族系殺菌剤の上位3位までは、下位3位までと比較して子宮内膜症のリスクが5倍(OR = 5.3;95%CI、1.2-23.6)であった。この効果量は大きく、他の前向き研究で独立した再現が必要であ る。

農業健康調査(Agricultural Health Study: AHS)のデータを用いて、閉経前の女性を対象とした前 向き調査において、農薬へのばく露と閉経時年齢との関連を調査した。年齢、喫煙状況、経口避妊薬の 過去の使用状況をコントロールした後、閉経までの期間の中央値は、農薬を使用した女性では約3ヵ月

(HR 0.87、95%CI: 0.78、0.97)、ホルモン活性農薬を使用した女性では約5ヵ月(HR 0.77、95%CI: 0.65、0.92) 増加した。農薬の使用は、これらの結果に基づいて、閉経年齢の遅延と関連している可能性がある。しかしながら、結果は偽陽性バイアスがかかりやすく、独立した再現が必要である。

#### 22.7. 症状及び一般的な疾患

吐き気、倦怠感、めまい、息切れなどの一般的な疾患を5つの研究で調査した。これらの結果の定義 は非常に難しく、大きな測定誤差と関連している。研究の質は中等度から低度で、すべての研究が職業 ばく露に関係していた。いくつかの統計的に有意な結果が観察されたが、報告されたデータの不均一 性とこれらの研究に関連する限界のため、現段階では決定的な結論には程遠い。

#### 22.8. 腎臟疾患

3つの研究では、慢性腎臓病や結石疾患などの腎臓病を調査した。1件の研究では、DDE及びDDT残留農薬と結石疾患との間に統計的に有意な結果が報告された。

#### 22.9. 良性腫瘍

聴神経腫瘍に関する集団ベースの症例対照研究では、農薬ばく露と聴神経腫瘍との関連は認められ なかった。

#### 22.10. 消化器疾患

農薬ばく露と肝臓酵素との関連を調査した 7 件の研究が同定された。すべての研究は横断的または 症例対照であった。1件の研究、国民健康・栄養調査(NHANES)では有機塩素について、もう1件の研究 では2,4-ジクロロフェノキシ酢酸(2,4-D)とパラコートへのばく露について、残りの研究では広く定 義された農薬のカテゴリーについて調査が行われた。これらの研究は限られた規模で質が低く、多く の場合調整なしで、被ばく露者と非ばく露者の酵素の平均値のみが提示されていた。ほとんどすべて の研究で、農薬にばく露された参加者の肝臓酵素(例:γ-グルタミルトランスフェラーゼ(GGT)、ア ラニンアミノトランスフェラーゼ(ALT)、アスパラギン酸アミノトランスフェラーゼ(AST))のレベ ルが高いほど、統計的に有意な結果が報告されている。しかし、データの質の低さと研究の数が限られ ているため、しっかりとした結論を出すことはできず、データは現段階では関連をほのめかすだけで ある。

#### 結論

約46,000の科学出版物を網羅的かつ包括的に検索した結果、602の出版物を確認した。農薬ばく露に 関連した健康影響の全領域については、これまでにも研究されたことがなかった。我々の結果は、24の 主要な疾患カテゴリーを含む非常に幅広いスペクトルを示している。これほど広範囲の影響と関連し た環境ばく露はこれまでほとんどなかった。最も一般的な影響は、がんと母子の健康影響である。しか し、神経疾患や生殖器疾患など、他の疾患カテゴリーにも注目が集まっている。利用可能なデータが大 量にあり、利用可能な分析の数が多い(6,000件以上)にもかかわらず、研究された影響の大部分につ いて確固たる結論を出すことはできない。この調査は、この分野の研究量の多さを考慮すると、特に残 念な結果となった。しかし、この調査は環境疫学、特に農薬に関するこれまでの研究と一致しており、 疫学研究には多くの限界があり、データの不均一性から確固たる結論を出すことができないことを認 めている。

研究されている農薬のカテゴリーの範囲は広いが、研究は多くの場合、広く定義された農薬のカテ ゴリーに集中しており、集団がどの農薬にばく露されているかを理解するのは難しい。研究では、欧米 の集団や欧州連合ですでに禁止されている農薬を調査することが多い。ばく露評価の手段としてバイ オマーカーを使用することはほとんどないが、ほぼ半数の研究ではまだ使用可能である。さらに、コホ ート研究はこの文献の中では少数派であり、症例対照研究と横断研究が対象となる論文のほぼ同じ割 合を占めている。症例対照研究や横断研究では、時間的関係を研究することができないため、関連の因 果関係に関する裏付けを提供することができない。ばく露の評価は、おそらくこれらの研究の最も重 要な方法論的限界である。研究では、ばく露の評価と割り付けに異なる方法が用いられていた。ほとん どの研究では、農薬へのばく露を、使用したことがあるかないか、あるいは定期的に使用したことがあ るかないかという自己申告に基づいていた。このような方法は、高い誤分類率に悩まされ、特に後ろ向 き研究の場合には、病気のある参加者で報告されたばく露量が多いほど誤分類に差が出てしまう(リ コールバイアス)。とりわけ、このような質問紙は、非常に高いばく露量の被験者と非常に低いばく露 量の被験者を区別することができるかもしれないが、ばく露の段階にわたって有効なばく露分類がで きないため、用量反応関係の研究を行うことができない。また、幅広いカテゴリーの農薬や一般的に使 用されている農薬ではばく露の精度が高いかもしれないが、特定の農薬ではそうではない。ばく露評 価に使用される質問紙の妥当性が確認されていることが重要である。しかし、研究では、ほとんどの場 合、質問紙の「自己流」バージョンが使用されており、ばく露評価に使用された実際の質問紙に関する 情報が得られないことがある。さらに、複数の物質への同時ばく露は一般的であり、結果にさらなる偏 りが生じる可能性がある。例えば、農薬への職業ばく露は、ベンゼン、重金属、溶剤、浮遊粒子状物質 などへのばく露と共存している可能性が高い。真の関連を明らかにするためには、複数の物質へのば く露による交絡を考慮することが不可欠であるが、ここで評価されたエビデンスの圧倒的多数では、 これは不可能であった。

さらに、ここで収集されて評価されたエビデンスは、選択的な報告と多重検定に悩まされている可 能性が高い。研究は非常に広範囲の分析を報告しており、602件の論文で6000件の分析が行われていた。 多重仮説検定の量は膨大である。これらの分析は多重仮説検定のために調整する必要があり、そうし ないと結果は高い偽陽性率に悩まされることになる。研究が1つの分析しか行われていない場合でも、 他の疫学分野でも示されているように、選択的な報告が行われる可能性は常にある。さらに、結果を解 釈する際には、特に特定の影響(がんなど)については、エビデンスの大部分が単一の研究集団と特に AHSから得られていることも考慮に入れるべきである。

ばく露の定義以外に、臨床所見の定義は妥当な疫学研究においても大きなばらつきを示しており、 これが結果のばらつきの原因となっている。おそらく、このような状況で最も重要なのは、調査された 代替健康影響の使用であろう。ここでは非常に多くの代替健康影響が観察された。代替健康影響とは、 特定の臨床所見の代用または予測因子として一般的に受け入れられているバイオマーカーまたは身体 測定値である。しかし、多くの場合、これらの代替健康影響は検証されておらず、代替健康影響の厳密 な定義を満たしていない。このような影響は、臨床所見の予測因子として定義される可能性はあるが、 代替健康影響の基準を満たしていない。検証されていない代替健康影響に関するエビデンスは、検証 されていない代替健康影響の暗黙の想定を考慮に入れて評価されることが不可欠である。

これらの限界を認識した上で、我々は本報告書で検索されたエビデンスを要約することを試みた。 ここで追加された重要な制限は、このレビューが2006年以降の出版物に限定されているという事実で ある。これにより、最近のエビデンスのみをレビューすることが可能となり、メタアナリシスは利用可 能なすべてのエビデンスを含んでいるわけではないため、非常に慎重な解釈が必要となる。2006年以 降に発表されたデータがそれ以前のエビデンスと異なる場合、結果に偏りが生じる可能性がある。こ の目的のために、主要な影響及び2006年以降に発表された関連するメタアナリシスが確認されたもの については、更新されたメタアナリシスも提供した。これは小児白血病とパーキンソン病についての み可能である。これらの影響については、以前のエビデンスに沿って、農薬ばく露と疾患との間に有意 な関連があることがわかった。有意な要約推定値は他の影響についても報告されており、以下の表25 にまとめられている。しかし、これらは2006年以降の研究であるため、結果はあくまでも関連を示唆す るものであり、特にばく露の不均一性に関する限界を常に考慮に入れるべきである。

# 表 25:本報告書で実施されたメタアナリシスの要約

健康影響	研究数	メタアナリシス結果	$I^2$
白血病	6	1.26 (0.93, 1.71)	59.40%
ホジキンリンパ腫	7	1.29 (0.81, 2.06)	81.60%
小児白血病(妊娠期の農薬ばく露)	6	1.67 (1.25, 2.23)	81.20%
小児白血病(妊娠期の殺虫剤ばく露)	5	1.55 (1.14, 2.11)	65%
小児白血病(妊娠期の殺虫剤ばく露-ターナー2010 年に更 新)	9	1.69 (1.35, 2.11)	49.80%
小児白血病(妊娠期の不特定農薬ばく露)	5	2.00 (1.73, 2.30)	39.60%
小児白血病(妊娠期の不特定殺虫剤ばく露-ターナー2010 年に更新)	11	1.30 (1.09, 1.56)	26.50%
小児白血病(小児期の農薬ばく露)	7	1.27 (0.96, 1.69)	61.10%
小児白血病(小児期の殺虫剤ばく露-ターナー2010 年に更 新)	8	1.51 (1.28, 1.78)	0%
小児白血病(小児期の不特定殺虫剤ばく露-ターナー2010 年に更新)	11	1.36 (1.19, 1.55)	0%
乳がん(DDE ばく露)	5	1.13 (0.81, 1.57)	0%
乳がん	11	1.24 (1.08, 1.43)	0%
精巣がん(DDE ばく露)	5	1.40 (0.82, 2.39)	59.50%
胃がん	6	1.79 (1.30, 2.47)	0%
肝臓がん	5	2.50 (1.57, 3.98)	25.40%
停留精巣	8	1.19 (0.96, 1.49)	23.90%
停留精巣(DDT ばく露)	4	1.47 (0.98, 2.20)	51%
尿道下裂(一般的な農薬ばく露)	6	1.01 (0.74, 1.39)	71.50%
尿道下裂(特定の農薬ばく露)	9	1 (0.84, 1.18)	65.90%
流産	6	1.52 (1.09, 2.13)	63.10%
パーキンソン病	26	1.49 (1.28, 1.73)	54.60%
パーキンソン病(DDT ばく露)	5	1.01 (0.78, 1.30)	0%
パーキンソン病(パラコートばく露)	9	1.32 (1.09, 1.60)	34.10%
筋萎縮性側索硬化症	6	1.58 (1.31, 1.90)	10%
喘息 (DDT ばく露)	5	1.29 (1.14, 1.45)	0%
喘息(パラコートばく露)	6	1.40 (0.95, 2.06)	53.30%
喘息(クロルピリホスばく露)	5	1.03 (0.82, 1.28)	0%
1 型糖尿病 (DDE ばく露)	8	1.89 (1.25, 2.86)	49%
1 型糖尿病 (DDT ばく露)	6	1.76 (1.20, 2.59)	76.30%
2 型糖尿病(DDE ばく露)	4	1.29 (1.13, 1.48)	0%

## 推奨事項

上述したように、本報告書のために収集された広範なエビデンスは、疫学研究から得られる農薬ば く露と健康影響に関する膨大な量の情報があることを浮き彫りにしている。しかし、これらのエビデ ンスの質は通常低く、多くのバイアスが結果に影響を与え、確固とした結論を出すことができない可 能性が高い。小児がんとパーキンソン病は、2006年以降に対応するメタアナリシスが行われた2つの 影響であり、農薬ばく露に関連したリスクの増加を示すデータが一貫している。しかし、特定の農薬ク ラスや個々の農薬の影響を切り離すためには、ばく露の研究をさらに進める必要がある。内分泌疾患、 喘息、アレルギー、糖尿病、肥満などの他の影響への影響はリスクの増加を示しており、さらに調査が 必要である。本報告書では、健康影響を個別に調査することに集中した。別のアプローチとしては、農 薬のクラス、サブクラス、あるいは個々の農薬でさえも、さまざまな影響にわたって調べることであろ う。これらのアプローチにより、ある農薬クラスが様々な疾患エンドポイントにおいて特定の有害な 影響を及ぼすかどうかを明らかにすることができる。最後に、ばく露疫学は長い間、ばく露の測定と定 義に悩まされてきたが、特に農薬については、これは常に評価と定義が非常に困難であった。技術的な 進歩により、オミクスのハイスループット技術を用いて、大規模かつ断定的でない方法でばく露のバ イオマーカーを測定することが可能になった。例えば、メタボローム分析は、最小限の測定誤差とばく 露を特定する能力で、環境ばく露の全範囲を捕捉する方法を提供している。これらのアプローチは現 在開発が進められており、食事ばく露を含む環境ばく露と健康影響との関連について、より明確な見 解を提供してくれる可能性が高い。

場所(大陸)	研究実施大陸
募集期間	研究参加者を募集した期間
ばく露期間(妊娠前、乳児期、小児期、成	農薬ばく露が発生した発育期(妊娠前、妊娠期、乳児期、小児
人期、妊娠期)	期、思春期、成人期)
追跡期間	前向き/後ろ向き研究の追跡予定期間
追跡期間(最大)	前向き/後ろ向き研究の最大追跡期間は年単位である。
追跡期間(年)(中央値/平均値)	前向き/後ろ向き研究の平均または中央値の追跡期間(年)。
研究の種類(コホート、コホート内症例対	疫学研究のデザイン:コホート、コホート内症例対照、症例対
照、症例対照、横断的)	照、横断的
コホート名	疫学研究の名称
年齢(年)(範囲/平均/中央値)	調査対象となった集団の年齢(平均年齢または中央値年齢を提示 することを好む。データは、別段の記載がない限り、年単位で表 示される。
性別(男性の割合)	調査対象集団における男性の割合
評価された有効成分	試験で定義・命名された試験で評価された農薬
有効成分のカテゴリー	農薬が分類されている化学的または機能的な農薬の分類
認可状況	EU 域内で認可された農薬有効成分(2013/09/06) Yes/No/NA (NA=該 当なし)
バイオマーカー名	農薬ばく露のバイオマーカー名(測定した場合)
対照定義	症例対照研究における対照群の定義
農薬の共ばく露(測定値)	その研究では、他の共ばく露農薬に関する情報を提供したか?(は い、いいえ)
集団の特徴	調査した集団の説明(性別、場所、病状)
ばく露の種類(職業的、環境的、両方)	農薬へのばく露源は何か:職業的(ばく露が特定の職業活動に関 連している場合);環境的(ばく露がいかなる職業活動にも関連し ていない場合(例えば、住居内での農薬使用、ガーデニングでの 農薬使用、ガーデニングに関連したばく露など);両方(職業ばく 露と環境ばく露の両方が存在する場合)。
ばく露評価の種類(直接ばく露についての 質問紙/バイオマーカー/居住履歴/職歴 /JEM/専門家評価/環境 odeling 誤植と 思われる	農薬ばく露の測定方法:直接ばく露についての質問紙(面接また は自己記入);体液中のバイオマーカーの測定;居住歴;職業歴; 職業ばく露マトリックス (JEM)。

EFSA 支援出版 2013:EN-497

# Ntzani EE, Chondrogiorgi M, Ntritsos G, Evangelou E, Tzoulaki I Pesticide epidemiology

ばく露の定義	研究に記載されているばく露の定義
質問紙の種類	質問紙の種類(面接または自己管理)(質問紙を用いてばく露を評
	価した研究の場合、そうでない場合は該当なし)
バイオマーカーの測定(全血、血漿、尿、	バイオマーカーが測定された体液または組織(全血、血漿、尿、
母乳、胎盤、爪、毛髪、唾液、脂肪組織)	母乳、胎盤、爪、毛髪、唾液、脂肪組織など)
アッセイタイプ	バイオマーカー測定に使用した生化学的アッセイの種類
ばく露期間	年単位での農薬ばく露期間 (入手可能な場合)
小児ばく露タイプ(母、父、小児、組合わ	小児の影響に関する研究については、自己ばく露または親のばく
せ)	露(母親、父親、小児、組合わせ)を通じたばく露手段を記述
小児ばく露時期(妊娠前、妊娠期、両方)	小児の影響に関する研究では、親のばく露は妊娠前、妊娠期、ま
	たは両方の期間に行われたか?
健康影響	研究に記載されている通りの健康影響
影響の定義	研究で使用された健康影響の定義
疾患カテゴリ	疾患カテゴリ
効果推定タイプ(RR、OR、HR、 $\beta$ 、MD、	農薬と健康影響の関係を評価するための効果推定値の種類 (RR,
SMD)	OR, HR, $\beta$ , MD, SMD)
効果(2変数、連続変数)	2変数法または連続変数法で推定された効果(2変数、連続変数)
比較単位(はい/いいえ、単位増加、	効果量を算出するための比較の定義(はい/いいえ、単位増加な
	ど)
効果推定	効果推定値
SE/SD 効果推定	効果推定値の標準誤差・標準偏差
95% CI の下限	効果推定値の 95%信頼区間の下限
95% CI の上限	効果推定値の 95%信頼区間の上限
調整	効果推定値の交絡因子/変数の調整
マッチした対照	対照の変数を症例にマッチさせた (症例対照研究のみ)
サンプルサイズ	参加者総数
N 症例	症例数
N 対照	対照数
統計的手法	効果量の計算に用いられる統計的手法
試験デザイン(前向き、後ろ向き、混合、	研究デザインの前向き型または後ろ向き型(前向き、後ろ向き、
横断)	混合、横断)
包含/除外の基準の明記	研究参加者(母集団)の説明は詳細に行われていましたか?(はい
(はい、一部、いいえ)	/一部/いいえ)
著者による検出力の言及	著者らは、統計分析の前または後に論文で検出力について言及し
(はい、いいえ)	ているか?(はい/いいえ)
ばく露レベル(高、中、低)の詳細記述	農薬ばく露の定義でばく露レベル(高、中、低)の詳細記述
ばく露量の妥当な測定 :	ばく露量の測定は妥当であったか:バイオマーカー(はい);小規
(バイオマーカー(有);小規模区域の生態	模区域の生態学的測定、職種、質問紙(一部);大規模区域の生態
学的測定、職種、質問紙(一部);大規模区	学的測定に基づいた(いいえ)
域の生態学的測定に基づいた(無))	
ばく露量の測定は特定のものであったか?	ばく露量の測定は特定のものであったか?(はい);より広範で化
はい;より広範で化学的に関連したグルー プに其べく (一部)・タばな化学的及び書	学的に関連したグループに基づく(一部);多様な化学的及び毒性
プに基づく(一部);多様な化学的及び毒	学的特性の広範なグループ化に基づく(いいえ)

EFSA 支援出版 2013:EN-497

性学的特性の広範なグループに基づく(い いえ)	
グループ間の配分のバランスを図る(層別 化、マッチングなど)	症例対照研究では、層別化またはマッチングによってグループ間 の配分のバランスをとる試みが行われたか? (はい/いいえ)
潜在的な交絡因子の調整を行った(はい、 いくつか、いいえ)	潜在的な交絡因子について効果量を調整したか? (はい、いくつ か、いいえ)
ばく露状況を盲検化された評価者(コホー ト研究の場合)	コホート研究では、評価者はばく露状況を盲検化されていたか? (はい/いいえ/;n/a:コホート研究でない場合は、成果なし、また は該当なし)
影響は、すべての研究参加者に一貫して実 施された有効かつ信頼性のある測定を用い て評価されたか?	影響は、すべての研究参加者に一貫して実施された有効で信頼性 のある測定を用いて評価されたか? (はい/いいえ)
サンプルサイズ(四分位数の上部[991]、 中間部、下部[104])	サンプルの大きさ
資金源の承認	著者は、資金調達の可能性があることを認めているか(はい/いい え)
大まかな品質評価	データ抽出フォームの品質評価の他のすべての列のデータを考慮 した大まかな品質評価
コメント	抽出されたデータの解釈に役立つ研究に関するコメント

# 用語解説と略語

AHS:農業健康調查

ベータ推定値:線形回帰の係数

バイアス:データの作成、収集、操作及び表示に採用されたプロセスの特性に起因する、または推定 手法の誤ったサンプルデザインに起因する、データの体系的な不正確さ。

バイオマーカー:体内の化学物質の存在、生物学的反応、または健康への有害影響を監視するために 使用できる、人体内の測定可能な物質または特性。ばく露のバイオマーカーは、体内に存在す

る化学物質の量を評価するために使用される。

盲検影響評価:ばく露を評価する個人は、参加者の健康状態を盲検化する。

CARDIA (カーディア): "Coronary Artery Risk Development In Young Adults (若年成人の冠状動 脈リスク発症) "研究、多施設、集団ベースの研究。

- 症例対照研究(Case-control study):観察研究の一種で、結果の異なる2つの既存のグループを特定し、何らかの因果関係に基づいて比較する研究。症例対照研究は、ばく露状況を後ろ向きに 評価する後ろ向き研究である。
- 症例報告:個々の患者の症状、徴候、診断、治療、経過観察の詳細な報告。
- 症例集積:同様の治療を受けたばく露が知られている患者を追跡したり、ばく露と影響について医療 記録を調べたりする記述研究。これらの研究には対照群がない。

センターごとの分析:複数のセンターから募集した参加者がいる研究におけるセンターごとの分析。

- CHAMACOS (チャマコス): Center for the Health Assessment of Mothers and Children of Salinas (CHAMACOS)。カリフォルニア州サリナスバレーに住む妊婦とその子供の健康に及ぼす農薬やそ の他の環境要因の関連を調べることを目的とした前向き出生コホート。
- CI: 信頼区間
- コホート研究:リスク因子を分析し、調査対象疾患を発症するまで疾患を持たない人のグループを追 跡調査する縦断的/前向き研究。
- 交絡因子(Confounders):従属変数(ばく露)と独立変数(影響)の両方と相関する(正または負の)統計モデルの外部変数。

横断研究:ある特定の時点での参加者全員の観察を行い、ばく露と影響を同じ時点で測定する研究。 生態学的研究:観察の単位が集団または共同体である研究。疾病率とばく露が各集団集積で測定さ

れ、それらの関係が調査される。

効果(2変数/連続変数):影響は2変数法(二項対立、例:がん(はい/いいえ))または連続変数法 (例:収縮期血圧(120mmHg))である。

効果推定値/サイズ:関連の強さの尺度

ESCALE: 全国登録ベースの症例対照研究「Etude sur les cancers de l'enfant」試験

- ファンネルプロット:システマティックレビューやメタアナリシスにおける出版バイアスの有無を確 認するために設計されたグラフ
- 不均一性:メタアナリシスは、類似した研究のグループから複合的な効果を推定するために使用される。しかし、治療効果の個々の推定値は偶然によって変動する;ある程度の変動は予想され

る。問題は、偶然だけで予想される以上の変動があるかどうかである。このような過度の変動 が生じる場合、それは不均一性と呼ばれる。

HR: ハザード比 (Hazard Ratio)

- I<sup>2</sup>:メタアナリシスにおける試験間の一貫性の尺度で、不均一性の測定であり、0(不均一性なし) から1(極端な不均一性)までの値をとる。
- INUENDO: "INUENDO-食品中の生物持続性有機塩素化合物とヒト生殖能、イヌイットと欧州の集団にお ける妊娠までの期間と精液の質の疫学研究"、欧州委員会(the 5th Framework Programme Quality of Life and Management of Living Resources, Key Action 4 on Environment and Health (Contract no. QLK4-CT-2001-00202)(契約番号: QLK4-CT-2001-00202)

(http://www.inuendo.dk))の支援を受けた不妊に関する欧州のプロジェクト。

IRR:発生率比

IQR:四分位間範囲

JEM:職業ばく露マトリックス

MD:平均差

- メタアナリシス (Meta-analysis):様々な統計的手法を用いて研究結果を統合し、以前の別々ではあ るが関連のある研究の結果を検索、選択、結合するプロセスまたは技術。
- Multiple testing (多重検定): 先験的に定義されていない、または先験的仮説に基づいていない、 多くの仮説を検定すること。
- 誤分類:測定誤差に起因する推定値のバイアス
- 多変量モデル:1つ以上の従属変数を持つ統計モデル。これらのモデルは通常、調査対象の分析の交 絡因子の数を調整する。
- コホート内症例対照研究:コホート内症例対照研究では、定義されたコホート内で発生した疾患の症 例が同定され、各症例の疾患発生時までに疾患を発症していないコホート内の患者の中から、 指定された数のマッチした対照が選択される。

NHANES:米国国民健康栄養調查

観察研究:観察研究とは、被験者に対する治療の効果について推論を行うもので、被験者を治療群と 対照群に割り当てるのは研究者の管理外である。

OR:オッズ比

統合効果推定値:メタアナリシスの要約した効果推定値、メタアナリシスの結果

POPs: 残留性有機汚染物質

- 前向き研究 (Prospective study): ある影響に影響を及ぼす可能性のある要因に基づいて個人 (コホ ート)のグループを選択する疫学研究
- 出版バイアス(Publication bias):研究者、編集者、製薬会社が、陽性(すなわち有意な知見を示 す)の実験結果の報告を、陰性(すなわち帰無仮説を支持する)または結論の出ない結果とは 異なる扱いをする傾向から生じたバイアス。
- 回想バイアス(Recall bias):過去の出来事や経験の記憶に対する回想の正確さや完全さの違いに よるシステマティックエラー。

残存交絡:残存交絡因子は、交絡因子が分析で十分に調整されていない場合に発生する(通常、交絡

因子が知られていないため)。

後ろ向き研究:参加した個人を何らかの影響あり(症例)と影響なし(対照)に分類する疫学研究

で、影響は特定の疾患である可能性があり、その影響と関連する可能性のある特定の因子について、その人の病歴を調べる。

- 逆因果関係:逆因果関係とは、因果関係の方向性のことで、ばく露が影響につながったのか、影響が ばく露につながったのかはわからない。
- RR:相対リスク
- ナラティブ・レビュー (Narrative review):実質的な知見や、特定のトピックに対する理論的・方 法論的な貢献を含めて、現在の知識の重要な点を調査するために書かれた論文
- SD:標準偏差

SE:標準誤差

- 代替健康影響(surrogate outcome):患者がどのように感じているか、機能しているか、または生存 しているかを直接測定するものや、ばく露の影響を予測することが期待されるものである臨床 的に意味のあるエンドポイントの代わりに試験で使用される測定値または物理的徴候。
- システマティックレビュー:関連する主要研究を特定、選択、批判的に評価し、レビューに含まれる 研究からデータを抽出、分析するために、体系的かつ明示的な方法を用いて、明確に定式化さ

れた問題に関するエビデンスのレビュー。

第一種の誤り:真の帰無仮説の誤った棄却

Department of Hygiene and Epidemiology, University of Ioannina Medical School, Ioannina, Greece

#### ABSTRACT

We performed a systematic and extensive literature review of epidemiological studies examining the association between pesticide exposure and any health outcome published after 2006. We searched 43,259 citations and identified 603 published articles examining a very wide variety of outcomes and presenting over 6.000 analyses between pesticide exposure and health outcomes. We divided the different outcomes into 23 major disease categories. The largest proportion of studies pertains to cancer outcomes (N=164) and outcomes related to child health (N=84). The majority of studies were case-control studies and cross-sectional studies (N=222) and examined occupational exposure to pesticides (N=329). A wide and diverse range of pesticides was studied with studies using various definitions of pesticides; it is very hard to harmonise between studies this information. Despite the large volume of available data and the large number (>6,000) of analyses available, firm conclusions cannot be made for the majority of the outcomes studied. This observation is disappointing especially when one accounts for the large volume of research in the area. However, this observation is in line with previous studies on environmental epidemiology and in particular on pesticides which all acknowledge that such epidemiological studies suffer from many limitations and that the heterogeneity of data is such that does not allow firm conclusions to de made. We also performed updated metaanalysis for major outcomes and for those where a relevant meta-analysis published after 2006 was identified. This has only been possible for childhood leukaemia and for Parkinson's disease. For both these outcomes we found significant associations between pesticide exposure and disease in line with previous evidence.

# 外部科学報告書

# 農薬ばく露と健康影響に関連する疫学研究に関する文献レビュー1

**Evangelia E Ntzani, Chondrogiorgi M, Ntritsos G, Evangelou E, Tzoulaki I** Department of Hygiene and Epidemiology, University of Ioannina Medical School, Ioannina, Greece

### 概要

我々は、2006年以降に発表された農薬ばく露と健康影響との関連を調査した疫学研究の系統的かつ 広範な文献レビューを行った。43,259件の引用文献を検索し、非常に多様な影響を調査した603件の 論文を同定し、6,000件以上の農薬ばく露と健康影響との間の分析結果を提示した。さまざまな影響を 23の主要な疾患カテゴリーに分類した。研究の中で最も多いのは、発がん影響(N=164)と子どもの健 康に関連した影響(N=84)であった。研究の大部分は症例対照研究と横断研究(N=222)で、農薬への 職業ばく露(N=329)を調査したものであった。さまざまな農薬の定義を用いて研究が行われ、広範囲 かつ多様な農薬が研究されていたため、これらの情報を研究間で調和させることは非常に難しい。利 用可能なデータの量が多く、分析の数も多い(6,000以上)にもかかわらず、研究された結果の大部分 について確固たる結論を出すことはできなかった。これは、この分野の研究量の多さを考慮すると、特 に残念な結果である。しかし、この結果は環境疫学、特に農薬に関するこれまでの研究と一致してお り、疫学研究には多くの限界があり、データの不均一性があるために確固たる結論を出すことができ ないことを認めている。我々はまた、主要な影響及び2006年以降に発表された関連するメタアナリシ スが確認されたものについて、更新されたメタアナリシスを実施した。これは小児白血病とパーキン ソン病についてのみ可能である。これらの影響については、以前のエビデンスに沿って、農薬ばく露と 疾患との間に有意な関連があることが分かった。

Pesticide epidemiology

5

#### BACKGROUND AND TERMS OF REFERENCE

Over the last years an abundance of epidemiological studies investigating possible associations of pesticide exposure with adverse health effects on humans have become available. In these studies exposure to pesticides e.g. via inhalation, ingestion, dermal contact or across the placenta has been established as being, or suggested to be, causative for instance for cancer in various organs and tissues, disturbed neurodevelopment of children, allergies, decreased fertility (male and female), birth defects and Parkinson's disease.

However, for many adverse health effects that are attributed to pesticide exposure contradictive or ambiguous studies also exist. Studies vary generally greatly in design (e.g. case control versus cohort studies), sample size and in many cases exposures are rather estimated or assumed than actually determined.

A comprehensive up-to-date literature collection and review covering relevant publications from 1<sup>st</sup> January 2006 to 31<sup>st</sup> March 2012 should be carried out in which also the quality of these studies is evaluated.

The objectives of the contract resulting from the present procurement procedure are as follows:

Objective 1: To collect and compile scientific publications in which possible links between pesticide exposure and adverse human health effects have been investigated.

Objective 2: To review and evaluate each collected study in regard to its qualitative aspects (e.g. the corner points of the investigations).

Objective 3: Provision of a database and a report of epidemiological studies.

This contract was awarded by EFSA to: The Department of Hygiene and Epidemiology, University of Ioannina Medical School, Ioannina, Grecce.

Contractor: The Department of Hygiene and Epidemiology, University of Ioannina Medical School, Ioannina, Grecce.

Contract title: Literature review on epidemiological studies linking exposure to pesticides and health effects.

Contract number: CFT/EFSA/PRAS/2012/04 - CT 01.

#### 背景と参考文献

ここ数年の間に、農薬ばく露とヒトへの有害健康影響との関連を調査する疫学研究が豊富に行われ るようになった。これらの研究では、例えば、吸入、経口、経皮及び経胎盤による農薬ばく露が、様々 な臓器や組織のがん、小児の神経発達障害、アレルギー、生殖能力の低下(男性と女性)、先天異常、 パーキンソン病などの原因となる、あるいはその可能性が示唆されていることが立証されている。

しかし、農薬ばく露に起因する多くの有害健康影響については、矛盾した、あるいは曖昧な研究も存 在する。研究は一般的にデザイン(例:症例対照研究とコホート研究)、サンプルサイズ、そして多く の場合、ばく露量は実際の測定値ではなく、むしろ推定値または想定値である。

2006年1月1日から2012年3月31日までの関連出版物を網羅した包括的な最新の文献収集とレビュー を実施し、これらの研究の質も評価すべきである。

今回の調達手続きによる契約の目的は以下の通りである。

目的1:農薬ばく露とヒトへの有害健康影響との関連が調査された科学的出版物を収集・集積する。

目的2:収集された各研究の質的側面(調査のコーナーポイントなど)をレビューし、評価する。

目的3:疫学研究のデータベースと報告書の提供。

本契約は、EFSAが次の者に授与した。イオアニナ大学医学部衛生・疫学部 (Ioannina, Grecce) 契約者: イオアニナ医科大学衛生・疫学部、イオアニナ大学、(Ioannina, Grecce)。 契約タイトル: 農薬へのばく露と健康影響を関連付ける疫学研究の文献調査 契約番号: CFT/EFSA/PRAS/2012/04 - CT 01

### INTRODUCTION AND OBJECTIVES

This project aims to systematically collect, review and appraise epidemiological studies carried out to investigate possible links of pesticide exposure to health-related outcomes in order to improve understanding of already established or suggested associations with adverse effects in humans. The review focuses on all exposure types either through occupation or in general population with a particular focus on investigating sources of heterogeneity. In particular, we have collected scientific publications in which possible links between pesticide exposure and adverse human health effects have been investigated. The available evidence is under review and evaluation with regard to its qualitative aspects. Finally, a database of studies, which examine adverse health effect of pesticides, was compiled.

The final report is structured around health outcome categories and is linked to a *data extraction database*. In the methods we provide a detailed documentation of the search criteria and search strategy used for the literature review and the study selection process. This section also describes the analytical framework with the detailed documentation on the selected exposure and indicators of exposure and the surrogate and clinical outcomes examined. We present the results of the literature search with the full list of eligible studies and the contents of the *data extraction database*. We also present the results of the outcomes and pesticides examined and conclusions based on the literature review findings.

#### BACKGROUND AND AIMS

Pesticides have been widely used against pests that can damage crops such as insects, fungi, rodents, noxious, weeds, in order to prevent or reduce losses and improve product quality, for many years. Their use is very popular; in 2006 and 2007, the world used approximately 5.2 billion pounds of pesticides. However, despite their extensive use, and the associated benefits from pesticide use, there have been concerns on adverse effects in human health as these chemicals are designed to have adverse biological effects on target organisms. Indeed, there is evidence between pesticide use and adverse health outcomes such as cancers, neurodegenerative disease and birth defects; however, results so far have been inconsistent and firm conclusions cannot be drawn for several pesticides.

The aim of this review is to systematically collect, review and appraise epidemiological studies carried out to investigate possible links of pesticide exposure to health-related outcomes. This review includes all exposure types either through occupation or in the general population with a particular focus on investigating sources of heterogeneity. In particular, we have collected and compiled scientific publications in which possible links between pesticide exposure and adverse human health effects have been investigated. The available evidence has been reviewed and evaluated with regard to its qualitative aspects and data from each eligible study has been extracted. Finally, a database of studies, which examine adverse health effects of pesticides, has been compiled with the aim to facilitate the continuous update of results.

The aforementioned aims constitute a stimulating task due to the methodological challenges of environmental epidemiology and pesticide exposure in particular and the vast volume of the peerreviewed literature. Ntzani EE, Chondrogiorgi M, Ntritsos G, Evangelou E, Tzoulaki I

### 序文と目的

本プロジェクトは、すでに確立されている、あるいは示唆されているヒトにおける有害影響との関 連についての理解を深めるために、農薬ばく露と健康関連影響との関連を調査するために実施された 疫学研究を体系的に収集し、レビューし、評価することを目的としている。このレビューでは、特に食 い違いの原因を調査することに焦点を当て、職業を通じた、あるいは一般集団におけるすべてのばく 露タイプに焦点を当てている。特に、農薬ばく露とヒトへの有害健康影響との関連が調査された科学 的出版物を収集した。利用可能なエビデンスは、その質的側面に関してレビューと評価が行われてい る。最後に、農薬の有害健康影響を調査した研究のデータベースを作成した。

最終報告書は、健康影響カテゴリーを中心に構成され、データ抽出データベースとリンクしている。 方法のセクションでは、文献レビューと研究の選択プロセスで使用した検索基準と検索戦略の詳細な 文書を提供している。このセクションでは、選択されたばく露とばく露指標及び検討された代用及び 臨床影響に関する詳細な文書を用いた分析的枠組みについても記述している。対象となる研究の完全 なリストとデータ抽出データベースの内容を含めた文献検索の結果を提示する。また、検討した影響 と農薬の結果及び文献レビューの結果に基づく結論を提示する。

### 背景と目的

農薬は、昆虫、真菌、野鼠、不快生物、雑草などの作物にダメージを与えることができる有害生物に 対して広く使用されており、長年にわたり、損失を防止または削減し、作物の品質を向上させるために 使用されている。2006年と2007年には、世界で約52億ポンドの農薬が使用された。しかし、農薬は広範 囲に使用されており、それに関連して農薬の使用による利益があるにもかかわらず、これらの化学物 質は対象生物に有害影響を及ぼすように設計されているため、ヒトへの有害健康影響が懸念されてい る。実際、農薬の使用とがん、神経変性疾患、先天異常などの健康有害影響との間にはエビデンスがあ るが、これまでのところ結果には一貫性がなく、いくつかの農薬について確固たる結論を出すことは できていない。

本レビューの目的は、農薬ばく露と健康関連影響との関連を調査するために実施された疫学研究を 体系的に収集し、レビューし、評価することである。このレビューでは、特に食い違いの原因を調査す ることに重点を置いて、職業を通じた、または一般集団におけるすべてのばく露タイプを対象として いる。特に、農薬ばく露とヒトへの有害健康影響との関連が調査された科学的出版物を収集し、まとめ た。利用可能なエビデンスは質的側面に関してレビューされ評価され、妥当な研究からデータが抽出 されている。最後に、結果の継続的な更新を容易にする目的で、農薬の有害健康影響を調査した研究の データベースを作成した。

前述の目的は、特に環境疫学と農薬ばく露の方法論的課題と、膨大な量の査読付き文献のため、刺激 的な課題を構成している。

# EFSA supporting publication 2013:EN-497

The present document has been produced and adopted by the bodies identified above as author(s). This task has been carried out exclusively by the author(s) in the context of a contract between the European Food Safety Authority and the author(s), awarded following a tender procedure. The present document is published complying with the transparency principle to which the Authority is subject. It may not be considered as an output adopted by the Authority. The European Food Safety Authority reserves its rights, view and position as regards the issues addressed and the conclusions reached in the present document, without prejudice to the rights of the authors.

### MATERIALS AND METHODS

### 1. Search strategy

A comprehensive literature search was conducted of peer-reviewed original research pertaining to pesticide exposure and any health outcome. The search strategy was designed so as to identify observational epidemiologic studies published between 1<sup>st</sup> of January 2006 to 30<sup>th</sup> of September 2012 and examining the relationship between pesticide exposures during critical exposure time windows (preconception, pregnancy, childhood, adulthood) and any health-related outcome as discussed previously. The search strategy was developed to search primarily the MEDLINE (1950–to date), and EMBASE (Excerpta Medica Database; 1980 to-date) databases as well as TOXNET (Toxicology Data Network; U.S. National Library of Medicine 2012), OpenSigle (2012), and ProQuest Digital Dissertations and Theses (2012) as supplemental searches.

# 2. Search algorithm for original studies in MEDLINE and EMBASE

This systematic review aimed to identify studies examining any clinical outcome or valid biomarker acting as surrogate for a clinical outcome that has been associated with exposure to pesticides. In order to achieve maximum sensitivity, we did not include any outcome-related search terms in the search algorithm that we developed. For the formation of the search algorithm, we concentrated on pesticides related terms, identified through the MEDLINEMESH terms and EMBASE classification trees on pesticides. In MEDLINE, the MESH terms of pesticides and pesticides (pharmacological action) were examined. Similarly, we examined the pesticide term in the EMBASE Emtree index. We have looked for pesticide categories (i.e. insecticides, herbicides, fungicide etc.) and for specific pesticide names as described in the literature or as pharmacological terms (e.g. DDT or Dichlorodiphenyltrichloroethane) in order to be comprehensive. We have also examined the search terms used in published systematic reviews on pesticide exposure during the past 10 years and looked for any additional terms.

Our first constructed algorithm was long including all aforementioned terms. We piloted different searches and shortened the search to improve the sensitivity of the algorithm with modest impact on the precision. All searches were limited to Humans and to publication date after 1<sup>st</sup> of January 2006.

The long list of pesticide names provided from the MESH database for pesticides pharmacological names only provided 2,270 citations on top of the pesticides related words search (pesticid\* OR pesticides"[MeSH Terms] OR "pesticides"[All Fields] OR "pesticide"[All Fields] OR "pesticides"[Pharmacological Action]) in MEDLINE. Examination of 200 from those 2,270 citations showed that these did not include epidemiological studies and referred to chemical studies on the substances and chemical formation of pesticides. We therefore adopted the search algorithm including the generic terms. The algorithm was constructed in EMBASE as the database provides a function to study MEDLINE and EMBASE simultaneously (see textbox below). The following algorithm was developed:

Ntzani EE, Chondrogiorgi M, Ntritsos G, Evangelou E, Tzoulaki I

### 材料と方法

### 1. 検索戦略

包括的な文献検索を実施し、農薬ばく露と健康影響に関する査読付きの原著研究を対象とした。検 索戦略は、2006年1月1日から2012年9月30日までに発表された観察疫学研究で、重要なばく露期間(妊 娠前、妊娠期、小児期、成人期)における農薬ばく露と健康関連影響との関係を調査したものを特定す るように設計された。検索戦略は、主にMEDLINE (1950年から現在まで)、EMBASE (Excerpta Medica Database、1980年から現在まで)データベースを使用し、TOXNET (Toxicology Data Network、U.S. National Library of Medicine 2012)、OpenSigle (2012)及びProQuest Digital Dissertations and Theseses (2012)を補足検索として使用した。

### 2. MEDLINE 及び EMBASE における原著論文の検索アルゴリズム

本システマティックレビューは、農薬へのばく露と関連した臨床影響または臨床影響の代用となる 有効なバイオマーカーを調査した研究を特定することを目的とした。最大限の感度を得るために、我々 が開発した検索アルゴリズムには影響に関連する検索用語は含まれていない。検索アルゴリズムの構 築にあたっては、MEDLINEMESHの用語とEMBASEの農薬分類ツリーを用いて同定された農薬関連の用語に 集中した。MEDLINEでは、農薬と農薬(薬理作用)のMESH用語を調べた。同様に、EMBASE Entreeインデ ックスの農薬用語を調べた。農薬のカテゴリー(例えば、殺虫剤、除草剤、殺菌剤など)と、文献に記 載されている特定の農薬名、または薬理学的用語(例えば、DDTまたはジクロロジフェニルトリクロロ エタン)を網羅的に調べた。また、過去10年間の農薬はく露に関する出版されたシステマティックレビ ューで使用された検索用語を調べ、追加の用語を調べた。

最初に構築したアルゴリズムは、前述のすべての用語を含む長いものであった。異なる検索を試験 的に行い、精度への影響を最小限に抑えながらアルゴリズムの感度を向上させるために検索を短縮し た。すべての検索はヒトに限定し、2006年1月1日以降の出版日に限定した。

農薬理学的名称のMESHデータベースから提供された農薬名の長いリストは、MEDLINEの農薬関連 語検索 (pesticid\* OR pesticides"[MeSH Terms] OR "pesticides"[All Fields] OR "pesticide"[All Fields] OR "pesticides"[Pharmacological Action])の上位2,270件の引用のみを提供していた。そ のうち2,270件の引用のうち200件を調査したところ、疫学研究は含まれておらず、農薬の物性や化学 構造に関する化学的研究を参照していることが判明した。そこで、一般用語を含む検索アルゴリズム を採用した。アルゴリズムは、データベースがMEDLINEとEMBASEを同時に検索する機能を提供している ため、EMBASEで構築した(下記のテキストボックスを参照)。以下のようなアルゴリズムを構築した。

EFSA supporting publication 2013:EN-497

The present document has been produced and adopted by the bodies identified above as author(s). This task has been carried out exclusively by the author(s) in the context of a contract between the European Food Safety Authority and the author(s), awarded following a tender procedure. The present document is published complying with the transparency principle to which the Authority is subject. It may not be considered as an output adopted by the Authority.  Table 1:
 Search algorithm for EMBASE and MEDLINE

pesticid\* OR 'pesticide'/exp OR 'chemical pest control'/exp OR fungicid\* OR 'fungicide'/exp OR herbicid\* OR 'herbicide'/exp OR insecticid\* OR 'insecticide'/exp OR molluscacid\* OR 'molluscacide'/exp OR molluscacid\* OR 'molluscacide'/exp OR rodenticid\* OR 'rodenticide'/exp OR carbamate' OR 'carbamate'/exp OR pyrethroid\* OR 'pyrethroid'/exp OR 'agricultural chemical'/exp AND [humans]/lim AND [2006-2013]/py

The algorithm resulted in 43,259 citations in EMBASE and MEDLINE combined. Of those, 14,539 were unique to EMBASE. The algorithm includes all pesticides related terms and subcategories used either as emtree entries with the explode option and also as text words. The explode option ensures that when a term has any more specific, or narrower, index terms within the Emtree thesaurus, they are also automatically retrieved as part of the search. Terms such as organochlorine, glyphosate, paraquat and maneb were excluded as they are part of the pesticide tree of the explode option and are searched. Inclusion of these terms would lead to the same set of results. Figure 1 below shows examples of the indexing trees in EMBASE for some of our search terms.

#### 3. Supplemental searches

The database of TOXNET, which lists databases on toxicology, hazardous chemicals, environmental health, and toxic releases, was also searched to identify any information missed from previous search in MEDLINE and EMBASE. We used only the Databases, which look for references in the biomedical literature (i.e. the Toxicology Literature Online (TOXLINE) and the Developmental Toxicology Literature (DART)). The remaining TOXNET databases provided summaries of Chemical, Toxicological, and Environmental Data per chemical substance and were not relevant to this search. For TOXLINE and DART, we used the generic terms "Pesticide OR Pesticides" as longer search algorithms with the inclusion of pesticides subcategories had only minor impact on the number of references identified. The searches were limited to publication dates after 2006, excluding references identified through MEDLINE. The function to identify chemical synonyms to the search term was enabled. Overall, 893 references were retreived from TOXLINE and 34 from DART.

EFSA supporting publication 2013:EN-497

The present document has been produced and adopted by the bodies identified above as author(s). This task has been carried out exclusively by the author(s) in the context of a contract between the European Food Safety Authority and the author(s), awarded following a tender procedure. The present document is published complying with the transparency principle to which the Authority is subject. It may not be considered as an output adopted by the Authority. The European Food Safety Authority reserves its rights, view and position as regards the issues addressed and the conclusions reached in the present document, without prejudice to the rights of the authors.

# 表1: EMBASE 及び MEDLINE の検索アルゴリズム

pesticid\* OR 'pesticide'/exp OR 'chemical pest control'/exp OR fungicid\* OR 'fungicide'/exp OR herbicid\* OR 'herbicide'/exp OR insecticid\* OR 'insecticide'/exp OR molluscacid\* OR 'molluscacide'/exp OR molluscicide'/exp OR molluscicide'/exp OR rodenticid\* OR 'rodenticide'/exp OR carbamat\* OR 'carbamate'/exp OR pyrethroid\* OR 'pyrethroid/exp OR 'chlorinated hydrocarbon//exp OR 'agricultural chemical//exp AND [humans]/lim AND [2006-2013]/py

このアルゴリズムにより、EMBASE と MEDLINE を合わせて 43,259 件の引用が行われた。そのうち 14,539 件は EMBASE に固有のものであった。このアルゴリズムには、分割オプションを使用して Emtree エン トリとして、またテキストワードとして使用された農薬関連の用語とサブカテゴリがすべて含まれて いる。分割オプションを使用すると、用語が Emtree のシソーラス内でより具体的な、またはより狭い インデックス用語を持つ場合、それらも検索の一部として自動的に検索される。有機塩素、グリホサー ト、パラコート、マネブなどの用語は、分割オプションの農薬ツリーの一部であり、検索されるため、 除外された。これらの用語を含めると、同じ結果が得られる。以下の図1は、EMBASE で検索された用 語のインデックスツリーの例を示している。

# 3. 補足検索

また、毒性学、有害化学物質、環境衛生、有害物質排出に関するデータベースを掲載しているTOXNET のデータベースを検索し、MEDLINEやEMBASEでの前回の検索で見逃した情報を特定した。生物医学文献 (Toxicology Literature Online (TOXLINE)及びDevelopmental Toxicology Literature (DART))の 文献を検索するデータベースのみを使用した。残りのTOXNETデータベースは、化学物質ごとの化学的 データ、毒物学的データ、環境データのサマリーを提供しており、今回の検索には関係なかった。 TOXLINEとDARTについては、「Pesticide OR Pesticides」という一般的な用語を使用したが、農薬のサ ブカテゴリを含む検索アルゴリズムが長くなっても、同定された参考文献の数にわずかな影響しかな かったためである。検索は2006年以降の出版日に限定し、MEDLINEで同定された文献は除外した。検索 語の化学物質の同義語を特定する機能を有効にした。全体では、TOXLINEから893件、DARTから34件の文 献が検索された。

また、ヨーロッパで出された灰色文献[非商業出版物](論文)の書誌的参考文献700,000件を収録したSystem for Information on Grey Literature in Europe (OpenSigle)も調べた。2006年以降に出

EFSA 支援出版 2013:EN-497

#### Ntzani EE, Chondrogiorgi M, Ntritsos G, Evangelou E, Tzoulaki I Pesticide epidemiology

We also looked into the System for Information on Grey Literature in Europe (OpenSigle), which includes 700.000 bibliographical references of grey literature (paper) produced in Europe. There were no bibliographical references on pesticides (search term pesticid\*) published after 2006.

We have also constructed a search algorithm to search the ProQuest Digital Dissertations and Theses database. We excluded from our search articles published in scholarly journals as those will have been identified through MEDLINE and EMBASE. We used the search term "pesticide\* AND health" and limited our search to specific subjects (environmental science OR public health OR environmental health OR epidemiology OR pesticides OR nutrition OR occupational health) and to publication dates between 2006 and 2012. This search strategy resulted in 1,713 results. Results were numerous when no subject limits were used (12,135) or when the term "health" was excluded from the initial algorithm (18,195).

Finally, the reference lists of all identified eligible studies and systematic reviews are scanned during data extraction for additional references.

#### 4. Search for literature systematic reviews and meta-analysis

We also performed targeted searches for systematic reviews and meta-analysis in relation to specific outcomes. We restricted the search for reviews on those outcomes where more than 4 studies had been identified and we performed targeted searches in MEDLINE using the name of the outcome along with the keywords "systematic review OR meta-analysis" limited to the title or the abstract of the paper.

### 5. Structure of this report

This report is structured around health outcome categories and provides the results for each outcome group separately. A section on general conclusions is presented at the end. At the end of each section on outcomes and tables and figures are presented to allow ease of reading. Also, the ID numbers of each eligible article are referenced throughout the text. These correspond to the ID for each health outcome group in the *data extraction database* which has been provided as a separate file to this report. The ID is defined with an abbreviation for the specific health outcome and a study number.

Ntzani EE, Chondrogiorgi M, Ntritsos G, Evangelou E, Tzoulaki I

Pesticide epidemiology

版された農薬(検索語pesticid\*)に関する書誌的文献はなかった。

また、ProQuest Digital Dissertations and Thesesデータベースを検索するための検索アルゴリズ ムを構築した。MEDLINEやEMBASEで検索した結果、学術雑誌に掲載された論文は検索対象から除外した。 検索語を"pesticide\* AND health "とし、特定の主題(環境科学 OR 公衆衛生 OR 環境保健 OR 疫学 OR 農薬 OR 栄養 OR 労働衛生)と、2006年から2012年までの出版日に限定して検索を行った。この検 索戦略の結果、1,713件の検索結果が得られた。主題制限が行われていない場合(12,135)、または「健 康」という用語が最初のアルゴリズムから除外されている場合(18,195)には、多くの検索結果が得ら れた。

最後に、特定されたすべての妥当な研究とシステマティックレビューの参考文献リストをデータ抽 出の際にスキャンして追加の参考文献を探した。

# 4. 文献システマティックレビューとメタアナリシスの検索

また、特定の健康影響に関連したシステマティックレビューやメタアナリシスを対象とした検索を 行った。MEDLINEでは、4件以上の研究が確認された健康影響を対象としたレビューに限定し、健康影響 名と「システマティックレビュー OR メタアナリシス」というキーワードを用いて、論文のタイトル または要約に限定して検索を行った。

### 5. 本報告書の構成

本報告書は、健康影響のカテゴリーを中心に構成されており、各健康影響のグループの結果を個別 に提供している。最後に一般的な結論のセクションが提示されている。また、各健康影響のセクション の最後には、読みやすいように表と図を掲載している。また、本文中では各対象論文の ID 番号を参 照している。これらは、本報告書に別ファイルとして提供されているデータ抽出データベースの各健 康影響グループの ID に対応している。IDは、特定の健康影響の略語と研究番号で定義されている。

### 6. Selection of studies

All titles identified through the literature search of various databases were screened to identify studies, which evaluated the association between pesticides and health outcomes including any surrogate outcome. All abstracts of the selected titles are then screened in duplicate to identify epidemiological studies linking pesticide exposure to any health outcome including surrogate outcome. Both primary studies and systematic reviews or meta-analyses are selected. Articles that potentially meet eligibility criteria at the abstract screening stage have been retrieved and the full text articles have been reviewed in duplicate for eligibility. The reason for rejection of all full text articles has been recorded.

#### 6.1. Eligibility criteria for full text articles

We included observational studies assessing the association between pesticide exposure and healthrelated outcomes. We included cohort, cross-sectional and case- control studies. We included studies performed in humans published from 1<sup>st</sup> of January 2006 to 30<sup>th</sup> of September 2012. Animal studies and studies performed in human cells have been excluded. We had no language, population or geographical restrictions. To enhance totality of the evidence, all types of pesticides have been considered. Exposure to pesticides was defined as reported use of pesticides by the study participant or by government registry data (self administrated questionnaires, interviewer administrated questionnaires, job exposure matrix (JEM)), by residential status (proximity to pesticide exposure), by detecting biomarkers associated with pesticide exposure or by any other means as defined by each study. Eligible health-related outcomes such as neurocognitive scales, or laboratory surrogate outcomes with an established association with clinical outcomes, such as liver enzymes.

Narrative reviews, case-series and case-reports (studies without control populations) are excluded. We also excluded studies assessing the health-related effect of pesticide poisoning or accidental high-dose pesticide exposure. We have excluded studies with no availability of sufficient quantitative information reported in the article (e.g. effect estimates) so that effect sizes or measures of associations can be calculated. Whenever reports pertained to the same study at different follow-up periods and examining the same outcome, we retained the one with the longer follow-up to avoid data duplication. We also excluded studies that referred to fertilizers (exploded from the algorithm term "agricultural chemical") as well as studies referred to the adverse effects of substances used as therapy for various medical conditions such as warfarin for anticoagulation or agents used in the treatment of scabies. Solvents and other non-active ingredients in pesticides/herbicides were not considered eligible. We excluded studies that investigate the various effects of Agent Orange on chemical warfare veterans as they represent cases of very high dose exposures. Finally, studies which examined the association between exposure and biomarkers of exposure were also not considered eligible as they do not examine health outcomes. Finally, following consultation with EFSA, we excluded studies/analyses investigating exposure to pesticides: arsenic,  $\alpha_i$ ,  $\beta_i$ , hexachlorocyclohexane (HCH), lead, dioxins and dioxin-like compounds including polychlorinated biphenyls (PCBs) as these chemicals were not considered relevant for the current project.

Regarding systematic reviews and meta-analyses, we considered all systematic reviews and metaanalyses that systematically assessed the effect of pesticide exposure to health-related outcomes, regardless of the pesticide, exposure window and outcome assessed. We included all publications where a systematic approach was endorsed (systematic literature search, assessment of methodological characteristics of the included studies and, if a meta-analysis was performed, the use of standard analytical tools including the use of a weighted summary estimate and a formal appraisal of heterogeneity). Narrative reviews are excluded.

#### 研究の選択

様々なデータベースの文献検索で特定されたすべてのタイトルをスクリーニングし、農薬と代替健 康影響を含む健康影響との関連を評価した研究を特定した。次に、選択したタイトルのすべての要約 を重複してスクリーニングし、農薬ばく露と代替健康影響を含むあらゆる健康影響との関連を評価す る疫学研究を特定した。主要研究とシステマティックレビューまたはメタアナリシスの両方を選択す る。要約審査の段階で妥当性基準を満たす可能性のある論文を検索し、全文論文を重複して審査して 妥当性を確認した。すべての全文論文の却下理由は記録されている。

### 6.1. 全文論文の妥当性基準

農薬ばく露と健康関連影響との関連を評価する観察研究を対象とした。コホート研究、横断研究、症 例対照研究を対象とした。2006 年 1 月 1 日から 2012 年 9 月 30 日までに発表されたヒトを対象 とした研究を対象とした。動物を対象とした研究及びヒトの細胞を対象とした研究は除外した。言語、 集団、地理的制限はなかった。エビデンスの全体性を高めるために、すべての種類の農薬を考慮した。 農薬へのばく露は、研究参加者による農薬の使用報告、または政府登録データ(自己管理質問紙、面接 官管理質問紙、職業ばく露マトリックス(JEM))、居住状況(農薬ばく露への近接性)、農薬ばく露 に関連するバイオマーカーの検出、または各研究で定義されたその他の手段によって定義されたもの とした。妥当な健康関連影響は、腫瘍形成やパーキンソン病などの「主要な」臨床影響、神経認知スケ ールなどの臨床代替健康影響、肝酵素などの臨床影響との関連が確立されている代用実験的影響とし た。

ナラティブレビュー、症例集積、症例報告(対照集団のない研究)は除外した。また、農薬中毒また は不慮の高用量農薬ばく露による健康関連の影響を評価する研究も除外した。論文で報告された十分 な量的情報(効果推定値など)が入手できない研究は除外し、効果量や関連の尺度を計算できるように した。異なる追跡期間で同じ研究に関連する報告があり、同じ結果を調査している場合は、データの重 複を避けるために、追跡期間が長い方の研究を保持した。また、肥料に言及した研究(アルゴリズム用 語「農薬」から分解)や、抗凝固剤のワルファリンや疥癬の治療に用いられる薬剤など、様々な病状の 治療に用いられる物質の副作用に言及した研究も除外した。農薬・除草剤に含まれる溶剤などの非有 効成分は対象外とした。化学戦経験者に対するオレンジ剤の様々な影響を調査した研究は、極高用量 ばく露の事例であるため除外した。最後に、ばく露とばく露のバイオマーカーとの関連を調査した研 究も、健康への影響を調査していないため、対象外とした。最後に、EFSAとの協議により、ヒ素、アル ファ及びベータへキサクロロシクロへキサン(HCH)、鉛、ポリ塩化ビフェニル(PCB)を含むダイオキ シン類などの農薬へのばく露を調査した研究/分析は、本プロジェクトには関係がないと考えられる ため除外した。

システマティックレビュー及びメタアナリシスについては、評価された農薬、ばく露城、影響にかか わらず、健康関連影響に対する農薬ばく露の影響をシステマティックに評価したすべてのシステマテ ィックレビュー及びメタアナリシスを調査した。系統的アプローチ(系統的文献検索、対象とした研究 の方法論的特徴の評価、メタアナリシスが実施された場合には重み付け要約推定値の使用や不均一性 の形式的評価を含む標準的な分析ツールの使用)が承認されているすべての出版物を対象とした。ナ ラティブレビューは除外する。

#### 6.2. Quality control measures

The pilot literature searches have all been performed in duplicate. In addition, the first 500 results of all title searches were performed in duplicate and results were compared between investigators, which displayed high levels of agreement. The kappa statistic for agreement was 0.78. Two independent research group members performed in duplicate the abstract screening, the full text screening and the data extraction. All discrepancies are resolved by consensus or by a third arbitrator.

#### 6.3. Data extraction database

We have constructed and tested the *data extraction database* with data extraction items and quality assessment items that were implemented through the whole process. The data extraction database has been structured in 7 domains: Reference, Time period, Study characteristics, Exposure assessment, Outcomes, Statistical analysis and Quality assessment (separate database file). The first 6 domains pertain to information directly extracted from the full-texts of eligible studies and would be primarily used to select studies for quantitative synthesis and aid quantitative synthesis. Studies contribute one row in the database for each outcome examined and for each exposure examined. When studies present various definitions of exposure we select for data extraction the most comprehensive definition of exposure and subsequently the one with the largest sample size. However when studies include any type of quantitative information for different biomarkers used for the identification of the same chemical substance e.g. p,p'-DDT and p,p'-DDE for dichlorodiphenyltrichloroethane (DDT), they are all reported in separate rows. When studies present data in subgroups (e.g. males and females) we extract only their main analysis (whole group) unless the data is only presented in subgroups in which case multiple rows are presented. Analyses regarding different pesticide classes and different health outcomes are extracted individually. Appendix II explains all the items used in the data extraction database.

The data extraction form was validated through a robust and systematic procedure. Specifically, various versions of the form were validated after blinded loops of extracting information for studies randomly selected from the database. We opted for the maximum agreement while preserving the comprehensiveness of the database. Two investigators extract each item independently and discrepancies are resolved with discussion.

#### 6.4. Quality appraisal

The last part of the *data extraction database*, concerns the methodological appraisal of each eligible paper. The areas that we have focused are the study design, the study population, the level of details in exposure definition and the methods of exposure measurement and the specificity of the measurement. These are crucial questions to be asked in exposure assessment epidemiology. We have also focused on the efforts undertaken to account for confounders through matching or multivariable models, blinded exposure assessment and well-defined and valid outcome assessment. We have also looked at whether the source of funding was acknowledged. The elements of the methodological appraisal were considered from the RTI item bank. The RTI item bank is a practical and validated item bank for evaluating the risk of bias and precision of observational studies of interventions or exposure included in systematic evidence reviews. The questions were adapted to reflect exposure assessment in green, orange and red with green representing low risk of bias and red high risk of bias. Table 3

The present document has been produced and adopted by the bodies identified above as author(s). This task has been carried out exclusively by the author(s) in the context of a contract between the European Food Safety Authority and the author(s), awarded following a tender procedure. The present document is published complying with the transparency principle to which the Authority is subject. It may not be considered as an output adopted by the Authority. The European Food Safety Authority reserves its rights, view and position as regards the issues addressed and the conclusions reached in the present document, without prejudice to the rights of the authors.

### 6.2. 品質管理対策

パイロット文献検索はすべて重複して実施した。さらに、すべてのタイトル検索の最初の500件の結 果は重複して行い、研究者間で結果を比較し、高いレベルの一致を示した。同意度のカッパ統計量は 0.78であった。2人の独立した研究グループのメンバーが、要約スクリーニング、全文スクリーニング、 データ抽出を重複して行った。すべての不一致は、合意または第三者の判定によって解決した。

### 6.3. データ抽出データベース

全工程を通じて実行されたデータ抽出項目と品質評価項目を用いて、データ抽出データベースの構 築及び確認を行った。データ抽出データベースは7つのドメイン:参考文献、期間、試験特性、ばく露 評価、影響、統計分析、品質評価(別々のファイル)で構成されている。最初の6つの領域は、対象 となる研究の全文から直接抽出された情報に関連しており、主に定量的統合のための研究を選択し、 定量的統合を支援するために使用される。研究は、調査された各影響と調査された各ばく露について、 データベースの一行を提供している。研究が様々なばく露の定義を提示している場合には、最も包括 的なばく露の定義をデータ抽出のために選択し、それに続いてサンプルサイズが最も大きいものを選 択する。しかし、同じ化学物質の同定に使用される異なるバイオマーカーの定量的情報を含む研究、例 えばジクロロジフェニルトリクロロエタン(DDT)の p,p'-DDT と p,p'-DDE のように、それらはすべ て別々の行で報告されている。研究がサブグループでデータを提示している場合(例:男性と女性) は、データがサブグループでのみ提示されている場合は複合論争が提示されている場合を除き、主分 析(グループ全体)のみを抽出している。異なる農薬クラスと異なる健康影響に関する分析は、個別に 抽出されている。付録IIでは、データ抽出データベースで使用されたすべての項目を説明している。

データ抽出フォームは、妥当で体系的な手順を経て検証された。具体的には、データベースから無作 為に選択された研究の情報を抽出するプラインドループの後、様々なバージョンのフォームを検証し た。データベースの網羅性を維持しつつ、最大の一致度が得られるものを選択した。各項目について は、2名の研究者がそれぞれ独立して抽出し、不一致は議論によって解決している。

### 6.4. 品質評価

データ抽出データベースの最後の部分は、対象となる各論文の方法論的評価に関するものである。 ここでは、研究デザイン、研究集団、ばく露の定義の詳細度、ばく露測定の方法、測定の特異性などに 焦点を当てている。これらはばく露評価の疫学において問われる重要な問題である。我々はまた、マッ チングモデルや多変量モデル、盲検化されたばく露評価、十分に定義された有効な影響評価によって 交絡因子を考慮するための努力にも焦点を当ててきた。また、資金源が認められているかどうかにも 注目した。方法論的評価の要素は RTI 項目バンクから調査した。RTI 項目バンクは、システマティッ ク・エビデンスレビューに含まれる介入またはばく露の観察研究のバイアスのリスクと精度を評価す るための実用的で妥当性のある項目バンクである。質問はばく露評価を反映するように適応されてい る。質的評価の質問では、質的評価への回答を一貫して緑、オレンジ、赤で色分けし、緑はバイアスの リスクが低く、赤はバイアスのリスクが高いことを表している。以下の表 3 は、それぞれどの回答が 低リスク、高リスクと考えられたかを説明したものである。しかし、品質評価の質問は、各研究に関連

#### Ntzani EE, Chondrogiorgi M, Ntritsos G, Evangelou E, Tzoulaki I Pesticide epidemiology

below explains which answers were considered low and high risk respectively. However, the quality appraisal questions should be interpreted with caution, as they are only suggestive of the risk of bias associated with each study. There may be studies which score high in this quality assessment and still have a high risk of bias and vice versa. A final column was constructed to grade the overall quality of the studies in low, intermediate and high. This classification was based on the answers to the methodological assessment questions as explained in Table 3.

#### Table 3: Methodological assessment of eligible studies

Question	High risk.	Low risk
Study design (prospective, retrospective, mixed, cross-sectional)	Retrospective, mixed, NA	Prospective
Inclusion/exclusion criteria clearly stated (yes, partially, no)	No	Yes
Authors mention power calculations (yes, no)		Yes
Level of detail in describing exposure (high, medium, low)	Low	High
Robust measurement of exposure. (biomarker (yes); small area ecological measures, job titles, questionnaire (partial); was based on large area ecological measures (no)	No	Yes
Were measures of exposure specific? yes; based on broader, chemically- related groups (partial); based on broad groupings of diverse chemical and toxicological properties (no)	No	Yes
Attempt to balance the allocation between the groups (e.g., through stratification, matching)	No	Yes
Adjustment performed for potential confounders (yes, some, no)	No	Yes
Assessors blinded to exposure status (for cohort studies)	No	Yes
Outcomes assessed using valid and reliable measures, implemented		
consistently across all study participants?	No	Yes
Sample size	Low	Тор
Rough quality assessment	>6 answers high risk.	>6 asnwers low risk

#### 6.5. Quantitative synthesis

Quantitative synthesis of the results was only attempted when there were more than 4 studies per examined outcome and when there was no substantial heterogeneity among the published evidence. The presence and extent of heterogeneity was assessed by the I<sup>4</sup> (ranging from 0% to 100%) (Ioannidis 2007). We have summarized the RR/OR estimates using fixed and random-effects models (Lau 1997). Fixed-effects models assume that there is a common underlying effect and the variability observed is attributed to chance alone; random effects models acknowledge that true between-study heterogeneity exists and take into account the presence of heterogeneity into their calculations. In the absence of heterogeneity, fixed-and random-effects models yield the same results. Publication bias was assessed using funnel plots and visual inspection of the results.

For each outcome with more than 5 eligible studies quantitative synthesis was attempted. We did not include data from the same cohort study; either presented in the same or in different publications in the same meta-analysis when the groups compared were not mutually exclusive. For each outcome with more than 4 studies, we also looked for previously published meta-analyses to compare results and to interpret our findings in the context of previous studies. Meta-analyses were found through a) systematic reviews and meta-analyses identified through our literature review and b) targeted searches in PUBMED to identify published meta-analyses for each outcome of interest. We attempted to update any previously published meta-analyses with our results when the meta-analysis a) included studies published by 2006 and b) when outcome and exposure definitions were comparable with the definitions used in this report. Finally, we also plotted funnel plots to visually inspect asymmetry when more than 10 studies were include in the meta-analysis.

被ばく状態に盲袂化された評価者(コホート研究の場合)	いいえ	1211
有効かつ信頼性の高い尺度を用いて評価された結果は、すべての研究 参加者に一貫して実施されているか?	11112	1211
サンプルサイズ	绝	最大
ラフな品質評価	6 以上の回答で高り スク	6 以上の回答で低リス ク

### 6.5. 定量的な統合

結果の定量的な統合は、調査された影響ごとに4件以上の研究があり、発表されたエビデンス間に実 質的な不均一性がない場合にのみ試みられた。不均一性の存在と程度は、I2(0%から100%の範囲)で 評価した(Ioannidis 2007)。固定効果モデルとランダム効果モデルを用いて、RR/ORの推定値をまと めた(Lau 1997)。固定効果モデルでは、共通の基礎となる効果が存在し、観察された変動は偶然のみ に起因すると想定している。不均一でない場合、固定効果モデルとランダム効果モデルでは同じ結果 が得られる。出版バイアスは、ファンネルプロットと結果の視覚的精査を用いて評価した。

5件以上の妥当研究がある各影響について、定量的な統合を試みた。比較するグループが相互に排他 的でない場合には、同じメタアナリシスにおいて、同じコホート研究からのデータはなかった。4件以 上の研究がある各影響については、結果を比較し、以前の研究の背景の中で我々の知見を解釈するた めに、以前に発表されたメタアナリシスも探した。メタアナリシスは、a)文献レビューで同定されたシ ステマティックレビュー及びメタアナリシス及びb)調査対象の各影響について公表されているメタア ナリシスを同定するために、PUBMDBDでの標的検索によって発見された。メタアナリシスのa) 2006年ま でに発表された研究が含まれており、b)影響及びばく露の定義が本報告書で使用されている定義と同 等である場合には、以前に発表されたメタアナリシスを我々の結果で更新するよう試みた。最後に、10 件以上の研究がメタアナリシスに含まれている場合に非対称性を視覚的精査するためにファンネルプ ロットをプロットした。

### RESULTS

### 7. Overall results

This section focuses on the literature review results including flowcharts with number of studies screened and deemed eligible as well as number of excluded studies and corresponding reasons. It also provides an overview of the studies identified and their main characteristics.

#### 7.1. Selection process for individual studies

Of the 43,259 retrieved citations, 40,477 were excluded at the title screening level. Of the 2,782 remaining titles, a further 1,654 were excluded after the abstract screening. We thus deemed eligible, 1,128 citations to be scrutinized at the full-text level of which 1,101 were original research articles and 27 were systematic reviews or meta-analyses. Of the 1,101 original articles, 184 were excluded (Figure 2). For few (101) publications were the full text (or abstract for conference presentations) has not been found online, we sought the full text through letters to authors and investigations from our library. This has not been possible for 58 studies for which we extracted information from the abstract only.

Main reasons for exclusion at the full-text level pertained to: no quantitative information/ data (these were mainly abstract presentations or comments/ editorials which did not present any quantitative information for the association between pesticides and health outcomes, n=108); duplicate records (n=28), no implied use of pesticides (n=18), studies on poisoning or accidental very high doses (n=11), reviews with no primary data (n=11), no data on health outcomes (n=8). Supplemental searches did not succeed to provide additional references as they resulted in a large number of policy documents, grant applications documents and studies already retrieved. Supplemental searches through reference lists of identified studies and especially the reference lists of identified systematic reviews will continue during data extraction and any new identified studies will be added to the current list of eligible studies. During full text screening and data abstraction a further 301 studies were excluded. The main reason for exclusion was no eligible pesticide, such as Polychlorinated Biphenyls (PCBs) (Figure 2). Overall, 602 individual publications were eligible for inclusion in the present review. These 602 publications correspond to 6,479 different analyses, which are also present in the *data extraction database*.

# 結果

### 7. 全体の結果

このセクションでは、スクリーニングされ、妥当と判断された研究の数、除外された研究の数とそれ に対応する理由を示すフローチャートを含む文献レビューの結果に焦点を当てている。また、同定さ れた研究とその主な特徴の概要についても説明する。

### 7.1. 個々の研究の選択プロセス

検索された43,259件の引用のうち、40,477件がタイトルのスクリーニングレベルで除外された。残 りの2,782タイトルのうち、さらに1,654タイトルが要約スクリーニングで除外された。その結果、1,128 件の引用文献のうち、1,101件が原著論文であり、27件がシステマティックレビューまたはメタアナリ シスであることが判明した。1,101 本の原著論文のうち 184 本が除外された(図 2)。また、全文(ま たは学会発表のための要約)がオンラインで見つからない出版物(101 件)については、著者への手紙 や蔵書からの調査により全文を検索したが、要約のみから情報を抽出した58研究については、これが 不可能であった。

全文レベルで除外した主な理由は次の通りである:定量的な情報/データがない(これらは主に、農 薬と健康影響との関連に関する定量的な情報を提示していない要約発表またはコメント/論説であっ た、n=108);記録の重複(n=28)、農薬の使用が示唆されていない(n=18)、中毒または不慮の極高 用量ばく露に関する研究(n=11)、主要データのないレビュー(n=11)、健康影響に関するデータがな い(n=8)。補足検索では、大量の政策文書、助成金申請書、研究が既に検索されたため、追加の参考 文献を提供することはできなかった。識別された研究の参照リスト、特に識別されたシステマティッ クレビューの参照リストからの補足検索は、データ抽出の間も継続され、新たに識別された研究は、現 在の妥当な研究リストに追加される。全文スクリーニングとデータ抽出の際に、さらに301研究が除外 された。除外の主な理由は、ポリ塩化ビフェニル(PCB)などの妥当な農薬がなかったことであった(図 2)。全体として、602の個別の出版物が本レビューに含めることができた。これらの602の出版物は、 6,479の異なる分析に対応しており、データ抽出データベースにも存在する。

#### 7.2. Evidence map tables and outcomes examined

We observed a great variety of assessed outcomes covering a wide range of pathophysiologies. "Hard" clinical outcomes as well as many surrogate outcomes are present in the database reflecting the different methodologies endorsed to approach the assessed clinical research questions. We divided the different outcomes into 23 major disease categories (Table 4 and Figure 3). The largest proportion of studies pertains to cancer outcomes (N=164) and outcomes related to child health (N=84). Table 4 corresponds to the Evidence map Table and shows the outcome mapping of the project describing all outcomes that have been associated with pesticide exposure between 2006 and 2012 and their frequency.

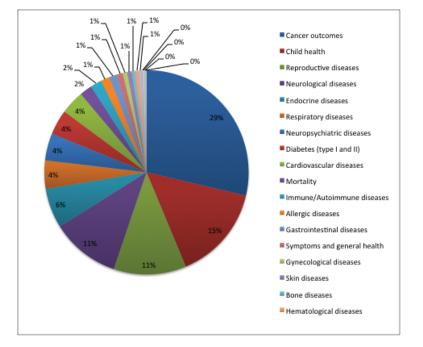

Figure 3: Major outcome categories and corresponding percentage of studies examining those outcomes among the eligible publications

Ntzani EE, Chondrogiorgi M, Ntritsos G, Evangelou E, Tzoulaki I

# 7.2. エビデンスマップ表と調査した影響

我々は、幅広い病態生理をカバーする多種多様な評価された影響を調査した。このデータベースに は、評価された臨床研究上の質問にアプローチするために承認された様々な方法論を反映して、「ハー ド」な臨床影響と多くの代替健康影響が存在している。我々は、異なる影響を23の主要な疾患カテゴリ ーに分類した(表4及び図3)。研究の中で最も多いのは、発がん(N=164)と小児の健康に関連する影 響(N=84)である。表4はエビデンスマップ表に対応し、2006 年から 2012 年の間に農薬ばく露に関 連したすべての影響とその頻度を記述したプロジェクトの影響マッピングを示したものである。

Men health	1
Metabolic diseases	1

#### 7.3. Characteristics of eligible studies

The eligible studies were published from 2006 to 2012. The observed distribution of the publication year of the eligible studies indicates an approximately equal distribution of studies throughout the past 5 years (Figure 4). Of note, we expected a considerable presence of the results of the various reports of the Agricultural Health Study (AHS), the largest to-date observational study performed in the field. Indeed, the AHS publications (n=42) represent a recognizable proportion of the included studies (7%). Another 22 studies come form the cross-sectional National Health and Nutrition Examination Survey (NHANES) cohorts.

The majority of studies were case-control studies (N=222) and cross-sectional studies (Figure 5) and examined occupational exposure to pesticides (N=329). Almost half of the studies (N=285) were based in America (Figure 6). The most frequent method of pesticide assessment was measurement of biomarker or use of self reported questionnaire (Figure 7). Approximately half (N=261) studies were classified as 'high' in the methodological assessment.

The present document has been produced and adopted by the bodies identified above as author(s). This task has been carried out exclusively by the author(s) in the context of a contract between the European Food Safety Authority and the author(s), awarded following a tender procedure. The present document is published complying with the transparency principle to which the Authority is subject. It may not be considered as an output adopted by the Authority. ### 7.3. 対象となる研究の特徴

対象となる研究は 2006 年から 2012 年までに発表されたものである。対象研究の発表年の分布を 見ると、過去 5 年間でほぼ均等に分布していることがわかる(図 4)。特筆すべきは、現場で実施さ れた今日までの観察研究の中で最大のものである Agricultural Health Study (AHS)の様々な報告書 の結果がかなりの割合で存在することである。実際、AHSの出版物 (n=42) は、含まれている研究の7% を占めている。その他の22件の研究は、国民健康・栄養調査 (NHANES) コホートの横断研究である。

研究の大部分は症例対照研究(N=222)と横断研究(図5)であり、農薬への職業ばく露(N=329)を 調査していた。研究のほぼ半数(N=285)はアメリカを拠点とした研究であった(図6)。農薬の評価方 法は、バイオマーカーの測定、または自記式質問紙の使用が最も多かった(図7)。約半数(N=261)の 研究が方法論的評価で「高」に分類された。

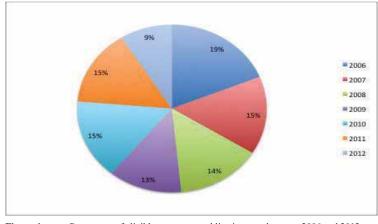

広範囲で多様な農薬が研究されており、様々な農薬の定義を用いた研究が行われている。また、公表 されている文献のかなりの割合が、欧州連合(EU)や先進国のほとんどで使用が承認されていない農薬 に焦点を当てていることも予想される。このような研究は、農薬の長期残留の根拠や、開発途上国での 継続的な農薬使用の根拠に関わるものであることを認識している。例えば、DDTとその代謝物のみに焦 点を当てた研究は、対象となる研究のほぼ10%を占めている。

EFSA supporting publication 2013:EN-497

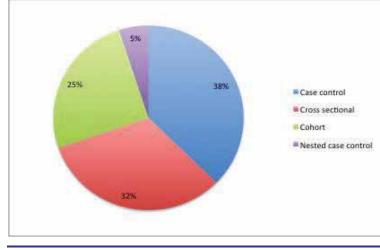

Pesticide epidemiology

18

A wide and diverse range of pesticides was studied with studies using various definitions of pesticides; it is very hard to harmonise between studies this information. We also anticipated a considerable proportion of the published literature to be focusing on pesticides no longer approved for use in the European Union and in most of the developed countries. We acknowledge that this research lies on the rational of pesticide long-term residuals, as well as of the continuing use of these pesticides in developing countries. For example, studies focusing solely on DDT and its metabolites constitute almost 10% of the eligible studies.

7.4. Systematic literature review of systematic reviews and meta-analysis

Throughout our search strategy we also identified systematic reviews and meta-analyses. Overall, 21 different eligible reviews were identified published after 2006. The outcomes examined are shown in Table 5 below. Most reviews examined cancer related outcomes and some claimed positive associations between pesticides and examined outcome. The reviews are discussed in relevant outcome categories along with the individual studies.

 Table 5:

### 8. Cancer Outcomes

Overall, 164 publications examined the effect of pesticide exposure on cancer outcomes, contributing more than 2000 separate analyses. As seen with other outcomes, the diversity of exposure definition is remarkable and poses special challenges to data synthesis. Only 36 out of the 164 were prospective cohort studies and other 13 were nested case-controls; the overwhelming majority of evidence comes from retrospective case-control analyses, which are prone to recall bias in exposure measurement. Also, out of the 49 prospective analyses, 30 (61%) were from the same prospective associations comes from a single population. The sample size of the analyses was often small; it ranged between 24 and 82,596 participants (median 301). In addition, 33 studies had information on biomarkers of exposure and only 7 assessed occupational exposures through job exposure matrix (JEM). Common limitations in studies included small sample sizes, self-reported exposure, potential for high false positive rates due to multiple testing (studies test multiple hypothesis without adjusting for multiple testing and therefore results are likely to be false positives), and retrospective design. A wide variety or pesticides were assessed, with many studies examining organochlorine insecticides.

The different cancer categories examined are presented in Table 6 along with the number of studies contributing to each outcome category and a recommendation for quantitative synthesis. Due to heterogeneity of data and small number of studies identified, statistical synthesis of the data (meta-analysis) was only performed for some cancer subgroups.

#### 8.1. Hematological neoplasms

#### 8.1.1. Leukemias

Overall, 26 studies (and 2 abstracts) examined associations between pesticide exposure and various forms of leukaemia. Fourteen out of these 26 studies were reports from the AHS with some overlapping results and examination of different pesticide groups. Only 2 studies, both on DDE (ID CAN 063, ID CAN 064) examined residential exposure and all the remaining studies examined occupation exposure to pesticides. Twelve out of 99 different analyses were statistically significant with effect sizes across all studies ranging between 6.1 and 0.2. Statistically significant results come from 7 different studies; with the exception of the AHS all were of modest to low quality. Table 7 shows summarised results across studies that reported information on the same pesticide class. The vast majority of results are non-significant and of small effect sizes. Figure 8 shows random effect meta-analyses keeping analyses with largest sample size form each study. The meta-analysis resulted in a non-significant pooled effect (OR 1.26, 95% CI 0.93, 1.71) and had modest heterogeneity. Previous meta-analyses on occupational exposure to pesticides and leukaemia were published in 2008 and 2007 (Merhi 2007, Van Maele-Fabry 2008). The overall summary effect estimates from previous meta-analyses suggested that there is a significantly positive, albeit weak, association between occupational exposure to pesticides and all hematopoietic cancers. But both reports acknowledged a wide range of limitations including the lack of sufficient data about exposure information and other risk factors for hematopoietic cancer and unclear definition of exposure and of leukemia type.

#### 8. 発がん

全体では164の出版物が農薬ばく露の発がんへの影響を調査し、2,000以上の個別の分析に貢献した。 他の影響に見られるように、ばく露の定義の多様性は驚くべきものであり、データ統合に特別な問題 をもたらしている。164件のうち36件のみが前向きコホート研究であり、他の13件はコホート内症例対 照研究であった。エビデンスの圧倒的多数は後ろ向き症例対照分析から来ており、ばく露測定におい てリコールバイアスがかかりやすい。また、49の前向き分析のうち、30(61%)は同じ前向き研究であ るAgricultural Health Study (AHS)からのものであり、この前向きコホートを超えたエビデンスは 限られている。これは重要な観察であり、前向きな関連のエビデンスの60%は単一の集団から得られ ているという事実を強調している。分析のサンプルサイズはしばしば小さく、参加者数は24~82,596 人(中央値301人)であった。さらに、33の研究ではばく露のバイオマーカーに関する情報が得られて おり、職業ばく露マトリックス(JEM)を用いて職業ばく露を評価したのは7件のみであった。研究に共 通する制限事項としては、サンプルサイズが小さいこと、ばく露が自己申告であること、多重検定によ る高い偽陽性率の可能性(多重検定を調整せずに複数の仮説を検定しているため、結果が偽陽性にな る可能性がある)及び後ろ向きなデザインなどが挙げられる。多くの研究で有機塩素系殺虫剤を調査 しており、多種多様な農薬が評価された。

調査されたさまざまながんのカテゴリーを、各影響カテゴリーに寄与した研究の数及び定量的統合 の推奨事項とともに表6に示す。データの不均一性と同定された研究数が少ないため、データの統計的 統合(メタアナリシス)は一部のがんサブグループについてのみ実施された。

### 8.1. 造血器新生物

### 8.1.1. 白血病

全体では、26件の研究(及び2件の要約)が農薬ばく露と様々な形態の白血病との関連を調査した。 これら26件の研究のうち14件はAHSからの報告であり、結果が重複していたり、異なる農薬群の調査が 行われていたりした。DDEに関する2件の研究(ID CAN\_063、ID CAN\_064)のみが住居ばく露を調査して おり、残りの研究はすべて農薬への職業ばく露を調査したものである。99の異なる分析のうち12の研 究は、6.1と0.2の間にあるすべての研究の効果量で統計的に有意であった。統計的に有意な結果が得 られたのは7つの研究であり、AHSを除くすべての研究の品質は中等度から低度であった。表7 は、同 じ農薬クラスに関する情報を報告した研究の結果をまとめたものである。結果の大部分は、有意では なく、効果量が小さいものであった。図8は、ランダム効果メタアナリシスを示しており、各研究で最 大のサンプルサイズで分析を行っている。このメタアナリシスでは、有意ではない統合効果(OR 1.26、 95% CI 0.93、1.71)が得られ、中等度の不均一性を有していた。農薬への職業ばく露と自血病に関す る以前のメタアナリシスからの全体的な要約効果推定値は、農薬への職業ばく露とすべての造血器がん との間には、弱いながらも有意に明確な関連があることを示唆していた。しかし、両報告とも、ばく露 情報や造血器腫瘍の他のリスク因子に関する十分なデータが不足していること、ばく露の定義や白血 病型の定義が不明確であることなど、幅広い限界があることを認めている。

EFSA supporting publication 2013:EN-497

The present document has been produced and adopted by the bodies identified above as author(s). This task has been carried out exclusively by the author(s) in the context of a contract between the European Food Safety Authority and the author(s), awarded following a tender procedure. The present document is published complying with the transparency principle to which the Authority is subject. It may not be considered as an output adopted by the Authority. The European Food Safety Authority reserves its rights, view and position as regards the issues addressed and the conclusions reached in the present document, without prejudice to the rights of the authors.

#### 8.1.2. Hodgkin lymphoma

Seven studies examined the associations between pesticide exposure and Hodgkin lymphoma. All studies assessed exposure through questionnaires, one studies had large sample size and all studies were retrospective. A wide range of pesticides classes was examined which did not allow any meaningful synthesis of the results. Twelve out of 75 separate analyses were statistically significant with effect sizes ranging from 8.4 to 0.4 across all analyses. We attempted random effects meta-analysis keeping only the Agricultural Health Study (AHS) analysis with the largest sample size. The result was not statistically significant and had high heterogeneity which can be attributed to the range of different pesticide classes examined by each study (Figure 9).

#### 8.1.3. Other lymphomas

A very wide variety of definitions of lymphomas other than Hodgkin lymphoma were used in 44 studies of which 21 were reports from the Agricultural Health Study (AHS) and 2 from the BC (British Columbia) sawmill workers cohort study. Studies examined broad definitions of lymphomas and lymphoproliferative syndromes (ID CAN\_047, ID CAN\_049, ID CAN\_074) and other examined more specific definitions of follicular lymphoma, diffuse large cell lymphoma and peripheral T-cell lymphoma. Twenty-one studies provided effect sizes between pesticide exposure and broad definitions of Non-Hodgkin lymphomas. Five of those studies were prospective (ID CAN\_063, ID CAN\_064, ID CAN\_067, ID CAN\_064, ID CAN\_067, ID CAN\_064, ID CAN\_067, ID CAN\_064, ID CAN\_065, ID CAN\_064, ID CAN\_052). However, the later analyses were all on organochlorine pesticides with only few significant results (6 analyses among a total of 35 analyses) without any firm evidence for associations. In the AHS, large and significant effect size was observed between butylate use and Non-Hodgkin lymphomas (RR 2.94, 95% 1.49–5.96, p=0.002; high vs. no exposure). However, again the AHS in the same publication has examined ten different outcomes and results need adjustment for multiple testing.

#### 8.1.4. Multiple myeloma

Also, 11 studies examined associations between pesticides and multiple myeloma, myelodysplastic syndromes and monoclonal gammopathy of undetermined significance. These studies were generally heterogeneous and no quantitative synthesis was suggested. Overall, some analyses were statistically significant, but those were mainly from the French case control study (ID CAN\_049) which presented overall 147 separate analyses and results are prone to bias. The AHS also reported significant associations between permethrin, dieldrin, Carbon-tetrachloride/carbon disulfide mix and Chlorthalonil but again these were amongst 52 other analyses and regulire cautious interpretation. One study, reported very high significant effect size of 7.3 for myelodysplastic syndrome (ID CAN\_070) but the quality of the study was poor and adjustment of covariates very limited and results were not replicated by other studies on the same phenotype.

#### 8.2. Prostate cancer

Overall, 39 studies (in 260 analyses) examined the effects of pesticide exposure on prostate cancer. One study was a conference abstract which provided little data on methodology to allow meaningful appraisal of its results (ID CAN\_107). Also, 25 of those 39 studies were studies from the AHS population with some overlapping results. For example, two studies (ID CAN\_022, ID CAN\_106) examined interactions between pesticide exposure and genetic variants in relation to prostate cancer. These AHS studies presented the same main effects for pesticide exposure; effects were largely null and, if anything, significant inverse effects were found e.g. for carbaryl, chlordane, metalachlor and

The present document has been produced and adopted by the bodies identified above as author(s). This task has been carried out exclusively by the author(s) in the context of a contract between the European Food Safety Authority and the author(s), awarded following a tender procedure. The present document is published complying with the transparency principle to which the Authority is subject. It may not be considered as an output adopted by the Authority. The European Food Safety Authority reserves its rights, view and position as regards the issues addressed and the conclusions reached in the present document, without prejudice to the rights of the authors.

#### 8.1.2. ホジキンリンパ腫

7件の研究が農薬ばく露とホジキンリンパ腫との関連を調査した。すべての研究は質問紙を用いてば く露を評価しており、1件の研究はサンプル数が多く、すべての研究は後ろ向きであった。広範囲の農 薬クラスが調査されたが、結果の意味のある統合はできなかった。75の個別分析のうち12の分析が統 計的に有意であり、すべての分析において効果量は8.4から0.4の範囲であった。我々は、最大のサンプ ルサイズを持つAgricultural Health Study (AHS)分析のみを残して、ランダム効果メタアナリシス を試みた。その結果は統計的に有意ではなく、各研究で調査された農薬クラスが異なることに起因す る可能性がある高い不均一性を有していた(図9)。

### 8.1.3. その他のリンパ腫

ホジキンリンパ腫以外のリンパ腫については、非常に多様な定義が44件の研究で使用されており、 そのうち21件は農業健康調査(Agricultural Health Study: AHS)からの報告で、2件はBC(プリティ ッシュコロンビア州)製材所の労働者コホート研究からの報告であった。研究ではリンパ腫及びリン パ増殖性症候群(ID CAN\_047、ID CAN\_049、ID CAN\_074)の広範な定義が調査され、他の研究では濾胞 性リンパ腫、びまん性大細胞リンパ腫及び末梢性T細胞リンパ腫のより具体的な定義が調査された。21 件の研究では、農薬ばく露と非ホジキンリンパ腫の幅広い定義との間の効果量が報告された。これら の研究のうち5件は前向き(ID CAN\_063、ID CAN\_064、ID CAN\_067、ID CAN\_118、ID CAN\_121)であり、 7件はばく露のバイオマーカーとの関連を調査した(ID CAN\_056、ID CAN\_057、ID CAN\_064、ID CAN\_065、 ID CAN\_067、ID CAN\_060、ID CAN\_052)。しかし、それ以降の分析はすべて有機塩素系農薬に関するも のであり、関連を示す確固たるエビデンスがないまま、有意な結果が得られたのはわずかであった(全 35 回の分析のうち 6 回の分析)。AHSでは、プチル酸塩の使用と非ホジキンリンパ腫との間に大きな 有意な効果量が観察された(RR 2.94、95%1.49-5.96、p=0.002;高ばく露と非ばく露との間に有意な 効果量が観察された)。しかし、同じ出版物のAHSは10種類の異なる影響を調査しており、結果は複数 の試験のための調整が必要であることを繰り返している。

### 8.1.4. 多発性骨髄腫

また、11件の研究では、農薬と多発性骨髄腫、骨髄異形成症候群及び意義不明の単クローン性免疫グ ロブリン血症との関連が調査された。これらの研究は全般的に異質であり、定量的な統合は示唆され なかった。全体的に、いくつかの分析は統計的に有意であったが、それらは主にフランスの症例対照研 究(ID CAN\_049)からのものであり、147の個別の分析が行われており、結果にバイアスがかかりやす い。AHSはまた、ペルメトリン、ディルドリン、四塩化炭素/二硫化炭素の混合物、クロルタロニルとの 間の有意な関連を報告しているが、これらは他の52分析の中に含まれており、慎重な解釈が必要であ る。ある研究では、骨髄異形成症候群(ID CAN\_070)に対して7.3という非常に高い有意な効果量が報 告されているが、研究の質が悪く、共変量の調整が非常に限られており、同じ表現型の他の研究で結果 が再現されていなかった。

### 8.2. 前立腺がん

全体では、39件の研究(260件の分析)で農薬ばく露が前立腺がんに及ぼす影響が調査された。その うちの1件は学会発表の要約であり、その結果を評価するための方法論に関するデータがほとんど提供 されていなかった(ID CAN\_107)。また、これら39件の研究のうち25件はAHS集団を対象とした研究で あり、いくつかの結果が重複していた。例えば、2つの研究(ID CAN\_022、ID CAN\_106)では、農薬ば く露と前立腺がんとの関連における遺伝子変異との相互作用が調査されていた。これらのAHS研究では、 農薬ばく露の主な効果は同じであったが、効果はほとんど無効であり、もしあるとすれば、カルバリ ル、クロルデン、メタクロルなどでは有意な逆効果が認められた。残りのAHS研究では、特定の農薬間

EFSA supporting publication 2013:EN-497

others. The remaining AHS studies, examined associations between specific pesticides, again showing no statistically significant associations between any of the examined pesticides and prostate cancer with the exception of a weak significant effect between butylate exposure and prostate cancer. The remaining evidence stems from, rather small and of modest quality, retrospective studies. Most studies (ID CAN 103, ID CAN 101, ID CAN 100, ID CAN 094, ID CAN 143, ID CAN 142) examined the effects of organochlorines with largely small and non-significant results. Two studies (IDs CAN 099, ID CAN 095) showed high significant increased risk associated with pesticide exposure and prostate cancer but both studies were of low quality, had very broad definitions of exposure and results need cautious interpretation and do not match with those reported from well conducted large prospective studies (e.g. AHS). Notably, one population-based case-control study (ID CAN 104) in a highly exposure area found strong association of ambient exposure to methyl bromide with prostate cancer risk, but the study did not observe evidence for exposure-response. In summary, most evidence for prostate cancer risk in relation to pesticide exposure concerns the effect of organoclorines with studies showing weak non-significant effects. A meta-analysis (Maele-Fabry 2003) on occupational exposure to pesticides and prostate cancer was also identified published. The pooled effect estimate, based on 22 epidemiological studies, was 1.13 (95% CI 1.04 to 1.22) with substantial heterogeneity across studies. In addition, the studies reviewed contained insufficient qualitative and quantitative information on exposure in order to distinguish the influence of pesticides from other occupational, environmental, and lifestyle factors (Maele-Fabry 2003). Overall, there is no evidence supporting an association between pesticide exposure and prostate cancer.

#### 8.3. Lung cancer

Thirty studies contributing 45 analyses examined associations between pesticide exposure and lung cancer; previously published meta-analysis was not identified. Again, 23 out of 30 published studies and 30 of the 45 analyses were analyses of the AHS. Amongst the 50 different analyses of the AHS, only one statistically significant result was observed. Three studies examined broad pesticides definition as their exposure (ID CAN\_080, ID CAN\_082, ID CAN\_083), one studied mosquito coil burns (ID CAN\_081), while the remaining studies examined a range of different pesticides with an emphasis on organochlorine insecticides. The diversity of pesticide categories and the repeated use of the same cohort population (AHS) in more than half of the studies does not allow for quantitative synthesis. Notably, the association between mosquito coil burn and lung cancer was statistically significant with large effect size (3.78 (1.55, 6.90); yes vs. no use) but the study is relative small, retrospective with limited examination of confounders and of overall modest quality. Two case-control studies (ID CAN\_082, ID CAN\_082) reported over a two-fold increased risk of lung cancer for occupational exposure to pesticides but individual pesticides were not examined. Another case-control study (ID CAN\_080) failed to replicate these observations between pesticide exposure and lung cancer mortality. Overall, the evidence on pesticide exposure and lung cancer is limited and inconclusive.

#### 8.4. Childhood cancer

#### 8.4.1. Childhood hematological neoplasms

Overall, 17 studies (and one abstract) which examined childhood hematological neoplasms in relation to pesticide exposure were identified. All 17 studies examined childhood leukemia and 4 of them also included other hematological neoplasms.

Previous meta-analysis on childhood leukemia concentrated on studies which assessed residential exposure to pesticides only. All studies that were included in the meta-analyses and were published after 2006 have been identified by our search which confirms that we identified all available evidence.

The present document has been produced and adopted by the bodies identified above as author(s). This task has been carried out exclusively by the author(s) in the context of a contract between the European Food Safety Authority and the author(s), awarded following a tender procedure. The present document is published complying with the transparency principle to which the Authority is subject. It may not be considered as an output adopted by the Authority. The European Food Safety Authority reserves its rights, view and position as regards the issues addressed and the conclusions reached in the present document, without prejudice to the rights of the authors.

#### Ntzani EE, Chondrogiorgi M, Ntritsos G, Evangelou E, Tzoulaki I

の関連を調査したが、いずれの農薬と前立腺がんとの間にも統計的に有意な関連は認められなかった が、ブチル酸塩へのばく露と前立腺がんとの間には弱い有意な影響が認められた。残りのエビデンス は、小規模で質の低い後ろ向き研究から得られたものである。ほとんどの研究(ID CAN\_103、ID CAN\_101、 ID CAN\_100、ID CAN\_094、ID CAN\_143、ID CAN\_142)では、有機塩素の影響を調査したが、ほとんどが 小規模で有意ではない結果であった。2件の研究(ID CAN\_099、ID CAN\_095)では、農薬ばく露と前立 腺がんに関連した高く有意に増加したリスクが示されたが、いずれの研究も質が低く、ばく露の定義 が非常に広く、結果は慎重な解釈が必要であり、適切に実施された大規模な前向き研究(AHSなど)で 報告されたものとは一致しない。特筆すべきは、ばく露量の多い地域で行われた1件の集団ベースの症 例対照研究(ID CAN\_104)では、臭化メチルへのばく露と前立腺がんリスクとの間に強い関連が認めら れたが、この研究ではばく露反応関係を示すエビデンスは観察されなかった。まとめると、農薬ばく露 に関連した前立腺がんリスクに関するほとんどのエビデンスは有機塩素の影響に関係しており、研究 では有意ではない弱い影響が示されている。農薬への職業ばく露と前立腺がんに関するメタアナリシ ス (Maele-Fabry 2003) も発表されている。22の疫学研究に基づく統合効果推定値は1.13 (95%CI 1.04 ~1.22) であり、研究間でかなりの不均一性があった。さらに、レビューされた研究には、農薬の影響 を他の職業的、環境的、生活習慣的要因と区別するためのばく露に関する質的及び量的情報が不十分 であった(Maele-Fabry 2003)。全体として、農薬ばく露と前立腺がんとの関連を支持するエビデンス はない。

#### 8.3. 肺がん

30件の研究が45の分析を行っており、農薬ばく露と肺がんとの関連を調べているが、これまでに発 表されたメタアナリシスは確認されなかった。ここでも、公表された30件の研究のうち23件、45件の分 析のうち30件がAHSの分析であった。AHSの50種類の分析のうち、統計的に有意な結果が観察されたの は1件のみであった。3つの研究では、ばく露としての農薬の定義が広く(ID CAN\_080、ID CAN\_082、ID CAN\_083)、1つの研究では蚊取り線香の火傷を調査し(ID CAN\_081)、残りの研究では有機塩素系殺虫 剤に重点を置いて様々な農薬を調査していた。殺虫剤のカテゴリーが多様であること、半数以上の研 究で同じコホート集団(AHS)を繰り返し使用していることから、定量的な統合はできなかった。特筆 すべきは、蚊取り線香の火傷と肺がんとの関連は、大きな効果量(3.78(1.55、6.90);使用あり vs 使用なし)で統計的に有意であったが、この研究は相対的に小規模であり、交絡因子の調査が限られた 後ろ向きであり、全体的に質は中等度であった。2件の症例対照研究(ID CAN\_082, ID CAN\_082)では、 農薬への職業ばく露による肺がんリスクの2倍以上の増加が報告されているが、個々の農薬については 調査されていない。別の症例対照研究(ID CAN\_080)では、農薬ばく露と肺がん死亡率との間のこれら の観察を再現することはできなかった。全体として、農薬ばく露と肺がんに関するエビデンスは限ら れており、結論は出ていない。

### 8.4. 小児がん

### 8.4.1. 小児の造血器新生物

全体として、農薬ばく露に関連して小児の造血器新生物を調査した17件の研究(及び1件の要約)が 同定された。17件の研究はすべて小児白血病を対象としており、そのうち4件には他の造血器新生物も 含まれていた。

小児白血病に関するこれまでのメタアナリシスは、農薬への住居内ばく露のみを対象とした研究に 集中していた。メタアナリシスに含まれ、2006年以降に発表されたすべての研究が我々の検索で同定 され、利用可能なすべてのエビデンスが同定されたことを確認した。特定された研究は、国の登録ベー スの症例対照研究ESCALE (Etude sur les cancers de l'enfant) (ID CAN\_073) とNorthern Region Young Persons' Malignant Disease Registry (ID CAN\_120) の2つの研究を除いて、一般的に小規模な

EFSA supporting publication 2013:EN-497

<sup>23</sup> 

Identified studies were generally small with the exception of two studies on national registries, the Northern Region Young Persons' Malignant Disease Registry (ID CAN 120) and the national registry-based case-control study ESCALE (Etude sur les cancers de l'enfant) (ID CAN 073). Results from these studies should be cautiously interpreted, despite their large sample size, due to the large number of hypothesis examined (high false positive rate); each study reported 42 and 64 separate analysis respectively. All were case control studies and vast majority examined residential exposures with few studies on occupation exposure identified. Although most studies assessed use of, or exposure to, pesticides or pesticide subgroups (insecticides, herbicides, fungicides), some studies also attempted to collect information on specific pesticides (ID CAN 031, ID CAN 032) and one study (ID CAN 032) assessed biomarker levels. There were few data regarding frequency or duration of pesticide use, with most studies reporting only "ever/never" use of/exposure to the pesticide of interest. Although confounding is difficult to assess because there are few established risk factors for childhood hematological neoplasms, most studies examined or adjusted for at least a range of sociodemographic and maternal characteristics. Almost all studies assessed pesticide exposure separately for preconception, pregnancy, and childhood time windows. One study of very low quality and incomplete statistical analyses results examined all exposure time windows and other 2 (ID CAN 073, ID CAN 044) examined preconception and pregnancy jointly.

Three studies were excluded from further quantitative analyses: study ID CAN\_040 was excluded due to lack of CIs; study ID CAN\_030 due to duplicate data from Northern California Childhood Leukemia Study (duplicate with ID CAN\_031), and study ID CAN\_037 due to a unique study population (Down syndrome cases only). We divided the quantitative synthesis of results by the time period (window of exposure).

#### 8.4.1.1. Exposure during pregnancy

Seven studies had information for pesticide exposures during pregnancy. Eleven out of 86 analyses were statistically significant corresponding to 5 studies which all examined acute leukaemia as outcome of interest. Largest effect estimates were reported from the national registry-based casecontrol study ESCALE (Etude sur les cancers de l'enfant). Insecticide use during pregnancy was significantly associated with childhood acute leukemia (OR = 2.1; 95% CI, 1.7–2.5) and paternal household use of pesticides was also related to acute leukemia (OR = 1.5; 95% CI, 1.2–1.8) in this study. We performed a series of quantitative synthesis of results. We first selected analyses with the largest sample size within each published report and synthesized results (Figure 10). This analysis was associated with large heterogeneity ( $I^{2}>80\%$ ) as each study had different exposure assessment (type of pesticide and parental route of exposure) and variability in outcome assessment. The remaining metaanalysis in Figure 10 show synthesis or results based on pesticide class examined in an effort to harmonize results with the previously published meta-analysis (Turner 2010) on 'Residential Pesticides and Childhood Leukemia'. We performed quantitative synthesis of all studies on insecticides and pesticides identified in this systematic review and subsequently we updated the previously published meta-analysis keeping only studies assessing residential exposure. Overall, the results show modest heterogeneity across studies, which can be attributed to variability in pesticide exposure definition, outcome definition, definition of exposure time windows etc. However, the metaanalysis show a consistent increased risk of childhood leukemia associated with exposure to unspecified pesticides and insecticide (Summary OR=1.69; 96% CI=1.35, 2.11). Our updated metaanalysis resulted in more conservative results compared to the meta-analysis published in 2010 but still supported an association between exposure to pesticides during pregnancy and childhood leukaemia. Still the evidence merits careful interpretation as there were concerns around publication bias in the original meta-analysis, the studies are typically small and the exposure is measured through non-validated self-reported questionnaires that are prone to misclassification. Funnel plot shows relative symmetry around studies of small size. Further evidence from large studies, using valid

#### Ntzani EE, Chondrogiorgi M, Ntritsos G, Evangelou E, Tzoulaki I

ものであった。これらの研究の結果は、サンブルサイズが大きいにもかかわらず、調査された仮説の数 が多い(偽陽性率が高い)ため、慎重に解釈されるべきである。各研究はそれぞれ42件、64件の個別の 分析結果を報告している。すべての研究は症例対照研究であり、大多数は住居内ばく露を調査してお り、職業ばく露に関する研究はほとんど見出されなかった。ほとんどの研究では、農薬または農薬のサ ブグループ(殺虫剤、除草剤、殺菌剤)の使用またはばく露を評価していたが、一部の研究では特定の 農薬に関する情報の収集を試みており(ID CAN\_031、ID CAN\_032)、1つの研究(ID CAN\_032)ではバ イオマーカーレベルを評価していた。農薬の使用頻度や使用期間に関するデータはほとんどなく、ほ とんどの研究では、対象となる農薬の「今までに使用したことがあるかないか」」「使用したことがある かないか」のみを報告している。小児の造血器新生物のリスク因子がほとんど確立されていないため、 交絡因子の評価は困難であるが、ほとんどの研究では、少なくとも様々な社会人口統計学的及び母性 の特性を調査または調整している。ほとんどすべての研究では、農薬はく露を妊娠前、妊娠期、小児期 に分けて評価している。非常に質が低く、統計分析の結果が不完全であった1件の研究では、すべての ばく露期間を調査し、他の2件(ID CAN\_073, ID CAN\_044)では、妊娠前と妊娠期を合わせて調査して いる。

研究ID CAN\_040はCIが不足していたため除外され、研究ID CAN\_030はNorthern California Childhood Leukemia Studyのデータが重複していたため(ID CAN\_031と重複)、研究ID CAN\_037は研 究集団が特殊であったため(ダウン症患者のみ)、3つの研究が定量分析から除外された。結果の定量 的統合を期間(ばく露の時間域)ごとに分けた。

### 8.4.1.1 妊娠期のばく露

7件の研究では妊娠期の農薬ばく露に関する情報が得られた。86件中11件の分析で統計的に有意な結 果が得られたのは5件であり、すべての研究で急性白血病を対象とした結果であった。最大の効果推定 値は、国の登録ベースの症例対照研究ESCALE (Etude sur les cancers de l'enfant) から報告されて いる。本研究では、妊娠期の殺虫剤使用は小児急性白血病と有意に関連し(OR = 2.1:95%CI, 1.7-2.5)、父方の住居での殺虫剤使用も急性白血病と関連し(OR = 1.5;95%CI, 1.2-1.8)、また、父方 の住居での殺虫剤使用も急性白血病と関連した(OR = 1.5;95%CI, 1.2-1.8)。結果の一連の定量的 統合を行った。まず、各発表報告書の中で最大のサンプルサイズを持つ分析を選択し、結果を統合した (図 10)。この分析は、各研究でばく露評価(農薬の種類と親のばく露経路)が異なり、影響評価に ばらつきがあったため、大きな不均一性(I2>80%)と関連していた。図10の残りのメタアナリシスは、 「住居用農薬と小児白血病」に関する以前に発表されたメタアナリシス(Turner 2010)と結果を調和 させるために、調査した農薬のクラスに基づいた統合または結果を示している。我々は、この系統的レ ビューで確認された殺虫剤及び農薬に関するすべての研究を定量的に統合し、その後、住居ばく露を 評価した研究のみを残して、以前に発表されたメタアナリシスを更新した。全体的に、結果は研究間で 中等度の不均一性を示しており、これは農薬ばく露の定義、影響の定義、ばく露時間域の定義などにば らつきがあることに起因していると考えられる。しかし、メタアナリシスでは、特定されていない農薬 及び殺虫剤へのばく露に関連した小児白血病のリスクの一貫した増加を示した(要約0R=1.69;96% CI=1.35,2.11)。我々の更新されたメタアナリシスでは、2010年に発表されたメタアナリシスと比較 して、より保守的な結果となったが、妊娠期の農薬へのばく露と小児白血病との関連は依然として支 持されている。しかし、元のメタアナリシスでは出版バイアスの懸念があったこと、研究の規模が一般 的に小さいこと、ばく露は誤分類されやすい検証されていない自記式質問紙で測定されていることな どから、エビデンスは慎重に解釈する必要がある。ファンネルプロットは、小規模な研究を中心とした 相対的な対称性を示している。住居用殺虫剤への出生前ばく露を減らすことに公衆衛生上のメリット があるかどうかを確認するためには、過去のばく露の有効なバイオマーカーを用いた大規模研究から のさらなるエビデンスが必要である。

biomarkers of past exposure are needed to confirm whether there is public health merit in reducing prenatal exposure to residential pesticides.

#### 8.4.1.2. Preconception

Four studies examined preconception as the time window of exposure (ID CAN\_032, ID CAN\_043, ID CAN\_073, ID CAN\_120) but none reported statistically significant results.

#### 8.4.1.3. Childhood

Seven studies with information on exposure during childhood were identified (ID CAN\_031, ID CAN\_032, ID CAN\_035, ID CAN\_036, ID CAN\_041, ID CAN\_043, ID CAN\_133). One study examined Endosulfan, which is no longer in use; the study was of very low quality and was not considered further. Meta-analysis of these studies is shown in Figure 14 below. Two analyses are presented A) one on identified studies from 2006 onwards based on the analysis of the largest sample size in each report (any pesticide) and B) an update on the 2010 meta-analysis on pesticide exposure during childhood and childhood leukemia. The meta-analysis on any pesticides had modest heterogeneity whereas the updated meta-analysis, which was restricted to residential exposure and insecticides/ unspecified pesticides only, displayed no heterogeneity in its results. The results of the updated meta-analysis are more conservative than the original meta-analysis but still very close to the pooled estimates reported in 2010 (Figure 14). Funnel plots indicated considerable symmetry around results. Overall, there is some evidence for association between childhood exposure to pesticide and childhood leukemia but this is weaker than exposure during pregnancy and requires more evidence from well-conducted large birth cohorts to draw firm conclusions.

#### 8.4.2. Lymphomas

Evidence beyond leukaemia for childhood hematological neoplasms comes only from 3 studies, which reported many analyses (IDs CAN\_073, ID CAN\_120, ID CAN\_133) among which analyses for Non-Hodgkin and Hodgkin lymphomas. All analyses were not statistically significant and had weak effect estimates.

#### 8.4.3. Other childhood cancers

Seven studies on other childhood cancers were identified. Four studies examined brain cancer (ID CAN\_006, ID CAN\_011, ID CAN\_089, ID CAN\_133), one childhood germ cell tumor (ID CAN\_114) and two examined a range of childhood cancers (ID CAN\_120, ID CAN\_133). Significant associations were only observed for brain cancers but again these pertain to only a small subset of many analyses and cannot be informative at this stage.

#### 8.5. Colorectal cancer

Overall, 26 identified studies examined associations between pesticide exposure and colorectal cancer in 207 analyses. Separate analyses for colon cancer and rectum cancer were available in 24 and 11 studies respectively. A very large body of evidence comes from the AHS study, which examined all these 3 outcomes for associations with 194 out of the 207 identified analyses on colorectal cancer examining 50 different pesticides with no adjustments for multiple testing. Out of these 194 analyses, only 7 were statistically significantly positively associated with the outcome (Carbaryl, Aldicarb,

The present document has been produced and adopted by the bodies identified above as author(s). This task has been carried out exclusively by the author(s) in the context of a contract between the European Food Safety Authority and the author(s), awarded following a tender procedure. The present document is published complying with the transparency principle to which the Authority is subject. It may not be considered as an output adopted by the Authority. The European Food Safety Authority reserves its rights, view and position as regards the issues addressed and the conclusions reached in the present document, without prejudice to the rights of the authors.

## 8.4.1.2. 妊娠前

4つの研究では、ばく露の時期として妊娠前を調査したが(ID CAN\_032、ID CAN\_043、ID CAN\_073、ID CAN\_120)、いずれも統計的に有意な結果の報告ではなかった。

### 8.4.1.3. 小児期

小児期のばく露に関する情報を有する7件の研究が確認された(ID CAN\_031、ID CAN\_032、ID CAN\_035、 ID CAN\_036、ID CAN\_041、ID CAN\_043、ID CAN\_133)。1件の研究では、現在使用されていないエンド スルファンを調査したが、その研究は非常に質が低く、これ以上の調査は行われなかった。これらの研 究のメタアナリシスを以下の図14に示す。2つの分析が提示されており、A) 各報告書の最大サンプルサ イズの分析に基づいて2006年以降に同定された研究(任意の農薬)についての分析と、B) 小児期及び 小児白血病における農薬ばく露に関する2010年のメタアナリシスについての更新である。あらゆる農 薬に関するメタアナリシスでは中等度の不均一性があったのに対し、更新されたメタアナリシスでは、 住居ばく露と殺虫剤/特定されていない農薬のみに限定されており、結果に不均一性は見られなかった。 更新されたメタアナリシスの結果は、元のメタアナリシスよりも保守的であるが、それでも2010年に 報告された統合推定値に非常に近いものであった(図14)。ファンネルプロットでは、結果にかなりの 対称性があることが示されている。全体的には、小児期の農薬ばく露と小児白血病との間には関連を 示すいくつかのエビデンスがあるが、これは妊娠期のばく露よりも弱く、確固とした結論を出すため には、適切に実施された大規模な出生コホートからのより多くのエビデンスが必要である。

#### 8.4.2. リンパ腫

白血病以外の小児の造血器新生物に関するエビデンスは3件の研究から得られているのみであり、その中には非ホジキンリンパ腫とホジキンリンパ腫に関する分析を含む多くの分析が報告されている (ID: CAN\_073、ID: CAN\_120、ID: CAN\_133)。すべての分析は統計的に有意ではなく、効果推定値も 弱いものであった。

### 8.4.3. その他の小児がん

その他の小児がんに関する研究が7件同定された。4件の研究では脳腫瘍(ID CAN\_006、ID CAN\_011、 ID CAN\_089、ID CAN\_133)、1件の小児生殖細胞腫瘍(ID CAN\_114)、2件の研究では様々な小児がん (ID CAN\_120、ID CAN\_133)が調査された。有意な関連が観察されたのは脳腫瘍のみであったが、これ らは多くの分析のごく一部のサブセットに関連しており、現段階では情報を得ることはできない。

### 8.5. 大腸がん

全体では、26件の研究で農薬ばく露と大腸がんとの関連性が 207 件の分析で調査された。大腸がん と直腸がんについては、それぞれ24件と11件の研究で別々の分析が行われた。非常に多くのエビデン スがAHS研究から得られている。この研究では、50種類の農薬を用いた大腸がんに関する207の分析の うち194の分析で、これら 3 つの影響発現事象すべてとの関連性が調査されており、多重試験の調整 は行われていない。これら194の分析のうち、影響発現事象と統計的に有意に関連したのは7つの分析 のみであった(カルバリル、アルジカルブ、トキサフェン、ペンディメタリン、ジプロピルチオカルバ ミン酸 S-エチル (EPTC)、イマゼタピル、フォノフォス)が、偽陽性確率が高いため、解釈には注意 が必要である。27の研究が発表されているにもかかわらず、全体的には7つの異なる集団からのエビデ ンスしか得られていない。この事実は、大腸がんに関連してこれらの研究のそれぞれで分析された異 なる農薬の範囲とともに、結果の意味のある定量的な統合を可能にするものではない。表8は、複数の 論文における1つのコホートからの重複データの公表の程度を示しており、結果の一貫性が良好である

EFSA supporting publication 2013:EN-497

Toxaphene, Pendimethalin, S-Ethyl dipropylthiocarbamate (EPTC), imazethapyr and Fonofos) but need to be interpreted with caution due to high false positive probability. Despite the fact that 27 published studies were identified, overall the evidence comes from only 7 different populations. This fact along with the range of different pesticides analysed by each of these studies in relation to colon cancer does not allow meaningful quantitative synthesis of the results. Table 8 shows the extent of publication of duplicate data from one cohort in multiple papers and shows good consistency of results. Previous meta-analyses on colorectal cancer and pesticide exposure have not been identified. Overall, the evidence for pesticides and colorectal cancer is very limited and current state of the literature does not support associations between pesticides and colorectal cancer.

### 8.6. Skin cancer

Seventeen studies examined associations between melanoma and pesticide exposure. The majority of studies assessed organochlorine pesticides. Again, 14 out of 17 studies on melanoma were results from the AHS examining in each paper different pesticides categories and different definitions of exposure with some supplication of results present. Of the 26 different analyses of the AHS, 8 were statistically significant and all stemming from the same publication (ID CAN\_085) on dose response relationships for 50 agricultural pesticides with cutaneous melanoma. The study reported significant associations between cutaneous melanoma and maneb/mancozeb ( $\geq$  63 exposure days: OR = 2.4; 95% CI, 1.2–4.9; trend *p* = 0.006), parathion ( $\geq$  56 exposure days: OR = 2.4; 95% CI, 1.3–4.4; trend *p* = 0.003), and carbaryl ( $\geq$  56 exposure days: OR = 1.7; 95% CI, 1.1–2.5; trend *p* = 0.013) (155). Other studies did not report results on these pesticides to allow examination of replication of results. One case-control study showed increased statistically significant risk between indoor pesticide exposure and melanoma whereas in the same study outdoors pesticide exposure was not associated with melanoma (106). The remaining studies on organochlorines showed heterogeneous results with few statistically significant results (Hexachlorobenzene (HCB), mirex), which do not provide evidence for an association between these pesticides and melanoma.

#### 8.7. Breast cancer

Overall, 14 studies (and 3 abstracts) after 2006 examined the relationship between pesticide exposure and breast cancer. The vast majority of studies and analyses concentrate on organochlorine pesticide, which they are assessed through biomarker analyses. Two previous meta-analyses on breast cancer and DDT exposure have been published (Khanjani 2007, López-Cervantes 2004). Overall, previous meta-analyses did not show a significant association between any cyclodiene chemical and breast cancer except for heptachlor, but that was based on only two studies. Meta-analysis on identified studies in this systematic review on Dichlorodiphenyldichloroethylene (DDE) and breast cancer (5 studies) also shows no evidence for association. We have also performed a meta-analysis across all identified studies on breast cancer, selecting each time the analysis within each study with the largest sample size. Studies ID CAN 019 and ID CAN 023 were excluded from synthesis, as effect sizes and confidence interval to allow synthesis were not provided and study ID CAN 022 was excluded as it reported very tight confidence intervals which did not were assumed to be reported incorrectly. The synthesis here involves the pooled effect of many different pesticides definitions and biomarkers (DDE, lindane, and broad pesticide definition) and is difficult to be interpreted. The pooled effect shows a statistically significant increased risk of breast cancer (1.07 (0.87 to 1.31)) but this result need cautious interpretation. The meta-analysis combines very different categories of pesticides and is largely dominated by one study (ID CAN 022), which assessed pesticide exposure by self-reported residential pesticide use and is therefore of modest quality compared to the rest of the studies which assessed pesticides via biomarkers.

26

The present document has been produced and adopted by the bodies identified above as author(s). This task has been carried out exclusively by the author(s) in the context of a contract between the European Food Safety Authority and the author(s), awarded following a tender procedure. The present document is published complying with the transparency principle to which the Authority is subject. It may not be considered as an output adopted by the Authority. The European Food Safety Authority reserves its rights, view and position as regards the issues addressed and the conclusions reached in the present document, without prejudice to the rights of the authors. ことを示している。大腸がんと農薬ばく露に関するこれまでのメタアナリシスは確認されていない。 全体的に、農薬と大腸がんに関するエビデンスは非常に限られており、現在の文献の状態では、農薬と 大腸がんの関連性を支持するものではない。

Ntzani EE, Chondrogiorgi M, Ntritsos G, Evangelou E, Tzoulaki I

### 8.6. 皮膚がん

17件の研究では、メラノーマと農薬ばく露との関連が調査された。大半の研究は有機塩素系農薬を 対象としたものであった。ここでも、メラノーマに関する17件の研究のうち14件がAHSの結果であり、 各論文では異なる農薬のカテゴリーやばく露の定義が異なっており、いくつかの結果が提示されてい た。AHSの26の異なる分析のうち、8つは統計的に有意であり、すべて同じ出版物(ID CAN\_085)に由来 するもので、50種類の農薬と皮膚メラノーマとの量反応関係が報告されている。この研究では、皮膚メ ラノーマとmaneb/mancozeb(63日以上のばく露日数:OR = 2.4;95%CI、1.2-4.9;トレンドp = 0.006)、 parathion(56日以上のばく露日数:OR = 2.4;95%CI、1.3-4.4;トレンドp = 0.003)及びcarbary1 (56日以上のばく露日数:OR = 1.7;95%CI、1.1-2.5;トレンドp = 0.013)との間の有意な関連が報 告されている(155)。他の研究では、これらの農薬に関して再現性を調査できるような結果を報告し ていない。1件の症例対照研究では、屋内での農薬ばく露とメラノーマとの間に統計的に有意なリスク の増加が示されたが、同じ研究では気を外での農薬ばく露はメラノーマとは関連していなかった(106)。 有機塩素系農薬に関する残りの研究では、統計的に有意な結果がほとんど得られない不均質な結果が 得られており(ハキサクロロベンゼン(HCB)、マイレックス)、これらの農薬とメラノーマとの関連 を示すエビデンスは得られてない。

### 8.7. 乳がん

全体では、2006年以降の14件の研究(うち3件は要約)が農薬ばく露と乳がんとの関係を調査した。 大半の研究と分析は有機塩素系農薬に焦点を当てており、バイオマーカー分析によって評価されてい る。乳がんとDDTばく露に関する2つの過去のメタアナリシスが発表されている(Khanjani 2007, López-Cervantes 2004)。全体的に、以前のメタアナリシスでは、ヘプタクロルを除き、シクロジエン系化学 物質と乳がんとの間に有意な関連は示されなかったが、それはわずか2件の研究に基づくものであった。 ジクロロジフェニルジクロロエチレン(DDE)と乳がんに関するシステマティックレビューで同定され た研究(5研究)のメタアナリシスでも、関連を示すエビデンスは示されなかった。我々はまた、乳が んに関する同定されたすべての研究でメタアナリシスを実施し、サンプルサイズが最も大きい各研究 内の分析を毎回選択した。研究ID CAN 019とID CAN 023は、統合を可能にする効果量と信頼区間が提 供されていなかったため、統合から除外された。また、研究ID CAN\_022は、誤って報告されたとは想定 されていない非常に狭い信頼区間を報告していたため除外された。ここでの統合には、多くの異なる 農薬の定義とバイオマーカー(DDE、リンデン、広義の農薬定義)の統合効果が含まれており、解釈が 難しい。統合効果は統計的に有意な乳がんリスクの増加(1.07(0.87~1.31))を示したが、この結果 は慎重な解釈が必要である。メタアナリシスでは、非常に異なるカテゴリーの農薬を組み合わせてお り、主に1つの研究(ID CAN 022)が占めているが、これは住居用農薬の自己申告による農薬ばく露を 評価したもので、バイオマーカーを介して農薬を評価した他の研究に比べて質が低いものである。

EFSA supporting publication 2013:EN-497

#### 8.8. Bladder cancer

Sixteen studies examining bladder cancer in relation to pesticide exposure were identified; however, 13 were studies from the same population the AHS as previously observed for other cancer outcomes. Among the 25 different analyses presented, only one provided statistically significant results for occupational exposure to imazethapyr in the AHS. However, due to multiple testing the results need cautious interpretation and based on the evidence reviewed in this report there is no suggestion for an association between pesticide exposure and bladder cancer.

#### 8.9. Kidney cancer

Ten studies examined kidney cancer in relation to pesticide exposure; however, data from two populations only, the AHS and the BC (British Columbia) sawmill workers cohort study. Results form the BC sawmill workers cohort study (ID CAN\_129 and ID CAN\_125) were both on occupational exposure to pentachlorophenol and tetrachlorophenol but examining different approaches to statistical analyses. Results from the AHS were on different pesticide classes. Overall, no statistically significant results were observed and the limited number of contributing populations (n=2) does not allow further quantitative synthesis.

#### 8.10. Pancreatic cancer

Seven studies examined pancreatic cancer in relation to pesticide exposure; 4 were reports from the AHS. The overwhelming majority of analyses considered organochlorine pesticides. In a small casecontrol study of modest quality significantly increased concentrations of hexachlorobenzene (HCB), sum of chlordanes and polybrominated diphenylethers (PBDEs) were found in the pancreatic cancer cases compared to healthy controls (ID CAN\_090). In the AHS, among 46 different analyses, significant associations were reported for Pendimethalin and S-Ethyl dipropylthiocarbamate (EPTC). Applicators in the top half of lifetime pendimethalin use had a 3.0-fold (95% CI 1.3–7.2, p-trend 5 0.01) risk compared with never users, and those in the top half of lifetime EPTC use had a 2.56-fold (95% CI 5 1.1–5.4, p-trend=0.01) risk compared with never users. Organochlorines were not associated with an excess risk of pancreatic cancer in the AHS. These findings suggest that herbicides may be associated with pancreatic cancer but require replication by future studies as they all come from a single population without adjustments for multiple testing.

#### 8.11. Testicular cancer

Overall, 8 studies examined testicular cancer. Two studies also reported outcomes for seminoma cancer. All but one study assessed biomarker levels and concentrated on organochlorine pesticides with a range of different biomarkers assessed and studies showing a weak effect for an association with testicular cancer. However, information on more than 4 studies was available for p-p'DDE only and quantitative synthesis showed a non-significant effect and modest heterogeneity (Figure 20). Quantitative synthesis across any pesticide was not performed due to heterogeneity of biomarkers assessed in each study. Overall, there is no evidence to support an association between pesticide exposure and testicular cancer based on evidence reviewed herein.

#### 8.12. Stomach cancer

Six studies examined association between pesticide exposure and stomach cancer. All studies examined occupational exposure to pesticides, a range of pesticide classes was studies; 2 studies had a prospective design but all had modest to small sample sizes. In agreement with previous meta-analysis

27

## Ntzani EE, Chondrogiorgi M, Ntritsos G, Evangelou E, Tzoulaki I

#### 8.8. 膀胱がん

農薬ばく露に関連して膀胱がんを調査した16件の研究が同定されたが、13件は他の発がん影響について以前に観察されたのと同様にAHSの同じ集団からの研究であった。25の異なる分析結果のうち、AHS におけるイマゼタビルへの職業ばく露について統計的に有意な結果を示したのは1件のみであった。しかし、複数の試験を行っているため、結果は慎重に解釈する必要があり、報告書で調査されたエビデンスに基づいても、農薬ばく露と膀胱がんとの関連は示唆されていない。

### 8.9. 腎臓がん

10件の研究が農薬ばく露に関連して腎臓がんを調査したが、データはAHSとBC(ブリティッシュコロ ンビア州)製材所労働者コホート研究の2つの集団からのみであった。BC州製材所労働者コホート研究 (ID CAN\_129及びID CAN\_125)の結果は、いずれもペンタクロロフェノール及びテトラクロロフェノ ールへの職業ばく露に関するものであったが、統計分析のアプローチが異なっていた。AHSの結果は、 異なる農薬クラスに関するものであった。全体的に、統計的に有意な結果は観察されず、寄与した集団 の数が限られているため(n=2)、これ以上の定量的な統合はできなかった。

### 8.10. 膵臓がん

農薬ばく露に関連して膵臓がんを調査した研究は7件、AHSからの報告は4件であった。分析の圧倒的 多数は有機塩素系農薬を対象としたものであった。質の低い小規模な症例対照研究では、ヘキサクロ ロベンゼン(HCB)、クロルデンの和及びポリ臭化ジフェニルエーテル(PBDE)の濃度が健常対照者と 比較して膵臓がん症例で有意に上昇していた(ID CAN\_090)。AHSでは、46種類の分析のうち、 PendimethalinとS-Ethyl dipropylthiocarbamate (EPTC)について有意な関連が報告されている。ペン ディメタリンの生涯使用量の上位半分の散布者は、非使用者と比較して3.0倍(95%CI 1.3-7.2、pトレ ンド5 0.01)のリスクを有し、EPTCの生涯使用量の上位半分の散布者は、非使用者と比較して2.56倍 (95%CI 5 1.1-5.4、pトレンド=0.01)のリスクを有していた。有機塩素系薬剤は、AHSにおける膵臓 がんの過剰リスクとは関連していなかった。これらの知見は、除草剤が膵臓がんと関連している可能 性を示唆しているが、これらはすべて単一の集団から得られたものであり、多重検定調整を行ってい ないため、今後の研究で反復する必要がある。

### 8.11. 精巣がん

全体では8件の研究で精巣がんが調査された。2件の研究では精上皮腫への影響も報告された。1件を 除くすべての研究がバイオマーカーレベルを評価し、有機塩素系殺虫剤に集中しており、さまざまな バイオマーカーが評価され、精巣がんとの関連には弱い影響を示した研究もあった。しかし、p-p'DDE のみについては4件以上の研究の情報が得られ、定量的統合では有意ではない効果と適度な不均一性が 示された(図20)。各研究で評価されたバイオマーカーの不均一性のため、どの農薬についても定量的 統合は行われなかった。全体的に、ここで調査されたエビデンスに基づいて、農薬ばく露と精巣がんと の関連を支持するエビデンスはない。

### 8.12. 胃がん

6件の研究で、農薬ばく露と胃がんとの関連が調査された。すべての研究は農薬への職業ばく露を調 査したもので、農薬のクラスは多岐にわたっていた;2件の研究は前向きデザインであったが、すべて の研究でサンプルサイズは中等度から低度であった。農家に関する以前のメタアナリシス(Saphir 1998)と一致するように、研究は不十分で、主に有意でない結果を報告していた。United Farm Workers of America (UFW) コホートにおける胃がんのコホート内症例対照研究(ID CAN\_028)では、有意な関 連が報告された。フェノキシ酢酸除草剤2,4-ジクロロフェノキシ酢酸(2,4-D)の使用量が多い地域で

The present document has been produced and adopted by the bodies identified above as author(s). This task has been carried out exclusively by the author(s) in the context of a contract between the European Food Safety Authority and the author(s), awarded following a tender procedure. The present document is published complying with the transparency principle to which the Authority is subject. It may not be considered as an output adopted by the Authority. The European Food Safety Authority reserves its rights, view and position as regards the issues addressed and the conclusions reached in the present document, without prejudice to the rights of the authors.

on farmers (Saphir 1998), studies reported weak and mainly non-significant results. A nested casecontrol study (ID CAN 028) of gastric cancer embedded in the United Farm Workers of America (UFW) cohort reported significant associations: working in areas with high use of the phenoxyacetic acid herbicide 2.4-dichlorophenoxyacetic acid (2.4-D) was associated with gastric cancer (OR 1.85; 95% CI 1.05-3.25); use of the organochlorine insecticide chlordane was also associated with the disease (OR 2.96; 95% CI 1.48-5.94). Gastric cancer was associated with use of the acaricide propargite (OR 2.86; 95% CI 1.56-5.23). Nonetheless, the study is limited by a relatively small number of cases and controls, multiple testing and exposure misclassification, as assessment was ecological in nature. In the AHS, based on 15 exposed cases, stomach cancer risk increased monotonically with increasing methyl bromide use (RR = 3.13; 95 % CI, 1.25–7.80 for high use compared with no use; p for trend = 0.02). However, again the associations suffer from multiple testing as all other cancer subtypes have been associated with methyl bromide use in this study (ID CAN 147). Meta-analysis selecting the analysis with largest sample size is shown in Figure 21 but results require careful consideration. Despite a statistical significant pooled large effect size, this is dominated by two studies (ID CAN 125, ID CAN 147), which examine pentachlorophenol and methyl bromide; two compounds that are not approved in the European Union.

Pesticide epidemiology

28

#### 8.13. Liver cancer

Five studies (including 11 separate analyses) and one conference abstract examined associations between pesticide exposure and liver cancer. The majority of analyses examined exposure to organochlorine pesticides and all studies examined occupational exposure to pesticides. Both studies on DDT (IDs CAN\_076 and ID CAN\_079) reported statistically significant associations with liver cancer; the remaining analyses were non-statistically significant. These two studies largely dominate the meta-analysis on liver cancer, which shows a statistically significant pooled result largely driven by the DDT studies.

#### 8.14. Cancer subgroups with few studies

As illustrated in Table 6, for a large number of individual cancers only very few studies are available to allow synthesis of evidence for each cancer subgroup. Our systematic review did not identify any previously published meta-analyses on these cancer subtypes to allow for comparisons with previously published evidence (prior to 2006). Generally the results on these cancer subtypes were of small effect and not statistically significant with few exceptions concerning occupational exposure only. Given the large number of analyses within each study, these results need cautious interpretation and, based on these data, there is no evidence to suggest association between pesticide exposure and these cancer subtypes.

There were also a large number of studies examining all cancers (composite cancer outcome) in relation to pesticide. Cancers represent a very heterogeneous group of disorders and simultaneous examination of all cancer subtypes may introduce bias in the associations. Overall, 30 analyses examining "all cancers" were identified and 28 of them were analyses of the same cohort, the AHS, not allowing further synthesis of the results. Only 4 results out of 31 were statistically significant were associated with poor quality of studies and therefore do not merit interpretation at this stage.

### Ntzani EE, Chondrogiorgi M, Ntritsos G, Evangelou E, Tzoulaki I

働くことは、胃がんと関連していた(OR 1.85;95%CI 1.05-3.25)。有機塩素系殺虫剤クロルデンの 使用もこの疾患と関連していた(OR 2.96;95%CI 1.48-5.94)。胃がんは、殺ダニ剤プロパルギトの 使用と関連していた(OR 2.86;95%CI 1.56-5.23)。にもかかわらず、評価が生態学的なものであっ たため、この研究は症例数と対照数が比較的少ないこと、多重検定及びばく露の誤分類によって制限 されている。AHSでは、15例のばく露例に基づいて、胃がんリスクは臭化メチルの使用量の増加ととも に単調に増加した(RR = 3.13;95%CI、非使用と比較して高頻度使用では1.25-7.80;トレンドのp = 0.02)。しかし、この研究では他のすべてのがんのサブタイプが臭化メチル使用と関連していたため、 やはり多重検定の問題がある(ID CAN\_147)。最大のサンプルサイズで分析を選択したメタアナリシス は図21に示されているが、結果は慎重に調査する必要がある。統計的に有意な統合された大きな効果 量にもかかわらず、この結果は、欧州連合で承認されていない2つの化合物であるペンタクロロフェノ ールと臭化メチルを調査している2つの研究(ID CAN\_125, ID CAN\_147)の影響が大きい。

### 8.13. 肝臓がん

5件の研究(11件の個別の分析を含む)と1件の学会発表の要約で、農薬ばく露と肝臓がんとの関連が 調査された。分析の大部分は有機塩素系農薬へのばく露を対象としており、すべての研究は農薬への 職業ばく露を対象としていた。DDTに関する両研究(ID:CAN\_076及びID:CAN\_079)では、肝がんとの 統計的に有意な関連が報告されたが、残りの分析では統計的に有意ではなかった。これら2つの研究が 肝臓がんに関するメタアナリシスの大部分を占めており、統合された結果は統計学的に有意であり、 主にDDT研究に牽引されている。

### 8.14. 研究数が少ないがんサブグループ

表6に示されているように、多数のがんについては、各がんサブグループのエビデンスを総合的に判 断できる研究は非常に限られている。我々のシステマティックレビューでは、過去に発表されたエビ デンス(2006年以前)との比較を可能にするために、これらのがんサブタイプに関する過去に発表され たメタアナリシスを確認しなかった。一般的に、これらのがんサブタイプに関する結果では影響は小 さく、職業ばく露のみに関する少数の例外を除いて統計的に有意ではなかった。各研究内の分析数が 多いことを考えると、これらの結果は慎重に解釈する必要があり、これらのデータに基づいて、農薬ば く露とこれらのがんサブタイプとの間の関連を示唆するエビデンスはない。

また、農薬に関連してすべてのがん(複合発がん影響)を調査した研究も多数あった。がんは非常に 異質な疾患群であり、すべてのがんサプタイプを同時に調査すると、関連にバイアスがかかる可能性 がある。全体では、「すべてのがん」を対象とした30の分析が同定されたが、そのうち28の分析は同じ コホート(AHS)を対象としたものであり、結果をさらに統合することはできなかった。31件のうち統 計的に有意な結果が得られたのは4件のみで、質の低い研究と関連していたため、現段階では解釈に値 しない。

Pesticide epidemiology

## 9. Child health

Overall, 84 individual studies examined the effect of pesticide exposure on child health outcomes (median sample size: 267; IOR 119-811), contributing 821 separate analyses in the data extraction database. More than 120 health-related outcomes were assessed with a large proportion focusing on congenital malformations and developmental parameters including but not restricting to somatometrics (Table 10). As seen with other outcomes, the diversity of the exposure definition is remarkable and poses special challenges to data synthesis. Only 38 out of the 84 were prospective cohort studies and other 5 were nested case-controls; the majority of evidence comes from retrospective case-control analyses, which are prone to recall bias in exposure measurement. The sample size in the reported analyses was often small; it ranged between 23 and 183,313 participants (median 267) and the largest studies in the domain are smaller than the largest studies assessed in the cancer field. Here, we observed no large clusters of publications coming from large, well-known studies in the field, such as the Agricultural Health Study (AHS), while 26 studies assessed occupational exposures. In addition, the presence of studies with information on biomarkers of exposure was more prominent here  $(n=49, \dots, n=4)$ 58%) while 3 studies assessed occupational exposure through JEM. The different outcome categories examined are presented in Table 10 along with the number of studies contributing to each outcome category and a decision on quantitative synthesis (Table 11). Due to heterogeneity of data and small number of studies identified, statistical synthesis of the data (meta-analysis) was only performed for urological malformations only.

## 9.1. Prematurity

Fifteen studies assessed the association between pesticide exposure during pregnancy and prematurity with a median sample size of 193 (IQR 87-469), contributing 54 separate extracted comparisons in the database. More than half of the studies were retrospective and in more than three-fourths of the studies, the exposure was assessed through a biomarker. A large variety of individual pesticides were assessed with DDT metabolites being assessed more frequently (8 studies). Nevertheless no single pesticide and related biomarker was assessed in more than 4 studies using the same comparison unit, thus a quantitative synthesis was not performed. The largest prospective study (ID CH 091) assessed a Dutch population of greenhouse workers and reported a decreased risk of preterm birth among male greenhouse workers (OR= 0.47; 95%CI= 0.35–0.65) while the observed increased risk in women was not statistically significant (OR= 1.14, 95%CI= 0.57–2.31). The remaining studies reported statistically non-significant results with effect estimates pointing towards a positive association. Moreover, no meta-analysis of published studies was identified. Based on these data, there is no recent evidence to suggest a robust, clinically significant association between pesticide exposure and prematurity in general.

#### 9.2. Restricted fetal growth

Twelve studies assessed the association between pesticide exposure during pregnancy and restricted fetal growth and/or small for gestational age neonates with a median sample size of 422 (IQR 178-1,630), contributing 44 separate extracted comparisons in the database. Sixty percent of the studies were prospective, three assessed occupational exposure and in more than two-thirds of the studies, the exposure was assessed through a biomarker. A large variety of individual pesticides were assessed with DDT metabolites being assessed more frequently (4 studies). Nevertheless no single pesticide and related biomarker was assessed in more than 4 studies using the same comparison unit, thus a

#### 9. 小児の健康

全体では 84 件の個別研究が農薬ばく露の小児への健康影響を調査し(サンプルサイズ中央値:267、 IQR 119-811)、データ抽出データベースでは 821 件の分析が行われた。120 以上の健康関連影響が 評価されており、その大部分は先天性奇形と身体測定を含むがそれに限定されない発生パラメータに 焦点を当てている(表 10)。他の影響に見られるように、ばく露の定義の多様性には目を見張るもの があり、データ統合に特別な問題を与えている。84 件のうち 38 件のみが前向きコホート研究であり、 他の 5 件はコホート内症例対照研究であった。エビデンスの大部分は後ろ向き症例対照分析に由来し ており、これはばく露量測定においてリコールバイアスがかかりやすい。報告された分析におけるサ ンプルサイズはしばしば小さく、23~183,313人(中央値267人)であり、この領域の最大の研究は、が ん分野で評価された最大の研究よりも小さい。ここでは、農業健康調査(Agricultural Health Study: AHS)のような、この分野の大規模でよく知られた研究に由来する多数の出版物まとまっては観察され なかったが、26件の研究が職業ばく露を評価していた。さらに、ばく露のバイオマーカーに関する情報 を有する研究の存在は、ここではより多かった(n=49、58%)が、3つの研究はJEMによる職業ばく露を 評価した。調査した異なるカテゴリーに属する影響を、各カテゴリーに寄与した研究数と定量的統合 の決定とともに表 10 に示す(表 11)。データの不均一性と同定された研究数が少なかったため、デ ータの統計的統合(メタアナリシス)は泌尿器の奇形のみを対象に実施した。

## 9.1. 未熟児

妊娠期の農薬ばく露と未熟児との関連を評価した研究は 15 件あり、サンプルサイズの中央値は 193 件 (IQR 87-469) で、データベースには 54 件の比較が抽出されている。半数以上の研究が後ろ 向きで、4分の3以上の研究ではバイオマーカーを用いてばく露が評価されていた。個々の農薬の評価 は多種多様で、DDT代謝物の評価がより頻繁に行われていた(8件の研究)。それにもかかわらず、同じ 比較単位を使用した 4 件以上の研究では、単一の農薬と関連するバイオマーカーの評価は行われず、 定量的な統合は行われなかった。最大の前向き研究 (ID CH 091) では、オランダの温室労働者を対象 とし、温室労働者の男性における早産リスクの減少 (OR= 0.47; 95%CI= 0.35-0.65) が報告されたが、 女性におけるリスクの増加は統計的に有意ではなかった (OR= 1.14, 95%CI= 0.57-2.31)。残りの研 究では、正の関連を示す推定効果が得られたが、統計的に有意な結果はなかった。さらに、発表された 研究のメタアナリシスは確認されなかった。これらのデータに基づいて、農薬ばく露と未熟児との間 に臨床的に有意な関連を示唆する最近のエビデンスはない。

## 9.2. 胎児の発育制限

12の研究では、妊娠期の農薬ばく露と胎児の発育制限及び/または在胎不当過小児との関連を評価し ており、サンプルサイズの中央値は422(IQR 178-1,630)で、データベースには44件の個別の比較が抽 出されていた。研究の60%は前向きで、3つの研究では職業ばく露を評価し、3分の2以上の研究ではバ イオマーカーを用いてばく露を評価している。個々の農薬の評価は多種多様で、DDT代謝物の評価がよ り頻繁に行われていた(4件の研究)。それにもかかわらず、同じ比較単位を使用した 4 件以上の研 究では、単一の農薬と関連するバイオマーカーの評価は行われず、定量的な統合は行われなかった。最 大の研究(ID RPD 26)では、後ろ向きコホートを対象に、飲料水中のアトラジンが在胎不当過小(SGA) 及び早産の罹患率の増加と関連しているかどうかを評価した。著者らの報告によると、妊娠第 3 期及 び全妊娠期間の飲料水中のアトラジンは、SGA(Small for Gestational Age)の罹患率の有意な増加

#### Ntzani EE, Chondrogiorgi M, Ntritsos G, Evangelou E, Tzoulaki I Pesticide epidemiology

quantitative synthesis was not performed. The largest study (ID RPD 26) assessed in a retrospective cohort whether atrazine in drinking water is associated with increased prevalence of small-forgestational age and preterm birth. The authors reported that atrazine in drinking water during the third trimester and the entire pregnancy was associated with a significant increase in the prevalence of SGA (Small for Gestational Age); atrazine in drinking water > 0.1 µg/L during the third trimester resulted in a 17–19% increase in the prevalence of SGA compared with the control group (< 0.1 µg/L). All the remaining studies reported statistically non-significant results without a consistent pattern regarding the effect direction of the effect magnitude. Moreover, no meta-analysis of published studies was identified. Based on these data, there is no recent evidence to suggest a robust, clinically significant association between pesticide exposure and prematurity in general.

#### 9.3. Somatometrics (Body size metrics)

Numerous studies examined the association between pesticide exposure and growth.

#### 9.3.1. Birth length / Height

Length at birth and height was assessed in 13 and 8 studies, respectively, contributing 78 separate comparisons in the database. In the vast majority of the studies, the exposure was assessed through a biomarker. A large variety of individual pesticides were assessed with DDT metabolites being assessed more frequently; nevertheless no single pesticide and related biomarker was assessed in more than 4 studies, thus a quantitative synthesis was not performed.

The largest prospective study (ID CH 073) assessing a North American population born before 1980, reported that only the highest prenatal concentrations of p,p'-DDE (>60 mg/l), as compared with the lowest (<15 mg/l), were statistically significantly associated with decreased height at age 7 years [adjusted coefficient (SE) -2.21 cm (0.67)]. The remaining studies reported conflicting results without a consistent pattern either towards the effect direction or the effect magnitude. Moreover, no meta-analysis was identified. Given the large number of analyses these results need cautious interpretation and, based on these data, there is no recent evidence to suggest a robust, clinically significant association between pesticide exposure and birth length or height in general.

#### 9.3.2. Body weight

Twenty-six studies assessed the association between pesticide exposure during pregnancy and birth weight, contributing 134 separate extracted comparisons in the database. Another 5 studies assessed the association between pesticide and ponderal index. In a large number of comparisons, the exposure was assessed through a biomarker. A large variety of individual pesticides were assessed with DDT metabolites being assessed more frequently (11 studies). Nevertheless no single pesticide and related biomarker was assessed in more than 4 studies using the same comparison unit, thus a quantitative synthesis was not performed. The largest prospective study (ID CH 014) was a Agricultural Health Study (AHS) publication and reported that first-trimester pesticide-related tasks were not associated with birth weight and that, after multiple analyses, ever use of the pesticide carbaryl was associated with decreased birth weight (-82 g, 95% CI = -132, -31). The remaining studies reported conflicting results without a consistent pattern either towards the effect direction or the effect magnitude. Moreover, no meta-analysis of published studies was identified. We identified though a meta-analysis of individual participants data from European cohorts which reported that a  $1-\mu g/L$  increase in p.p'-

The European Food Safety Authority reserves its rights, view and position as regards the issues addressed and the conclusions reached in the present document, without prejudice to the rights of the authors.

#### Ntzani EE, Chondrogiorgi M, Ntritsos G, Evangelou E, Tzoulaki I

と関連しており、妊娠第3期に飲料水中のアトラジンが0.1 µg/Lを超えると、対照群(0.1 µg/L 未満)と比較してSGAの罹患率が17~19%増加した。残りのすべての研究では、効果量の方向性に 関する一貫したパターンがなく、統計的に有意ではない結果が報告された。さらに、発表された研究の メタアナリシスは確認されなかった。これらのデータに基づいて、農薬ばく露と未熟児との間に臨床 的に有意な関連を示唆する最近のエビデンスはない。

## 9.3. 身体測定(体格計測)

農薬ばく露と発育の関連を調査した研究は数多くある。

## 9.3.1. 出生時の体長/身長

出生時の体長と身長はそれぞれ13件と8件の研究で評価され、データベースでは78件の比較が行われた。大半の研究では、パイオマーカーを用いてばく露が評価されている。個々の農薬の評価は多種多様で、DDT代謝物の評価がより頻繁に行われていたが、4件以上の研究では単一の農薬と関連するパイオマーカーの評価は行われておらず、定量的な統合は行われていない。

1980 年以前に生まれた北米の集団を対象とした最大の前向き研究(ID CH 073)では、出生前の p,p'-DDE の最高濃度(>60 mg/1)のみが、最低濃度(<15 mg/1)と比較して、7 歳時の身長低下と統 計的に有意に関連していることが報告された[調整係数(SE) -2.21 cm (0.67)]。残りの研究では、 効果の方向性または効果量に一貫したパターンがなく、相反する結果が報告された。さらに、メタアナ リシスは確認されなかった。多数の分析を考慮すると、これらの結果は慎重に解釈する必要があり、こ れらのデータに基づいて、農薬ばく露と出生時の体長または身長の間に、妥当で臨床的に有意な関連 を示唆する最近のエビデンスはない。

#### 9.3.2. 体重

妊娠期の農薬ばく露と出生時体重との関連を評価した研究は 26 件あり、データベースには 134 件 の個別抽出比較が掲載されている。他の 5 件の研究では、農薬とポンデラル指数との関連を評価した。 多くの比較では、バイオマーカーを用いてばく露が評価された。個々の農薬の評価は多種多様で、DDT の代謝物の評価がより頻繁に行われた(11 研究)。しかし、同じ比較単位を使用した 4 件以上の研 究では、単一の農薬と関連するバイオマーカーの評価は行われず、定量的な統合は行われなかった。最 大の前向き研究(ID CH 014)は農業健康研究(Agricultural Health Study: AHS)の論文で、妊娠3ヶ 月までの農薬関連作業は出生時体重とは関連しておらず、複数回の分析の結果、カルバリル農薬の使 用があった場合は出生時体重の減少と関連していた(-82 g、95% CI = -132, -31)と報告された。残 りの研究では、効果の方向性や効果量に一貫したパターンがなく、相反する結果が報告された。さら に、発表された研究のメタアナリシスは確認されなかった。しかし、我々はp,p<sup>´</sup>-DDEの1µg/Lの増加は 出生時体重の7gの減少(95% CI = -18, 4g)と関連していた(Govarts E 2012)ことを報告したヨーロ ッパのコホートの個々の参加者のデータのメタアナリシスを同定した。分析の数が多いことを考える と、これらの結果は慎重な解釈が必要であり、これらのデータに基づくと、農薬ばく露と出生体重との 間の妥当で臨床的に有意な関連を示唆する最近のエビデンスはない。

#### Ntzani EE, Chondrogiorgi M, Ntritsos G, Evangelou E, Tzoulaki I Pesticide epidemiology

DDE was associated with a 7-g decrease in birth weight (95% CI= -18, 4 g) (Govarts E 2012). Given the large number of analyses these results need cautious interpretation and, based on these data, there is no recent evidence to suggest a robust, clinically significant association between pesticide exposure and birth weight in general.

Twenty-six studies assessed the association between pesticide exposure and body weight at various time-points after birth, contributing 68 separate extracted comparisons in the database. In almost 85% of the assessed comparisons, the exposure was assessed through a biomarker. A large variety of individual pesticides were assessed with DDT metabolites being assessed more frequently (10 studies). Nevertheless no single pesticide and related biomarker was assessed in more than 4 studies using the same outcome definition, the same time-point for the outcome assessment, the same pesticide, and the same comparison unit, thus a quantitative synthesis was not performed. The largest study (ID CH 074) assessing DDT exposure in a Mexican population of boys born in 2002 and 2003, reported that, overall, associations between prenatal DDE level and Body Mass Index (BMI) at any given age were not observed and that the predicted values showed that children with the highest exposure (DDE: 49.00 mg/g) compared to those least exposed (DDE: <3.01 mg/g) grew similarly and they had a BMI similar to the referent group. The remaining studies reported conflicting results without a consistent pattern either towards the effect direction or the effect magnitude. Moreover, no meta-analysis was identified. Given the large number of analyses these results need cautious interpretation and, based on these data, there is no recent evidence to suggest a robust, clinically significant association between pesticide exposure and body weight in general.

## 9.3.3. Head circumference

Fourteen and three studies assessed the association between pesticide exposure during pregnancy and head circumference at birth and after birth, respectively, contributing 85 separate extracted comparisons in the database. In more than two-thirds of the comparisons, the exposure was assessed through a biomarker. A large variety of individual pesticides were assessed for birth head circumference, with DDT metabolites being assessed more frequently (7 studies). Nevertheless no single pesticide and related biomarker was assessed in more than 4 studies using the same comparison unit, thus a quantitative synthesis was not performed. The largest prospective study (ID CH 026) was a Generation R study publication which explored associations between maternal occupational exposure to various chemicals and fetal growth in 4,680 pregnant women participating in this population-based prospective cohort study in the Netherlands (2002-2006). For fetal head circumference, only maternal occupational exposure to alkylphenolic compounds showed a statistically significant lower growth rate (-0.01752 SD per gestational week) compared with nonexposed mothers, adjusted for potential confounders. The remaining studies reported conflicting results without a consistent pattern either towards the effect direction or the effect magnitude. Moreover, no meta-analysis of published studies was identified. Given the large number of analyses the reported study results need cautious interpretation and, based on these data, there is no recent evidence to suggest a robust, clinically significant association between pesticide exposure and head circumference in general.

#### 9.3.4. Congenital malformations

Five studies examined the association between pesticide exposure and congenital malformations in general. The largest study (ID CH 002) assessed a Canadian farm population, reported 146 potential associations, did not yield statistically significant results in the primary analysis and proposed that pre-

### Ntzani EE, Chondrogiorgi M, Ntritsos G, Evangelou E, Tzoulaki I

Pesticide epidemiology

26件の研究が、出生後の様々な時点での農薬ばく露と体重との関連を評価しており、データベース には68件の個別の比較が抽出された。評価された比較のほぼ85%では、バイオマーカーを介してばく 露が評価された。個々の農薬の評価は多岐にわたり、DDT代謝物の評価がより頻繁に行われた(10研究)。 しかし、同じ定義の影響、同じタイムポイントでの影響評価、同じ農薬、同じ比較単位を使用した4件 以上の研究において評価された単一の農薬とそれに関連するバイオマーカーはなく、定量的な統合は 行われなかった。2002年と2003年に生まれたメキシコの男子集団におけるDDTばく露を評価した 最大の研究(ID CH 074)では、全体的に、出生前のDDEレベルと任意の年齢におけるBMI(Body Mass Index)との間の関連は観察されず、予測値は、最も高いばく露量(DDE: 49.00 mg/g)の小児と最も低 いばく露量(DDE: <3.01 mg/g)の小児とでは発育が似通っており、BMIは参照グループと同程度であ ったことを示した。残りの研究では、効果の方向性や効果量に一貫したパターンがなく、相反する結果 が報告された。さらに、メタアナリシスは確認されなかった。分析数が多いことから、これらの結果は 慎重な解釈が必要であり、これらのデータに基づいて、農薬ばく露と体重との間に臨床的に有意な関 連を示唆する最近のエビデンスはない。

## 9.3.3. 頭囲

妊娠期の農薬ばく露と出生時及び出生後の頭囲との関連を評価した研究はそれぞれ 14 件と 3 件 あり、データベースには 85 件の個別比較が抽出されている。3 分の 2 以上の比較では、バイオマー カーを用いてばく露が評価されていた。出生時の頭囲については、多種多様な農薬が評価されており、 中でも DDT 代謝物がより頻繁に評価されていた (7 研究)。それにもかかわらず、同じ比較単位を用 いた 4 件以上の研究では、単一の農薬と関連するバイオマーカーの評価は行われず、定量的な統合は 行われていない。最大の前向き研究 (ID CH 026) は、オランダの集団ベースの前向きコホート研究 (2002-2006) に参加した 4,680 人の妊婦を対象に、様々な化学物質への母親の職業ばく露と胎児の 発育との関連を調査したジェネレーション R 研究の出版物である。胎児頭囲については、アルキルフ ェノール化合物への母親の職業ばく露のみが、潜在的な交絡因子を調整した上でばく露していない母 親と比較して統計的に有意に低い成長率(妊娠週あたり-0.01752 SD)を示した。残りの研究では、効 果の方向性や効果量に一貫したパターンがなく、相反する結果が報告されている。さらに、発表された 研究のメタアナリシスは確認されなかった。分析数が多いことを考えると、報告された研究結果は慎 重に解釈する必要があり、これらのデータに基づいて、農薬ばく露と頭囲との間に臨床的に有意な関 連を示唆する最近のエビデンスはない。

## 9.3.4. 先天性奇形

5件の研究では、農薬ばく露と先天性奇形全般との関連が調査された。最大の研究(ID CH 002) はカ ナダの農場の集団を評価し、146の潜在的な関連を報告したが、主要分析では統計的に有意な結果は得 られず、シアナジン(OR = 4.99、95%CI:1.63-15.27) 及びジカンバ(OR = 2.42、95%CI:1.06-5.53) への妊娠前のばく露が、男児の先天性奇形のリスクの増加と関連していることが提案された。それに もかかわらず、利用可能な比較研究の数及び本研究におけるばく露と影響が自己報告であることを考 慮すると、今回の知見は慎重に調査されるべきである。残りの4件の後ろ向き研究では、相反する結果 が報告された(ID CH 043、職業ばく露(父親)、OR: 3.42、95% CI:1.97-5.92; ID CH 035、少な くとも片方の親の職業ばく露、OR = 1.3、95%CI = 0.4-3.9; ID CH 008、母体の尿中メトラクロルの HR、95% 0.4-1.4)。)多数の分析を考慮すると、これらの結果は慎重な解釈が必要であり、これらの

Pesticide epidemiology

conception exposure to cyanazine (OR = 4.99, 95% CI: 1.63–15.27) and dicamba (OR = 2.42, 95% CI: 1.06–5.53) were associated with increased risk of birth defects in male offspring. Nevertheless, given the number of the available comparisons and the self-reported nature of the exposure and outcomes in this study, the present findings should be considered with caution. The remaining four retrospective studies reported conflicting results (ID CH 043, occupational exposure (father), OR: 3.42, 95% CI: 1.97–5.92; ID CH 035, at least one parent exposed, OR = 1.3, 95%CI = 0.4 - 3.9; ID CH 008, HR for maternal urine metolachor, 95% 0.4-1.4). Given the large number of analyses these results need cautious interpretation and, based on these data, there is no recent evidence to suggest association between pesticide exposure and congenital malformations in general.

## 9.3.5. Neural tube defects

Identified studies examined associations between pesticide exposure and neural tube defects (N=4 studies), including anencephaly and spina bifida and providing a very large number of reported analyses between different pesticides and neural tube defects, anencephaly and spina bifida with no adjustments for multiple testing (average 27 analyses per paper). Out of the 134 extracted analyses, 43 were statistically significantly positively associated with the outcome (of which 14 borderline significant) but need to be interpreted with caution due to high false positive probability. The range of different pesticides analysed by each of the 5 studies as well as the varying definitions of pesticide exposure do not allow for a meaningful quantitative synthesis of the results even using the "any pesticide" exposure definition since there is also considerable heterogeneity between studies regarding the exposure period as well as the parent analysed; three studies assessed maternal exposure, one study assessed paternal exposure and one study both. Previous meta-analyses on neural tube defects and pesticide exposure have not been identified. Overall, the evidence for pesticides and neural tube defects is limited and the current state of the most recent literature does not support a robust association. Of note, the largest study in the field (ID CH 044) investigated whether maternal residential proximity to applications of specific pesticides or physicochemical groups of pesticides during early gestation increases the risk of these malformations, included 731 cases and 940 controls and after reporting 107 different analyses for individual pesticides, pesticide physicochemical categories and any exposure, no exposure and multiple exposure definitions yielded 15 statistically significant results without correction for multiple testing and without a particular pattern with regards to a pesticide category or an additive effect.

#### 9.3.6. Urogenital malformations

Overall, 19 studies examined urogenital malformations, namely cryptorchidism (n=9) and hypospadias (n=9).

Cryptorchidism was assessed in nine mostly retrospective studies, of a median sample size of 199 (IQR 136-710). Four studies assessed DDT levels; hexachorobenzene (HCB) and chrordane were assessed in one study each, while general pesticide exposure was assessed in 2 studies. When we attempted to investigate the association between exposure to any pesticide and cryptorchidism across all assessed studies, the observed effect was not statistically significant (OR 1.19, 95% CI 0.96 - 1.49,  $I^2$  24%) (Figure 23). Moreover, when we assessed the potential association between DDT exposure and cryptorchism, we again observed a statistically non-significant association (OR 1.47, 95% CI 0.98 - 2.2,  $I^2$  51%) (Figure 24). Given the large number of analyses, these results need cautious interpretation and, based on these data, there is no recent evidence to suggest a robust, clinically significant association between any pesticide exposure and cryptorchidism.

## EFSA supporting publication 2013:EN-497

The present document has been produced and adopted by the bodies identified above as author(s). This task has been carried out exclusively by the author(s) in the context of a contract between the European Food Safety Authority and the author(s), awarded following a tender procedure. The present document is published complying with the transparency principle to which the Authority is subject. It may not be considered as an output adopted by the Authority. The European Food Safety Authority reserves its rights, view and position as regards the issues addressed and the conclusions reached in the present document, without prejudice to the rights of the authors. データに基づいて、農薬ばく露と先天性奇形との関連を示唆する最近のエビデンスはない。

## 9.3.5. 神経管閉鎖障害

同定された研究では、農薬ばく露と無脳症や二分脊椎を含む神経管閉鎖障害との関連を調査しており(N=4研究)、種々の農薬と神経管閉鎖障害、無脳症、二分脊椎との間の分析が非常に多く報告されており、多重検定の調整は行われていない(1論文あたり平均27分析)。抽出された134の分析のうち、43の分析は結果と統計的に有意に関連していたが(うち14の分析は境界線上で有意であった)、偽陽性の確率が高いので注意して解釈する必要がある。5つの研究のそれぞれで分析された農薬の種類の多さと、農薬ばく露の定義の違いにより、ばく露期間や対象とした親に関しても研究間でかなりの不均一性があるため、「何らかの農薬」ばく露の定義を用いても、結果の意味のある定量的な統合を行うことはできない。神経管閉鎖障害と農薬ばく露に関するこれまでのメタアナリシスは確認されていない。 全体的に、農薬と神経管閉鎖障害に関するエビデンスは限られており、最新の文献の現状では、妥当な関連を支持するものではない。注目すべきは、この分野で最大の研究(ID CH 044)では、妊娠初期に特定の農薬または農薬の物理化学的グループの使用に母親が居住している場所に近いことが、これらの奇形のリスクを増加させるかどうかが調査され、731例と940例の対照が含まれ、個々の農薬、農薬の物理化学的カテゴリー、任意のばく露、ばく露なし、多重はく露の定義について107の異なる分析を報告した後、多重試験の補正なして、農薬のカテゴリーまたは相加効果に関して特定のパターンを持たない15の統計的に有意な結果が得られたことである。

## 9.3.6. 泌尿生殖器の奇形

全体では、19件の研究で泌尿生殖器の奇形、すなわち停留精巣(n=9)と尿道下裂(n=9)が調査された。

停留精巣は9件の研究で評価されたが、そのうちの9件はほとんどが後ろ向き研究であり、サンプルサ イズの中央値は199件(IQR 136-710)であった。4件の研究ではDDTレベルが評価され、ヘキサクロロベ ンゼン(HCB)とクロルデンはそれぞれ1件ずつ評価され、一般的な農薬はく露は2件の研究で評価され た。評価したすべての研究で、いずれかの農薬へのばく露と停留精巣との関連を調査しようとしたと ころ、観察された影響は統計的に有意ではなかった(OR 1.19、95%CI 0.96~1.49、I2 24%)(図 23)。 さらに、DDTばく露と停留精巣との間の潜在的な関連を評価したところ、再び統計的に有意ではない関 連が観察された(OR 1.47、95% CI 0.98~2.2、I2 51%)(図 24)。多数の分析を考慮すると、これら の結果は慎重に解釈する必要があり、これらのデータに基づいて、あらゆる農薬ばく露と停留精巣と の間に、臨床的に有意な関連を示唆する最近のエビデンスはない。

尿道下裂は主に9件の後ろ向き研究で評価され、サンプルサイズの中央値は784人(IQR 200 - 861) であった。2件の研究ではDDTレベルが評価され、6件の研究では農薬はく露一般が評価された。評価さ れたすべての研究において、何らかの農薬への母親のばく露(妊娠前及び妊娠期)と尿道下裂との関連 を調査しようとしたところ、観察された影響は統計的に有意ではなかった(OR 1.02、95%CI 0.74-1.39、I2 72%)(図25)。特定の農薬を評価した3つの研究(DDT、n=2;クロルデン、n=1)を分析 に含めると、再び統計的に有意でない関連が観察された(OR 1.00、95%CI 0.84-1.16、I2 66%)(図 26)。我々のシステマティックレビューでは、1966年1月から2008年3月までに英語で出版され、PubMed に索引付けされたオリジナルの研究を含む1つのメタアナリシスを検索した(Rocheleau CM, 2009)。 2007年以前に発表された9件の研究がすべての研究の包含基準を満たしており、著者らは、尿道下裂の

#### Ntzani EE, Chondrogiorgi M, Ntritsos G, Evangelou E, Tzoulaki I Pesticide epidemiology

Hypospadias was assessed in 9 mostly retrospective studies, of a median sample size of 784 (IQR 200

- 861). Two studies assessed DDT levels, while general pesticide exposure was assessed in 6 studies. When we attempted to investigate the association between maternal exposure to any pesticide (during preconception and pregnancy) and hypospadias across all assessed studies, the observed effect was not statistically significant (OR 1.02, 95% CI 0.74 – 1.39,  $I^2$  72%) (Figure 25). When we included in the analysis the three studies that assessed a specific pesticide (DDT, n=2; chrordane, n=1), we again observed a statistically non-significant association (OR 1.00, 95% CI 0.84-1.16, I<sup>2</sup> 66%) (Figure 26). Our systematic review retrieved one meta-analysis including original research published in English and indexed in PubMed from January 1966 through March 2008 (Rocheleau CM, 2009). Nine studies published before 2007 met all study inclusion criteria and the authors reported that elevated but marginally significant risks of hypospadias were associated with maternal occupational exposure (PRR of 1.36, CI=1.04-1.77), and paternal occupational exposure (PRR of 1.19, CI=1.00-1.41). Due to the different time-periods for the literature assessment and the resulting minimal overlap between our review and the published meta-analysis, we were able to synthesize the two efforts and again we retrieved a statistically non-significant result (OR 1.14, 95% CI 0.84 – 1.55, I<sup>2</sup> 73%). Thus, there is no recent evidence to suggest a robust, clinically significant association between any pesticide exposure and cryptorchidism.

#### 9.4. Child health outcomes with few studies

For all the assessed outcomes not included in Table 10, too few studies are available to allow synthesis of evidence for each outcome alone; these outcomes comprise a vast variety of captured information ranging from well-defined clinical entities yet with too few studies, such as gastroschisis, cardiac birth defects, diaphragmatic hernia, and esophageal atresia, as well as a large numbers of metrics pertaining to broad clinical entities but with a prominent lack of harmonization and standardization in the outcome definition. For example, outcomes related to neurodevelopment were assessed extensively; nevertheless the metrics used, ranging from IQ measurement to perceptual reasoning, deemed any further attempt towards a quantitative synthesis impossible. Our systematic review did not identify any previously published meta-analyses on these outcomes to allow for comparisons with previously published evidence (prior to 2006). Generally the results on these outcomes were of small effect and not statistically significant with few exceptions. Given the large number of analyses these results need cautious interpretation and, based on these data, there is no evidence to suggest association between pesticide exposure and these outcomes.

## Ntzani EE, Chondrogiorgi M, Ntritsos G, Evangelou E, Tzoulaki I

Pesticide epidemiology

リスクの上昇は、母親の職業ばく露(PRR1.36、CI=1.04-1.77)及び父親の職業ばく露(PRR1.19、CI=1.00-1.41)と関連していたが、わずかに有意であったと報告している。異なる期間に文献評価した結果とし て、我々のレビューと発表されたメタアナリシスとの重複が最小限であったために、我々は2つの成果 を統合することができ、再び我々は統計的に有意ではない結果を取得した(OR 1.14、95%CI 0.84 -1.55、I2 73%)。このように、いかなる農薬ばく露と停留精巣との間に、妥当で臨床的に有意な関連 を示唆する最近のエビデンスはない。

## 9.4. 研究が少ない小児健康影響

Table 10にはない健康影響には、個々の健康影響のエビデンスの統合には研究数が少なすぎるもの がある。すなわち、これらの健康影響には、腹壁裂、心臓先天異常、横隔膜ヘルニア、食道閉鎖症など のような明確に定義されてはいるが研究数が少ない臨床所見から、広範な臨床所見に関連する多数の 指標からなるが健康影響の定義の一致と標準化が著しく欠如しているものまで、多種多様な情報が収 集されている。例えば、神経発達に関連した健康影響は広範囲に評価されているが、IQ測定から知覚推 論に至るまで使用されている指標は、定量的な統合を目指したさらなる試みは不可能であると考えら れた。我々のシステマティックレビューでは、以前に発表されたエビデンス(2006年以前)との比較を 可能にするために、これらの健康影響に関する以前に発表されたメタアナリシスは確認されなかった。 一般的に、これらの健康影響に関する結果は効果量が小さく、統計的に有意ではなかった(少数の例外 を除く)。分析数が多いことを考えると、これらの結果は慎重に解釈する必要があり、これらのデータ に基づいて、農薬ばく露とこれらの影響との関連を示唆するエビデンスはない。

 Table 10:
 Assessed outcomes in the field of child health as defined by eligible studies

Pesticide epidemiology

Health outcome		
Abnormal urogenital distance	Body mass index (BMI) Z-score	Increased serum prolactin levels
Abnormal body mass index (BMI)	Body fat percentages (log transformed)	Increased serum total testosterone leve
Abnormal bone age	Chordee	IQ
Abnormal breast size	Coarctation of the aorta	LH dysregulation
Abnormal change of body mass index	Congenital diaphragmatic hernia (CDH)	Low annual height velocity
Abnormal change of height	Congenital heart defects	Major congenital anomalies
Abnormal chest circumference	Congenital malformations	Male genital malformations
Abnormal gestational age	Cretinism	Maternal age
Abnormal head circumference-for-age	Crown-Heel Length	Maternal weight gain
Abnormal height	Cryptorchidism	Miscarriage or stillbirth
Abnormal hip circumference	Decreased inhibin B levels	Musculoskeletal defects
Abnormal length	Decreased serum FSH levels	Neural tube defects
Abnormal ovarian measurements	Decreased serum inhibin B levels	Obesity
Abnormal penis length (stretched)	Decreased serum SHBG levels	Oestradiol dysregulation
Abnormal penis width	Decreased testicular volume	Perceptual Reasoning
Abnormal serum DHT levels	Decreased testosterone levels	Performance IQ
Abnormal sitting height	Decresed serum LH levels	Ventricular septal defect
Abnormal standing height	Duration of lactation	Placental weight
Abnormal Tanner stage	Esophageal atresia	Placental weight
Abnormal upper arm circumference	Fetal death	Ponderal Index
Abnormal upper arm fold circumference	Fetal head circumference	Ponderal index
Abnormal uterine measurements	Fetal length	Precocious puberty
Abnormal waist circumference	Fetal weight	Preeclampsia
Abnormal weight	FGR	Premature breast development
Abnormal weight-for-length	Freedom from distractability	Premature oestradiol secretion
Affected breast development	FSH dysregulation	Premature puberty onset (pubic hair)
Anal position index	Gastroschisis	Prematurity
Androstendione dysregulation	Gestational age	Processing speed
Anencephaly	Gynecomastia	Rapid infant weight gain
Anti-mullerian hormone dysregulation	Head Circumference	SGA
APGAR 1-minute score	Hypospadias	SHC
APGAR 5-minute score	Idiopathic precocious puberty	Spina bifida
Atrioventricular septal defect	Increased FSH levels	Sum of four skin folds
Birth head circumference	Increased levels of SHBG	Testosterone dysregulation

アンドロステンジオンの調節障害     在胎月齢     処理速度       無脳症     女性化乳房     乳幼児の急激な体重増加       抗ミュラーホルモンの調節障害     頭囲     SGA       APGAR 1分間のスコア     尿道下裂     S H C       APGAR 5分間のスコア     特発性早熟性思春期     二分脊椎       房室中隔欠損症     FSH 値の上昇     皮下脂肪計測       出生時の頭囲     6     アムトステロンの調節障害	乳房の発達への影響	FSH の調節障害	思春期早発症(陰毛)
無脳症         女性化乳房         乳幼児の急激な体重増加           抗ミュラーホルモンの調節障害         頭囲         SGA           APGAR 1分間のスコア         尿道下裂         S H C           APGAR 5分間のスコア         特発性早熟性思春期         二分育椎           房室中隔欠損症         FSH 値の上昇         皮下脂肪計測           出生時の頭囲         6         アムトステロンの調節障害	Anal position index	腹壁裂	未熟児
抗ミュラーホルモンの調節障害     頭囲     SGA       APGAR 1 分間のスコア     尿道下裂     S H C       APGAR 5 分間のスコア     特発性早熟性思泰期     二分脊椎       房室中隔欠損症     FSH 値の上昇     皮下脂肪計測       出生時の頭囲     SHG の増加     テストステロンの調節障害	アンドロステンジオンの調節障害	在胎月齡	処理速度
APGAR 1分間のスコア         尿道下裂         SHC           APGAR 5分間のスコア         特発性早熟性思春期         二分脊椎           房室中隔欠損症         FSH 値の上昇         皮下脂肪計測           出生時の頭囲         SHBG の増加         テストステロンの調節障害	無脳症	女性化乳房	乳幼児の急激な体重増加
APGAR 5 分間のスコア         特発性早熟性思春期         二分脊椎           房室中隔欠損症         FSH 値の上昇         皮下脂肪計測           出生時の頭囲         SHBG の増加         テストステロンの調節障害	抗ミュラーホルモンの調節障害	頭囲	SGA
房室中隔欠損症         FSH 値の上昇         皮下脂肪計測           出生時の頭囲         SHBG の増加         テストステロンの調節障害	APGAR 1 分間のスコア	尿道下裂	SHC
出生時の頭囲 SHBG の増加 テストステロンの調節障害 (1)	APGAR 5分間のスコア	特発性早熟性思春期	二分脊椎
	房室中隔欠損症	FSH 値の上昇	皮下脂肪計測
出生時の体長 LH/テストステロン比率の増加 ファロー四徴症	出生時の頭囲	SHBG の増加	テストステロンの調節障害
	出生時の体長	LH/テストステロン比率の増加	ファロー四徴症

Birth height	Increased ratio LH/testosterone	Tetralogy of Fallot
Birth Weight	Increased serum AMH levels	Transposition of the great arteries
Birth weight, adjusted for gestational age	Increased serum androstenedione levels	Verbal comprehension
BMI	Increased serum DHEAS levels	Verbal IQ
BMI at delivery	Increased serum free testosterone level	Working memory

Pesticide epidemiology

出生時体重	血清 AMH 値の上昇	大動脈の転換
出生時体重、在胎月齢で調整	血清アンドロステンジオン値	言語理解
	の上昇	
BMI	血清 DHEAS 値の上昇	言語性 IQ
出産時の BMI	血清遊離テストステロン値の	ワーキングメモリ
	上昇	
妊娠前の BMI

## 10. Reproductive diseases

Overall, 63 publications examined the effect of pesticide exposure on child health outcomes (median sample size: 299; IOR 111-544), contributing 578 separate analyses in the data extraction database. More than one third of the analyses (n=217, 38%) assess the sperm/semen quality, whereas other cluster of studies/analyses examine among others reproductive related hormones, infertily and spontaneous abortion As seen with other outcomes, the diversity of the exposure definition is remarkable and poses special challenges to data synthesis. Only 4 out of the 64 were prospective cohort studies whereas the vast majority of the studies were cross sectional (n=45, 70%). The sample size in the reported analyses was rather small; it ranged between 41 and 29,649 participants (median 161) and the largest studies in the domain are smaller than the largest studies assessed in the cancer field. Here, we observed a cluster of publications coming from INUENDO (INUit-ENDOcrine) research group (n=8), a project that has been established in three European countries together with a population of Inuits from Greenland and aims to enlighten the impact of Persistent Organic Pollutants (POPs) on human reproductive function. Almost 2/3 of the studies were conducted in Europe and America (n=22 and 20 respectively). Twenty-two studies assessed occupational exposures and, in addition, more than half of the studies had information on biomarkers of exposure (n=38, 59%), 3 studies assessed occupational exposure through Job Exposure Matrix (JEM), whereas 2 studies used both questionnaires and biomarkers. The different outcome categories examined are presented in Table 12 along with the number of studies contributing to each outcome category and a decision on quantitative synthesis. Due to heterogeneity of data, statistical synthesis of the data (meta-analysis) was only performed for abortion.

#### 10.1. Impaired sperm parameters

Twenty-five studies (median 189: IQR 87-336) assessed the association of pesticides on sperm/semen quality using a variety of outcomes. The total analyses conducted for these outcomes are 217 and the sample size of the conducted analyses is small ranging from 41 to 763. The largest study is a European cross-sectional study from INDUENDO research group (ID RPD 009) and assess the impact of p,p'-DDE to sperm concentration, sperm motility and sperm morphology and showed that the sperm motility was negatively associated with p,p'-DDE across the four populations under study. Another large study from the same group (ID RPD 012) did not provide evidence that Persistent Organic Pollutants (POPs) may interfere with male reproductive function. Even though a large number analyses have been conducted no single pesticide and related biomarker was assessed in more than 4 studies using the same comparison unit and analysis, thus a quantitative synthesis was not performed.

#### 10.2. Fecundability disorders

Eight studies including 30 different analyses assess the effect of pesticides on low fecundability. The sample sizes are rather small ranging from 41 to 2,365 participants. Different effect sizes and analyses are used for the assessment of potential associations therefore the synthesis of the results through meta-analysis is not feasible. The largest study (ID RPD 038) that examined pesticide exposure of female greenhouse farm workers reported a reduced fecundability (OR=0.68, 95% CI=0.49-0.94). However the second largest study in the field (ID RPD 034) on female greenhouse farm workers did not shown a significant association (OR=1.11, 95%CI=0.96-1.29). Fourteen additional analyses did not report significant findings; therefore the evidence is contradictory in the field.

EFSA supporting publication 2013:EN-497

59

#### 10. 生殖疾患

全体では、63の論文が農薬ばく露の小児健康影響を調査しており(サンプルサイズ中央値:299、IQR 111-544)、データ抽出データベースには578の個別の分析が含まれていた。分析の3分の1以上(n=217、 38%)が精子/精液の質を評価しているのに対し、他の研究/分析では生殖関連ホルモン、不妊、自然流 産などを評価している。他の影響に見られるように、ばく露の定義の多様性は顕著であり、データ統合 に特別な問題を与えている。64件のうち4件のみが前向きコホート研究であり、大多数の研究は横断研 究であった(n=45、70%)。報告されている分析のサンプルサイズはかなり小さく、41人から29,649人 の範囲であった(中央値161)。この領域での最大の研究は、がん分野で評価された最大の研究よりも 小規模である。ここでは、グリーンランドのイヌイットの集団とともにヨーロッパ3カ国で設立された プロジェクトであるINUEND0(INUIt-ENDOcrine)研究グループ(n=8)からの出版物を調査した。研究 のほぼ3分の2がヨーロッパとアメリカで実施された(それぞれn=22と20)。22件の研究が職業ばく露を 評価し、さらに半数以上の研究がばく露のバイオマーカーに関する情報を有し(n=38,59%)、3件の研 究が職業ばく露を職業ばく露マトリックス(JEM)で評価し、2件の研究が質問紙とバイオマーカーの両 方を使用した。調査した異なる影響カテゴリーを、各カテゴリーに寄与した研究の数と定量的統合の 決定とともに表12に示した。データの不均一性のため、データの統計的統合(メタアナリシス)は流産 についてのみ実施された。

## 10.1 障害のある精子パラメータ

25件の研究(中央値189件:IQR 87-336)が、様々な影響を用いて農薬と精子/精液の質との関連を 評価した。これらの結果について実施された分析の総数は217件で、実施された分析のサンプルサイズ は41~763件と小規模である。最大の研究はINDUENDO研究グループによるヨーロッパの横断研究(ID RPD 009)で、p,p'-DDEの精子濃度、精子運動性、精子形態への影響を評価し、精子運動性は研究対象 の4つの集団においてp,p'-DDEと負の関係があることが示された。同じグループによる別の大規模研 究(ID RPD 012)では、残留性有機汚染物質(POPs)が男性の生殖機能を阻害する可能性のエビデンス は示されていない。多数の分析が行われたにもかかわらず、同じ比較単位と分析を用いた4件以上の 研究では、単一の農薬と関連するバイオマーカーは評価されていないため、定量的な統合は行われな かった。

## 10.2 生殖能障害

30種類の分析を含む 8件の研究が、低生殖能に対する農薬の影響を評価している。サンプルサイズ は 41 から2,365 人とかなり小さい。潜在的な関連の評価には異なる効果量と分析が使用されている ため、メタアナリシスによる結果の統合は不可能である。温室栽培農場の女性労働者の農薬ばく露を 調査した最大規模の研究(ID: RPD 038)では、生殖能の低下が報告された(OR=0.68、95% CI=0.49-0.94)。しかし、温室栽培農場の女性労働者を対象とした2番目に大きなフィールド研究(ID RPD 034) では、有意な関連は示されなかった(OR=1.11、95%CI=0.96-1.29)。14の追加分析では有意な結果は報 告されなかったため、フィールド調査ではエビデンスが矛盾している。

The present document has been produced and adopted by the bodies identified above as author(s). Pesticide epidemiology

60

#### 10.3. Spontaneous abortion

Ten studies of spontaneous abortion focused on occupational exposure. We were able to synthesize data from six studies that provided an effect estimate and a metric of its variation. The summary OR was 1.52 (95%: 1.09-2.13) using random effects models and large heterogeneity was observed (I<sup>2</sup>=63%) (Figure 27). However, the largest cross-sectional study on this outcome conducted by the INUENDO research group (ID RPD 003) did not shown any statistical effect (OR=1) between p,p'-DDE and abortion. One more study compared full-time vs. part time farming and did not report a significant association (p-value=0.99). Three other studies did not provide adequate information for their inclusion in the meta-analysis.

## 10.4. Reproductive hormones

Nineteen studies (median sample size 257: IQR 97-322) contributing with 250 analyses for various reproductive hormones were identified in this systematic review. The studies were comparable to the other large group of impaired sperm parameters sample size-wise; their range was from 62 to 887. The largest study is a European cross-sectional study that assess the effect of hexachlorobenzene on the levels of testosterone and estradiol. Hormonal status of 14- to 15- year-old male adolescents was studies in relation to internal exposure to pollutants. The study shows that the exposure is associated with substantial differences in hormone concentrations. Different patterns were observed in study conducted by the INUENDO research group where the overall analysis between DDE and reproductive related hormones did not reveal any significant results. However in center-specific analysis, gonadotropin levels and sex-hormone-binding globulin seem to be affected by exposure on p,p'-DDE supporting substantial variations between different populations. The large variety of outcomes and pesticides assessed did not allow for any quantitative synthesis of the data.

#### 10.5. Reproductive outcomes with few studies

For all the assessed outcomes not included in Table 12, assessment of menstrual cycles cannot allow synthesis of the available evidence. Our systematic review did not identify any previously published meta-analyses on these outcomes to allow for comparisons with previously published evidence (prior to 2006). Results on different menstrual outcomes showed that it is unlikely that exposure to DDE is a main cause of menstrual disturbances.

#### 10.3. 自然流産

自然流産に関する10件の研究では、職業ばく露に焦点が当てられていた。効果推定値とその変動の 指標を提供した6件の研究からデータを統合することができた。ランダム効果モデルを用いた要約0Rは 1.52 (95%:1.09-2.13) であり、大きな不均一性が観察された(I2=63%)(図27)。しかし、INUENDO 研究グループが実施したこの影響に関する最大の横断研究(ID RPD 003)では、p,p'-DDEの農業労働 と流産との間に統計的効果(OR=1)は示されなかった。さらに1つの研究では、フルタイムとパート タイムを比較したが、有意な関連は報告されていない(p値=0.99)。他の3つの研究では、メタア ナリシスに含めるのに十分な情報が得られなかった。

## 10.4 生殖ホルモン

このシステマティックレビューでは、様々な生殖ホルモンについて250の分析を行った19の研究(サ ンプルサイズ中央値257:IQR 97-322)が同定された。これらの研究は、精子障害パラメータに関する 他の大規模なグループのサンプルサイズに匹敵するものであり、その範囲は62から887までであった。 最大の研究は、テストステロンとエストラジオールのレベルに対するヘキサクロロベンゼンの影響を 評価したヨーロッパの横断研究である。14~15歳の男性青年のホルモン状態は、汚染物質への内部ば く露に関連して研究された。この研究では、ばく露はホルモン濃度の大きな差異と関連していること が示された。INUENDO研究グループが行った研究では、DDEと生殖関連ホルモンの全体的な分析では有 意な結果は得られなかったが、異なるパターンが観察された。しかし、センターごとの分析では、ゴナ ドトロピン濃度と性ホルモン結合グロブリンはp,p' -DDEばく露の影響を受けているようであり、母集 団間に大きなばらつきがあることが示唆された。評価された結果と農薬の種類が多いため、データの 定量的な統合はできなかった。

## 10.5.研究数が少ない生殖影響

表12に含まれていないすべての影響については、月経周期の評価では利用可能なエビデンスを統合 することができない。我々のシステマティックレビューでは、過去に発表されたエビデンス(2006年以 前)との比較を可能にするために、これらの影響に関する過去に発表されたメタアナリシスは確認し なかった。異なる月経影響に関する結果から、DDEへのばく露が月経障害の主な原因であるとは考えに くいことが示された。

#### 11. Neurological diseases

Overall, 60 publications examined the effect of pesticide exposure on neurological outcomes (median sample size: 390; IQR 246-781), contributing 573 separate analyses in the data extraction database. More than thirty health-related outcomes were assessed with the largest proportion focusing on Parkinson's disease with 32 studies (Table 13). As seen with other outcomes, the diversity of the exposure definition is remarkable and poses special challenges to data synthesis. Only 8 out of the 60 were prospective cohort studies and other 2 were nested case-controls; the majority of evidence comes from retrospective case-control analyses, which are prone to recall bias in exposure measurement. The sample size in the reported analyses was often small; it ranged between 46 and 143,325 participants (median 390) and the largest studies in the domain are smaller than the largest studies assessed in the cancer field. Here, we also observed large clusters of publications coming from large, well-known studies in the field, such as the Agricultural Health Study (AHS), while 43 studies assessed occupational exposures. In addition, the presence of studies with information on biomarkers of exposure was far less prominent here (n=7, 12%). The different outcome categories examined are presented in Table 13; due to the small number of studies identified per assessed outcome, statistical synthesis of the data (meta-analysis) was only performed for Parkinson's disease and amyotrophic lateral sclerosis

## 11.1. Parkinson's disease

Thirty-two studies assessed the association between pesticide exposure and Parkinson's disease with a median sample size of 399 (IQR 286-711), contributing 266 separate extracted comparisons in the database. Eighty percent of the retrieved studies assessed occupational exposures, only 10% were prospective and the exposure was assessed through a biomarker in a small number of studies (10%). A large variety of individual pesticides were assessed with the following pesticides being assessed more frequently: general pesticide (28 studies), as well as DDT (5 studies), paraquat (9 studies).

We initially assessed the association between general pesticide use and Parkinson's disease. The observed effect indicated a statistically significant association with the presence of considerable heterogeneity (random-effects OR 1.58, 95% CI 1.35 – 2.85, I<sup>2</sup> 61%) (Figure 28). With the exception of four studies where specific pesticides were assessed (e.g. paraquat), all the other studies assessed mainly occupational general pesticide use in mainly a retrospective fashion via a questionnaire. The results of the meta-analysis are in accordance with the largest studies on that research question.

We then proceeded to assess the association between DDT exposure and Parkinson's disease. The observed effect indicated a non-statistically significant association without the presence of heterogeneity (random-effects OR=1.01, 95% CI=0.78–1.30,  $I^2$ =0%) (Figure 29). Finally, we assessed the association between paraquat exposure and Parkinson's disease. The observed effect indicated a statistically significant association with the presence of moderate heterogeneity (random-effects OR=1.32, 95% CI=1.10–1.60,  $I^2$ =34%) (Figure 30). The results of the meta-analysis are in accordance with the largest studies on these research questions.

Our literature search yielded 7 systematic reviews and/or meta-analyses on the association between pesticide exposure and Parkinson's disease published from 2000 to 2013 (Pezzoli 2013, Van-Maele Fabry 2012, van der Mark 2012, Dick 2006, Priyadarshi 2001, Priyadarshi 2000, Allen 2013). Despite the considerable time interval between the oldest and most recent research synthesis effort and the different methodologies endorsed (prospective studies only assessed, methodological assessment of

62

#### 11. 神経疾患

Ntzani EE, Chondrogiorgi M, Ntritsos G, Evangelou E, Tzoulaki I

全体では 60 の論文が農薬ばく露の神経学的影響に及ぼす効果を調査しており(サンプルサイズ中央 値:390、IQR 246-781)、データ抽出データベースでは 573 件の個別分析が行われた。30 以上の健康 関連影響が評価されており、パーキンソン病に焦点を当てた研究が最も多く 32 件あった(表 13)。他 の影響に見られるように、ばく露の定義の多様性には目を見張るものがあり、データ統合に特別な問 題を与えている。60 件のうち 8 件のみが前向きコホート研究で、残りの 2 件はコホート内症例対照研 究であった。報告された分析におけるサンプルサイズはしばしば小さく、参加者数は 46~143,325 人 (中央値 390 人)であり、この領域における最大の研究は、がん分野で評価された最大の研究よりも 小規模であった。ここでは、農業健康調査(Agricultural Health Study: AHS)のようなこの分野の大 規模でよく知られた研究からの多くの出版物のまとまりも観察されたが、一方で 43 件の研究が職業ば く露を評価していた。さらに、ばく露のバイオマーカーに関する情報を持つ研究の存在は、ここではあ まり目立たなかった(n=7,12%)。評価された影響カテゴリーを表 13 に示す。評価された影響ごとに 同定された研究の数が少ないため、データの統計的統合(メタアナリシス)はパーキンソン病と筋萎縮 性側索硬化症についてのみ実施された。

## 11.1 パーキンソン病

農薬ばく露とパーキンソン病との関連を調査した研究は32件あり、サンプルサイズの中央値は399件 (IQR 286-711)で、データベースには266件の比較が抽出されている。検索された研究の80%は職業ば く露を評価していたが、前向き研究はわずか10%で、ばく露をバイオマーカーを介して評価した研究 は少数であった(10%)。個々の農薬の評価は多岐にわたったが、一般的な農薬(28件)、DDT(5件)、 パラコート(9件)などの農薬がより頻繁に評価されていた。

まず、一般的な農薬の使用とパーキンソン病との関連を評価した。観察された効果は、かなりの不均 一性が存在し、統計的に有意な関連を示した(ランダム効果0R 1.58、95%CI 1.35~2.85、I2 61%) (図 28)。特定の農薬を評価した 4 つの研究(例:パラコート)を除いて、他のすべての研究では、 主に質問紙による後ろ向きな方法で、主に職業上の一般的な農薬使用を評価している。メタアナリシ スの結果は、この研究の課題に関する最大の研究と一致している。

次に、DDTばく露とパーキンソン病との関連を評価した。観察された効果は、不均一性の存在なしに 統計学的に有意ではないことが示された(ランダム効果0R=1.01、95%CI=0.78-1.30、I2=0%)(図29)。 最後に、パラコートばく露とパーキンソン病との関連を評価した。観察された効果は、中等度の不均一 性の存在下で統計的に有意な関連を示した(ランダム効果0R=1.32、95%CI=1.10-1.60、I2=34%)(図 30)。メタアナリシスの結果は、これらの研究課題に関する最大規模の研究と一致している。

我々の文献検索では、2000年から2013年までに発表された農薬ばく露とパーキンソン病との関連に 関する7つのシステマティックレビュー及び/またはメタアナリシスが得られた (Pezzoli 2013, Van-Maele Fabry 2012, van der Mark 2012, Dick 2006, Priyadarshi 2001, Priyadarshi 2000, Allen 2013)。研究統合の最も古い取り組みと最新の取り組みとのかなりの時間的間隔、また、方法論(前向 き研究のみの評価、対象研究の方法論的評価など)の違いにもかかわらず、結果はメタアナリシス全体 で一貫しており、2006年からの現在の取り組みとも一致している(表14)。

The present document has been produced and adopted by the bodies identified above as author(s). This task has been carried out exclusively by the author(s) in the context of a contract between the European Food Safety Authority and the author(s), awarded following a tender procedure. The present document is published complying with the transparency principle to which the Authority is subject. It may not be considered as an output adopted by the Authority. Pesticide epidemiology

63

the included studies, etc.), the results are consistent across the meta-analyses and are also consistent with the present effort spanning from 2006 (Table 14).

#### 11.2. Amyotrophic lateral sclerosis (ALS)

Seven studies assessed the association between pesticide exposure and amyotrophic lateral sclerosis with a median sample size of 356 (IQR 201-1156), contributing 11 separate extracted comparisons in the database. All the retrieved studies assessed occupational exposures, while 4 also assessed residential exposure. Only one study was prospective and the exposure was assessed through a questionnaire in most of the studies (n=6).

We assessed the association between general pesticide use and ALS. The observed effect indicated a statistically significant association with the presence of small heterogeneity (fixed-effects OR=1.58, 95% CI=1.31 – 1.90, I<sup>2</sup> 10%) (Figure 31) and the results of the meta-analysis are in accordance with the largest studies on that research question.

Our literature search yielded 2 systematic reviews and/or meta-analyses on the association between pesticide exposure and ALS published in 2012 (Kamel 2012, Malek 2012). Regarding these efforts, the results are consistent with our findings and the authors' report of evidence on an association of exposure to pesticides and risk of ALS in male cases compared to controls (OR=1.88, 95% CI: 1.36-2.61), although the chemical or class of pesticide was not specified by the majority of studies.

#### 11.3. Neurological outcomes with few studies

With the exception of Parkinson's disease and amyotrophic lateral sclerosis, for all the remaining neurological outcomes, too few studies are available after 2006 to allow synthesis of evidence for each outcome alone; these outcomes comprise a vast variety of captured information ranging from well-defined clinical entities yet with too few studies, such as hearing loss or diabetic neuropathy, as well as a large number of metrics pertaining to neurological endophenotypes but with a prominent lack of harmonization and standardization in the outcome definition. Our systematic review did not identify any previously published meta-analyses on these outcomes to allow for comparisons with previously published evidence (prior to 2006). Generally the results on these outcomes were of small effect and not statistically significant with few exceptions. Given the large number of analyses these results need cautious interpretation and, based on these data, there is no evidence to suggest association between pesticide exposure and these outcomes.

## Ntzani EE, Chondrogiorgi M, Ntritsos G, Evangelou E, Tzoulaki I

## 11.2. 筋萎縮性側索硬化症(ALS)

7件の研究が農薬ばく露と筋萎縮性側索硬化症との関連を評価しており、サンプルサイズの中央値は 356 (IQR 201-1156)で、データベースには11件の個別の比較が抽出されている。検索されたすべての 研究は職業ばく露を評価しており、4つの研究は住居ばく露も評価していた。前向き研究は1件のみで、 ほとんどの研究では質問紙を用いてばく露を評価していた (n=6)。

我々は一般的な農薬使用とALSとの関連を評価した。観察された効果は、小さな不均一性(固定効果 OR=1.58、95%CI=1.31~1.90、I2 10%)の存在とともに統計的に有意な関連を示し(図31)、メタア ナリシスの結果は、その研究課題に関する最大の研究に沿ったものであった。

文献検索を行った結果、2012 年に発表された農薬ばく露と ALS の関連に関する 2 つのシステマティックレビュー及び/またはメタアナリシスが得られた(Kamel 2012, Malek 2012)。これらの結果によれば、大多数の研究では農薬の化学物質やクラスが特定されていなかったが、我々の知見や男性で対照と比較して農薬へのばく露とALSの関連を示すエビデンス(OR=1.88、95% CI: 1.36-2.61) についての著者らの報告と一致していた。

## 11.3. 研究数の少ない神経学的影響

パーキンソン病と筋萎縮性側索硬化症を除いて、残りのすべての神経学的影響については、2006年 以降の研究が少なすぎて、それぞれの影響だけでエビデンスを統合することができない。我々のシス テマティックレビューでは、2006年以前に発表されたエビデンスとの比較を可能にするために、これ らの影響に関する以前に発表されたメタアナリシスは確認されなかった。一般的に、これらの影響に 関する結果は効果が小さく、統計的に有意ではなかったが、少数の例外を除いては有意であった。分析 数が多いことを考えると、これらの結果は慎重に解釈する必要があり、これらのデータに基づいて、農 薬ばく露とこれらの影響との関連を示唆するエビデンスはない。

Pesticide epidemiology

72

### 12. Endocrine diseases

Overall, 35 publications examined the effect of pesticide exposure on thyroid hormone dysregulation (median sample size: 226; IOR 130-453), contributing 343 separate analyses in the data extraction database. The main outcomes assessed were thyroxin (T4), triiodothyronine (T3) and thyroid stimulating hormone (TSH) levels. Only 3 prospective cohort studies were conducted in the field; the majority of evidence comes from retrospective case-control or cross-sectional analyses, which are prone to recall bias in exposure measurement. The sample size in the reported analyses was often small; it ranged between 27 and 16,529 participants (median 341). Here, we observed no large clusters of publications coming from large, well-known studies in the field, while the vast majority of the studies assessed environmental exposures (n=28, 80%). However, the presence of studies with information on biomarkers of exposure was more prominent here (n=29, 83%). Even though hypothyroidism, hyperthyroidism and other thyroid diseases contribute with more than 1/3 of the total analyses (n=123) the available evidence derives from Agricultural Health Study (AHS) which apparently is the largest in the field and examines the association between pesticide use and thyroid diseases in females. The study found an association between hypothyroidism and ever use of organochlorine insecticides (OR=1.2, 95% CI= 1.0-16) and fungicides (OR=1.4, 95% CI= 1.1-1.8). However, the results should be interpreted with caution due to borderline significance levels and absence of type-I error corrections due to multiple comparisons. Other studies in the field assessing several thyroid hormone levels are quite smaller and provide contradictory results. As seen with other outcomes, the diversity of the exposure definition is remarkable and poses special challenges to data synthesis. Due to heterogeneity of data and different analyses, effect sizes and metrics provided, statistical synthesis of the data (meta-analysis) was not performed.

#### Ntzani EE, Chondrogiorgi M, Ntritsos G, Evangelou E, Tzoulaki I

#### 12. 内分泌疾患

全体では、35の出版物で農薬ばく露が甲状腺ホルモン調節障害に及ぼす影響が調査され(中央値サ ンプルサイズ226: IQR 130-453)、データ抽出データベースでは343の個別の分析が行われた。評価さ れた主な影響は、サイロキシン(T4)、トリヨードサイロニン(T3)、甲状腺刺激ホルモン(TSH)レ ベルであった。この分野で実施された前向きコホート研究は3件のみであり、エビデンスの大部分は後 ろ向き症例対照または横断分析によるものであるが、これらはばく露測定においてリコールバイアス がかかりやすい。報告されている分析におけるサンプルサイズはしばしば小さく、参加者数は27~ 16,529人(中央値341人)であった。ここでは、この分野でよく知られた大規模な研究からの出版物の 大きなクラスタは観察されず、大多数の研究は環境ばく露を評価していた(n=28、80%)。しかし、ば く露のバイオマーカーに関する情報を有する研究の存在は、ここではより多数であった(n=29、83%)。 甲状腺機能低下症、甲状腺機能亢進症、その他の甲状腺疾患が分析全体の1/3以上を占めているにもか かわらず(n=123)、利用可能なエビデンスは、この分野では明らかに最大規模で農薬使用と女性の甲 状腺疾患との関連を調査している農業健康調査 (Agricultural Health Study: AHS) に由来している。 この研究では、甲状腺機能低下症と有機塩素系殺虫剤(OR=1.2、95% CI=1.0-16)及び殺菌剤(OR=1.4、 95% CI=1.1-1.8)の使用歴との間に関連があることが明らかになった。しかし、この結果は、有意水準 の境界線上であったことと多重比較によるタイプIの誤差補正がないため、注意して解釈されるべきで ある。この分野でいくつかの甲状腺ホルモンレベルを評価している他の研究は非常に小規模であり、 矛盾する結果を示している。他の影響に見られるように、まちまちなばく露の定義に注目すべきであ り、データ統合に特別な問題を及ぼしている。データの不均一性と異なる分析、効果量及び指標の使用 のために、データの統計的統合(メタアナリシス)は行われていない。

Pesticide epidemiology

### 13. Mental and psychomotor development outcomes

Overall, 32 publications examined the effect of pesticide exposure on mental and psychomotor development outcomes in pediatric populations (median sample size: 238, IOR 109-305), contributing 462 separate analyses in the data extraction database. Only one study was performed in a population of non-European (Asian) ancestry, while seventeen health-related outcomes were assessed with a large proportion focusing on attention-deficit hyperactivity disorder (ADHD, 6 studies, 102 analyses). As seen with other outcomes, the diversity of the exposure definition is considerable and poses special challenges to data synthesis. A large majority of the studies (23 publications, 72%) referred to prospective cohort studies, while the sample size in the reported analyses was often small; it ranged between 25 and 7,440 participants with the largest study assessing retrospectively maternal residence near agricultural pesticide applications and autism spectrum disorders among children in the California Central Valley. Here, we also observed clusters of publications coming from large, well-known studies in the field, such as the CHAMACOS (The Center for Health Assessment of Mothers and Children of Salinas) (5 publications), while 84% of the studies assessed environmental exposures. In addition, the presence of studies with information on biomarkers of exposure was prominent here (n=28, 88%). The different outcome categories examined are presented in Table 15 along with the number of studies contributing to each outcome category and a decision on quantitative synthesis. Due to heterogeneity of data and small number of studies identified, no statistical synthesis of the data (meta-analysis) was performed for any outcome.

#### 13.1. Mental and psychomotor development outcomes with few studies

With the exception of mental and psychomotor development and Attention-deficit hyperactivity disorder (ADHD), for all the remaining assessed outcomes included in Table 15, too few studies are available to allow synthesis of evidence for each outcome alone; these outcomes comprise a variety of captured information ranging from well-defined clinical entities yet with too few studies, such as autism, or pervasive developmental disorder, as well as a vast number of outcomes representing neurodevelopmental endo-phenotypes such as communication, fine and gross motor development or expressive language development. Our systematic review did not identify any previously published meta-analyses on these outcomes to allow for comparisons with previously published evidence (prior to 2006). Generally the results on these outcomes were of small effect and not statistically significant with few exceptions. Given the large number of analyses and the small number of studies and sample sizes, these results need cautious interpretation and, based on these data, there is no evidence to suggest a robust association between pesticide exposure and these outcomes.

#### 13.2. Attention-deficit hyperactivity disorder (ADHD)

Six studies assessed the association between pesticide exposure and ADHD with a sample size ranging from 278 to 2,539 participants, contributing 102 separate extracted comparisons in the database. Three studies were cohorts, all assessed environmental exposure and in all the exposure was assessed through a biomarker. General organophosphate exposure was assessed in the extudies, DDT exposure in two studies, while trans-nonachlor, hexachlorobenzene, and 2,4,6-Trichlorophenol (TCP) were assessed in one study each. Thus, no single pesticide and related biomarker was assessed in more than 4 studies using comparable outcome definitions or the same comparison unit, thus a quantitative synthesis was not performed. The largest study in the field is a National Health and Nutrition Examination Survey (NHANES) report (ID 17) used data from the 1999-2004 NHANES to evaluate the association between urinary trichlorophenols (TCPs) and parent-reported ADHD among 2546 children aged 6-15 years. The authors report that children with low levels (<3.58 mg/g) and high levels EFSA supporting publication 2013:EN-497 73

## 13. 精神及び精神運動発達影響

全体では、32の出版物が小児集団における精神及び精神運動発達影響に対する農薬ばく露の影響を調 査しており(サンプルサイズ中央値:238、IQR 109-305)、データ抽出データベースでは462の個別の 分析が行われた。非ヨーロッパ系(アジア系)の集団を対象とした研究は1件のみであり、注意欠陥多 動性障害(ADHD、6件、102件の分析)を中心に17件の健康関連影響が評価されていた。他の影響に見ら れるように、ばく露の定義はかなりまちまちであり、データ統合に特別な問題をもたらしている。大多 数の研究(23の論文、72%)は前向きコホート研究を参考にしているが、報告されている分析における サンプルサイズはしばしば小さく、25~7,440人の範囲で、最大のものはカリフォルニア・セントラル バレーの小児における農薬散布付近の母親の居住と自閉症スペクトラム障害の後ろ向き研究であった。 ここで、我々はまた、CHAMACOS(サリナスの母と小児の健康評価センター)(5出版物)などの大規模 な、この分野でよく知られた研究から来ている出版物のクラスタを観察したが、研究の84%が環境ば く露を評価していた。さらに、ばく露のバイオマーカーに関する情報を有する研究の存在がここでは 多数であった(n=28、88%)。調査したさまざまな影響カテゴリーを、各カテゴリーに寄与した研究の 数と定量的統合の決定とともに表15に示す。データの不均一性と同定された研究数が少なかったため、 どの影響についてもデータの統計的統合(メタアナリシス)は行われなかった。

## 13.1. 研究が少ない精神及び精神運動発達影響

精神及び精神運動発達影響と注意欠陥多動性障害(ADHD)を除いて、表15に記載の影響はすべて、そ れぞれの影響だけでエビデンスを総合的に判断するには、利用可能な研究が少なすぎる。これらの影 響は、自閉症や広汎性発達障害のように研究数が少ないが適切に定義された臨床所見から、コミュニ ケーション、微細及び粗大な運動発達、または表現的言語発達などの神経発達の中間形質を表す多数 の影響まで収集されたさまざまな情報で構成されている。我々のシステマティックレビューでは、2006 年以前に発表されたエビデンスとの比較を可能にするために、これらの影響に関する以前に発表され たメタアナリシスは確認しなかった。一般的に、これらの影響に関する結果は影響が小さく、統計的に 有意ではなかったが、少数の例外はあった。分析数が多く、研究数やサンプル数が少ないことを考える と、これらの結果は慎重に解釈する必要があり、これらのデータに基づいて、農薬ばく露とこれらの影 響との間に妥当な関連を示唆するエビデンスはない。

## 13.2. 注意欠陥多動性障害(ADHD)

6件の研究では、278人から2,539人の参加者のサンプルサイズで農薬ばく露とADHDとの関連を評価し、 データベースに102件の別個に抽出された比較を提供した。3つの研究はコホートであり、すべての研 究は環境ばく露を評価し、すべての研究でばく露はバイオマーカーを介して評価された。一般的な有 機リン剤へのばく露は3つの研究で、DDTへのばく露は2つの研究で評価され、trans-ノナクロル、ヘキ サクロロベンゼン、2,4,6-トリクロロフェノール (TCP) はそれぞれ1つの研究で評価された。このよう に、同等の影響の定義または同一の比較単位を用いた4 つ以上の研究では、単一の農薬と関連するバ イオマーカーは評価されておらず、定量的な統合は行われなかった。この分野で最大の研究は、国民健 康・栄養調査(NHANES)の報告書(ID 17)で、1999年から2004年のNHANESのデータを使用して、6歳か ら15歳の小児2546人の間で尿中トリクロロフェノール (TCPs)と親が報告したADHDとの関連を評価し

Pesticide epidemiology

74

(>3.58 mg/g) of urinary 2,4,6-Trichlorophenol (TCP) had a higher risk of parent-reported ADHD compared to children with levels below the limit of detection (OR 1.54, 95% CI 0.97 to 2.43 and OR 1.77, 95% CI 1.18 to 2.66, respectively; p for trend=0.006) after adjusting for covariates.

Our systematic review did not identify any previously published meta-analyses on ADHD to allow for comparisons with previously published evidence (prior to 2006). Generally the results on ADHD were of small effect and not statistically significant with few exceptions. Thus, given the large number of analyses these results need cautious interpretation and, based on these data, there is no evidence to suggest association between pesticide exposure and ADHD.

#### 13.3. Neurodevelopment

Thirty-one studies assessed the association between pesticide exposure and aspects of neurodevelopment with a sample size ranging from 25 to 1,041 contributing 325 separate extracted comparisons in the database. Only one study assessed neurodevelopmental aspects in Asian children; all the rest pertained to populations of European ancestry. Seventy-four percent of the studies were cohort studies and, in 27 studies the exposure was assessed through a biomarker. A large variety of individual pesticides were assessed with the general category of organophosphate pesticides being assessed more frequently (Table 16). No single pesticide and related biomarker was assessed in more than 4 studies using comparable outcome definitions or the same comparison unit, thus a quantitative synthesis was not performed. Actually, the assessment of neurodevelopment, as seen for cognitive function, is another typical example of a general outcome category where the multiplicity and complexity of the 35 tools and sub-tools used (Table 17) renders the attempt to systematically and quantitatively synthesize the results of the published literature fruitless.

The largest study in the field is a Collaborative Perinatal Project report (ID MPD 029) assessing inutero exposure to dichlorodiphenyltrichloroethane and cognitive development among infants and school-aged children. The authors report that although levels of DDT and DDE were relatively high in this population (median DDT concentration, 8.9 g/L; DDE, 24.5 g/L), neither were related to Mental or Psychomotor Development scores on the Bayley Scales nor to Full-Scale Intelligence Quotient at 7 years of age.

Our systematic review did not identify any previously published meta-analyses on these outcomes to allow for comparisons with previously published evidence (prior to 2006). Generally the results on neurodevelopmental outcomes were of small effect and not statistically significant with few exceptions. Thus, given the large number of analyses these results need cautious interpretation and, based on these data, there is no evidence to suggest association between pesticide exposure and these outcomes.

The present document is published complying with the transparency principle to which the Authority is subject. It may not be considered as an output adopted by the Authority. The European Food Safety Authority reserves its rights, view and position as regards the issues addressed and the conclusions reached in the present document, without prejudice to the rights of the authors.

#### Ntzani EE, Chondrogiorgi M, Ntritsos G, Evangelou E, Tzoulaki I

ている。著者らの報告によると、尿中の2,4,6-トリクロロフェノール (TCP) の濃度が低値 (3.58 mg/g 未満)及び高値 (3.58 mg/g以上) の小児は、検出限界値未満の小児に比べて、親に報告されたADHDの リスクが高かった (OR 1.54、95%CI 0.97~2.43、OR 1.77、95%CI 1.18~2.66、それぞれpはトレン ド=0.006)。

我々のシステマティックレビューでは、以前に発表されたエビデンス(2006年以前)との比較を可能 にするために、ADHDに関する以前に発表されたメタアナリシスは確認しなかった。一般的にADHDに関 する結果は効果が小さく、少数の例外を除いて統計的に有意ではなかった。したがって、多数の分析を 考慮すると、これらの結果は慎重な解釈が必要であり、これらのデータに基づいて、農薬ばく露とADHD との関連を示唆するエビデンスはない。

## 13.3. 神経発達

31件の研究が農薬ばく露と神経発達の関連を評価しており、サンプルサイズは25~1,041で、データ ベースには325件の個別比較が掲載されている。アジア系の小児の神経発達を評価した研究は1件のみ であり、その他の研究はすべてヨーロッパ系の集団を対象としたものであった。研究の74%はコホー ト研究で、27の研究ではパイオマーカーを用いてばく露が評価されていた。個々の農薬の評価は多種 多様で、有機リン系農薬一般というカテゴリーがより頻繁に評価されている(表16)。比較可能な影響 の定義または同一の比較単位を用いた4件以上の研究では、単一の農薬と関連するバイオマーカーの 評価は行われていないため、定量的な統合は行われていない。実際、神経発達の評価は、認知機能に見 られるように一般的な影響カテゴリーのもう一つの典型的な例であり、使用されている35のツール とサブツールの多様性と複雑性(表17)は、公表されている文献の結果を体系的かつ定量的に統合し ようとする試みを無意味なものにしている。

この分野で最大の研究は、Collaborative Perinatal Projectの報告書(ID MPD 029)であり、ジク ロロジフェニルトリクロロエタンへの胎内ばく露と乳児及び学童期の小児の認知発達を評価している。 著者らの報告によると、この集団では DDT と DDE の濃度は比較的高かったが(DDT 濃度中央値 8.9 g/L、DDE 24.5 g/L)、7歳時のベイリー尺度の精神・精神運動発達スコアやフルスケール知能指数のい ずれにも関連していなかった。

我々のシステマティックレビューでは、2006年以前に発表されたエビデンスとの比較を可能にする ために、これらの結果に関する過去に発表されたメタアナリシスは確認しなかった。一般的に、神経発 達の影響に関する結果は、ほとんどの例外を除いて効果が小さく、統計的に有意ではなかった。したが って、多くの分析が行われたことを考えると、これらの結果は慎重に解釈する必要があり、これらのデ ータに基づいて、農薬ばく露とこれらの影響との関連を示唆するエビデンスはない。

#### 14. Respiratory diseases

Overall, 29 publications examined the effect of pesticide exposure on respiratory outcomes (median sample size: 249, IQR 126-1728), contributing 399 separate analyses in the *data extraction database*. Sixty-seven percent came from Europe and America, while ten health-related outcomes were assessed with a large proportion focusing on asthma (N=9). As seen with other outcomes, the diversity of the exposure definition is considerable and poses special challenges to data synthesis. Only 6 out of the 29 publications referred to prospective cohort studies and 12 were cross-sectional studies. The sample size in the reported analyses was often small; it ranged between 35 and 47,756 participants with the largest study being the Singapore Chinese Health Study. Here, we also observed large clusters of publications coming from large, well-known studies in the field, such as the AHS (6 publications), while 17 studies (68%) assessed occupational exposures. In addition, the presence of studies with information on biomarkers of exposure was less prominent here (N=8, 34%) while 1 study assessed occupational exposure through JEM. The different outcome categories examined are presented in Table 18 along with the number of studies contributing to each outcome category and a decision on quantitative synthesis. Due to heterogeneity of data and small number of studies identified, statistical synthesis of the data (meta-analysis) was only performed for asthma.

#### 14.1. Respiratory outcomes with few studies

With the exception of asthma, for all the remaining assessed outcomes included in Table 18, too few studies are available to allow synthesis of evidence for each outcome alone; these outcomes comprise a variety of captured information ranging from well-defined clinical entities yet with too few studies, such as idiopathic pulmonary fibrosis, or sarcoidosis, as well as a numbers of biomarkers such as forced expiratory volume (FEV). Our systematic review did not identify any previously published meta-analyses on these outcomes to allow for comparisons with previously published evidence (prior to 2006). Generally the results on these outcomes were of small effect and not statistically significant with few exceptions. Given the large number of analyses and the fact that most of the results come from the Agricultural Health Study (AHS), these results need cautious interpretation and, based on these data, there is no evidence to suggest a robust association between pesticide exposure and these outcomes.

## 14.2. Asthma

Nine studies assessed the association between pesticide exposure and asthma with a median sample size of 402 (IQR 127-724), contributing 196 separate extracted comparisons in the database. More than half of the studies were cross-sectional and in more than two-thirds of the studies, the exposure was assessed through a questionnaire. A large variety of individual pesticides were assessed with DDT, paraquat and chlorpyrifos being assessed more frequently. With the exception of DDT, chlorpyrifos and paraquat (Table 19), no other single pesticide and related biomarker was assessed in more than 4 studies using the same comparison unit, thus a quantitative synthesis was not performed.

When we attempted to investigate the association between exposure to DDT and asthma across the 5 available studies, the observed effect was statistically significant without indications of heterogeneity (OR 1.29, 95% CI 1.14 - 1.45, I<sup>2</sup> 0%) (Figure 32). We then attempted to investigate the association between exposure to paraquat and asthma across the 6 available studies and the observed effect was not statistically significant with indications of heterogeneity (OR=1.40, 95%CI=0.95-2.06, I<sup>2</sup>=53%) (Figure 33). We finally attempted to investigate the association between exposure to chlorpyrifos and

#### 14. 呼吸器疾患

全体では、29の出版物が呼吸器影響に対する農薬ばく露の効果を調査しており(サンプルサイズ中 央値:249、IQR 126-1728)、データ抽出データベースでは399の個別の分析が行われた。そのうち67% はヨーロッパとアメリカからのもので、10の健康関連影響が評価されており、その中でも特に喘息に 焦点を当てた影響が多かった(N=9)。他の影響に見られるように、ばく露の定義はかなりまちまちで あり、データ統合に特別な問題をもたらしている。29の出版物のうち、前向きコホート研究に言及して いるのは6件のみで、12件は横断研究であった。報告された分析におけるサンプルサイズはしばしば小 さく、35~47,756人の範囲であり、最大の研究はSingapore Chinese Health Studyであった。ここで は、AHS (6件)のようなこの分野でよく知られた大規模な研究からの出版物の大規模なクラスタも観察 され、17件(68%)の研究が職業的ばく露を評価していた。さらに、ばく露のバイオマーカーに関する 情報を持つ研究の存在は、ここではあまり目立たなかった(N=8、34%)が、1件の研究ではJEMによる 職業的ばく露を評価していた。調査したさまざまな影響カテゴリーを、各カテゴリーに寄与した研究 の数と定量的統合の決定とともに表 18 に示した。データの不均一性と同定された研究数が少ないた め、データの統計的統合(メタアナリシス)は喘息についてのみ実施した。

## 14.1. 研究数が少ない呼吸器影響

これらの影響は、特発性肺線維症やサルコイドーシス、努力性呼気量(FEV)などの多数のバイオマ ーカーに加えて、研究数が少なすぎるが、明確に定義された臨床所見まで、様々な情報を収集したもの で構成されている。我々のシステマティックレビューでは、以前に発表されたエビデンス(2006年以 前)との比較を可能にするために、これらの影響に関する以前に発表されたメタアナリシスは確認し なかった。一般的に、これらの影響に関する結果は効果が小さく、統計的に有意ではなかったが、少数 の例外を除いては有意であった。分析数が多く、結果のほとんどが農業健康調査(Agricultural Health Study: AHS)からのものであることを考えると、これらの結果は慎重に解釈する必要があり、これらの データに基づいて、農薬ばく露とこれらの結果との間に妥当な関連を示唆するエビデンスはない。

## 14.2. 喘息

9件の研究が農薬ばく露と喘息との関連を評価しており、サンプルサイズの中央値は402 (IQR 127-724) で、データベースには196件の比較が抽出されている。半数以上の研究が横断的に行われ、3分の 2以上の研究ではばく露は質問紙で評価されていた。個々の農薬の評価は多岐にわたり、DDT、パラコー ト、クロルピリホスがより頻繁に評価されている。DDT、クロルピリホス、パラコートを除いて(表 19)、 同じ比較単位を用いた 4 件以上の研究では、他の単一の農薬と関連するバイオマーカーは評価されて おらず、定量的な統合は行われていない。

利用可能な 5 つの研究で DDT へのばく露と喘息との関連を調査しようとしたところ、観察された 影響は不均一性を示すことなく統計的に有意であった (OR 1.29、95%CI 1.14~1.45、I2 0%) (図 32)。 次に、利用可能な6つの研究について、パラコートへのばく露と喘息との関連を調査しようとしたが、 観察された効果は、不均一性を示すもので統計的に有意ではなかった (OR=1.40、95%CI=0.95-2.06, I2=53%) (図33)。最後に、利用可能な5つの研究でクロルピリホスへのばく露と喘息との関連を調査 しようとしたが、観察された効果は、不均一性を示し統計的に有意ではなかった (OR=1.03、95% CI=0.82-1.28、I2=0%) (図34)。メタアナリシスの結果は主にAHSによるものであること、また、男 女別、アレルギー性・非アレルギー性喘息別に報告されているため、4つがAHSに属していることに注 意が必要である。また、メタアナリシスの結果は2006年以降に発表されたデータに限定されているこ とも認めている。したがって、DDTについては、これらの農薬へのばく露と喘息との間に統計的に有意 な中等度の関連を示唆する最近のエビデンスがあると結論付けたが、クロルピリホスとパラコートに ついてはそうではない。

Pesticide epidemiology

asthma across the 5 available studies and the observed effect was not statistically significant without indications of heterogeneity (OR= 1.03, 95% CI= 0.82–1.28,  $I^2$ =0%) (Figure 34). We caution that the meta-analyses results are largely driven by the AHS; in the meta-analyses 4 entries belong to the AHS as the results were separately reported for men and women and for allergic and non-allergic asthma. We also acknowledge that the results of the meta-analyses are restricted to data published after 2006. We thus conclude that for DDT, but not for chlorpyrifos and paraquat, there is recent evidence to suggest a statistically significant, moderate association between exposure to this pesticides and asthma.

### 15. Neuropsychiatric diseases

Overall, 15 publications examined the effect of pesticide exposure on neuropsychiatric outcomes in adult populations (median sample size: 596, IOR 158-12,263), contributing 358 separate analyses in the data extraction database. Three-quarters came from Europe and America, while 17 health-related outcomes were assessed with a large proportion focusing on cognitive function (9 studies, 246 analyses). As seen with other outcomes, the diversity of the exposure definition is considerable and poses special challenges to data synthesis. Only 2 out of the 15 publications referred to prospective cohort studies and 60% of the publications were cross-sectional studies. The sample size in the reported analyses was often small; it ranged between 66 and 112,683 participants with the largest study being a retrospective American study. Here, we also observed clusters of publications coming from large, well-known studies in the field, such as the Agricultural Health Study (AHS) (4 publications), while all but one study assessed occupational exposures. In addition, the presence of studies with information on biomarkers of exposure was far less prominent here (n=2, 13%). The different outcome categories examined are presented in Table 20, along with the number of studies contributing to each outcome category and a decision on quantitative synthesis. Due to heterogeneity of data and small number of studies identified, no statistical synthesis of the data (meta-analysis) was performed for any outcome.

# 15.1. Cognitive function

Nine studies assessed the association between pesticide exposure and cognitive function with a median sample size of 80 (IQR 141-205), contributing 246 separate extracted comparisons in the database. All but one of the studies were cross-sectional and, in seven studies the exposure was assessed through a questionnaire. A large variety of individual pesticides were assessed with the general category of organophosphate pesticides being assessed more frequently. No single pesticide and related biomarker was assessed in more than 4 studies using comparable outcome definitions or the same comparison unit, thus a quantitative synthesis was not performed. Actually, the assessment of cognitive function is a typical example of a general outcome category where the multiplicity and complexity of the 62 tools and sub-tools used in the 15 available studies (Table 21) renders the attempt to systematically and quantitatively synthesize the results of the published literature fruitless.

The largest study in the field is an AHS report (ID NPD 014) assessing potential associations between long-term pesticide use and neurobehavioral function, with relevant tests administered to licensed pesticide applicators. The authors report that "test performance was associated with lifetime days of use of some pesticides". Ethoprop was significantly associated with reduced performance on a test of motor speed and visual scanning. Malathion was significantly associated with poor performance on a test of five organophosphate pesticides. Specifically, chlorpyrifos, coumaphos, parathion, phorate, and tetrachlorvinphos were associated with better verbal learning and memory; coumaphos was associated with better performance on a test of motor speed and visual scanning; and parathion was associated with better performance on a test of sustained attention. Overall, we found no consistent evidence of an association between organophosphate pesticide use and adverse test performance among this older sample of pesticide applicators. Potential reasons for these mostly null results include a true absence of effect as well as possible selective participation by healthier applicators.

Our systematic review did not identify any previously published meta-analyses on these outcomes to allow for comparisons with previously published evidence (prior to 2006). Generally the results on neuropsychiatric outcomes were of small effect and not statistically significant with few exceptions.

### 15. 神経精神疾患

全体では、15の出版物が成人集団の神経精神影響に対する農薬ばく露の影響を調査しており(サン プルサイズ中央値:596、IQR158-12263)、データ抽出データベースでは358の個別の分析が行われてい る。4分の3はヨーロッパとアメリカの研究者であり、17の健康関連影響が評価され、大部分が認知機能 に焦点を当てていた(9研究、246の分析)。他の影響に見られるように、ばく露の定義はかなりまちま ちであり、データ統合に特別な問題を与えている。15の出版物のうち、前向きコホート研究に言及して いるのは2件のみで、出版物の60%は横断研究であった。報告された分析におけるサンプルサイズはし ばしば小さく、66~112,683人の範囲であり、最大の研究は米国の後ろ向き研究であった。ここでは、 農業健康調査(Agricultural Health Study、AHS)(4件)のようなこの分野でよく知られた大規模な 研究からの出版物のクラスタも観察されたが、1件を除いてすべての研究が職業ばく露を評価していた。 さらに、ばく露のバイオマーカーに関する情報を有する研究の存在は、ここではあまり目立たなかっ た(n=2、13%)。調査したさまざまな影響カテゴリーを、各カテゴリーに寄与した研究の数と定量的 統合の決定とともに表20に示した。データの不均一性と同定された研究数が少ないため、どの影響に ついてもデータの統計的統合(メタアナリシス)は行われていない。

# 15.1. 認知機能

9件の研究が農薬ばく露と認知機能との関連を評価しており、サンプルサイズの中央値は80(IQR 141-205)で、データベースには246件の比較が抽出されている。1件を除くすべての研究が横断的で、 7件の研究では質問紙でばく露が評価されていた。個々の農薬の評価は多種多様で、有機リン系農薬の 一般的なカテゴリーがより頻繁に評価されていた。比較可能な影響の定義や同じ比較単位を用いた4件 以上の研究では、単一の農薬と関連するバイオマーカーの評価は行われておらず、定量的な統合は行 われていない。実際、認知機能の評価は一般的な影響カテゴリーの典型的な例であり、利用可能な 15 の研究(表21)で使用された62のツールとサブツールの多様性と複雑性のため、公表されている文献の 結果を体系的かつ定量的に統合する試みは実りのないものとなっている。

この分野で最大の研究は、農薬の長期使用と神経行動機能との間の潜在的な関連を評価したAHSの報告書(ID NPD 014)であり、農薬散布者にこれらに関連する検査を行っている。著者らは、「検査結果は一部の農薬の生涯使用日数と関連していた」と報告している。エトプロプは、運動速度と視覚走査のテストのパフォーマンス低下と有意に関連していた。マラチオンは、視覚的走査と処理のテストのパフォーマンス低下と有意に関連していた。逆に、5種類の有機リン系農薬では、検査結果の有意な改善が観察された。具体的には、クロルビリホス、クマホス、パラチオン、ホレート、テトラクロルビンホスは言語学習と記憶力の向上と関連しており、クマホスは運動速度と視覚走査のテストの成績向上と関連しており、パラチオンは持続注意力のテストの成績向上と関連していました。全体的に、有機リン系農薬の使用とテスト成績低下との間には、この高齢の農薬使用者のサンプルでは一貫した関連のエビデンスは見られなかった。これらのほとんどが無効な結果となった理由としては、真の効果がないことや、より健康的な農薬使用者が選択的に参加している可能性が考えられる。

我々のシステマティックレビューでは、以前に発表されたエビデンス(2006年以前)との比較を可能 にするために、これらの結果に関する以前に発表されたメタアナリシスは確認しなかった。一般的に、 神経精神影響に関する結果は効果が小さく、統計的に有意ではなかったが、いくつかの例外を除いて

Thus, given the large number of analyses these results need cautious interpretation and, based on these data, there is no evidence to suggest association between pesticide exposure and these outcomes.

### 15.2. Neuropsychiatric outcomes with few studies

With the exception of cognitive function, for all the remaining assessed outcomes included in Table 20, too few studies are available to allow synthesis of evidence for each outcome alone; these outcomes comprise a variety of captured information ranging from well-defined clinical entities yet with too few studies, such as depression, or obsessive-compulsive disorder, as well as a numbers of outcomes representing neuropsychiatric endo-phenotypes such as hostility or orientation disorders. Our systematic review did not identify any previously published meta-analyses on these outcomes to allow for comparisons with previously published evidence (prior to 2006). Generally the results on these outcomes were of small effect and not statistically significant with few exceptions. Given the large number of analyses and the fact that a number of the results come from the AHS, these results need cautious interpretation and, based on these outcomes.

# 16. Diabetes

Overall, 23 publications examined the effect of pesticide exposure on diabetes related outcomes (median sample size: 430; IQR 192-1721), contributing 125 separate analyses in the data extraction database. Four health-related outcomes were assessed with a large proportion focusing on type 1 diabetes (n=93, 74%) whereas 18 analyses focused on type 2 diabetes. The rest of the outcomes assessed was prediabetes (n=10), gestational diabetes (n=2) and other glucose and insulin related outcomes (n=2). Only one prospective cohort study was performed; the large majority was crosssectional designs (n=15), whereas 3 studies were case-controls and 4 studies used a nested casecontrols. The large majority of the studies was conducted in America (n=15, 65%) whereas 7 studies where Europeans and only one Asian. Here, we did not observe large clusters of publications coming from large, well-known studies in the field, such as the AHS. Only three study assessed occupational exposures the rest examined environmental exposures (n=19) or both (n=1). In addition, the presence of studies with information on biomarkers of exposure was limited to 9 studies, whereas 10 studies included information both on questionnaire and biomarkers. The different outcome categories examined are presented in Table 22 along with the number of studies contributing to each outcome category. For the pesticides accessed meta-analysis was feasible for DDE and DDT exposure and type 1 diabetes and DDE exposure and type 2 diabetes.

### 16.1. Type 1 diabetes

Thirtheen studies assessed the effect of pesticides on type 1 diabetes (median sample size: 309, IQR: 159-398) and a meta-analysis of ORs was feasible for DDE and DDT exposure. For DDE, 9 studies contributed a median sample size of 202, IQR=142-334. We were not able to include a prospective study that reported a (significant) Incidence Rate Ratio (IRR) of 7.1 and compared the highest vs. the lowest tertile of exposure with DDE. The computed summary OR was 1.90 (95% CI: 1.25-2.86) for the DDE exposure using random effects models. Moderate heterogeneity was observed ( $I^2$ =49%). For DDT, 6 studies had available data for synthesis (median sample size: 577, IQR: 272-2163) providing a summary effect of 1.76 (95% CI: 1.20-2.59) with very large heterogeneity observed (( $I^2$ =76%). Main source of heterogeneity is the different exposure levels used for the calculations of the effect estimates. Even though there is evidence from the random effects meta-analysis that an increased risk for type 1 diabetes exists, however the findings should be interpreted with caution due to the heterogeneity that was observed.

### 16.2. Type 2 diabetes

Four studies were eligible for the assessment of the DDE exposure and risk for type 2 diabetes (median sample size: 471, IQR=292-642). The summary OR derived from those studies was 1.30 (95% CI: 1.13-1.48). No heterogeneity was observed, however the summary results is driven by a case-control study that reported an effect size OR=1.30 (95% CI=1.11-1.52). Even though, there is evidence suggesting that DDE exposure is a risk factor for developing type 2 diabetes, this is based on small studies.

### 16. 糖尿病

全体として、糖尿病関連影響に対する農薬ばく露の効果を調査した論文は23編(サンプルサイズ中 央値:430、IQR 192-1721)で、データ抽出データベースには125の個別の分析結果が掲載されていた。 4つの健康関連影響が評価されており、1型糖尿病(n=93、74%)に大きな割合を占めていたのに対し、 18の分析では2型糖尿病に焦点が当てられていた。評価されたその他の影響は、前糖尿病(n=10)、妊 娠糖尿病(n=2)、その他のグルコース及びインスリン関連影響(n=2)であった。前向きコホート研究 は1件のみで、大多数は横断的デザイン(n=15)であったが、3件は症例対照、4件はコホート内症例対 照を使用した研究であった。大多数の研究はアメリカで行われており(n=15、65%)、7研究はヨーロ ッパ人であり、アジア人は1研究のみであった。ここでは、AHSのような分野でよく知られた大規模な研 究からの出版物の大規模なクラスターは観察されなかった。3つの研究のみが職業ばく露を評価し、残 りは環境ばく露(n=19)またはその両方(n=1)を調査した。さらに、ばく露のバイオマーカーに関す る情報がある研究は9件に限られていたが、10件の研究では質問紙とバイオマーカーの両方の情報が含 まれていた。調査した異なる影響カテゴリーを、各カテゴリーに寄与した研究の数とともに表 22 に 示す。DDE と DDT ばく露と 1 型糖尿病、DDE ばく露と 2 型糖尿病についてはメタアナリシスが可能 であった。

# 16.1.1型糖尿病

1型糖尿病に対する農薬の影響を評価した研究は3件あり(サンプルサイズ中央値309、IQR:159-398)、DDE と DDT ばく露については OR のメタアナリシスが可能であった。DDEについては、9件の 研究がサンプルサイズ中央値202、IQR=142-334であった。我々は、(有意な)罹患率比(IRR)7.1を示 し、DDE被曝の最上位層と最下位層を比較した前向き研究を含めることができなかった。計算された要 約0Rは、ランダム効果モデルを用いたDDEばく露で1.90(95%CI:1.25-2.86)であった。中等度の不均 一性が観察された(I2=49%)。DDTに関しては、6件の研究が統合に利用可能なデータを持っていた(サ ンプルサイズ中央値:577、IQR:27-2-2163)ため、1.76(95%CI:1.20-2.59)の要約効果が得られ、 非常に大きな不均一性が観察された(I2=76%)。不均一性の主な原因は、効果推定値の計算に使用さ れた異なるばく露レベルである。ランダム効果メタアナリシスでは、1型糖尿病リスクの増加が存在す るというエビデンスがあるとはいえ、観察された不均一性のため、この結果は慎重に解釈されるべき である。

# 16.2.2型糖尿病

DDEばく露と2型糖尿病リスクを評価するために4件の研究が対象となった(サンプルサイズ中央値: 471、IQR=292-642)。これらの研究から得られた要約0Rは1.30(95%CI:1.13-1.48)であった。不均 一性は観察されなかったが、要約結果は、効果量0R=1.30(95%CI=1.11-1.52)を報告した症例対照研 究に牽引されている。DDEばく露が2型糖尿病発症のリスク因子であることを示唆するエビデンスはあ るが、これは小規模な研究に基づくものである。

### 17. Cardiovascular diseases

This section includes hard cardiovascular outcomes (myocardial infraction, stroke etc.), cardiovascular risk factors (lipids, blood pressure) and other cardiometabolic outcomes (metabolic syndrome and obesity). No previous meta-analysis has been identified for any of these traits. The evidence collected in this systematic review provides weak suggestions of associations in particular regarding cardiometabolic risk factors and organochlorines; however, other classes of pesticides were not studied and even results on organochlorines were limited and require prospective replication.

#### 17.1. Hard cardiovascular outcomes

Five studies examined hard cardiovascular outcomes including myocardial infarction (ID CVD 005, ID CVD 006), peripheral arterial disease (PAD) (ID CVD 007), stroke (ID CVD 008), and composite cardiovascular disease (ID CVD 009). The Agricultural Health Study (AHS) contributed two prospective analyses (ID CVD 005, ID CVD 006) and National Health and Nutrition Examination Survey (NHANES) other two cross-sectional analyses (ID CVD 007, ID CVD 009). Studies on myocardial infarction (ID CVD 005, ID CVD 006) showed no evidence of an association between having used pesticides, individually or by class, and myocardial infarction mortality among men in the AHS. Similarly, among women of AHS, no overall association with pesticide use and myocardial infarction was seen. Six of 27 individual pesticides evaluated were significantly associated with nonfatal myocardial infarction among women (ID CVD 006), including chlorpyrifos, coumaphos, carbofuran, metalaxyl, pendimethalin, and trifluralin, which all had relatively high odds ratios (>1.7) but also high probability of false positive due to multiple testing.

Another prospective study (8) examined 21 persistent organic pollutants (POPs) in relation to stroke. After adjusting for known stroke risk factors, most polychlorinated biphenyls (PCBs) with 4, 5, or 6 chlorine atoms, p.p'-DDE, trans-nonachlor, and octachlorodibenzo-p-dioxin significantly predicted the risk of stroke. Nonetheless, results need replication from future studies. Peripheral arterial disease (PAD) and composite cardiovascular disease were studied in the cross-sectional NHANES cohort in relation to POPs. Compared with subjects without PAD, those with PAD had significantly higher concentrations of organochlorine pesticides but associations were not seen among non-obese participants. For composite cardiovascular disease, significant associations were observed for chlordane only. These findings need to be carefully interpreted because of the cross-sectional design and use of self-reported cardiovascular disease.

Overall, evidence for associations between pesticide exposure and cardiovascular outcomes is weak and mainly concentrated on organochlorine pesticides.

# 17.2. Cardiovascular risk factors

### 17.2.1. Blood pressure

Five studies examined associations between pesticides and blood pressure (ID CVD 002, ID CVD 003, ID CVD 004, ID CVD 010, ID CVD 011). All but one study (ID CVD 011) had cross-sectional

# Ntzani EE, Chondrogiorgi M, Ntritsos G, Evangelou E, Tzoulaki I

### 17. 循環器疾患

重篤な心血管影響(心筋梗塞、脳卒中など)、心血管リスク因子(脂質、血圧)、その他の心血管影響(メタボリックシンドローム、肥満)を含む。これらのいずれについても、これまでのメタアナリシスは同定されていない。この系統的レビューで収集されたエビデンスは、特に心血管リスク因子と有機塩素に関する関連を弱く示唆しているが、他のクラスの農薬は研究されておらず、有機塩素に関する結果でさえ限られており、前向き研究の反復が必要である。

# 17.1. 重篤な心血管影響

心筋梗塞(ID CVD 005、ID CVD 006)、末梢動脈疾患(PAD)(ID CVD 007)、脳卒中(ID CVD 008)、 複合心血管疾患(ID CVD 009)を含む5つの研究が重篤な心血管影響を調査した。Agricultural Health Study (AHS)は2つの前向き分析(ID CVD 005、ID CVD 006)、National Health and Nutrition Examination Survey (NHANES)は他の2つの横断分析(ID CVD 007、ID CVD 009)を提供している。心筋梗塞に関す る研究(ID CVD 005、ID CVD 006)では、AHSの男性の心筋梗塞死亡率と農薬使用(個人またはクラス 別)との関連を示すエビデンスは示されなかった。同様に、AHSの女性では、農薬の使用と心筋梗塞と の全体的な関連は認められなかった。評価された27種類の農薬のうち、クロルビリホス、クマホス、カ ルボフラン、メタラキシル、ペンディメタリン、トリフラリンを含む6種類の農薬が女性の非致死的心 筋梗塞と有意に関連し(ID CVD 006)、いずれも比較的高いオッズ比(1.7以上)を示したが、複数回 の検査による偽陽性の確率も高かった。

別の前向き研究(8)では、脳卒中との関連で21種類の残留性有機汚染物質(POPs)を調査した。既 知の脳卒中リスク因子を調整した後、塩素原子が4、5、または6個のボリ塩化ビフェニル(PCB)、p、 p'-DDE、トランスノナクロル及びオクタクロロジベンゾーp-ジオキシンのほとんどが脳卒中のリスク を有意に予測した。にもかかわらず、結果は今後の研究で再現する必要がある。末梢動脈疾患(PAD) 及び複合心血管疾患が、横断的なNHANESコホートでPOPsとの関連で研究された。PADのない被験者と比 較して、PADのある被験者では有機塩素系殺虫剤の濃度が有意に高かったが、肥満でない被験者では関 連は認められなかった。複合心血管疾患については、クロルデンのみに有意な関連が観察された。横断 的なデザインと自己申告による心血管疾患のため、これらの所見は慎重に解釈する必要がある。

全体的に、農薬ばく露と心血管影響との間の関連エビデンスは弱く、主に有機塩素系農薬に集中している。

# 17.2. 心血管リスク因子

# 17.2.1. 血圧

5件の研究で農薬と血圧の関連が調査された(ID CVD 002、ID CVD 003、ID CVD 004、ID CVD 010、 ID CVD 011)。1件の研究(ID CVD 011)では、横断的な研究が行われていた。

Pesticide epidemiology

92

designs. All effect sizes were very small and not suggestive of an association between pesticide exposure and blood pressure.

### 17.2.2. Metabolic syndrome components

Nine studies examined components of metabolic syndrome in relation to pesticide exposure including lipids levels, glucose and insulin levels. All but one study examined exposure to organochlorine pesticides and significant associations for some classes and lipid levels or glucose levels were observed. Highest quality evidence comes from the prospective Coronary Artery Risk Development in Young Adults (CARDIA) Study (ID CVD 016). In CARDIA, p.p<sup>+</sup>-DDE most consistently predicted higher triglycerides, and homeostasis model assessment value for insulin resistance (HOMA–IR) and lower High Density Lipoprotein (HDL)-cholesterol at year 20 after adjusting for various confounders. Oxychlordane, trans-nonachlor, and hexachlorobenzene also significantly predicted higher triglycerides. Finally, a case-control study in China, examined differences in glucose regulation in participants highly exposed to pyrethroids (occupational exposure) (OR = 1.48, 95%CI = 1.24–1.77) (ID CVD 021). However, these results need external replication in other populations as the study is retrospective and residual confounding cannot be excluded.

### 17.2.3. Subclinical atherosclerosis

The population-based Prospective Investigation of the Vasculature in Uppsala Seniors examined in a cross-sectional study, whether POP levels were related to subclinical atherosclerosis. Circulating levels of PCBs were associated with atherosclerotic plaques and echogenicity of the intima-media complex independent of cardiovascular risk factors, but associations need to be confirmed in prospective studies.

# 17.3. Metabolic syndrome and obesity

Three studies (ID CVD 010, ID CVD 011) examined associations between organochlorine exposure and prevalence of metabolic syndrome. In National Health and Nutrition Examination Survey (NHANES) (ID CVD 010) significant association between organochlorine exposure and prevalence of Metabolic Syndrome was reported with ORs of 1.0, 1.5, 2.3 and 5.3 across organochlorine pesticide quartiles (p for trend <0.01). In the other case-control study (ID CVD 011) significant associations were noted for heptachlor only.

Overall, 12 cross-sectional studies examined associations between pesticide exposure and measures of body fatness or obesity. Also, 10 out of 12 studies examined associations between organochlorines and obesity or body fatness; evidence around other pesticide classes was scarce. Three studies (ID CVD 012, ID CVD 013, ID CVD 014) only presented correlation analysis with measures of body fatness. The remaining studies have shown some significant associations between waist circumference, Body Mass Index (BMI) and organochlorines (DDT and chlordane) but the evidence is limited to cross-sectional analysis and results are only suggestive of an association.

EFSA supporting publication 2013:EN-497

すべての効果量は非常に小さく、農薬ばく露と血圧との関連を示唆するものではなかった。

# 17.2.2. メタボリックシンドロームの構成要素

9件の研究では、脂質レベル、グルコース、インスリンレベルを含む農薬ばく露に関連したメタボリ ックシンドロームの構成要素が調査された。1件を除くすべての研究で有機塩素系農薬へのばく露が調 査され、いくつかのクラスと脂質レベルまたはグルコースレベルとの有意な関連が観察された。最も 質の高いエビデンスは、前向きCARDIA(Coronary Artery Risk Development in Young Adults)研究 (ID CVD 016)から得られている。CARDIAでは、様々な交絡因子を調整した後、20年目にp,p'-DDEが 最も一貫してトリグリセリド、インスリン抵抗性のホメオスタシスモデル評価値(HOMA-IR)及び高密 度リポ蛋白(HDL)コレステロールの低下を予測していた。また、オキシクロルデン、トランスノナク ロル、ヘキサクロロベンゼンもトリグリセリドの上昇を有意に予測した。最後に、中国で行われた症例 対照研究では、ピレスロイド(職業ばく露)に高度にばく露された参加者のグルコース調節の違いが調 査された。その結果、ピレスロイドにばく露されると異常なグルコース調節のリスクが高まることが 示された(OR = 1.48、95%CI = 1.24-1.77)(ID CVD 021)。しかし、この研究は後ろ向きであり、 残留交絡因子を除外できないため、これらの結果は他の集団で外部で再現の必要がある。

# 17.2.3. 無症候性アテローム性動脈硬化症

集団ベースの Prospective Investigation of the Vasculature in Uppsala Seniors (ウプサラ高 齢者の血管系に関する前向き調査)では、POPのレベルが無症候性アテローム性動脈硬化症と関連して いるかどうかを横断研究で調査した。循環中のPCBレベルは、心血管リスク因子とは無関係に、アテロ ーム性動脈硬化性斑点と内膜複合体の超音波反射性と関連していたが、関連は前向き研究で確認する 必要がある。

# 17.3. メタボリックシンドロームと肥満

3件の研究(ID CVD 010、ID CVD 011)で有機塩素ばく露とメタボリックシンドローム罹患率との関 連を調査した。国民健康・栄養調査(NHANES)(ID CVD 010)では、有機塩素系農薬の四分位間の0Rが 1.0、1.5、2.3、5.3であり、有機塩素ばく露とメタボリックシンドロームの罹患率との間に有意な関連 が報告された(傾向<0.01の場合はp)。他の症例対照研究(ID CVD 011)では、ヘプタクロルのみで 有意な関連が認められた。

全体として、12件の横断研究で農薬ばく露と体脂肪率または肥満度の測定値との関連が調査された。 また、12件中10件の研究では有機塩素系農薬と肥満または体脂肪率との関連が調査されていたが、他 のクラスの農薬についてはエビデンスが乏しかった。3件の研究(ID CVD 012、ID CVD 013、ID CVD 014)では、体脂肪率の測定値との相関分析のみが示された。残りの研究では、ウエスト周囲長、体格 指数(BMI)、有機塩素系農薬(DDTとクロルデン)との間に何らかの有意な関連が示されているが、エ ビデンスは横断的な分析に限られており、結果は関連を示唆するものに過ぎない。

93

# 18. Mortality

Overall, 11 publications examined the effect of pesticide exposure on mortality (median sample size: 1,986), contributing 318 separate analyses in the *data extraction database*. This section consists of a heterogeneous group of publications, which assessed associations between pesticides and all cause mortality of major mortality outcomes. Despite the fact that these studies were large, they were of modest quality and they are not very informative as they test a wide range of diseases simultaneously without corrections for multiple testing. The results do not show any apparent trend of pesticide exposure with overall mortality.

# Ntzani EE, Chondrogiorgi M, Ntritsos G, Evangelou E, Tzoulaki I

# 18. 死亡率

全体では 11 の論文が農薬ばく露の死亡率への影響を調査し (サンプルサイズ中央値:1,986)、デ ータ抽出データベースでは 318 の個別分析が行われた。このセクションは、農薬と主要な死因との関 連を評価した異種の出版物群で構成されている。これらの研究は大規模なものであったにもかかわら ず、質は中等度であり、多重検定の補正を行わずに種々の疾患を同時に検定しているため、あまり有益 ではなかった。結果は、農薬ばく露と死亡との明らかな傾向を示していない。

94

### 19. Immune/ Autoimmune diseases

Overall, 10 publications examined the effect of pesticide exposure on immune disorders (median sample size: 196, IQR 81-476), contributing 67 separate analyses in the *data extraction database*. Sixty studies were conducted in America, 3 in Europe and one study was Asian. Various health related outcomes including arthritis, osteoarthritis, rheumatoid arthritis and an extensive list of various antibodies, cytokines etc. as summarized in Table 23. Seven out of the 10 publications referred to prospective cohort studies whereas 2 studies were cross-sectional and only one was case-control. The sample size in the reported analyses was rather small; it ranged between 19 and 532 participants with the largest study being the Carolina Lupus Study. Half of the studies assess occupational exposures and information on biomarkers of exposure was available in 2 studies whereas 4 studies used both biomarkers and questionnaires. As seen with other outcomes, the diversity of the exposure definition and the outcomes assessed are extensive and poses special challenges to data synthesis. No single outcome was assessed in more than two studies therefore synthesis of the data was not feasible for the field of immune disorders.

# Table 23: Health outcomes assessed in the field of immune disorders

Health outcome	
Antinuclear antibodies	Interleukin-4 (IL-4)
Arthritis	Interleukin-13 (IL-13)
Complement components C3, C4	Immunologic effects
Eosinophils	Leucocyte counts
Erythrocyte counts	Lymphocyte levels
Glycoproteins	Neutrophils
Hematocrit/Hemoglobin	Natural Killers (NK) cells
Interferon-γ (IFN-γ)	Osteoarthritis
Immunoglobulin 1 (IgG1)	Rheumatoid arthritis
Immunoglobulin 4 (IgG4)	Systematic Lupus
Immunoglobulin M (IgM)	

### 19. 免疫疾患/自己免疫疾患

全体では、農薬ばく露が免疫障害に及ぼす影響を調査した論文は 10 (サンプルサイズ中央値 196、 IQR 81-476)で、データ抽出データベースでは 67 の個別の分析が行われた。60の研究はアメリカで 実施され、3つの研究はヨーロッパで実施され、1つの研究はアジアで実施された。関節炎、変形性関節 炎、関節リウマチ、様々な抗体、サイトカインなどの広範なリストを含む様々な健康関連影響が表 23 にまとめられている。10の出版物のうち7つは前向きコホート研究に言及していたが、2つの研究は横 断的であり、1つだけが症例対照であった。報告されている分析のサンプル数はかなり少なく、19~532 人で、最大の研究はCarolina Lupus Studyであった。研究の半分は職業ばく露を評価しており、ばく 露のバイオマーカーに関する情報は2つの研究で得られたが、4つの研究ではバイオマーカーと質問紙 の両方を使用していた。他の影響に見られるように、ばく露の定義と評価された影響はまちまちであ り、データ統合に特別な問題をもたらしている。2件以上の研究で単一の影響が評価されたものはなく、 免疫障害の分野ではデータの統合は不可能であった。

# 表23:免疫障害の分野で評価された健康影響

健康影響	
抗核抗体	インターロイキン-4 (IL-4
関節炎	インターロイキン13(IL-13
補体成分 C3、C4	免疫学的効果
好酸球	白血球数
赤血球数	リンパ球レベル
糖タンパク質	好中球
ヘマトクリット/ヘモグロビン	ナチュラルキラー (NK) 細胞
インターフェロンγ	変形性関節症
免疫グロブリン1 (IgG1)	関節リウマチ
免疫グロブリン4 (IgG4)	全身性エリテマトーデス
免疫グロブリン M (IgM)

95

### 20. Allergic diseases

Nine studies from eight different populations reported associations between pesticide exposure and allergic disorders. Seven studies examined occupational exposure whereas two studies examined environmental exposure. Eight studies were cross-sectional investigations and therefore conclusions are prone to reverse causality and other biases. In terms of outcomes examined, five studies examined self-reported allergic rhinitis, one examined self-reported asthma and the remaining 3 examined selfreported skin irritation, contact dermatitis, food allergy, hay fever and fragrance allergies. Statistically significant results were reported by four studies on allergic rhinitis (ID ALL 003, ID ALL 004, ID ALL 005, ID ALL 006). These studies reported significant association between various pesticide classes and allergic rhinitis. In particular, the Agricultural Health Study (AHS) reported significant association between allergic rhinitis and exposure to the herbicides 2,4-Dichlorophenoxyacetic acid (2,4-D) glyphosate and petroleum oil, the insecticide diazinon and the fungicide benomyl. However, the study has many limitations and results need cautious interpretation and require replication by future prospective studies. The study is limited by its ability to distinguish allergic from non-allergic symptoms of rhinitis and to establish temporality between exposure and symptoms due to its crosssectional design. One study with low overall quality reported high effect sizes (OR, 12.50; 95% CI, 2.00-78.05) for allergic rhinitis in greenhouse flower and ornamental plant growers with pesticide application by hand pump vs. without (ID ALL 006). Again, the study has low overall quality, concerns a heavily exposed population with definition of exposure related to the method of application rather than a chemical class. Overall, the evidence around allergic disorders and pesticide exposure is weak.

### 20. アレルギー疾患

8つの異なる集団における9つの研究が、農薬ばく露とアレルギー性障害との関連を報告した。7件の 研究では職業ばく露が調査され、2件の研究では環境ばく露が調査された。8件の研究は横断的な調査 であったため、結論は逆因果関係やその他のバイアスがかかりやすい。結果については、5件の研究が 自己申告によるアレルギー性鼻炎、1件の研究が自己申告による喘息、残りの3件の研究が自己申告に よる皮膚刺激、接触性皮膚炎、食物アレルギー、花粉症、香料アレルギーを調査した。アレルギー性鼻 炎に関する4件の研究 (ID ALL\_003、ID ALL\_004、ID ALL\_005、ID ALL\_006) で統計学的に有意な結果 が報告された。これらの研究では、様々な農薬クラスとアレルギー性鼻炎との間に有意な関連が報告 されている。特に、Agricultural Health Study (AHS) では、アレルギー性鼻炎と除草剤である2.4-ジ クロロフェノキシ酢酸(2.4-D)グリホサート及び石油油、殺虫剤であるジアジノン及び殺菌剤である ベノミルへのばく露との間に有意な関連が報告されている。しかし、この研究には多くの限界があり、 結果は慎重な解釈が必要であり、将来の前向き研究での再現が必要である。この研究は、アレルギー性 鼻炎と非アレルギー性鼻炎の症状を区別できているか、また、横断的なデザインのためにばく露と症 状の間の時系列を示せるかという点で制限されている。全体的に質の低い1件の研究では、温室内の花 卉及び観賞用植物の栽培者におけるアレルギー性鼻炎について、手押しポンプによる農薬散布と農薬 散布なしの比較で高い効果量(OR、12.50;95%CI、2.00-78.05)が報告されている(ID ALL\_006)。 ここでも、この研究は全体的に質が低く、化学物質の種類ではなく散布方法に関連して定義された高 濃度ばく露集団に関係している。全体的に、アレルギー性障害と農薬ばく露に関するエビデンスは弱 W.

## 21. Haematological diseases

### 21.1. Aplastic anaemia

Three studies examined associations between pesticide exposure and aplastic anaemia; a rare hematologic condition. All studies were case-control designs and had small sample sizes (range 9-310). Two studies reported significant associations with large effect sizes but it is difficult to draw firm conclusions due to the small number of studies available and the limitations of these studies (Table 24). The other case control study (ID APL\_002) did not report effect sizes but only the p value of association, which was non-significant. Further evidence is required to throw light into these suggestive results.

 Table 24:
 Summary of results between pesticide exposure and aplastic anemia in 2 case-control studies that reported effect sizes

Study ID	Pesticide assessed	Comparison		Lower 95% Cl	Higher 95% CI	N cases	N controls
APL_001	Organophosphates	yes/no	2.1	1.1	4.2	21	32
APL_001	DDT	yes/no	6.7	1.5	30	5	4

APL_003	Pyrenthroids	highest tertile of exposure/no exposure	1.8	1	3.1	23	57
APL_003	Herbicides	yes/no	2.4	0.9	6	8	15

### 21.2. Haematological and biochemical alterations

Fourteen studies examined various haematological and biochemical alterations in relation to pesticide exposure. Main alterations studied were basic haematology and vitamin levels. The sample size ranged between 51 and 1,275. The quality of these studies was modest to low. Most studies reported unadjusted correlation statistics or means between haematological parameters and pesticide exposure and no effect sizes beyond the p values were reported. All studies provided cross-sectional evidence. Despite the fact than many of the reported analyses were statistically significant, results should not be interpreted at this stage due the limited evidence and modest quality associated with these data.

# 21.2. 血液学的及び生化学的変化

14の研究では、農薬ばく露に関連した様々な血液学的及び生化学的変化を調べた。主に一般血液検 査とビタミンレベルであった。サンプル数は51~1,275人であった。これらの研究の質は中等度から低 度であった。ほとんどの研究では、血液学的パラメータと農薬ばく露との間の無補正相関統計値また は平均値が報告されており、p値以外に効果量は報告されていない。すべての研究は横断的なエビデン スを提供している。報告された分析の多くが統計的に有意であったにもかかわらず、これらのデータ に関連するエビデンスが限られており、質も中等度であるため、現段階では結果を解釈すべきではな い。

The present document has been produced and adopted by the bodies identified above as author(s). # 22. Other outcomes

Overall, 30 publications examined the effect of pesticide exposure on other outcomes. Based on our criteria for data synthesis no meta-analysis was performed for those outcomes.

# 22.1. Bone diseases

Three studies examined the effect of pesticide exposure on osteoporosis including 13 different analyses. We identified two European cross-sectional studies and one Asian cohort (median sample size: 176, IQR: 153-908). All studies assess environmental exposure with information on biomarkers of exposure and all studies examined exposure to organochlorines only. Osteoporosis was assessed via ultrasound measurements and bone mineral density. The largest study of 908 women showed that p,p'-DDE was positively associated with bone mineral density, the association remained after adjustment for confounders, but the effect was weak.

### 22.2. Skin diseases

Six studies examined the effect of pesticide exposure on skin lesion (median sample size: 356, IQR 262-2203) including 11 analyses. Four studies used cross-sectional design. Environmental exposure was assessed in 3 studies. The definition of outcome was often skin rash or eczema. The resulst were largely not statistical significant. One prospective study (ID SKD 004) on 5,042 men from the Health Effects of Arsenic Longitudinal Study in Araihazar reported highly significant effect sizes for skin lesions and pesticide use but study also evaluated arsenic exposure and it is difficult to differentiate between the effect of each exposure.

# 22.3. Dental diseases

One study cross-sectional study from America including 496 participants assessed two outcomes. The study assessed environmental exposure with information of biomarkers (ID PER 001). In this study, organochlorine (OC) pesticides were strongly associated with periodontal disease.

# 22.4. Metabolic diseases

One European cross-sectional study assessed the effect of pesticides on metabolic diseases and specifically on levels of various prorfyrins including 8 analyses but no significant results were reported. Environmental exposure was studied using biomarkers for the assessment of exposure.

# 22.5. Men health

One case-control study reported association between pesticide exposure and erectile dysfunction. The study focused on organochlorine pesticides and compared 101 cases with erectile dysfunction to 234 comparable control subjects. The results were no statistically significant and do not provide evidence of an association.

The present document has been produced and adopted by the bodies identified above as author(s). This task has been carried out exclusively by the author(s) in the context of a contract between the European Food Safety Authority and the author(s), awarded following a tender procedure. The present document is published complying with the transparency principle to which the Authority is subject. It may not be considered as an output adopted by the Authority. The European Food Safety Authority reserves its rights, view and position as regards the issues addressed and the conclusions reached in the present document, without prejudice to the rights of the authors.

# 22. その他の影響

Ntzani EE, Chondrogiorgi M, Ntritsos G, Evangelou E, Tzoulaki I

全体では 30 の論文がその他の影響に対する農薬ばく露の効果を調査した。データ統合のための 我々の基準に基づき、これらの影響に対するメタアナリシスは実施されなかった。

# 21.1. 骨疾患

農薬ばく露が骨粗鬆症に及ぼす影響を調査した研究は3件あり、13の異なる分析を行った。我々は2 つのヨーロッパの横断研究と1つのアジアのコホート研究を同定した(サンプルサイズ中央値:176、 IQR:153-908)。すべての研究は、ばく露のバイオマーカーに関する情報とともに環境ばく露を評価し ており、すべての研究は有機塩素へのばく露のみを調査している。骨粗鬆症は超音波測定と骨密度に よって評価された。908名の女性を対象とした最大の研究では、p,p'-DDEが骨密度と明確な関連を示 し、交絡因子を調整した後も関連は維持されたが、効果は弱いことが示された。

# 22.2. 皮膚疾患

11件の分析のうち農薬ばく露が皮膚病変に及ぼす影響を調査した研究は6件(サンプルサイズ中央値 356、IQR 26-2203)であった。4件の研究では横断的デザインが用いられていた。環境ばく露は3件の研 究で評価された。影響の定義は多くの場合、発疹や湿疹であった。結果はほとんど統計的に有意ではな かった。1つの前向き研究(ID SKD 004)では、男性5,042人を対象としたAraihazarのヒ素の健康影響 縦断研究から、皮膚病変と農薬使用について非常に有意な効果量が報告されているが、この研究では ヒ素ばく露も評価されており、それぞれのばく露の効果を区別することは困難であった。

# 22.3. 歯科疾患

アメリカで行われた1つの横断研究では、496人の参加者が2つの影響で評価された。この研究では、 バイオマーカー (ID PER 001)の情報を用いて環境ばく露を評価した。この研究では、有機塩素系(0C) 農薬は歯周病と強く関連していた。

# 22.4. 代謝性疾患

ヨーロッパで行われた横断研究では、農薬が代謝性疾患、特に様々なprorfyrins (誤植?)のレベル に及ぼす影響を評価し、8つの分析を行ったが、有意な結果は報告されていない。環境ばく露は、ばく 露評価のためのバイオマーカーを用いて研究された。

# 22.5. 男性機能疾患

1件の症例対照研究では、農薬ばく露と勃起不全との関連が報告されている。この研究では有機塩素 系農薬に焦点を当て、勃起不全の症例101例を234例の同等の対照群と比較した。結果は統計的に有意 ではなく、関連を示すエビデンスとはならなかった。

<sup>97</sup> 

### 22.6. Gynaecological diseases

In this group we included gynaecological outcomes not included in the previous outcome categories. Four studies are included in this group, three examined endometriosis and one the timing of menopause. The three studies on endometriosis (ID GYN 001, ID GYN 002, ID GYN 003) were all cross-sectional and all examined organochlorines. One out of 12 separate analyses on endometriosis and organochlorines was statistically significant; the highest tertile of aromatic fungicide was associated with a fivefold risk of endometriosis (OR = 5.3; 95% CI, 1.2-23.6) compared to the lowest tertile. This effect size is large and requires independent replication in other prospective studies.

Data from the Agricultural Health Study (AHS) was used to study associations between exposure to pesticides and age at menopause in a prospective investigation of pre-menopausal women. After control for age, smoking status, and past use of oral contraceptives, the median time to menopause increased by approximately 3 months for women who used pesticides (HR 0.87, 95% CI: 0.78, 0.97) and by approximately 5 months for women who used hormonally active pesticides (HR 0.77, 95% CI: 0.65, 0.92). Pesticide use may be associated with a later age at menopause based on these results; however results are prone to false positive bias and independent replication is needed.

## 22.7. Symptoms and general health

Five studies examined general health symptoms such as nausea, fatigue, dizziness, and shortness of breath. The definition of these outcomes is very hard and associated with large measurement errors. Studies were of modest to low quality and all concerned occupational exposures. Some statistically significant results were observed but are far form conclusive at this stage due to heterogeneity of data reported and the limitations associated with these studies.

## 22.8. Kidney diseases

Three studies examined kidney diseases including chronic kidney disease and gallstone disease. One study reported statistically significant results between DDE and DDT residues and gallstone disease.

### 22.9. Benign tumours

One a population-based case-control study on acoustic neuroma found no link between pesticide exposure and acoustic neuroma.

# 22.10. Gastrointestinal diseases

Seven studies examining associations between pesticide exposure and liver enzymes were identified. All studies were cross-sectional or case-control. One study, the National Health and Nutrition Examination Survey (NHANES), examined organochlorines, another one examined exposure to 2,4dichlorophenoxyacetic acid (2,4-D) and paraquat and the remaining studies examined broadly defined pesticide categories. The studies were of modest and low quality and presented only the means of enzymes in exposed and unexposed participants often without adjustments. Almost all studies reported statistically significant results with higher level of liver enzymes (e.g. Gamma-glutamyltransferase (GGT), Alanine aminotransferase (ALT), Aspartate aminotransferase (AST)) in participants exposed to pesticides. However, due to the low quality of the data and the limited number of studies firm conclusions cannot be drawn and data is only suggestive of associations at this stage.

# EFSA supporting publication 2013:EN-497

The present document has been produced and adopted by the bodies identified above as author(s). This task has been carried out exclusively by the author(s) in the context of a contract between the European Food Safety Authority and the author(s), awarded following a tender procedure. The present document is published complying with the transparency principle to which the Authority is subject. It may not be considered as an output adopted by the Authority. The European Food Safety Authority reserves its rights, view and position as regards the issues addressed and the conclusions reached in the present document, without prejudice to the rights of the authors.

# 22.6. 婦人科疾患

このグループには、上述の影響カテゴリーには含まれていない婦人科学的影響が含まれている。こ のグループには4件の研究が含まれており、3件は子宮内膜症、1件は閉経のタイミングを調査した。子 宮内膜症に関する3件の研究(ID GYN 001、ID GYN 002、ID GYN 003)はすべて横断的であり、すべて 有機塩素を調査していた。子宮内膜症と有機塩素に関する12の個別分析のうち1つは統計学的に有意で あった;芳香族系殺菌剤の上位3位までは、下位3位までと比較して子宮内膜症のリスクが5倍(OR = 5.3;95%CI、1.2-23.6)であった。この効果量は大きく、他の前向き研究で独立した再現が必要であ る。

農業健康調査(Agricultural Health Study: AHS)のデータを用いて、閉経前の女性を対象とした前 向き調査において、農薬へのばく露と閉経時年齢との関連を調査した。年齢、喫煙状況、経口避妊薬の 過去の使用状況をコントロールした後、閉経までの期間の中央値は、農薬を使用した女性では約3ヵ月 (HR 0.87、95%CI:0.78、0.97)、ホルモン活性農薬を使用した女性では約5ヵ月(HR 0.77、95%CI: 0.65、0.92)増加した。農薬の使用は、これらの結果に基づいて、閉経年齢の遅延と関連している可能 性がある。しかしながら、結果は偽陽性バイアスがかかりやすく、独立した再現が必要である。

# 22.7. 症状及び一般的な疾患

吐き気、倦怠感、めまい、息切れなどの一般的な疾患を5つの研究で調査した。これらの結果の定義 は非常に難しく、大きな測定誤差と関連している。研究の質は中等度から低度で、すべての研究が職業 ばく露に関係していた。いくつかの統計的に有意な結果が観察されたが、報告されたデータの不均一 性とこれらの研究に関連する限界のため、現段階では決定的な結論には程遠い。

# 22.8. 腎臟疾患

3つの研究では、慢性腎臓病や結石疾患などの腎臓病を調査した。1件の研究では、DDE及びDDT残留農 薬と結石疾患との間に統計的に有意な結果が報告された。

# 22.9. 良性腫瘍

聴神経腫瘍に関する集団ベースの症例対照研究では、農薬ばく露と聴神経腫瘍との関連は認められ なかった。

# 22.10. 消化器疾患

農薬ばく露と肝臓酵素との関連を調査した7件の研究が同定された。すべての研究は横断的または 症例対照であった。1件の研究、国民健康・栄養調査(NHANES)では有機塩素について、もう1件の研究 では2,4-ジクロロフェノキシ酢酸(2,4-D)とパラコートへのばく露について、残りの研究では広く定 義された農薬のカテゴリーについて調査が行われた。これらの研究は限られた規模で質が低く、多く の場合調整なしで、被ばく露者と非ばく露者の酵素の平均値のみが提示されていた。ほとんどすべて の研究で、農薬にばく露された参加者の肝臓酵素(例:y-グルタミルトランスフェラーゼ(GGT)、ア ラニンアミノトランスフェラーゼ(ALT)、アスパラギン酸アミノトランスフェラーゼ(AST))のレベ ルが高いほど、統計的に有意な結果が報告されている。しかし、データの質の低さと研究の数が限られ ているため、しっかりとした結論を出すことはできず、データは現段階では関連をほのめかすだけで ある。

### CONCLUSIONS

After an exhaustive and comprehensive search of almost 46,000 scientific publications we identified 602 publications, which examine epidemiologic associations between pesticide exposure and diverse health outcomes. The entire spectrum of health outcomes related to pesticide exposure has not been studied before. Our results show a very wide spectrum including 24 major disease categories. Few environmental exposures have been associated with such a wide range of outcomes. The most prevalent outcomes are cancers and mother and child health outcomes. But other disease categories have received considerable attention such as neurological conditions and reproductive diseases. Despite the large volume of available data and the large number (>6,000) of analyses available, firm conclusions cannot be made for the majority of the outcomes studied. This observation is disappointing especially when one accounts for the large volume of research in the area. However, this observation is in line with previous studies on environmental epidemiology and in particular on pesticides which all acknowledge that such epidemiological studies suffer from many limitations and that the heterogeneity of data is such that does not allows firm conclusions to de made.

The range of categories of pesticide studied is wide but studies very often concentrate on a broadly defined pesticide category, and it is hard to understand which pesticide the population is exposed to. Studies often examine pesticides that have already been banned in western populations and the European Union. The use of biomarkers as means of exposure assessment is infrequent but still available in almost half of the studies. In addition, cohort studies represent a minority of this literature with case control and cross-sectional studies representing an approximately equal proportion of eligible articles. Case-control and cross-sectional evidence does not allow the study of temporal relations and thus are unable to provide support regarding the causality of associations. The assessment of exposure is perhaps the most important methodological limitation of the studies. Studies used different methods for exposure assessment and assignment. Most studies were based on selfreported exposure to pesticides, defined as ever versus never use or as regular versus non-regular use. Such methods suffer from high misclassification rates and especially in the case of retrospective studies where misclassification would be differential with higher exposures reported in participants with disease (recall bias). Above all, such questionnaires might be capable of differentiating subjects with very high and very low exposure levels but are not capable of valid exposure classification across an exposure gradient thus not allowing the study of dose-response relationships. Also, the accuracy of exposure might be high for broad categories of pesticides and commonly used pesticides, but not for specific pesticides. It is important that questionnaires used for exposure assessment are validated. However, studies largely used "home- made" versions of questionnaires, sometimes not giving the information on the actual questions used to assess exposure. In addition, exposure simultaneously in multiple agents is common which may introduce further bias in the results. For example, occupational exposure to pesticides is likely to coexist with exposure to benzene, heavy metals, solvents, suspended particulate matter etc. all of which have adverse health outcomes. It is essential to account for confounding from exposure to multiple agents in order to delineate true associations but this has not been possible in the overwhelming majority of evidence assessed herein.

In addition, the evidence collected and appraised herein is likely to suffer from selective reporting and multiple testing. The studies reported a very wide range of analyses; 602 publications resulted in 6000 analyses. The amount of multiple hypothesis testing is enormous. These analyses need to be adjusted for multiple hypothesis testing else the results suffer from high false positive rate. Even when studies present only one analysis, selective reporting is always a possibility as has been shown in other epidemiological fields as well. In addition, when interpreting results one should also take into account that, especially for certain outcomes (e.g. cancers), the majority of evidence comes from single study populations and the AHS in particular.

# 結論

約46,000の科学出版物を網羅的かつ包括的に検索した結果、602の出版物を確認した。農薬ばく露に 関連した健康影響の全領域については、これまでにも研究されたことがなかった。我々の結果は、24の 主要な疾患カテゴリーを含む非常に幅広いスペクトルを示している。これほど広範囲の影響と関連し た環境ばく露はこれまでほとんどなかった。最も一般的な影響は、がんと母子の健康影響である。しか し、神経疾患や生殖器疾患など、他の疾患カテゴリーにも注目が集まっている。利用可能なデータが大 量にあり、利用可能な分析の数が多い(6,000件以上)にもかかわらず、研究された影響の大部分につ いて確固たる結論を出すことはできない。この調査は、この分野の研究量の多さを考慮すると、特に残 念な結果となった。しかし、この調査は環境疫学、特に農薬に関するこれまでの研究と一致しており、 疫学研究には多くの限界があり、データの不均一性から確固たる結論を出すことができないことを認 めている。

研究されている農薬のカテゴリーの範囲は広いが、研究は多くの場合、広く定義された農薬のカテ ゴリーに集中しており、集団がどの農薬にばく露されているかを理解するのは難しい。研究では、欧米 の集団や欧州連合ですでに禁止されている農薬を調査することが多い。ばく露評価の手段としてバイ オマーカーを使用することはほとんどないが、ほぼ半数の研究ではまだ使用可能である。さらに、コホ ート研究はこの文献の中では少数派であり、症例対照研究と横断研究が対象となる論文のほぼ同じ割 合を占めている。症例対照研究や横断研究では、時間的関係を研究することができないため、関連の因 果関係に関する裏付けを提供することができない。ばく露の評価は、おそらくこれらの研究の最も重 要な方法論的限界である。研究では、ばく露の評価と割り付けに異なる方法が用いられていた。ほとん どの研究では、農薬へのばく露を、使用したことがあるかないか、あるいは定期的に使用したことがあ るかないかという自己申告に基づいていた。このような方法は、高い誤分類率に悩まされ、特に後ろ向 き研究の場合には、病気のある参加者で報告されたばく露量が多いほど誤分類に差が出てしまう(リ コールバイアス)。とりわけ、このような質問紙は、非常に高いばく露量の被験者と非常に低いばく露 量の被験者を区別することができるかもしれないが、ばく露の段階にわたって有効なばく露分類がで きないため、用量反応関係の研究を行うことができない。また、幅広いカテゴリーの農薬や一般的に使 用されている農薬ではばく露の精度が高いかもしれないが、特定の農薬ではそうではない。ばく露評 価に使用される質問紙の妥当性が確認されていることが重要である。しかし、研究では、ほとんどの場 合、質問紙の「自己流」バージョンが使用されており、ばく露評価に使用された実際の質問紙に関する 情報が得られないことがある。さらに、複数の物質への同時ばく露は一般的であり、結果にさらなる偏 りが生じる可能性がある。例えば、農薬への職業ばく露は、ベンゼン、重金属、溶剤、浮遊粒子状物質 などへのばく露と共存している可能性が高い。真の関連を明らかにするためには、複数の物質へのば く露による交絡を考慮することが不可欠であるが、ここで評価されたエビデンスの圧倒的多数では、 これは不可能であった。

さらに、ここで収集されて評価されたエビデンスは、選択的な報告と多重検定に悩まされている可 能性が高い。研究は非常に広範囲の分析を報告しており、602件の論文で6000件の分析が行われていた。 多重仮説検定の量は膨大である。これらの分析は多重仮説検定のために調整する必要があり、そうし ないと結果は高い偽陽性率に悩まされることになる。研究が1つの分析しか行われていない場合でも、 他の疫学分野でも示されているように、選択的な報告が行われる可能性は常にある。さらに、結果を解 釈する際には、特に特定の影響(がんなど)については、エビデンスの大部分が単一の研究集団と特に

Beyond definition of exposure, the definition of clinical outcomes displayed large variability in eligible epidemiological studies, which can further cause the variability in results. Perhaps most important in this setting is the use of surrogate outcomes examined. Here we observed a great number of surrogate outcomes. Surrogate outcomes are biomarkers or physical measures that are generally accepted as substitutes for or predictors of specific clinical outcomes. However, many times these surrogate outcomes can be defined as possible predictors of clinical outcomes but do not fulfil the criteria for a surgate outcome. It is essential that the evidence around unvalidated surrogate outcomes are appraised taking into account the implicit assumptions of unvalidated surrogate outcomes.

Acknowledging these limitations we attempted to summarise the evidence retrieved in this report. An added important limitation here is the fact that this review is limited to publications after 2006. This allows us only to review recent evidence and any meta-analysis needs very cautious interpretation, as it does not include all available evidence. Results might be biased if data published after 2006 are different from earlier evidence. To this end, we also provided updated meta-analysis for major outcomes and for those that a relevant meta-analysis published after 2006 was identified. This has only been possible for childhood leukaemia and for Parkinson's disease. For both these outcomes we found significant associations between pesticide exposure and disease in line with previous evidence. Significant summary estimates have also been reported for other outcomes as summarised in Table 25 below. However, as they represent studies form 2006 onwards results should be regarded as suggestive of associations only and limitations especially regarding the heterogeneity of exposure should always been take into consideration.

Ntzani EE, Chondrogiorgi M, Ntritsos G, Evangelou E, Tzoulaki I

Pesticide epidemiology

AHSから得られていることも考慮に入れるべきである。

ばく露の定義以外に、臨床所見の定義は妥当な疫学研究においても大きなばらつきを示しており、 これが結果のばらつきの原因となっている。おそらく、このような状況で最も重要なのは、調査された 代替健康影響の使用であろう。ここでは非常に多くの代替健康影響が観察された。代替健康影響とは、 特定の臨床所見の代用または予測因子として一般的に受け入れられているバイオマーカーまたは身体 測定値である。しかし、多くの場合、これらの代替健康影響は検証されておらず、代替健康影響の厳密 な定義を満たしていない。このような影響は、臨床所見の予測因子として定義される可能性はあるが、 代替健康影響の基準を満たしていない。検証されていない代替健康影響に関するエビデンスは、検証 されていない代替健康影響の暗黙の想定を考慮に入れて評価されることが不可欠である。

これらの限界を認識した上で、我々は本報告書で検索されたエビデンスを要約することを試みた。 ここで追加された重要な制限は、このレビューが2006年以降の出版物に限定されているという事実で ある。これにより、最近のエビデンスのみをレビューすることが可能となり、メタアナリシスは利用可 能なすべてのエビデンスを含んでいるわけではないため、非常に慎重な解釈が必要となる。2006年以 降に発表されたデータがそれ以前のエビデンスと異なる場合、結果に偏りが生じる可能性がある。こ の目的のために、主要な影響及び2006年以降に発表された関連するメタアナリシスが確認されたもの については、更新されたメタアナリシスも提供した。これは小児白血病とパーキンソン病についての み可能である。これらの影響については、以前のエビデンスに沿って、農薬ばく露と疾患との間に有意 な関連があることがわかった。有意な要約推定値は他の影響についても報告されており、以下の表25 にまとめられている。しかし、これらは2006年以降の研究であるため、結果はあくまでも関連を示唆す るものであり、特にばく露の不均一性に関する限界を常に考慮に入れるべきである。

#### RECOMMENDATIONS

As discussed above, the extensive evidence gathered for this report highlights that there is immense amount of information available on pesticide exposure and health outcomes from epidemiological studies. Nonetheless, the quality of this evidence is usually low and many biases are likely to affect the results to an extent that firm conclusions cannot be made. Childhood cancers and Parkinson's disease are the two outcomes for which a corresponding meta-analysis after 2006 was found and for which data are consistent to show an increased risk associated with pesticide exposure. Nonetheless, the exposure needs to be studies further in order to disentangle the effect of specific pesticide classes or even individual pesticides. Effects on other outcomes, such as endocrine disorders, asthma and allergies, diabetes and obesity, are showing increased risk and should be explored further. This report concentrated on examining separately health outcomes. An alternative approach would be to look for pesticide classes, subclasses or even individual pesticides across a range of outcomes. These approaches could highlight whether a pesticide class has a particular detrimental effect across a variety of disease endpoints. Finally, exposure epidemiology has long suffered from exposure measurement and definition and in particular for pesticides this has always been exceptionally difficult to assess and define. Technological advances now enable us to measure in a large scale and agnostic way biomarkers of exposure using high throughput technologies of omics. For example, metabolomic analysis offers a way to capture a whole range of environmental exposures with minimal measurement error and ability to specify the exposure. These approaches are now being developed and are likely to offer much clearer view on the associations between environmental exposures, including dietary exposures, and health outcomes.

### 推奨事項

上述したように、本報告書のために収集された広範なエビデンスは、疫学研究から得られる農薬ば く露と健康影響に関する膨大な量の情報があることを浮き彫りにしている。しかし、これらのエビデ ンスの質は通常低く、多くのバイアスが結果に影響を与え、確固とした結論を出すことができない可 能性が高い。小児がんとパーキンソン病は、2006年以降に対応するメタアナリシスが行われた2つの 影響であり、農薬ばく露に関連したリスクの増加を示すデータが一貫している。しかし、特定の農薬ク ラスや個々の農薬の影響を切り離すためには、ばく露の研究をさらに進める必要がある。内分泌疾患、 喘息、アレルギー、糖尿病、肥満などの他の影響への影響はリスクの増加を示しており、さらに調査が 必要である。本報告書では、健康影響を個別に調査することに集中した。別のアプローチとしては、農 薬のクラス、サブクラス、あるいは個々の農薬でさえも、さまざまな影響にわたって調べることであろ う。これらのアプローチにより、ある農薬クラスが様々な疾患エンドポイントにおいて特定の有害な 影響を及ぼすかどうかを明らかにすることができる。最後に、ばく露疫学は長い間、ばく露の測定と定 義に悩まされてきたが、特に農薬については、これは常に評価と定義が非常に困難であった。技術的な 進歩により、オミクスのハイスループット技術を用いて、大規模かつ断定的でない方法でばく露のバ イオマーカーを測定することが可能になった。例えば、メタボローム分析は、最小限の測定誤差とばく 露を特定する能力で、環境ばく露の全範囲を捕捉する方法を提供している。これらのアプローチは現 在開発が進められており、食事ばく露を含む環境ばく露と健康影響との関連について、より明確な見 解を提供してくれる可能性が高い。

# APPENDIX II. EXPLANATIONS TO THE DATA EXTRACTION DATABASE

Study ID	This is the unique ID of the study given sequentially for each
	study major outcome
PUBMED_ID	This is the PUBMED ID of the study (if not available ID in
	EMBASE was provided and when this was not available the
	title of the study was provided)
First author	First author's last name
Journal	Journal in which the study was published
Year	Year of publication
Country	Country where the study was conducted
Location (continent)	Continent where the study was conducted
Recruitment period	Period during which the study participants were recruited
Exposure Period (preconception,	Growth period in which the pesticide exposure occurred
infancy, childhood, adulthood,	(preconception, pregnancy, infancy, childhood, adolescence,
pregnancy)	adulthood)
Follow-up period	Follow-up calendar period for prospective/ retrospective studies
Follow-up duration (maximum)	Maximum follow-up period in years for prospective/
	retrospective studies
Follow-up duration (years)	Mean or median follow-up period in years for prospective/
(median/mean)	retrospective studies
Study type (cohort, nested case-	The epidemiological study design: cohort, nested case-control,
control, case-control, cross- sectional)	case-control, cross-sectional
Cohort name	The name of the epidemiological study
Age (years) (range/mean/median)	The age of the population studied (preference is to provide
	the mean or meadian age, when not available the range is
	given). Data is presented in years unless otherwise stated.
Gender (% male)	Percentage of males in study population
Active substance assessed	Pesticide assessed in the study as defined/named in the study
Active substance category	Chemical or functional pesticide category in which the
	pesticide is classified
Authorisation status	Pesticide active substances authorized within EU
	(06/09/2013). Yes/No/NA (NA=not applicable)
Biomarker name	The name of the biomarker of exposure to pesticide (if
	measured)
Control definition	Definition of the control group in case-control studies
Pesticide co-exposure (measured)	Did the study provided information on other co-exposed pesticides? (yes, no)
Population characteristics	Description of the population examined (gender, location,
	disease status)
Type of exposure (occupational,	What is the source of exposure to pesticides: occupational (if
environmental, both)	the exposure is related to a specific occupational activity);
	environmental (if the exposure is not related to any

# 付録 II. データ抽出データベースの説明

Study ID	これは、研究の主要な影響ごとに順次与えられる研究の固有 ID である。
PUBMED _ID	これがその研究の PUBMED ID である(EMBASE の ID が提供されてい
	ない場合に PUBMED ID が提供され、PUBMED ID が提供されていない
	場合は研究のタイトルが提供された)。
筆頭著者	筆頭著者の姓
ジャーナル	研究が掲載された雑誌
年	出版年
围	研究実施国
場所(大陸)	研究実施大陸
募集期間	研究参加者を募集した期間
ばく露期間(妊娠前、乳児期、小児期、成	農薬ばく露が発生した発育期(妊娠前、妊娠期、乳児期、小児
人期、妊娠期)	期、思春期、成人期)
追跡期間	前向き/後ろ向き研究の追跡予定期間
追跡期間(最大)	前向き/後ろ向き研究の最大追跡期間は年単位である。
追跡期間(年)(中央値/平均値)	前向き/後ろ向き研究の平均または中央値の追跡期間 (年)。
研究の種類(コホート、コホート内症例対	疫学研究のデザイン:コホート、コホート内症例対照、症例対
照、症例対照、横断的)	照、横断的
コホート名	疫学研究の名称
年齢(年)(範囲/平均/中央値)	調査対象となった集団の年齢(平均年齢または中央値年齢を提示
	することを好む。データは、別段の記載がない限り、年単位で表
	示される。
性別(男性の割合)	調査対象集団における男性の割合
評価された有効成分	試験で定義・命名された試験で評価された農薬
有効成分のカテゴリー	農薬が分類されている化学的または機能的な農薬の分類
認可状況	EU 城内で認可された農薬有効成分(2013/09/06) Yes/No/NA (NA=該 当なし)
バイオマーカー名	農薬ばく露のバイオマーカー名(測定した場合)
対照定義	症例対照研究における対照群の定義
農薬の共ばく露(測定値)	その研究では、他の共ばく露農薬に関する情報を提供したか?(は
	い、いいえ)
集団の特徴	調査した集団の説明(性別、場所、病状)
ばく露の種類(職業的、環境的、両方)	農薬へのばく露源は何か:職業的(ばく露が特定の職業活動に関
	連している場合);環境的(ばく露がいかなる職業活動にも関連し
	ていない場合(例えば、住居内での農薬使用、ガーデニングでの
	農薬使用、ガーデニングに関連したばく露など);両方(職業ばく
	露と環境ばく露の両方が存在する場合)。
ばく露評価の種類(直接ばく露についての	農薬ばく露の測定方法:直接ばく露についての質問紙(面接また
質問紙/バイオマーカー/居住履歴/職歴	は自己記入);体液中のバイオマーカーの測定;居住歴;職業歴;
/JEM/専門家評価/環境 odeling 誤植と	職業ばく露マトリックス (JEM)。
思われる	

	occupational activity (e.g. domestic use of pesticides, use of pesticides in gardening, exposure related to gardening etc.); both (when both occupation and environmental exposure is present).
Type of exposure assessment (direct exposure questionnaire/ biomarker/residential history/occupational history/ JEM/ expert evaluation/ environmental odeling)	Means of measuring pesticide exposure: direct exposure questionnaire (interview or self-administered); measurement of biomarker in biological fluids; residential history; occupational history; Job Exposure Matrix (JEM)
Exposure definition	Definition of exposure as described in the study
Questionnaire type	Questionnaire type (interview or self administrated) (for studies which assessed exposure through questionnaires, else state n/a)
Measurement of biomarker (whole blood, plasma, urine, breast milk, placenta, nails, hair, saliva, adipose tissue)	Body fluid or tissue in which the biomarker was measured (whole blood, plasma, urine, breast milk, placenta, nails, hair, saliva, adipose tissue etc.)
Assay type	Type of biochemical assay used for biomarker measurement
Exposure duration	Duration of exposure to pesticides in years (when available)
Pediatric exposure type (mother, father, child, combinations)	For studies on child outcomes, describe means of exposure through self-exposure or parental exposure (mother, father, child, combinations)
Pediatric exposure time (preconception, pregnancy, combination)	For studies on child outcomes, was parental exposure during preconception, pregnancy or combinations?
Health outcome	Health outcome as described in the study
Outcome definition	Health outcome definition used in the study
Disease category	Disease category
Effect estimate type (RR, OR, HR, beta, MD, SMD)	Type of effect estimate for the assessment of pesticide and health outcome relationship (RR, OR, HR, beta, MD, SMD)
Effect (binary, continuous)	Effect estimated on a binary or continuous manner (binary, continuous)
Comparison unit (yes/no, unit increase,)	The definition of comparison for the calculation of the effect size (yes/no, unit increase etc.)
Effect estimate	Value of effect estimate
SE/SD effect stimate	Standard error/Standard deviation of effect estimate
Lower 95% CI	Lower 95% confidence interval of the effect estimate
Higher 95% CI	Higher 95% confidence interval of the effect estimate
Adjustment for	Confounders/ variables for which the effect estimate was adjusted for
Controls matched for	Variables for which controls were matched to cases (case control studies only)
Sample size	Total number of participants
N cases	Number of cases

Pesticide epidemiology

バノボージャ	研究に記掛きしていてばく雪のウギ
ばく 露の 定義	研究に記載されているばく露の定義 質問紙の種類(面接または自己管理)(質問紙を用いてばく露を評
資間紙の種類	負向紙の種類(面接または自己管理)(負向紙を用いてはく露を許 価した研究の場合、そうでない場合は該当なし)
バイオマーカーの測定(全血、血漿、尿、	バイオマーカーが測定された体液または組織(全血、血漿、尿、
母乳、胎盤、爪、毛髪、唾液、脂肪組織)	母乳、胎盤、爪、毛髪、唾液、脂肪組織など)
アッセイタイプ	バイオマーカー測定に使用した生化学的アッセイの種類
ばく露期間	年単位での農薬ばく露期間(入手可能な場合)
小児ばく露タイプ(母、父、小児、組合わ	小児の影響に関する研究については、自己ばく露または親のばく
せ)	露(母親、父親、小児、組合わせ)を通じたばく露手段を記述
小児ばく露時期(妊娠前、妊娠期、両方)	小児の影響に関する研究では、親のばく露は妊娠前、妊娠期、または両方の期間に行われたか?
健康影響	研究に記載されている通りの健康影響
影響の定義	研究で使用された健康影響の定義
疾患カテゴリ	疾患カテゴリ
効果推定タイプ (RR、OR、HR、β、MD、	農薬と健康影響の関係を評価するための効果推定値の種類(RR,
SMD)	OR, HR, $\beta$ , MD, SMD)
効果(2変数、連続変数)	2変数法または連続変数法で推定された効果(2変数、連続変数)
比較単位(はい/いいえ、単位増加、	効果量を算出するための比較の定義(はい/いいえ、単位増加な ど)
効果推定	効果推定値
SE/SD 効果推定	効果推定値の標準誤差・標準偏差
95% CI の下限	効果推定値の 95%信頼区間の下限
95% CI の上限	効果推定値の 95%信頼区間の上限
調整	効果推定値の交絡因子/変数の調整
マッチした対照	対照の変数を症例にマッチさせた(症例対照研究のみ)
サンプルサイズ	参加者総数
N症例	症例数
N 対照	対照数
統計的手法	効果量の計算に用いられる統計的手法
試験デザイン(前向き、後ろ向き、混合、	研究デザインの前向き型または後ろ向き型(前向き、後ろ向き、
横断)	混合、横断)
包含/除外の基準の明記	研究参加者(母集団)の説明は詳細に行われていましたか?(はい
(はい、一部、いいえ)	/一部/いいえ)
著者による検出力の言及	著者らは、統計分析の前または後に論文で検出力について言及し
(はい、いいえ)	ているか?(はい/いいえ)
ばく露レベル(高、中、低)の詳細記述	農薬ばく露の定義でばく露レベル(高、中、低)の詳細記述
ばく露量の妥当な測定 :	ばく露量の測定は妥当であったか:バイオマーカー(はい);小規
(バイオマーカー(有);小規模区域の生態	模区域の生態学的測定、職種、質問紙(一部);大規模区域の生態
学的測定、職種、質問紙(一部); 大規模区	学的測定に基づいた(いいえ)
域の生態学的測定に基づいた(無))	
ばく露量の測定は特定のものであったか?	ばく露量の測定は特定のものであったか?(はい);より広範で化
はい;より広範で化学的に関連したグルー	学的に関連したグループに基づく(一部);多様な化学的及び毒性
プに基づく (一部);多様な化学的及び毒	学的特性の広範なグループ化に基づく(いいえ)

# Ntzani EE, Chondrogiorgi M, Ntritsos G, Evangelou E, Tzoulaki I

N controls	Number of controls
Statistical method	Statistical method used to calculate the effect size
Study design (prospective, retrospective, mixed, cross- sectional)	Prospective or retrospective type of study design (prospective, retrospective, mixed, cross-sectional)
Inclusion/exclusion criteria clearly stated (yes, partially, no) Authors mention power calculations (yes, no) Level of detail in describing exposure (high, medium, low) Robust measurement of exposure. (biomarker (yes); small area ecological measures, job titles, questionnaire (partial); was based on large area ecological measures (no)	Was the description of study participants (population) inclusion and exclusion criteria detailed? (yes/partially/no) Do the authors mention power calculations in the manuscript preceding or proceeding their statistical analysis (yes/no) Level of detail in which the definition of exposure to pesticides is provided (high/medium/low) Was the measurement of exposure robust: biomarker (yes); small area ecological measures, job titles, questionnaire (partial); was based on large area ecological measures (no)
Were measures of exposure specific? Yes; based on broader, chemically-related groups (partial); based on broad groupings of diverse chemical and toxicological properties (no)	Were measures of exposure specific? (yes); based on broader, chemically-related groups (partial); based on broad groupings of diverse chemical and toxicological properties (no)
Attempt to balance the allocation between the groups (e.g., through stratification, matching)	Was an attempt to balance the allocation between the groups in case-control studies either through stratification or matching (yes/no)?
Adjustment performed for potential confounders (yes, some, no)	Was the effect size adjusted for potential confounders (yes, some, no)?
Assessors blinded to exposure status (for cohort studies)	Were the assessors blinded to exposure status in cohort studies (yes/no/;n/a:not available or not applicable when studies are not cohorts)?
Outcomes assessed using valid and reliable measures, implemented consistently across all study participants?	Were the outcomes assessed using valid and reliable measures implemented consistently across all study participants (yes/no)
Sample size (top [991], middle, bottom quartiles[104])	The size of the sample
Was source of funding acknowledged	Do the authors acknowledge any possible source of funding (yes/no)
Rough quality assessment	Rough quality assessment taking into account the data in all other columns of the quality assessment of data extraction form
COMMENTS	Any comments related to the study that help interpretation of the data extracted

Pesticide epidemiology

#### **GLOSSARY AND ABBREVIATIONS**

AHS: Agricultural Health Study

Beta estimate: coefficient of linear regression

Bias: A systemic inaccuracy in data due to the characteristics of the process employed in the creation, collection, manipulation and presentation of the data or due to faulty sample design of the estimating technique

Biomarker: A measurable substance or characteristic in the human body that can be used to monitor the presence of a chemical in the body, biological responses, or adverse health effects. Biomarkers of exposure are used to assess the amount of a chemical that is present within the body.

Blinded outcome assessment: Individuals who assess the exposure are blinded to the health outcome status of the participants.

CARDIA: The "Coronary Artery Risk Development In Young Adults" study, a multi-center, population-based study.

Case-control study: A type of observational study in which two existing groups differing in outcome are identified and compared on the basis of some supposed causal attribute. Case-control studies are retrospective, as the exposure status is assessed retrospectively.

Case reports: Detailed reports of the symptoms, signs, diagnosis, treatment, and follow-up of individual patients.

Case series: descriptive study that tracks patients with a known exposure given similar treatment or examines their medical records for exposure and outcome. These studies lack control groups.

Center-specific analysis: Analysis per centre in studies, which have participants, recruited from more than one centre.

CHAMACOS: The Center for the Health Assessment of Mothers and Children of Salinas (CHAMACOS). A prospective birth cohort aimed at studying the association of pesticides and other environmental agents on the health of pregnant women and their children living in the Salinas Valley, California.

CI: Confidence Interval

Cohort study: A longitudinal/prospective study, which analyses risk factors and follows a group of people who do not have the disease until participants develop the disease(s) of interest

Confounders: Extraneous variables in a statistical model that correlate (positively or negatively) with both the dependent variable (exposure) and the independent variable (outcome)

Cross-sectional study: A study that involves observation of all of participants at one specific point in time, exposure and outcome are measured in the same time point.

Ecological study: Studies in which the unit of observation is the population or community. Disease rates and exposures are measured in each of a series of populations and their relation is examined.

#### 用語解説と略語

AHS:農業健康調査

ベータ推定値:線形回帰の係数

バイアス:データの作成、収集、操作及び表示に採用されたプロセスの特性に起因する、または推定 手法の誤ったサンプルデザインに起因する、データの体系的な不正確さ。

バイオマーカー:体内の化学物質の存在、生物学的反応、または健康への有害影響を監視するために 使用できる、人体内の測定可能な物質または特性。ばく露のバイオマーカーは、体内に存在す る化学物質の量を評価するために使用される。

盲検影響評価:ばく露を評価する個人は、参加者の健康状態を盲検化する。

- CARDIA (カーディア): "Coronary Artery Risk Development In Young Adults (若年成人の冠状動 脈リスク発症) "研究、多施設、集団ベースの研究。
- 症例対照研究 (Case-control study):観察研究の一種で、結果の異なる2つの既存のグループを特 定し、何らかの因果関係に基づいて比較する研究。症例対照研究は、ばく露状況を後ろ向きに 評価する後ろ向き研究である。
- 症例報告:個々の患者の症状、徴候、診断、治療、経過観察の詳細な報告。
- 症例集積:同様の治療を受けたばく露が知られている患者を追跡したり、ばく露と影響について医療 記録を調べたりする記述研究。これらの研究には対照群がない。
- センターごとの分析:複数のセンターから募集した参加者がいる研究におけるセンターごとの分析。
- CHAMACOS (チャマコス): Center for the Health Assessment of Mothers and Children of Salinas (CHAMACOS)。カリフォルニア州サリナスバレーに住む妊婦とその子供の健康に及ぼす農薬やそ の他の環境要因の関連を調べることを目的とした前向き出生コホート。

CI:信頼区間

- コホート研究:リスク因子を分析し、調査対象疾患を発症するまで疾患を持たない人のグループを追 跡調査する縦断的/前向き研究。
- 交絡因子 (Confounders): 従属変数(ばく露)と独立変数(影響)の両方と相関する(正または負の)統計モデルの外部変数。

横断研究:ある特定の時点での参加者全員の観察を行い、ばく露と影響を同じ時点で測定する研究。

生態学的研究:観察の単位が集団または共同体である研究。疾病率とばく露が各集団集積で測定さ れ、それらの関係が調査される。

効果(2変数/連続変数):影響は2変数法(二項対立、例:がん(はい/いいえ))または連続変数法 (例:収縮期血圧(120mmHg))である。

効果推定値/サイズ:関連の強さの尺度

ESCALE:全国登録ベースの症例対照研究「Etude sur les cancers de l'enfant」試験

- ファンネルプロット:システマティックレビューやメタアナリシスにおける出版バイアスの有無を確 認するために設計されたグラフ
- 不均一性:メタアナリシスは、類似した研究のグループから複合的な効果を推定するために使用され る。しかし、治療効果の個々の推定値は偶然によって変動する;ある程度の変動は予想され

The present document has been produced and adopted by the bodies identified above as author(s). #### Ntzani EE, Chondrogiorgi M, Ntritsos G, Evangelou E, Tzoulaki

Pesticide epidemiology

Effect (binary/continuous): Outcome is binary (dichotomous, e.g. cancer (yes/no)) or continuous (e.g. systolic blood pressure (120mmHg)).

Effect estimate/ size: A measure of the strength of association

ESCALE: The "Etude sur les cancers de l'enfant" study, a national registry-based case-control study

Funnel plots: graph designed to check the existence of publication bias in systematic reviews and meta-analyses

Heterogeneity: meta-analysis is used to estimate a combined effect from a group of similar studies. However, the individual estimates of treatment effect will vary by chance; some variation is expected. The question is whether there is more variation than would be expected by chance alone. When this excessive variation occurs, it is called heterogeneity

#### HR: Hazard Ratio

 $I^2$ : measure of the consistency between trials in a meta-analysis, it is a measurement of heterogeneity and takes values form 0 (no heterogeneity) to 1 (extreme heterogeneity)

INUENDO: "INUENDO—Biopersistent organochlorines in diet and human fertility" Epidemiological studies of time to pregnancy and semen quality in Inuit and European populations", a European project on fertility that was supported by the European Commission to the 5th Framework Programme Quality of Life and Management of Living Resources, Key Action 4 on Environment and Health (Contract no. QLK4-CT-2001-00202) (http://www.inuendo.dk).

IRR: Incidence rate ratio

IQR: Interquartile Range

JEM :Job Exposure Matrix

MD: Mean Difference

Meta-analysis: The process or technique of synthesizing research results by using various statistical methods to retrieve, select, and combine results from previous separate but related studies.

Multiple testing: Testing many hypotheses, which are not a priori defined or based on a priori hypothesis.

Misclassification: Bias in an estimate arising from measurement error

Multivariable models: Statistical models with more than one dependent variable. These models typically adjust for a number of confounders the analysis of interest.

Nested case-control study: In a nested case-control study, cases of a disease that occur in a defined cohort are identified and, for each, a specified number of matched controls is selected from among those in the cohort who have not developed the disease by the time of disease occurrence in the case

NHANES: National Health and Nutrition Examination Survey

158

Ntzani EE, Chondrogiorgi M, Ntritsos G, Evangelou E, Tzoulaki I Pesticide epidemiology る。問題は、偶然だけで予想される以上の変動があるかどうかである。このような過度の変動 が生じる場合、それは不均一性と呼ばれる。 HR: ハザード比 (Hazard Ratio) I<sup>2</sup>: メタアナリシスにおける試験間の一貫性の尺度で、不均一性の測定であり、0(不均一性なし) から1(極端な不均一性)までの値をとる。 INUENDO: "INUENDO-食品中の生物持続性有機塩素化合物とヒト生殖能、イヌイットと欧州の集団にお ける妊娠までの期間と精液の質の疫学研究"、欧州委員会(the 5th Framework Programme Quality of Life and Management of Living Resources, Key Action 4 on Environment and Health (Contract no. QLK4-CT-2001-00202) (契約番号: QLK4-CT-2001-00202) (http://www.inuendo.dk))の支援を受けた不妊に関する欧州のプロジェクト。 IRR:発生率比 IQR:四分位間範囲 JEM:職業ばく露マトリックス MD:平均差 メタアナリシス (Meta-analysis): 様々な統計的手法を用いて研究結果を統合し、以前の別々ではあ るが関連のある研究の結果を検索、選択、結合するプロセスまたは技術。 Multiple testing (多重検定): 先験的に定義されていない、または先験的仮説に基づいていない、 多くの仮説を検定すること。 誤分類:測定誤差に起因する推定値のバイアス 多変量モデル:1つ以上の従属変数を持つ統計モデル。これらのモデルは通常、調査対象の分析の交 絡因子の数を調整する。 コホート内症例対照研究:コホート内症例対照研究では、定義されたコホート内で発生した疾患の症 例が同定され、各症例の疾患発生時までに疾患を発症していないコホート内の患者の中から、 指定された数のマッチした対照が選択される。 NHANES: 米国国民健康栄養調査 観察研究:観察研究とは、被験者に対する治療の効果について推論を行うもので、被験者を治療群と 対照群に割り当てるのは研究者の管理外である。 OR: オッズ比 統合効果推定値:メタアナリシスの要約した効果推定値、メタアナリシスの結果 POPs: 残留性有機汚染物質 前向き研究 (Prospective study):ある影響に影響を及ぼす可能性のある要因に基づいて個人 (コホ ート)のグループを選択する疫学研究 出版バイアス (Publication bias):研究者、編集者、製薬会社が、陽性(すなわち有意な知見を示 す)の実験結果の報告を、陰性(すなわち帰無仮説を支持する)または結論の出ない結果とは 異なる扱いをする傾向から生じたバイアス。 回想バイアス (Recall bias): 過去の出来事や経験の記憶に対する回想の正確さや完全さの違いに よるシステマティックエラー。 残存交絡:残存交絡因子は、交絡因子が分析で十分に調整されていない場合に発生する(通常、交絡 EFSA 支援出版 2013:EN-497 158

EFSA supporting publication 2013:EN-497

Observational study: an observational study draws inferences about the possible effect of a treatment on subjects, where the assignment of subjects into a treated group versus a control group is outside the control of the investigator

#### OR: Odds ratio

Pooled effect estimate: Summary effect estimate of the meta-analysis, the result of meta-analysis

POPs: Persistent Organic Pollutants

Prospective study: An epidemiologic study in which the groups of individuals (cohorts) are selected on the bases of factors that are to be examined for possible effects on some outcome

Publication bias: Bias arisen from the tendency for <u>researchers</u>, editors, and pharmaceutical companies to handle the reporting of experimental results that are *positive* (i.e. showing a <u>significant</u> finding) differently from results that are <u>negative</u> (i.e. supporting the <u>null hypothesis</u>) or inconclusive.

Recall bias: Systematic errors due to differences in accuracy or completeness of recall to memory of past events or experiences.

Residual confounding: Residual confounding occurs when a confounder has not been adequately adjusted for in the analysis (usually because the confounder is not known)

Retrospective study: an epidemiologic study in which participating individuals are classified as either having some outcome (cases) or lacking it (controls); the outcome may be a specific disease, and the persons' histories are examined for specific factors that might be associated with that outcome

Reverse causality: Reverse causality refers to the direction of cause-and-effect, it is not known whether the exposure has led to the outcome or the outcome has led to the exposure.

RR: Relative Risk

Narrative review: An article written to consider the critical points of current knowledge including substantive findings, as well as theoretical and methodological contributions to a particular topic

SD: Standard Deviation

SE: Standard Error

Surrogate outcome: A laboratory measurement or physical sign that is used in trials as a substitute for a clinically meaningful endpoint that is a direct measure of how a patient feels, functions, or survives and is expected to predict the effect of the exposure

Systematic reviews: Reviews of the evidence on a clearly formulated question that use systematic and explicit methods to identify, select and critically appraise relevant primary research, and to extract and analyse data from the studies that are included in the review

Type-I error: The incorrect rejection of a true null hypothesis

UFW: United Farm Workers

要約

ばく露評価の質は、環境疫学研究の全体的な質を決定する主要な要素である。生理的半減期の 短い至る所に存在する(ユビキタス)化学物質へのばく露を評価するためのツールとしてのバイ オモニタリングの使用は比較的最近になってから始まった。これらの化学物質には、分析室やサ ンプリング機器に含まれる化学物質の存在、横断研究における時間的順序の確立の難しさ、ばく 露とバイオマーカーの濃度の短期及び長期の変動、適切なばく露分類に必要な測定数に関する情 報不足など、いくつかの問題がある。現在までのところ、科学研究分野において、ばく露指標と してバイオモニタリングを使用する短寿命化学物質の研究を計画、実行、解釈するための体系的 なガイドラインを開発しておらず、また、この種の研究の質を評価するための WOE 評価、また は助成金や出版物のピアレビューのための体系的なガイドラインを開発していない。本研究では、 短寿命化学物質のバイオモニタリングデータを用いた疫学研究に影響を与える重要な問題点を説 明し、短寿命化学物質のバイオモニタリングデータを取り入れた研究提案や研究の質を評価する ための体系的な指標であるバイオモニタリング、環境疫学、短寿命化学物質(BEES·C)を提案 する。短寿命化学物質の生物学的測定を含む疫学研究の評価に不可欠と考えられる3つの分野の 品質基準について説明している。1)バイオマーカーの選択と測定、2)試験デザインと実行、3) 一般的な疫学研究デザインに関する考察。BEES-C のような評価ツールの開発は単純ではなく、 議論の余地のないものでもないことを認識している。

## 1. 序文

疫学研究は、様々な化学的、物理的、生物学的、放射線学的、行動学的なばく露がヒトの健康 に及ぼす影響を評価する上で重要な役割を果たしている。しかし、ヒトにおける因果関係の仮説 を検証するために特別に設計され、厳密に実行された疫学研究であっても、しばしば矛盾した結 果が報告される。保健政策の提言を行う規制機関やコンセンサス・パネルは、一般的に疫学研究 結果を評価するために WOE (weight-of-evidence) アプローチに依存している。

WOE 評価は、結論が利用可能な最も強力な証拠に基づいていることを確認するために研究の 質を評価しない場合、不完全であったり、誤解を招く可能性がある。さらに、助成金申請書や原 稿のピアレビューにおける研究の質を評価することで、ヒトのばく露や健康に関する研究の全体 的な質を高めるのに役立つ。

研究の質の決定には常にある程度専門的な判断が必要であるが、疫学的証拠の強さの評価は、 体系的に適用される合意された基準に依存すべきであるという考えが出てきている

(Vandenbroucke ら、2007 年)。これらの考えが、いくつかの研究の質評価ツールの開発と改善の動機となった。これらのツールのいくつか(例えば、STROBE(Vandenbroucke ら、2007 年);CONSORT(Moher ら、2001 年))は、分野を超えて適用される一般的な問題を扱っている。他のツールは、医学や生命科学の様々な分野に特化して開発された(例えば、遺伝学的研究のための STREGA(Little ら、2009 年)、治療効果の比較研究のための GRADE(Owens ら、2010 年)、診断精度の研究のための STARD(Bossuyt ら、2004 年))。

研究の質を取り入れた WOE 評価の標準化が進んでいる現在の傾向に鑑みると、環境疫学研究 を評価するための手段が、研究デザインの開発段階や原稿の審査段階でも、相対的に少なくなっ ていることは注目に値するが、説明が難しい。エビデンスの重み付け評価のための研究の質の評 価に焦点を当てた評価スキーム(Harmonization of Neurodevelopmental Environmental Epidemiology Studies)(Youngstrom ら、2011 年)では、診断精度研究の質の評価

(QUADAS)をコーディングツールの基礎として使用しているが(Whiting ら、2003 年)、その名が示すように、この評価指標は神経発達研究を中心としたものである。National Toxicology Program は最近、研究の質を評価するためのアプローチを開発し(NTP、2013 年)、これを用いて環境化学物質と糖尿病に関する文献を調査した(Kuo ら、2003 年)。この事業計画には、疫学及び毒性学の文献の評価を含み、非難分解性及び難分解性の化学物質は含まれていたが、短寿命化学物質のバイオモニタリング固有の問題は含まれていなかった。

環境疫学研究の最適な実行に関する体系的なガイダンスを提供するツールがないことは、集団 ベースの研究に依存する規制上の意思決定にとって重要な制約となっている。他の研究分野とは 異なり、ヒトに有害性影響を誘発することを目的とした介入研究は、倫理的に可能であるとして も、ほとんど行われていないため、環境疫学データに基づく WOE 評価は、独特のものである。 そのため、環境疫学研究はほとんど常に観察的な研究であり、様々な情報源から生じる避けられ ない不確実性の影響を受けている。環境疫学における不確実性の重要なソースの一つであると同 時に、急速に進展している分野でもあるのが、ばく露科学である。

ばく露評価は、生理学的半減期の短い化学物質を含む環境疫学研究(Hertz-Picciotto、1998 年)において、全体的なデータの質を決定する主要な要素である。短寿命化学物質とは、化学物 質分量の半分を体外に排出するのに必要な時間が、およそ数分から数時間あるいは数日である化 学物質のことである。短寿命化学物質のばく露評価の質は、ばく露の様々な側面を調べるための バイオモニタリングを用いた研究と同様に、健康影響との関連性を評価するためのデータの有用 性と密接に関連している。近年、ばく露科学の手法は、バイオモニタリングによる環境化学物質 の検出能力の向上により、特に恩恵を受けている。バイオモニタリングとは、血液、尿、呼気、 母乳、毛髪など、ヒトの様々なマトリックス中の化学物質を測定することである。バイオモニタ リングデータは、すべての経路(経口、吸入、経皮、経胎盤)からのばく露を統合したものであ り、以下のような場合に有用である。(1)集団参照範囲の設定、(2)亜集団における異常ばく 露の特定、(3)集団内の時間的変動と傾向の評価、(4)個人のばく露量を推定するためにデザ インされたアンケートの検証、(5)疫学研究における健康影響との関連性の検討。

難分解性有機汚染物質や金属のばく露量を測定するための基礎としてのバイオモニタリングを 用いた疫学研究は、何十年にもわたって実行されてきた。対照的に、至る所に存在する(ユビキ タス)生理的半減期の短い化学物質(ベンゼン、フタル酸エステル類、特定の農薬など)のバイ オモニタリングは、比較的最近始まったもので、ばく露のばらつきや、分析室やサンプリング機 器に含まれる多くの化学物質のユビキタスな性質によって複雑になるため、これらの化学物質に 関するデータの解釈にはいくつかの新たな問題がある。また、これらの化学物質は、研究に使用 するマトリックスを選択する際にも問題となる。現在までのところ、これらの化学物質のバイオ モニタリング研究を実行し、解釈するための体系的なガイドラインは開発されていない。同様に、 WOE 評価あるいは助成金や出版物の査読のため、この種の研究の質を評価するための公表され た方法はない。

この知識ギャップは、2013年の国際ワークショップ「Best Practices for Obtaining, Interpreting and Using Human Biomonitoring Data in Epidemiology and Risk Assessment: Chemicals with Short Biological Half-Lives (疫学とリスク評価におけるヒトのバイオモニタリ ングデータの取得、解釈、利用のための最適な実行:生物学的半減期の短い化学物質)」の明確 な目的となった。このワークショップには、分析化学、ばく露とリスクの評価、疫学、医学、生 理学的薬物動態 (PBPK) モデリング、臨床バイオマーカーを専門とする政府機関、学界、民間 機関の専門家が参加した。ワークショップの目的は以下の通りであった。(i) 生理的半減期の 短い化学物質の生物学的モニタリングデータを用いた疫学研究に影響を与える問題を説明するこ と。(ii) 短寿命化学物質のバイオモニタリングデータを取り入れた研究提案や研究の質を評価 するための体系的なスキームを構築する。

本論文では、短寿命化学物質の生物学的測定を含む疫学研究の評価の基礎となると考えられる 3 つの分野の品質基準について説明する。1) バイオマーカーの選択と測定、2) 試験デザインと 実行、3) 一般的な疫学研究デザインの考慮事項である。これらのトピック領域の主要な側面に ついて議論し、次に、階層化されたマトリックスとして構成された評価指標(バイオモニタリン グ(Biomonitoring)、環境疫学(Environmental Epidemiology)、短寿命化学物質(Short-Lived Chemicals (BEES-C))の指標)の提案に組み入れた(表1)。提案されている評価指標 のいくつかの側面には、難分解性化学物質と短寿命化学物質の両方の疫学研究に関連する研究デ ザインの要素が含まれている。実際、STROBE のような広く受け入れられている評価指標の側 面は、ここで提案する評価指標に意図的に織り込まれている(Gallo ら、2011 年; Little ら、 2009 年; Vandenbroucke ら、2007 年) (STROBE は、観察研究の報告を改善するための方法 や、これらの研究を批判的に評価するためのガイダンスを提供している。STROBE は査読者、 ジャーナル編集者、読者が利用できるようにデザインされている「(Vandenbroucke ら、 2007)」。)。STROBE の既定及び新規の側面は、ばく露評価のアプローチとして短寿命化学 物質のバイオモニタリングを用いた研究の質を評価する上で批判的な要素であるが、本コミュニ ケーションの第一の目的は、短寿命化学物質の研究の批判的な側面をカバーすることである。

ある研究を評価するために使用できる品質問題のリストは長い。すべてを網羅しているが扱い にくい手段を開発することと、最も重要な問題のみを含む(短寿命化学物質に特有の、あるいは 特に重要な研究の側面に焦点を当てている)より差別化された実用的な手段を開発することとの 間とは対立する状態にある。提案された BEES-C 指標を開発するにあたり、後者を選択した。

この指標は、ばく露と健康影響との関係を調べる研究だけでなく、ばく露の様々な側面(例え ば、時間的・空間的傾向)を調べるバイオモニタリングデータを用いた研究にも適用可能である。 ここで提起され、BEES-C指標によって対処された問題は、職業に関係のある研究と栄養疫学を 含めて短寿命化学物質の生物学的指標に関わる複数の分野に影響を及ぼす。

環境疫学研究における短命化学物質の特徴として、特に注意が必要なのは、対象となる健康影響に関連するばく露範囲を表すサンプルの数と時期、パーソナルケア製品、実験器具、塵埃、食品など、現在製造されている製品にはこれらの化学物質の多くが普遍的に存在しているため、サ

ンプルの汚染を避けるために特別な配慮が生じること、適切な生物学的マトリックスの選択により、1 つのサンプルで多数の化学物質を測定することができるため、完全な報告と多重比較に関する問題に注意を払う必要性が高まることである。

これらについては、以下のセクションで詳しく説明し、それぞれの問題について例を示す。機器 のトピックのほとんどはばく露のバイオマーカーに関連するものであるが、効果のバイオマーカ ーについても関連性があれば記載している。

## 2. BEES-C 指標の使用

BEES-C 指標は、研究デザインの開発、助成金提案書のレビュー、論文原稿のピアレビュー、 WOE 評価の実行など、複数の目的に使用することができる。

#### 2.1. BEES-C の使用目的

BEES-C ツールの最終的な目標は、ヒトにおける短寿命化学物質の研究に関する文献全体の改善で研究者を支援することである。BEES-C は、以下のような目的で使用されることを意図したものではない: (i)研究者が仮説作成のための研究を行わないようにすること、(ii)低レベルの研究をWOE 評価に含めないようにすること。

どのようなタイプの検査機器でもそうであるように、評価プロセスには、階層化の観点からも、 また、検査機器のどの点が特定の研究に関連しているかを判断するためにも専門家の判断が必要 である。

以下の項では、BEES-C の主な特徴を事例を交えて説明する。ここでは、BEES-C を利用する ための推奨事項について述べる。BEES-C は、ばく露のバイオマーカーと何らかの効果指標 (例:効果のバイオマーカー、医師による診断疾患)との関連性に関する疫学研究の一部である ヒトのバイオモニタリング研究に適用されるが、他の目的(例:時間的または空間的傾向分析のためのばく露評価)のために計画されたヒトのバイオモニタリング研究には、BEES-C指標の一部のみが適用される。

#### 2.2. BEES-C の利用方法

表1は、研究デザインの側面(行)と評価段階(列)に沿って整理されている。審査対象の各 研究について、重要な側面が行ごとに評価され、該当するセルは色分けされている(図1)。こ れにより、研究者/査読者は研究の質の全体像を把握することができる。この指標の使用者は、 各決定に対して正当な根拠を示す必要がある(表1);これはプロセスの透明性を高めることに なる。BEES-C 指標は以下のように使用される: (i)提案された研究デザインを評価する研究 者が、研究の質が最大化されていることを確認するための手段として使用、(ii)研究の質を体 系的に評価し、質を向上させることができる分野を特定するために、論文や出版物の査読者が使 用、(iii)意思決定(例:規制基準の策定に使用するには十分に質の高い研究か?研究はメタ解 析に含まれるか?)を通知する手段として研究の質を評価するためにシステマティックレビュー を実行している者が使用、(iv) BEES-C を現在の既存のレビュースキームに組み入れたいと望 む者が使用。例えば、短寿命化学物質に特異的に適用可能な我々の提案するアプローチの問題点 の多くは、OHAT (Office of Health Assessment and Translation Approach)の草案(NTP、 2013 年)にはまだ含まれていないが、「環境化学物質、天然物質、または混合物(総称して 「物質」と呼ばれる)が有害性健康影響を引き起こすという証拠を評価するための文献ベースの 評価」を実行するためのアプローチに組み込まれる可能性がある。

本研究の品質評価指標には、以下の各項目について、原稿または企画書で明示的に報告するこ とが暗黙の了解となっている。言い換えれば、その研究が特定のレベルの基準を満たしているか どうかを評価するためには、その問題に関する情報が明確に記述されていなければならないとい うことである。以前に発表されたバイオモニタリングデータ(例:米国国民健康栄養調査 (NHANES))に依存している研究については、同じ報告要件を満たさなければならない。著 者は、研究の検出限界、相対標準偏差、関連する品質管理パラメータなどの関係がある項目を含 め、方法の記述を明確にすべきである。

このプロセスに数値スコアリングがないのは意図的なものである。ほとんどの構成要素につい ては質の高い研究であるにもかかわらず、研究結果の信憑性を大幅に低下させるような重要な問 題に対処していない場合があることは間違いない。全体的に高い「スコア」は、この問題を覆い 隠す。その代わりに、柔軟性を高める質的アプローチを提案する。

補足:評価のすべての側面でTier1に分類される研究は知られていない。すべての側面でTier 1 に分類される研究は確かに目標であり、強固なデータを提供することになるが、ほとんどの研 究はTier2 またはTier3と考えられる側面を含むことになる。研究データに対する利用者の意 図にもよるが、評価上の問題点によっては問題にならない場合もある。一方、Tier3の指定によ り、その研究の有用性が低いと判断される問題もある(例:サンプルに汚染がないことを証明で きない)。

#### 3. BEES-C の構成要素

最初に、短寿命バイオマーカーに関連した BEES-C の構成要素について説明する。これに続いて、より一般的な疫学研究デザインの問題に関連する BEES-C の側面について述べる。 3.1. バイオマーカーの選択と測定

バイオマーカー/生物学的マーカーは、「生物学的システムにおける変化や事象の指標」と定 義されている。「ばく露の生物学的マーカーとは、組織、細胞、または体内液などの生物学的媒 体から得られる細胞状、生化学的、分析的、または分子的な測定値を指し、薬剤へのばく露を示 すものである」(Zartarian ら、2005 年)。このように、バイオマーカーは、体内の化学物質や その代謝物の量を測定することで、化学物質へのばく露を評価するために使用することができる。 さらに、バイオマーカーは健康影響の指標として使用することができる。ばく露と効果のバイオ マーカーの多くは短寿命であり、環境化学物質へのばく露と環境化学物質による健康影響に関するヒトの研究では、両方のタイプのバイオマーカーが一般的に使用されている。この評価ツールは主にばく露のバイオマーカーに焦点を当てているが、ここで明らかにした原則の多くは効果のバイオマーカーにも適用される。

一般的なルールとして、ばく露と健康影響との関連を観察するように設計された研究は、適切 に確立されたバイオマーカーをばく露または健康のエンドポイントの代替として使用される場合 において、より正当性が高まる。バイオマーカーが高品質とみなされるために満たすべき基準に ついては、一般的なコンセンサスが得られている(NRC、2006 年; Zelenka ら、2011 年)。こ れらの基準の中には、バイオマーカーに固有の特性(例えば、化学物質ばく露との関連性や生物 学的関連性)に基づくものもある。その他の基準は、バイオマーカーの測定に関するもので、す なわちバイオマーカーを定量するために使用される方法の精度と正確さ、保存中のバイオマーカ ーの安定性、バイオマーカーの定量に誤差をもたらすサンプル汚染の可能性、測定誤差を引き起 こす可能性のある生物学的マトリックスの効果を調整する必要性などがある。バイオマーカーの 選択と測定の重要な側面については以下のサブセクションで説明し、BEES-C のために提案して いる階層化スキームを表1に示す。

#### 3.1.1. 関連性

化学物質の生成からヒトへの接触、目標の投与量、ならびにその後の分子、細胞、器官、個体、 集団での反応までの経路を示すために発生源から結果までの連続性が頻繁に使用される。

図 1. BEES-C 指標を用いてバイオモニターされた短寿命化学物質の 2 つの仮想研究についての品質比較の例。各 仮想研究のレビューでは、重要な側面が行ごとに評価され、適切なセルが色分けされているため、研究者/査読者 は研究の質の全体像を把握することができる。セル内のテキストは読みやすくするために削除されている。

またバイオマーカーは、ばく露、用量、及び生物学的反応を経験的に特徴付ける手段として使用 されることがある。本セクションでは、ばく露のバイオマーカー(すなわち、標的における親化 合物、代謝物、相互作用生成物(WHO、2001 年))と効果のバイオマーカー(すなわち、測定 可能な生化学的または生理学的反応で、健康影響に関連するもの(WHO、2001 年))の両方を、 ばく露と健康影響との関連性に関する疫学研究の重要な構成要素として検討する。

3.1.1.1. ばく露のバイオマーカー 疫学研究は、仮説駆動型の研究であってもよいし、より仮説

生成に向けた研究であってもよい。後者の場合、ばく露の最も適切なバイオマーカーは、外部ば く露または内部ばく露の正確で精密な代替となるものである。強固な生物学的根拠が存在し、生 物学的な「標的」が分かっている場合、最も適したバイオマーカーは、標的(分子、細胞、また は臓器レベル)で直接測定されるもの、または目標の用量を正確かつ精密に代替するものである。

理想的には、疫学研究で使用されるバイオマーカーについて、ばく露、用量、バイオマーカー のレベル間の定量的な関連性を明確に理解していることが必要である。標的組織のサンプリング の侵襲性を考慮すると、ほとんどのバイオマーカーベースの疫学研究では、血液、尿、毛髪、ま たはその他の容易にアクセス可能なマトリックスのサンプルを利用している。これらのマトリッ クスからのバイオマーカー測定値とばく露/用量のレベルとの間の定量的関係を解明するには、 化学物質の吸収、分布、代謝、排泄(ADME)の理解が必要である;これらのプロセスは、しば しば薬物動態(PK)モデルまたは生理学的薬物動態(PBPK)モデルを用いて記述される。疫 学研究でバイオマーカーを使用する前に、ADME に影響を与える可能性のある内的要因(例え ば、遺伝、ライフステージ、妊娠、性別)と外的要因(例えば、食事、薬、病状)と同様に、化 学物質の ADME についてもしっかりと理解しておく必要がある。さらに、短寿命のバイオマー カーについては、サンプル採取に関連して、特定のタイミングの詳細(例えば、時間帯、食事ば く露に関連する化学物質については最後の食事をしてからの時間、最後の尿を排泄してからの時 間)を知ることが重要である。理想的には、バイオマーカー濃度とばく露/用量のレベルとの関 係、及び疫学研究でバイオマーカーを使用する前に、これらの関係に対する内的、外的、タイミ ングの要因の影響を徹底的に評価する。(ばく露/用量に関する)バイオマーカーを適切に解釈 するために必要な重要情報は、その後、研究の一部として収集され、慎重に評価されるべきであ る。ばく露の各バイオマーカーの経費と利益は、疫学評価の一部として慎重に検討され、解釈さ れるべきである。

マトリックスの選択はばく露研究や疫学研究に不可欠な要素であり、測定能力、汚染の問題、 ばく露や健康影響と標的分析物との関連性など、複数の要因を考慮しなければならないことに注 意することが重要である。BEES-Cでは、これらの問題を個別に扱う。

3.1.1.1.1. 短寿命化学物質の例 ビスフェノール A (BPA) は、遊離形 (親化合物)、硫酸抱 合体またはグルクロン酸抱合体、または遊離形と抱合体の組み合わせ(総 BPA)として尿中に 存在する(Harthé ら、2012年; LaKind ら、2012年 a; Völkel ら、2008年; Ye ら、2005年)。 最近のいくつかの研究では、BPA ばく露に関連した内分泌関連の健康影響が調査されている。 最も生物学的に有用性の高いバイオマーカーは遊離(親化合物)BPA であるが、これは親化合 物 BPA のみがエストロゲン活性を有すると考えられているためである(EPA、2013年; WHO、 2011 年)。尿中の遊離 BPA の定量は、非抱合体の BPA がごく一部しか存在しないため、分析 が困難である(Ye ら、2005年)。この限界を考えると、抱合体または総 BPA の測定が遊離 BPAの有用な代替となる可能性がある。特に、個人内と個々人の間での遊離 BPAと抱合体 BPA の比率にばらつきが少ない場合(ばく露レベルのばらつきに対して)、抱合体 BPA または総 BPA は、遊離 BPA 及び一般的な BPA ばく露での正確で精密な代替となりうる。この事例は、 ばく露とバイオマーカー、異なるタイプのバイオマーカー(親化合物と代謝物のマトリックス)、 バイオマーカーと生物学的標的の関係を理解することの重要性を強調している。さらに、個々の ばく露のバイオマーカーを選択する際には、トレードオフの可能性があることを強調している (BPA の場合、生物学的関連性を最適化するために、化学物質の検出能力を犠牲にすることが ある)。

以下 200 ページ

3.1.1.1.2. 研究の評価(表 1) 標的マトリックス中のばく露の Tier 1 バイオマーカーは、目標用量(既知の標的がある仮説駆動型の研究の場合)または外部ばく露(既知の標的がない研究の場合)の正確で精密な代替である。Tier 2 のバイオマーカーについては、特定マトリックス中のバイオマーカーと外部ばく露、内部ばく露、または目標用量との間に関係があることを示す証拠が存在する。標的マトリックス中の Tier 3 バイオマーカーは、ばく露/用量の低い代替(精度と正確さが低い)である。

3.1.1.2. 効果のバイオマーカー 疫学研究では、短期的なバイオマーカー測定値と長期的な健康 影響の意味のある比較することが困難な場合がある。特に横断的な研究では、現在のバイオマー カーレベルが疾患発症に関連する時間帯の過去のばく露を再現していることが重要な前提となる。 効果のバイオマーカーのレベルは、疾患発症前の重要な時間帯に、対象となる集団におけるばく 露と反応の関係を評価する手段となる。調査結果は、ばく露のバイオマーカーとばく露効果、及 びばく露効果のバイオマーカーと有害性健康影響の関連性の強さに基づいて解釈される。

ばく露事象から健康への有害性影響への進行は、有害性転帰経路(AOP)を用いて定義するこ とができる(Ankley ら、2010年)。特定の健康影響の AOP は、体内の標的における分子的な 開始イベントから始まる。分子レベルでの効果は、ばく露イベントによって開始され、細胞レベ ル、体内液レベル、臓器レベルでの効果へと進行し、最終的には生体全体へと効果を及ぼすこと になる。"キーイベント"とは、AOP に沿った中間的なステップであり、AOP に沿った進行を評 価するために実験的にモニターすることができる。これらの重要な事象を、生体から採取可能な 媒体を用いて測定することを、バイオマーカーと呼ぶ。バイオマーカーは、特定の有害性発現事 象に関連する生物学的機能を反映しているため、理想的な効果をもつバイオマーカーと考えられ、 「個人または集団における潜在的有害性影響の予測で信頼性が高い」 (www.epa.gov/pesticides/science/biomarker.html)とされている。一方、「未確定の結果」に 分類される効果のバイオマーカーは、変化を特定疾患の発現事象への結びつける経路があまり確 実ではないことを反映している(www.epa.gov/pesticides/science/biomarker.html))。したがっ て、バイオ指標の代わりにこれらのバイオマーカーを使用した場合、個人または集団の発現事象 の予測は、確実性が低くなる。

3.1.1.2.1 研究の評価(表1) Tier1効果のバイオマーカーは、AOPにおける重要なイベントのバイオ指標である。Tier2の効果のバイオマーカーは、健康影響との関係があることが示されているが、作用機序は解明されていない。結果が不確定な効果のバイオマーカーは、Tier3と考えられる。

### 3.1.2. 特異度

単一のばく露のバイオマーカーが複数の親化合物に由来する場合があり、親化合物へのばく露 の評価は困難である(Barr and Needham、2002年; Barr ら、1999年、2006年)。ばく露評価 や疫学研究の解釈において、親化合物の毒性や作用機序が異なる場合に特に問題となる。さらに、 親化合物へのばく露評価を阻害する事例として、代謝物の一つが環境中にも存在する場合(外的 ソース)がある。

3.1.2.1. 短寿命化学物質の例 3-フェノキシ安息香酸(3PBA)は、研究の質を評価する際に特異度の評価の重要性を強調する短寿命化学物質の一例である。3PBAは、少なくとも18種類の合成ピレスロイドの代謝物であり(Barr ら、2010年; Leng ら、1997年)、3PBA環境分解物である3-フェノキシベンジルアルコールの潜在的な代謝物でもある。尿中3PBA測定は、神経毒性が知られていない環境分解物へのばく露に加えて、神経毒性の程度が異なる複数の殺虫剤へのばく露を表している(Barr ら、2010年)。尿中3PBA測定は、ピレスロイドへのばく露の保守的な推定値を提供することができるが、追加のばく露データがない場合、ピレスロイド系殺虫剤へのばく露に関連した神経毒性作用を正確に推定することはできない。神経毒性とばく露の関係を明らかにすることは、真のばく露量が不明であるため、より困難であると考えられる。

3.1.2.2. 研究の評価(表 1) Tier 1 研究には、1 つの親化合物へのばく露に由来するばく露のバイオマーカーが含まれる。Tier 2 研究には、同様の種類の有害性エンドポイントを持つ複数の親化合物に由来するバイオマーカーが含まれる。Tier 3 研究には、有害性エンドポイントの種類が異なる複数の親化合物に由来するバイオマーカーが含まれる。

### 3.1.3. 手法の感度

バイオマーカーは、分析対象のマトリックス中に評価できるほどに存在しなければならない

(Calafat and Needham, 2008 年)。ばく露に関係なく、マトリックス中で頻繁に検出されない バイオマーカーは、結果の有用性が限定的となる可能性があるため、環境疫学研究では望ましく ない。

3.1.3.1. 短寿命化学物質の例 4 つ以上の環を持ついくつかの多環芳香族炭化水素(PAH) は、 ヒトでの発がん性が疑われているか、または既知の発がん性物質である(例:benzo[a]pyrene)。 標準的な分析法(例えば、GC-MS [ガスクロマトグラフィー/質量分析]または LC-MS/MS [液体 クロマトグラフィー/タンデム質量分析]) は、採取可能な媒体(例えば、尿)中でのこれらの PAH の代謝物を定量するのに十分な感度を持っていないことが多く(Bouchard and Viau、 1997 年)、疫学調査の妨げとなっている。ナフタレン、フェナントレン及びピレンを含む低分 子量の PAH のバイオマーカーは、より高分子量の発がん性化学種の代替として評価されている (Bouchard ら、1998 年;Sobus ら、2009 年;Viau ら、1999 年;Withey ら、1991 年)。こ れらの代替物質は分析上の限界を克服する手段を提供するが、標的化学種のばく露を反映する能 力、PAH 間の共起を評価する能力、ばく露ソースの相関関係に関する情報を評価する能力につ いて十分に評価されなければならない。

3.1.3.2. 研究の評価(表 1) Tier 1 研究手法は、研究の問題に対処するために十分な割合のサンプルから化学物質を検出するのに十分な検出限界を持っている(例えば、研究仮説が母集団濃度の代表値と上端の両方の推定を必要とする場合、50~60%の検出値を有する) (Barr ら、2010年; Zota ら、2014年)。この要素はTier 2 にはない。Tier 3 の研究では、検出頻度が低すぎて研究仮説に対応できない。

#### 3.1.4. バイオマーカーの安定性

バイオマーカーは、保存及び使用の時間にわたって、所定のマトリックス中で安定でなければ ならない(Barr ら、2005 年 a)。サンプルの安定性は記録されるべきである。凍結/融解サイク ルを経たサンプルを用いた研究では、それらのサンプルの安定性を実証すべきである。試料の採 取から測定までの時間を記録すべきである。

3.1.4.1. 短寿命化学物質の例 難分解性有機汚染物質は、通常、-20℃以下で凍結した場合、血液 製剤中では永久に安定であるが、難分解性でない化学物質は血液中での安定性が低い場合がある。 例えば、現在使用されている殺虫剤は非常に反応性が高く、血液中の酵素で容易に分解される (Barr ら、1999 年)。EDTA を事前に添加した血液は、エステラーゼ活性を最小限に抑えるが、 測定は採取後数ヶ月以内に行う必要がある。解凍/再凍結の過程や熱湯での試料の解凍も分解の 原因となる。長期間保存された尿または血液サンプルを使用することで、背景的に収集されたサ ンプル(NHANES III サンプルなど)のデータが得られるが、多くの場合、解凍/再凍結の過程 が発生し、敏感な化学物質の劣化やサンプル自体の汚染が生じる可能性がある。背景的なサンプ ルの安定性を確認するために、1 つのサンプルを小量で複数に等分して保存する必要がある。バ イオマーカーの損失は、容器の壁との結合や揮発によっても発生する可能性がある。

以下 201 ページ

プラスチック容器はガラスに比べて安価で取り扱いや凍結が容易であるが、一部の化学物質の汚 染源になることがある。また、金属や有機化合物を吸収してしまうため、化学物質の濃度を過小 評価してしまうこともある。保存中や解凍・凍結の過程で損失がないことを検証するために、実 際のサンプルに含まれると予想されるレベルと一致するレベルのスパイクされたマトリックスを 使用した保存研究や、保存前のサンプルに安定同位体標識された化合物を添加することが必要で ある。

3.1.4.2. 研究の評価(表 1) Tier 1 研究には、既知の履歴と記録された安定性データを持つサンプルが含まれる。Tier 2 の研究では、保存中の損失は判明しているが、低量ばく露と高量ばく 露の違いを定性的に評価することができる(すなわち、研究の目的上、試験参加者を低量ばく露 か高量ばく露かのどちらかに分類することは十分に可能である)。Tier 3の研究では、目的とする分析物の履歴が不明なサンプル、または安定性データがないサンプルを使用している。

#### 3.1.5. 試料の汚染

この BEES・C 評価基準は、至る所に存在する(ユビキタス)短寿命化学物質を測定する研究を 評価する上で最も重要な基準の一つである。これは、汚染を避けるために多大な時間をかけてい るにもかかわらず、これらの化学物質の多くについて、採取時から測定時までの間に試料が汚染 される可能性があることが実証されているからである。生理的半減期の短い化学物質は、環境的 に至る所に存在するもの(ユビキタス)であるだけでなく、疫学研究で使用されるサンプリング や分析機器にも含まれている可能性がある。したがって、試料採取から試料測定までの研究のす べての段階において試料汚染を回避/防止するためには、細心の注意が必要である(Barr ら、 1999年; Calafat and Needham、2008年、2009年; Needham ら、2007年)。試料採取中に、 標的の化学物質を含む物や、採取材料やマトリックスを環境媒体(空気や水など)にさらすと、 測定された濃度が誤って上昇する可能性がある。予防措置を講じたとしても、研究では分析物の 汚染が問題であることが報告されており、研究結果の解釈に不確実性をもたらしている。

3.1.5.1. 短寿命化学物質の例 Ye ら(2013 年)は、最善の努力をしたにもかかわらず、米国疾 病予防管理センター(Centers for Disease Control Prevention)の研究室のサンプルがトリクロ サンで汚染されていたことを指摘している。同様に、いくつかの研究グループは、このような汚 染を避けるために細心の注意を払っているにもかかわらず、(溶剤や試薬を含む)汚染が原因で、 血液サンプル中の BPA を測定することが困難であったことを指摘している(Calafat ら、2013 年、Markham ら、2010年、Teeguarden ら、2011年、Ye ら、2013年)。

3.1.5.2. 研究の評価(表 1) Tier 1 研究では、サンプルが収集時から測定時まで汚染されてい ないことを保証する(例えば、分析物を含まないと保証された収集用品や標準物質を使用したり、 現場と実験室の両方でブランクを適切に使用したりする)。研究では、研究データが信頼性が高 く正確であることを保証するために必要な手順を記録したものを含む。これらの手順を使用して いない、または記録していない研究は Tier 2 に分類される。Tier 3 の研究では、既知の汚染問題 があり、その問題に対処したという記録がない。

#### 3.1.6. 手法の要件

ばく露を評価するためのバイオマーカーの品質は、測定に使用される手法の質に大きく依存す る。これは、バイオマーカー測定の評価が難しい側面となる。例えば、習熟度テスト練習への研 究室参加と成果は、Tier 1 研究のための合理的なテストのように見えるかもしれないが、多くの 習熟度テスト研究では、200%変動する可能性のある許容範囲がある(すなわち、「許容できる」 分析物濃度値は、真の値の±200%になる)。一般的に、研究手法は適切な機器を備え、付随す る手順(例えば、QC、手法の強固性、確認イオンの存在、同位体希釈の使用)を記述しておく 必要がある。

3.1.6.1. 研究の評価(表 1) Tier 1 研究では、バイオマーカーの明確な同定と定量を必要な感度で提供する機器が含まれている(例:GC-HRMS [ガスクロマトグラフィー/高分解能質量分析]、GC-MS/MS、LC-MS/MS)。Tier 2 研究では、高度な信頼性と必要な感度でバイオマーカーの同定を可能にする機器を使用する(例:GC-MS、GC-ECD [ガスクロマトグラフィー・電子捕足検出器])。Tier 3 の研究では、バイオマーカーの定量化のみを可能にする機器を使用するが、その手法には既知の干渉物質が含まれている(例えば、GC-FID [ガスクロマトグラフィー・炎イオン化検出器]、分光器)。

#### 3.1.7. マトリックスの調整

バイオマーカーは濃度の単位で最も一般的に測定され、報告される。尿のバイオマーカー濃度 は、尿量変動(食事、運動、水分補給、年齢、病状などによって引き起こされる)によって強く 影響を受け、血液中のバイオマーカー濃度は、血液量と脂肪含量によって強く影響を受ける。尿 のバイオマーカー濃度は、クレアチニン濃度(筋肉内でのクレアチン・リン酸分解に由来する)、 比重、尿量、及びその他の手法を用いて、被験者間及び被験者内で尿希釈の変動を補正するため に標準化されている。しかし、補助情報のないスポット試料の未補正の尿中濃度は、一般に報告 され、ばく露や健康影響との関係の評価に利用される(Barr ら、2005 年 b; LaKind and Naiman、2008 年、2011 年; Lorber ら、2011 年; Meeker ら、2005 年)。尿希釈の変動に対す る尿のバイオマーカー測定値を「補正」するための最良の手法については、現在のところコンセ ンサスはない。最低限、研究間での適切な比較を可能にするために、容量ベースの濃度と補正さ れた(クレアチニンまたは他の手法)濃度の両方が提供されるべきである。また、全排尿量と排 尿間隔時間を取得することも有益である。

血液ベースのバイオマーカーレベルは、全血、血清、血漿、及び脂質調整値として報告されて いる。脂質調整を決定するために使用した手法、または血液中の脂質の異なる成分を分離するた めに使用した手法を提供し、入手可能な場合には、すべての濃度を報告すべきである(例えば、 全体量及び脂質調整値)。同様に、親油性化学物質の測定における絶食サンプル及び血清脂質調 整に関連する問題も考慮しなければならない(Schisterman ら、2005 年)。脂質やその他の組 織成分の調整の妥当性は、現在使用されている農薬のような特定の短寿命化学物質については確 立されていない。このような場合には、調整の妥当性が確立されていないことを明記して、全量 濃度と調整濃度を報告すべきである。さらに、血漿量は妊娠中に増加し(また、いくつかの既往 症や健康状態でも増加する可能性がある)、妊娠前や集団間で血漿濃度を比較する際にも考慮す る必要があるかもしれない(Hytten、1985 年)。

サンプル収集要件とマトリックス処理に関する情報は、研究間のデータを比較したり、基準範囲と比較したりする際に重要である。異なる政府機関(例えば、欧州連合、特定の欧州諸国、米国NHANES、カナダ健康測定調査、欧州規模でヒト・バイオモニタリングを実行する共同体、州ベースのHANES)及び他の大規模なバイオモニタリングデータ収集による研究では、マトリックス及び報告されたバイオマーカー濃度を変化させる可能性のあるサンプルの収集及び処理のための異なるプロトコルを持っている可能性がある。例えば、サンプル採取前の絶食についての参加者への指示は、血液中の脂質含有量を最小化することができるため、サンプル中の親油性バイオマーカー濃度を最小化することができる(Barr ら、2005年 a)が、これらの指示は国によって必ずしも同じではない(LaKind ら、2012年 a)。同様に、朝の起床直後の尿では、単純なスポットサンプルよりもマトリックス成分の濃度が高い可能性があり、分析対象物を検出または識別する能力が変化する可能性がある(Kissel ら、2005年; Scher ら、2007年)。

以下 202 ページ

さらに、朝の起床直後の尿収集は、以前のばく露とサンプルの収集・測定の間の関係によってデ ータにバイアス(システマティックエラー)をもたらす。抗凝固剤として EDTA とヘパリンを 用いて採取した血漿は、マトリックスの特性を変化させる可能性がある(Barr ら、2005 年 a)。 採取要件及びサンプル処理の違い(及びバイオマーカー濃度に影響を与える可能性のある腎臓病 などの研究参加者の健康状態)は、研究間で結果を比較する際に報告され、考慮され、それに応 じて重み付けされる必要がある。

3.1.7.1. 研究の評価(表 1) マトリックス調整のための最良の手法は、調査する仮説と目的の 特定化学物質が密接に関連していることであるが、この分野でのコンセンサスはまだ得られてい ないことを認識している。ただし、調整は研究結果に大きな影響を与える可能性がある。したが って、Tier 1 研究では、調整濃度と非調整濃度(調整が必要な場合)の結果を提供し、それによ ってマトリックス調整の影響について読者が独自の結論に達することができるようにすることを 提案する。Tier 2 研究は、1 つの手法(マトリックス調整の有無にかかわらず)を用いた結果の みを提示する研究である。Tier 3 の研究には、有効な調整手法がまだ確立されていないマトリッ クス中の化学物質の測定が含まれている。 3.2. 研究デザインと実行

研究デザイン、ばく露のばらつきと誤分類の両方を考慮することは、短寿命化学物質では特に 重要である。

3.2.1. 疫学研究のデザイン

短寿命化学物質に関するバイオモニタリングデータと疾患との関連性を探る研究は、バイオマ ーカーの血中または尿中のレベルが、通常数時間前または数日前に発生した最近のばく露を再現 しており、バイオマーカーのサンプル採取に関連したばく露のタイミングは通常知られていない ため、独特の問題を抱えている。しかし、目的の健康影響の多くは、発症に数年から数十年を要 する慢性疾患(例:肥満、高血圧、生殖機能の測定値)である。このため、短寿命化学物質を測 定する研究における因果関係仮説の評価は複雑であり、状況によっては実行不可能な場合もある。 因果関係の決定的で異論のない特性は時系列性であり、発現事象に先行する因果ばく露の観察に よって裏付けられなければならないということである(Potischman and Weed、1999 年; Rothman and Greenland、2005 年; Weed、1997 年; Weed and Gorelic、1996 年)。

時系列性を確立することができるのは、発症時の新たな疾患症例や、ベースラインと比較した 健康関連指標の変化など、健康関連のイベントを特定する「発生率」研究のみである(Pearce、 2012 年)。発生率研究には、介入研究(例:臨床試験)と観察研究(コホート研究や症例を確 認する症例対照研究)がある。しかし、どのようなデザインであっても、発生率研究の主な特徴 は、疾病の発症時期(または少なくとも診断時期)を特定できることであり、それによってばく 露と発現事象の順序を評価できる可能性がある。ばく露レベルが時間の経過とともに急速に変化 する場合、有用なアプローチは、ばく露の反復測定値と健康バイオマーカーの反復測定値との関 係を評価する縦断研究である。

因果関係を評価するためには時間的関係を確立する能力が重要であるが、環境疫学研究ではば く露と研究の発現事象との間の間隔が別の研究デザインの問題となっている。ヒトのバイオモニ タリングデータを病因研究に利用するためには、ばく露は疾患発症に関連する時期に測定されな ければならない。これは簡単な作業ではないが、関連する時間帯に難分解性化学物質のばく露を 調査し、それらのばく露と特定の有害性発現事象の発生とを相関させたバイオモニタリング研究 の成功例がある。

例えば、鉛の血中濃度は、過去 5~6 週間のばく露を反映しており、適切に実行された疫学研 究では、子供の血中濃度と認知能力への有害性影響を関連付けることができた(Lanphear ら、 2000 年)。しかし、半減期の短い化学物質の場合、関連するばく露と疾患発症の間の間隔を評 価することは困難である。研究デザインは、後述するばく露の誤分類とともに、短寿命化学物質 のバイオモニタリング研究において最も重要であり、まだ十分に調査されていない側面である。

「有病率」研究では、「罹患」研究に比べて時系列性の立証が困難であり、因果関係についての 結論を出すことが困難である。典型的な有病率調査は、ばく露と疾病情報を同時に把握する横断 的デザインに依存している(Rothman and Greenland、1998年)。短寿命化学物質に焦点を当 てた研究の場合、多くの症例対照研究は、たとえ症例を用いていたとしても、バイオマーカーレ ベルが病気の発症に先行するのではなく、最近のばく露を反映しているため、解釈は困難である。 特筆すべき例外は、コホート内症例対照研究やケース・コホート研究で行われているように、将 来の使用のために採取したサンプルを使用する研究である(Gordis、2008年)。

3.2.1.1. 短寿命化学物質の例 フタル酸代謝物と肥満、糖尿病、心血管疾患との関連性に関する 最近の疫学文献のレビュー(Goodman ら、2014 年)において、研究の大部分は横断的デザイン であった。研究結果は発現事象の間で一貫性がなく、フタル酸代謝物への事前ばく露とそれに伴 う健康影響との関係を識別する能力における重要な制限要因として、時系列性の欠如が考えられ た。

3.2.1.2. 研究の評価(表 1) Tier 1 研究は、追跡期間または反復測定値の縦断分析を含む発生 率研究であり、ばく露と発現事象の間の時間順序と関連する間隔の両方が確立される(表 1)。 Tier 2 研究には、ばく露が発現事象に先行する発生率研究が含まれるが、ばく露の特定の関連範 囲は考慮されない。最も情報量の少ない(Tier 3)研究は、現在のばく露(例:化学物質の血中 レベル)と、急性ばく露ではなく慢性ばく露に関連している可能性が高くて頻繁に測定される発 現事象(例:BMI)との関連を検討する研究である(この評価基準は、集団内または集団間の時 間的または空間的な関係を調査する研究といったばく露のみに焦点を当てた研究には適用されな いことに注意する。)。

## 3.2.2. ばく露のばらつきと誤分類

多くの短寿命化学物質については、個人内での時間的変動が大きい場合があり、そのような化 学物質と疾患との間の関連を特定しようとすることは支持できない。個人の食生活、健康状態、 製品の使用、活動または場所の変化による短寿命化学物質のバイオモニターされたレベルの違い が予想される(Pleil and Sobus、2013 年)。Meeker ら(2013 年)が指摘しているように「ば く露測定基準における時間的変動を特徴づけることは、特に非難分解性化合物のバイオマーカー において、ばく露測定誤差の可能性に関連する疫学研究をデザインし解釈する上で重要なステッ プである。」

慢性ばく露または平均的ばく露を推定しようとする短寿命化学物質の多くの発表された研究は、 尿または血液の一回限りのサンプルを使用したばく露の一つの尺度に依存しているため、誤差が 生じる可能性がある(Goodman ら、2014 年; LaKind ら、2012 年 b、2014 年; Preau ら、2010 年; Wielgomas、2013 年)。バイオマーカーレベルの時間的変動を平均化するために、同じ個人 から異なる時間に複数のサンプルを採取することで、ばく露を推定する能力を向上させることが できる(NRC、2006 年)。信頼性は通常、クラス内相関係数(ICC)を計算することによって 測定される。ICC は、数時間、数日または数週間に渡って反復収集されたサンプル中の化学物質 を測定し、個々人の間の分散を総分散で割った値を計算することで推定できる。

以下 203 ページ

ICC の値は 0 から 1 の範囲であり、1 に等しいまたは 1 に近い ICC 値は、単一のサンプルから 集団の長期ばく露を推定する際の信頼性が高いことを示唆している。Symanski ら(1996 年) は、職業ばく露における安定しない行動を考慮するために混合効果モデルを使用し、ばく露にお ける系統的な変化が適切にモデル化されていない場合、分散成分(ICC の計算に使用される)の 推定値が大幅に偏る可能性があることを発見した。「もし ICC が数週間または数ヶ月間の反復サ ンプルを採取して作成された場合、その値は目的の多くの慢性疾患の発症の時間枠である数年間 のばく露に関連するか?」という疑問について提起されなければならない。この問題については、 標的の短寿命化学物質の多くについて現在のところ研究が進んでいない。

短寿命化学物質の単一の測定値を使用する場合のもう一つの問題は、ばく露の誤分類を引き起 こす可能性のあるエラーである。ばく露の誤分類は、割り当てられたばく露が実際のばく露レベ ルやカテゴリーを正しく再現していない場合に起こる。ばく露の誤分類は、方向性と大きさの両 方の観点から予測することが困難であることが示されている(Cantor ら、1992 年; Copeland ら、 1977 年; Copeland ら、1977 年; Dosemeci ら、1990 年; Sorahan and Gilthorpe、1994 年; Wacholder ら、1995 年)。ばく露誤差とばく露誤分類の用量反応関係への効果は問題である (Rhomberg ら、2011 年)。ばく露の誤分類は、重大なばく露が発生する際に関連するサンプ ル収集のタイミングを含め、測定誤差の多くのソースから発生する。例えば、多くの揮発性有機 化合物は半減期が数分のオーダーである。すなわちばく露は毎日発生しても、短い時間間隔で発 生する。このように、ばく露のバイオマーカーの濃度は、ばく露が発生した際に関連してサンプ ルが採取された時期に大きく依存しており、体内の長期的なレベルを適切に反映しない場合があ る。

複数のサンプルの使用または長時間(例:24 時間)のサンプル収集は、時間的変動、研究の 亜集団の特性、及びサンプルに関連する問題の効果を軽減することにより、誤差を減少させるの に役立つかもしれない(Scherら、2007年)。誤差が回避できない場合(例:利用可能なすべて のサンプルが絶食後に得られた場合)は、感度と特異度を計算することにより、ばく露特性の精 度を評価することが重要である(Jurek ら、2006 年)。感度とは、もしも個人が本当に高いば く露カテゴリーに属しているならば、高レベルのばく露を受けた個人と正しく分類できる確率で ある。特異度とは、本当に低レベルのばく露を受けた参加者を正しく低レベルばく露と割り当て る確率である。感度と特異度の推定値は、多くの測定値に対する真の感度と特異度は不明である ので、被験者ごとに複数のサンプルを絶対的基準として使用して1つの尿サンプルについて計算 される。これは、研究期間中に収集された各個人の反復サンプルの中から無作為に1つのサンプ ルを選択することによって実行される(2008 年に Adibi らによってフタル酸エステル類につい て実証されたように)。

3.2.2.1. 短寿命化学物質の例 Goodman ら (2014 年) は、フタル酸エステル類と肥満、糖尿病、 心血管疾患との関連性に関する疫学文献の最近のシステマティックレビューにおいて、利用可能 な 26 件の研究のうち、3 件を除くすべての研究がフタル酸エステル類の単一の測定値に依存し ていることを明らかにした。同様に、BPA と肥満、糖尿病、心血管疾患に関するシステマティ ックレビューでは、LaKind ら (2014 年) は、利用可能な 45 件の研究のうち、4 件を除くすべ ての研究が BPA の単一測定値に依存していたことを明らかにした。しかし、BPA の個人内変動 は大きく (ICC は 0.10~0.35 の範囲) (Lassen ら、2013 年; Teitelbaum ら、2008 年)、1 人 の長期ばく露を記述するには複数のばく露尺度が必要である。フタル酸エステル類の ICC は BPA よりも高いことが報告されているが (例えば、フタル酸モノエチルは 0.18~0.61、フタル 酸モノイソブチルは 0.21~0.51、フタル酸モノ (2-エチルへキシル) は 0.08~0.27 (Goodman ら、2014 年でレビュー)、個人間のばらつきは依然として大きい。最近、Attfield ら (2014 年) は、小児における尿中農薬測定値の変動性に関する研究において、各研究参加者からのサンプル 数が少ない研究では、「…不正確な四分位分類によるばく露の誤分類の可能性が高く、ばく露を 正確に特定のカテゴリーに分類するための保証はほとんどない」と述べた。

3.2.2.2. 研究の評価(表 1) 上記の考察により、利用可能な文献を以下の段階に分けることができる(表 1)。Tier 1 には、ばく露評価が、適切な期間にわたるばく露量を推定するために、 一人当たりのサンプル数が十分な数であるか、または適切な長期サンプリング(例えば、複数の 24 時間尿採取)を使用している研究が含まれている。Tier 1 に含まれるためには、研究は、精度(例:感度及び特異度)及び信頼性(例:ICC)の測定値を計算することによって誤差を評価 すべきである。化学物質によっては、ばく露を完全に特徴づけるには 1 つのサンプルで十分であ る可能性がある。このような場合、Tier 1 研究では、単一の測定の誤差が十分に小さいと考えら れるという証拠を提供する必要がある。これは常に実現可能なことではないが、研究者がバリデ ーション研究を実行する必要があると考える状況があることは理解している(Teeguarden ら、 2011年)。Tier 2 には、2 つ以上のサンプルを使用する研究が含まれるが、測定数の選択に根拠 を示さず、誤差の明示的な評価も含まれていない。Tier 3 は、誤差を考慮せずに単一のサンプル に基づいてばく露評価を行う研究のためにある。

### 3.3. 一般的な疫学研究デザインの考察

このセクションでは、必ずしも短寿命化学物質に特化したものではないが、研究全体の質を評価する上で重要な研究デザインの側面について議論する。これらの問題のいくつかは、ばく露と 健康影響との関連性を検討する研究に適用できるものもあれば、ばく露のみに焦点を当てた研究 に適用できるものもある。

#### 3.3.1. 研究の論拠

このセクションでは、バイオモニタリングデータと健康影響データの間の関連性を検証する仮 説検証研究を述べる。臨床観察または基礎科学実験から生じる十分に練られた仮説は、研究の種 類にかかわらず、疫学調査の基礎となるものである(Boet ら、2012 年; Fisher and Wood、2007 年; Moher and Tricco、2008 年)。現在、様々な分野で推奨されているのは、目的の集団、調査 対象のばく露(またはそれに対応するマーカー)及び懸念される結果に関する情報を伝えるよう に構成された調査課題を提起することの重要性を強調している(Sampson ら、2009 年; Walker ら、2012 年)。

バイオモニタリング研究、特に1つのサンプルが多数の化学物質に関するデータを提供できる

ような短寿命化学物質を対象とした研究では、多くの場合、複数の変数を含むデータを生成し、 複数の仮説検証を同時に行う機会を得ることができる。バイオモニタリング研究のこの特徴は、 いくつかの関連する発現事象に対して有意な関連性が観察された場合(Lord ら、2004 年)のよ うな状況では、強みとみなすことができる。例えば、仮説を立てられた肥満因子が体重指数、ウ エスト周囲長、または体脂肪率に同様の影響を及ぼす場合である。一方で、複数のばく露-発現 事象の関連を評価する能力は、特に過去に収集されたデータを扱う場合、結果の解釈を複雑にす る(Clarke ら、2003 年; Lee and Huang、2005 年; Marco and Larkin、2000 年)。過去に収集 されたデータを使用した研究の中で、優先的に定式化された仮説に導かれた研究と、強い生物学 的根拠を持たずに実行された研究を区別することが重要であるが、後者のカテゴリーは新しい仮 説の策定に役立つことが証明されている(Liekens ら、2011 年; Oquendo ら、2012 年)。仮説 が十分に定式化されている研究は、その研究がこれまでの知識の上に築かれていることを示して おり、これは WOE 評価にとって重要な考慮事項である。既存の知識ベースに追加するために特 別にデザインされた研究は、より容易に WOE に組み込むことができる。

3.3.1.1 研究の評価(表1) 優先的に定式化された仮説を、この仮説に対処するために特別に 設計されたバイオモニタリング戦略で評価する研究は、最高品質(Tier 1)と考えるべきである。 Tier 2 の研究とは、優先的に定式化された仮説を評価するために既存のサンプルやデータを使用 した研究であり、この目的のために特別にデザインされたバイオモニタリング戦略ではない。

以下 204 ページ

Tier 3 の研究では、事前に定められた仮説を持たずに既存のサンプルやデータに依存する研究または複数の同時仮説検証を含む。現在のところ、短寿命化学物質を対象としたほとんどのバイオモニタリング研究の研究理論拠は、Tier 3 研究として記述されることになると認識している。

## 3.3.2. 研究参加者

研究参加者の選択に関する評価方法は、難分解性化学物質と短寿命化学物質の両方の研究に適用される。疫学研究における参加者選択の目的は、サンプルから得られる情報と対象となる集団について求められる情報との間を「仲立」することである(Kalsbeek and Heiss、2000 年)。 偏りのない集団サンプルを選択する実際のプロセスは、症例対照研究、縦断(コホート)研究、 横断研究において継続的な問題である(Vandenbroucke ら、2007 年)。

参加者選択の問題は、短寿命化学物質の疫学研究に特有のものではない。しかし、バイオモニ タリング研究はこの問題に十分な注意を払っていない。これまでのバイオモニタリング研究のレ ビューでは、選択バイアスが内的妥当性に対する重要な脅威となる可能性があるという証拠が示 されている(Bull ら、2006 年; Faust ら、2004 年)。同じ問題は、フタル酸エステル類のよう な短寿命化学物質のバイオモニタリング研究にも当てはまる(Durmaz ら、2010 年; Wang ら、 2013 年; Wirth ら、2008 年)。

3.3.2.1. 研究の評価(表 1) Tier 1 研究には、偏りのない選択またはフォローアッププロトコルが含まれており、横断研究または症例対照研究では高い(例:80%以上)応答率、コホート研究では低い(例:20%未満)脱落例が認められる。Tier 2 の研究は、偏りのない選択/フォローアッププロトコルを有し、横断研究または症例対照研究では低い(例:50%~80%)、応答率、コホート研究では高い(例:20%~50%)脱落例が認められる。Tier 3 の研究とは、望ましい参加者の数が 50%未満であるか、サンプルの選択方法、無応答率または脱落例率を報告していない研究である。この情報が報告されていない研究は、Tier 3 研究とみなされるべきである。

低い応答率や高頻度の脱落例を選択バイアスと同一視すべきではないことを念頭に置いておく ことが重要である。選択バイアスは、最終のデータセットに含まれる個人の割合(別名:選択確 率)がばく露と発現事象の両方で異なる場合に起こる(例えば、ばく露群の発症例、非ばく露群 の発症例、ばく露群の非発症例、非ばく露群の非発症例の間で)。実際の選択確率は通常不明で あるが、望ましい参加者の10%しか脱落していない研究では、バイアスの大きさは、被験者の 50%以上が脱落している研究でのバイアスの大きさよりもはるかに小さいと予想できる。 3.3.3. データ分析

疫学研究におけるデータ分析に必須な側面は他で検討されており、生理学的半減期が短い化学 物質には特化したものではない。しかし、提案されている段階的評価システムの完全性のために、 これらの考慮事項を簡単に説明する。観察研究における全体的な分析戦略は、研究の主な目的に よって決まる。一般的に、統計モデルは予測分析と説明分析の2つのカテゴリーに分類される (Shmueli、2010年)。予測分析では、モデルへの変数の選択はデータに基づいて行われ、デ ータセットごとに異なる場合がある。このアプローチの目標は、モデル適合を最大化することで あり、目的の特定の共変量を保持するかどうかの決定は、目的の特定のばく露なしで、統計的検 定と適合良好に基づいて行われる(Bellazzi and Zupan、2008年)。説明的(仮説検証)分析 では、発現事象とリスク因子の関係が交絡している場合に、潜在的に重要な変数を誤って排除し たり、交絡因子として作用しない変数を間違って保持したりする可能性があるので、このアプロ ーチは不適切であるかもしれない(Kleinbaum and Klein、2002年)。

事前に定義されたばく露と発現事象の関係に焦点を当てた説明モデルでより重要なことは、コントロール変数(交絡因子、媒介因子、または効果修飾因子)の包含と排除は、少なくとも部分的には、先験的な理由に基づいて行われるべきである(Beran and Violato、2010年; Concato ら、1993年; Hernan ら、2002年)。

観察研究の結果は必然的に不確実性の影響を受けることを念頭に置くことが重要である。この 不確実性は、原因不明のバイアスの様々なソースや、様々なデータ処理の決定や仮定に起因して いる可能性がある。不確実性の大きさは、定量的な感度分析によって正式に評価できる。感度分 析を通じた残留バイアスへの対処方法は、基礎的な理論(Greenland、1996 年)と実践的な応 用の両面で十分に発達している(Goodman ら、2007 年; Lash and Fink、2003 年; Maldonado ら、2003 年)。代替的な決定や仮定の感度分析に関しては、経済学、ばく露評価、定量的リス ク分析の過去の経験から多くを学ぶことができる(Koornneef ら、2010 年; Leamer、1985 年; Spiegelman、2010 年)。

3.3.3.1. 研究の評価(表 1) Tier 1 の研究には、因果関係モデルと予測モデルを明確に区別し、 効果修飾と交絡因子の調整を評価して外的要因を十分に考慮していることを論証することが含ま れる。Tier 1 の資格を得るためには、研究は正式な感度分析も行うべきである。外部要因の考慮 が十分であり、モデル選択が適切であると考えられる場合でも、感度分析のない研究は不完全と みなされる可能性がある。このような研究は Tier 2 に分類される。Tier 3 の研究は、共変量の選 択方法が不適切であったり、重要な交絡因子を考慮していなかったり、効果修飾を考慮に入れて いなかったりするために、外部要因を適切にコントロールできなかった研究である。

「外部要因」という用語は、対照となるばく露や発現事象以外の参加者の特性を示しており、 それらは交絡因子または効果修飾因子あるいはその両方として作用するので、研究のデザインま たは解析の段階で考慮する必要がある(Kleinbaum ら、2007年)。

3.3.4. 結果報告

報告の3つの側面(透明性、複数のテスト、報告の偏り)を考慮する。

*3.3.4.1. 報告の透明性* STROBE 声明で述べられているように、結果の報告は「観察研究において何が計画され、何が行われ、何が発見されたかを明確に提示」(Vandenbroucke ら、2007 年) すべきである。これらの考慮事項はすべての研究に当てはまるが、短寿命化学物質のバイオモニタリング研究には特に関連性のある研究報告の側面がある。

生物学的サンプル分析は、1回の分析で複数の分析物を迅速に分析できるように、ますます最 適化されてきている。このような技術の発展により、ばく露(及び該当する場合は発現事象)バ イオマーカーの完全なリストを含むデータの完全な報告の重要性が増してきており、代表値や分 散などの要約統計量の提示も重要である。その他の重要な情報要素には、欠落データのパターン とその取り扱い、及び LOD 以下の測定値の説明が含まれるべきであり、これらはすべて研究結 果の解釈に影響を及ぼす(Albert ら、2010 年; Barnes ら、2008 年; LaKind ら、2012 年 b)。 さらに、研究参加者の数を決定する際に使用された検出力計算や、有意な関連性を特定する能力 に影響を与えるばく露勾配に関する情報も提供されるべきである。これらの情報の一部は、スペ ースの制約のために論文には含まれないかもしれないが、補足資料に組み入れたり、要望に応じ て提供したりすることが可能となる。

3.3.4.2. 多重検定の問題点 複数の仮説検定を行う場合の主な懸念は、偽陽性(FP)の結果となる可能性が高まることである(Boffettaら、2008年; Ioannidis、2014年; Jager and Leek、2014年; Rothman、1990年; Sabatti、2007年)。その他、FPの結果の問題は、対応する偽陰性(FN)の問題よりも重要ではないとの主張がある(Blair ら、2009年)。どのタイプのエラー(FPか、FNか)がより大きな懸念をもたらすかの決定は、化学的特性及び発現事象特性であり、ケース・バイ・ケースで行われるべきである。

以下 205 ページ

遺伝疫学及び分子疫学における最近の進歩は、FN 結果のリスクを増加させることなく FP (PFP) の確率を減少させることを目的とした新しいアプローチの開発された(Datta and Datta、2005 年; Wacholder ら、2004 年)。さらに最近になって、これらのアプローチは、さらに FP:FN 比を計算できるまでに及んだ(Ioannidis ら、2011 年)。

3.3.4.3. バイアス報告 メタ分析や WOE 評価のために一連の研究を評価する際には、利用可能 なデータの分析と統合の両方に影響を及ぼす可能性のある 2 つの特定のバイアスのソース、すな わち、出版バイアスと論文報告バイアスを考慮しなければならない。出版バイアスとは、「研究 者や編集者が研究結果の方向性や強さに基づいて研究結果を発表しない傾向」と定義されている (Dickersin and Min、1993 年)。これと密接に関連する概念として、選択的研究内報告(別 名:結果報告バイアス)があり、これは「論文に含めるために記録された元の変数の一部の結果 に基づいて選択すること」と定義されている(Dwan ら、2008 年)。

出版バイアスは短寿命化学物質を含む研究には特有のものではない。しかし、上記の理由から、 短寿命化学物質の研究では、発現事象報告バイアスがより問題になる可能性がある。特に、高性 能分析設備が利用しやすくなることで、より多くのサンプル数でより多くの分析物を測定するこ とが可能になっている。

3.3.4.4. 研究の評価 Tier1 研究では、その目的が明確に述べられており、読者は検証された仮説の数(結果が与えられた仮説の数だけではない)を評価することができる。複数の同時仮説検証が行われている場合は、その影響が評価し、可能なら PFP または FP: FN 比を推定することで評価を行う。結果報告バイアスの証拠はなく、結論は観察された結果を超えたものではない。 Tier 2 の研究では、結論は正当であると思われるが、検証された仮説の数が不明確(明示されていないか、識別が困難である)であり、及び/または多重牲の検討がなされていない。データ要約を選択的に報告し、提示された結果の方法や選択に関して透明性を欠いている研究は Tier 3 に含まれる。

## 4. 考察/結論

環境疫学研究の質を評価するための体系的なアプローチの必要性は明らかである。評価スキー ムを開発するための2つの先行研究は、環境化学物質ばく露と神経発達に関する疫学研究に焦点 を当てたものであった(Amler ら、2006年; Youngstrom ら、2011年)。これらの提案された スキームで提示された概念の多くは、生理学的半減期の短い化学物質のバイオモニタリングを検 討する際に、研究の質を評価し、研究結果を伝える上で貴重なものである。例えば、Amler ら、

(2006 年)が提示した基本的な最適な実行/基準は以下とおりである。明確に定義された生物学的に妥当な仮説、前向きで縦断的なコホートデザインの使用、研究間での研究デザインプロトコルの一貫性、研究結果がどの程度決定的で一般化可能であるかについての率直で規律正しく知的に正直な扱い、実際の研究課題、検証手順及び研究での発見についての報告の制限、否定的な結果も報告する倫理的義務の研究者の認識ならびに結果を最小化したり誇張したり

## しないことの重要性。

生理的半減期が短い化学物質は、分析室やサンプリング機器に存在すること、横断研究における時間的順序の確立が困難であること、ばく露とバイオマーカー濃度の短期及び長期の変動性、 正確なばく露分類に必要な測定数に関する情報不足など、いくつかの重要な問題を抱えている。 BEES-Cは、研究や提案の中でこれらの問題を評価するためにデザインされている。

BEES-C のような評価ツールの開発は、単純でもなく、議論の余地のないものでもないことを 認識しており、CONSORT やその他の既存方法の一部、あるいは臨床データの質評価であるデ ータ品質スキームと同様に、これが反復的なプロセスになることを期待している。この種の評価 スキームは探索的研究には有用ではなく、むしろ、半減期の短い化学物質へのばく露と有害性健 康影響の関連性の理解を深めるために最も有用な研究をデザインし、特定することに焦点が当て られていることにも留意したい。本ワークショップで開発された評価指標が、このテーマについ てのさらなる議論のきっかけとなることを期待する。

#### 利益相反

本ワークショップは、米国化学協議会(ACC)の Polycarbonate/BPA Global Group が主催した。ACC は、本ワークショップの設計、運営、開発、原稿の作成、承認には関与していない。 ワークショップ参加者、または、その関係機関は、謝礼(JSL, ES, GS, JS, JT, Y-MT, RT-V, TA を除く)と旅費(TA, Y-MT, DB, ES を除く)を受け取った。JSL はワークショップの開発とフ ァシリテーションの支援を受けた。MG は定期的に政府や民間セクターのコンサルタントを務め ている。その他の利害関係は表明していない。

#### 免責事項

ここで表明された見解は著者のものであり、ACC、米国環境保護庁、カナダ保健省、または国 立成育医療研究センターの見解を必ずしも代表するものではない。米国環境保護庁は研究開発局 を通じて、ここに記載されている研究に協力した。この研究は、米国環境保護庁の審査を受け、 出版の承認を受けている。

## 謝辞

本書に記載されている見解は、2013 年 4 月にメリーランド州ボルチモアで開催されたワーク ショップで発表されたものである。運営委員会には以下が含まれている。運営委員会には、米国 環境保護庁国立計算毒性学センターの Elaine Cohen Hubal 博士、Judy S. LaKind 博士、メリー ランド大学メリーランド校 LaKind Associates LLC の Judy S. LaKind 博士が参加している。 LaKind、博士、LaKind Associates LLC、メリーランド大学医学部及びペンシルバニア州立大 学医学部、Enrique F. Schisterman、博士、ユーニス・ケネディ・シュライバー国立小児保健・ 人間発達研究所疫学統計・予防研究部門、国立衛生研究所、及び Justin Teeguarden、博士、 DABT、Pacific ノースウエスト国立研究所から構成されている。米国 EPA とカナダ保健省から 3人の匿名査読者の思慮深いコメントに感謝する。

## Harmonization Project Document No. 4

# PART 1: IPCS FRAMEWORK FOR ANALYSING THE RELEVANCE OF A CANCER MODE OF ACTION FOR HUMANS AND CASE-STUDIES

# PART 2: IPCS FRAMEWORK FOR ANALYSING THE RELEVANCE OF A NON-CANCER MODE OF ACTION FOR HUMANS

This project was conducted within the IPCS project on the Harmonization of Approaches to the Assessment of Risk from Exposure to Chemicals.

Published under the joint sponsorship of the World Health Organization, the International Labour Organization, and the United Nations Environment Programme, and produced within the framework of the Inter-Organization Programme for the Sound Management of Chemicals.

The International Programme on Chemical Safety (IPCS), established in 1980, is a joint venture of the United Nations Environment Programme (UNEP), the International Labour Organization (ILO), and the World Health Organization (WHO). The overall objectives of the IPCS are to establish the scientific basis for assessment of the risk to human health and the environment from exposure to chemicals, through international peer review processes, as a prerequisite for the promotion of chemical safety, and to provide technical assistance in strengthening national capacities for the sound management of chemicals.

The Inter-Organization Programme for the Sound Management of Chemicals (IOMC) was established in 1995 by UNEP, ILO, the Food and Agriculture Organization of the United Nations, WHO, the United Nations Industrial Development Organization, the United Nations Institute for Training and Research, and the Organisation for Economic Co-operation and Development (Participating Organizations), following recommendations made by the 1992 UN Conference on Environment and Development to strengthen cooperation and increase coordination in the field of chemical safety. The purpose of the IOMC is to promote coordination of the policies and activities pursued by the Participating Organizations, jointly or separately, to achieve the sound management of chemicals in relation to human health and the environment.

### FOREWORD

Harmonization Project Documents are a family of publications by the World Health Organization (WHO) under the umbrella of the International Programme on Chemical Safety (IPCS) (WHO/ILO/UNEP). Harmonization Project Documents complement the Environmental Health Criteria (EHC) methodology (yellow cover) series of documents as authoritative documents on methods for the risk assessment of chemicals.

The main impetus for the current coordinated international, regional, and national efforts on the assessment and management of hazardous chemicals arose from the 1992 United Nations Conference on Environment and Development (UNCED). UNCED Agenda 21, Chapter 19, provides the "blueprint" for the environmentally sound management of toxic chemicals. This commitment by governments was reconfirmed at the 2002 World Summit on Sustainable Development and in 2006 in the Strategic Approach to International Chemicals Management (SAICM). The IPCS project on the Harmonization of Approaches to the Assessment of Risk from Exposure to Chemicals (Harmonization Project) is conducted under Agenda 21, Chapter 19, and contributes to the implementation of SAICM. In particular, the project addresses the SAICM objective on Risk Reduction and the SAICM Global Plan of Action activity to "Develop and use new and harmonized methods for risk assessment".

The IPCS Harmonization Project goal is to improve chemical risk assessment globally, through the pursuit of common principles and approaches, and, hence, strengthen national and international management practices that deliver better protection of human health and the environment within the framework of sustainability. The Harmonization Project aims to harmonize global approaches to chemical risk assessment, including by developing international guidance documents on specific issues. The guidance is intended for adoption and use in countries and by international bodies in the performance of chemical risk assessments. The guidance is developed by engaging experts worldwide. The project has been implemented using a stepwise approach, first sharing information and increasing understanding of methods and practices used by various countries, identifying areas where convergence of different approaches would be beneficial, and then developing guidance that enables implementation of harmonized approaches. The project uses a building block approach, focusing at any one time on the aspects of risk assessment that are particularly important for harmonization.

The project enables risk assessments (or components thereof) to be performed using internationally accepted methods, and these assessments can then be shared to avoid duplication and optimize use of valuable resources for risk management. It also promotes sound science as a basis for risk management decisions, promotes transparency in risk assessment, and reduces unnecessary testing of chemicals. Advances in scientific knowledge can be translated into new harmonized methods.

This ongoing project is overseen by a geographically representative Harmonization Project Steering Committee and a number of ad hoc Working Groups that manage the detailed work. Finalization of documents includes a rigorous process of international peer review and public comment.

### PART 1

### IPCS FRAMEWORK FOR ANALYSING THE RELEVANCE OF A CANCER MODE OF ACTION FOR HUMANS AND CASE-STUDIES

### PREFACE

Following publication of the International Programme on Chemical Safety (IPCS) Conceptual Framework for Evaluating a Mode of Action for Chemical Carcinogenesis (in animals),<sup>1</sup> an IPCS Cancer Working Group convened on 3–5 March 2004 in Arlington, Virginia, USA. The working group agreed that the issue of human relevance of animal tumours should be further explored with the goal of developing a unified IPCS Human Relevance Framework for use of mode of action information in risk assessment for regulatory and other purposes, and it provided initial guidance for this task. The members of this working group, including secretariat support and a representative of the Organisation for Economic Co-operation and Development, were as follows:

- Professor Hermann Bolt, Institut für Arbeitsphysiologie, Germany
- Professor Alan R. Boobis, Department of Health Toxicology Unit, Imperial College London, United Kingdom
- Dr John Bucher, National Institute of Environmental Health Sciences, USA
- Dr Vincent Cogliano, Unit of Carcinogen Identification and Evaluation, International Agency for Research on Cancer, France
- Dr Samuel M. Cohen, Pathology and Microbiology, Havlik-Wall Professor of Oncology, University of Nebraska Medical Center, USA
- Dr William Farland, Office of Research and Development, Environmental Protection Agency, USA
- Dr Jun Kanno, Division of Cellular & Molecular Toxicology, National Institute of Health Sciences, Japan
- Dr Lois D. Lehman-McKeeman, Bristol-Myers Squibb, USA
- Ms Bette Meek, Environmental Health Centre, Health Canada, Canada
- Ms Laurence Musset, Environment, Health and Safety Division, Organisation for Economic Co-operation and Development, France
- Dr Jerry Rice, Consultant, USA
- Ms Cindy Sonich-Mullin, International Programme on Chemical Safety, World Health Organization, USA
- Ms Carolyn Vickers, International Programme on Chemical Safety, World Health Organization, Switzerland
- Ms Deborah Willcocks, Existing Chemicals, National Industrial Chemicals Notification and Assessment Scheme (NICNAS), Australia

Extending the Mode of Action Framework to include consideration of human relevance, taking into account guidance from the Arlington meeting, was the subject of an IPCS international workshop convened in Bradford, United Kingdom, from 21 to 23 April 2005. This workshop prepared draft text for an IPCS Human Relevance Framework, including updating the 2001 Mode of Action Framework. The workshop participants, including

<sup>&</sup>lt;sup>1</sup> Sonich-Mullin C, Fielder R, Wiltse J, Baetcke K, Dempsey J, Fenner-Crisp P, Grant D, Hartley M, Knaap A, Kroese D, Mangelsdorf I, Meek E, Rice J, Younes M (2001) IPCS conceptual framework for evaluating a mode of action for chemical carcinogenesis. *Regulatory Toxicology and Pharmacology*, **34**:146–152.

secretariat support and representatives of the European Food Safety Authority and European Chemicals Bureau, were as follows:

- Dr Peter Abbott, Scientific Risk Assessment and Evaluation Branch, Food Standards Australia New Zealand, Australia
- Dr Antero Aitio, International Programme on Chemical Safety, World Health Organization, Switzerland
- Dr Diana Anderson, Department of Biomedical Sciences, University of Bradford, United Kingdom
- Professor Sir Colin Berry, United Kingdom
- Professor Hermann Bolt, Institut für Arbeitsphysiologie, Germany
- Professor Alan R. Boobis, Department of Health Toxicology Unit, Imperial College London, United Kingdom
- Dr Susy Brescia, Health and Safety Executive, United Kingdom
- Dr John Bucher, National Institute of Environmental Health Sciences, USA
- Dr Vincent Cogliano, Unit of Carcinogen Identification and Evaluation, International Agency for Research on Cancer, France
- Dr Samuel M. Cohen, Pathology and Microbiology, Havlik-Wall Professor of Oncology, University of Nebraska Medical Center, USA
- Dr Vicki Dellarco, Office of Pesticide Programs, Environmental Protection Agency, USA
- Ms Christine Dove, School of Life Sciences, University of Bradford, United Kingdom
- Dr Jun Kanno, Division of Cellular and Molecular Toxicology, National Institute of Health Sciences, Japan
- Dr Janet Kielhorn, Department of Chemical Risk Assessment, Fraunhofer Institute for Toxicology and Experimental Medicine, Germany
- Mrs Sandra Kunz, International Programme on Chemical Safety, World Health Organization, Switzerland
- Dr Christian Laurent, Scientific Expert Services, European Food Safety Authority, Italy
- Dr Douglas McGregor, Toxicity Evaluation Consultants, United Kingdom
- Ms Bette Meek, Environmental Health Centre, Health Canada, Canada
- Ms Sharon Munn, Toxicology and Chemical Substances, European Chemicals Bureau, Italy
- Dr R. Julian Preston, National Health and Environmental Effects Research Laboratory, Environmental Carcinogenesis Division, Environmental Protection Agency, USA
- Dr Jerry Rice, Consultant, USA
- Dr Hans-Bernhard Richter-Reichhelm, Federal Institute for Risk Assessment (BfR), Germany
- Ms Carolyn Vickers, International Programme on Chemical Safety, World Health Organization, Switzerland
- Ms Deborah Willcocks, Existing Chemicals, National Industrial Chemicals Notification and Assessment Scheme (NICNAS), Australia
- Dr William P. Wood, Risk Assessment Forum, Environmental Protection Agency, USA
- Dr Zheng Yuxin, Institute for Occupational Health and Poison Control, Chinese Center for Disease Control and Prevention, and WHO Collaborating Centre of Occupational Health, People's Republic of China

The draft was published on the Internet for public comment and sent to a number of WHO Collaborating Centres and IPCS Participating Institutions for peer review. An expert meeting that convened in London in December 2005 considered the comments received and finalized the framework. The expert meeting participants were as follows:

- Professor Alan R. Boobis, Department of Health Toxicology Unit, Imperial College London, United Kingdom (*Rapporteur*)
- Dr Samuel M. Cohen, Pathology and Microbiology, Havlik-Wall Professor of Oncology, University of Nebraska Medical Center, USA
- Dr Vicki Dellarco, Office of Pesticide Programs, Environmental Protection Agency, USA
- Dr William Farland, Office of Research and Development, Environmental Protection Agency, USA (Chair)

Dr Douglas McGregor, Toxicity Evaluation Consultants, United Kingdom

- Ms Carolyn Vickers, International Programme on Chemical Safety, World Health Organization, Switzerland
- Ms Deborah Willcocks, Existing Chemicals, National Industrial Chemicals Notification and Assessment Scheme (NICNAS), Australia

### IPCS FRAMEWORK FOR ANALYSING THE RELEVANCE OF A CANCER MODE OF ACTION FOR HUMANS<sup>1</sup>

Alan R. Boobis, Samuel M. Cohen, Vicki Dellarco, Douglas McGregor, M.E. (Bette) Meek, Carolyn Vickers, Deborah Willcocks, & William Farland

The use of structured frameworks can be invaluable in promoting harmonization in the assessment of chemical risk. The International Programme on Chemical Safety (IPCS) has therefore updated and extended its Mode of Action (MOA) Framework for cancer to address the issue of human relevance of a carcinogenic response observed in an experimental study. The first stage is to determine whether it is possible to establish an MOA. This comprises a series of key events along the causal pathway to cancer, identified using a weight-of-evidence approach based on the Bradford Hill criteria. The key events are then compared first qualitatively and then quantitatively between the experimental animals and humans. Finally, a clear statement of confidence, analysis, and implications is produced. The IPCS Human Relevance Framework for cancer provides an analytical tool to enable the transparent evaluation of the data, identification of key data gaps, and structured presentation of information that would be of value in the further risk assessment of the compound, even if relevancy cannot be excluded. This might include data on the shape of the dose–response curve, identification of any thresholds, and recognition of potentially susceptible subgroups, for example, the basis of genetic or life stage differences.

Fundamental to the evolution of cancer risk assessment over the last three decades has been our increasing understanding of the biology of cancer and the identification of key events in carcinogenesis. Through the mid-1980s, national and international assessments of human cancer hazard and risk depended primarily on lifetime assays in rodents of potentially carcinogenic agents. For few agents was there sufficient human evidence on which to base retrospective cancer assessments, and fewer still would be expected to be detected prospectively, given modern controls on general exposures in the workplace and in the environment generally. Inherent in rodent-based assessments was the assumption that the observation of tumours in laboratory animals could be meaningfully extrapolated to identify potential human carcinogens and, by the use of mathematical models, to provide upper-bound estimates of risk at human doses of regulatory significance. During the same period, the potential significance of mutagenesis in carcinogenesis was becoming accepted by the scientific community. Subsequently, it has become increasingly apparent that an appreciable number of chemicals cause cancer in laboratory animals by processes that do not involve direct interaction with DNA. These developments in our understanding of the biological basis of carcinogenesis in both laboratory animals and humans have benefited risk assessment processes by providing more data on the pharmacokinetics and pharmacodynamics of suspect carcinogenic agents. Consideration of the biological processes involved in the carcinogenesis of specific compounds has led to the concept of mode of action (MOA).

<sup>&</sup>lt;sup>1</sup> This article, to which WHO owns copyright, was originally published in 2006 in *Critical Reviews in Toxicology*, Volume 36, pages 781–792. It has been edited for this WHO publication and includes corrigenda.

A postulated MOA for carcinogenesis is a biologically plausible sequence of key events leading to an observed effect supported by robust experimental observations and mechanistic data. It describes key cytological and biochemical events—that is, those that are both measurable and necessary to the observed carcinogenicity—in a logical framework. MOA contrasts with mechanism of action, which generally involves a sufficient understanding of the molecular basis for an effect and its detailed description so that causation can be established in molecular terms.

In 2001, as part of its efforts to harmonize risk assessment practices, the International Programme on Chemical Safety (IPCS) (WHO/ILO/UNEP) published a framework for assessment of MOA for carcinogenesis in laboratory animals (animal MOA), based on Bradford Hill criteria for causality. The IPCS Human Relevance Framework (HRF) presented in this document updates this MOA Framework and extends it to consider human relevance. It is an analytical tool to provide a means of evaluating systematically the data available on a specific carcinogenic response to a chemical in a transparent manner. While it is envisaged that the framework will be of value to risk assessors both within and outside of regulatory agencies, it will also be a valuable tool to the research community. Among reasons for using the framework are:

- to provide a generic approach to the analysis of data to contribute to harmonization;
- to encourage transparency of the consideration and use of available data and reasons for the conclusions drawn;
- to provide guidance in the presentation of data;
- to identify critical data deficiencies and needs;
- to inform the quantitative assessment of carcinogenic risk to humans.

These and other topics will be discussed in more detail below.

## THE ROLE OF IPCS IN DEVELOPING THE FRAMEWORK FOR ANALYSING THE RELEVANCE OF A CANCER MOA FOR HUMANS

IPCS has been leading an effort to harmonize approaches to cancer risk assessment as part of its larger project on the Harmonization of Approaches to the Assessment of Risk from Exposure to Chemicals. The first phase of this work resulted in the publication of the IPCS Conceptual Framework for Evaluating a Mode of Action for Chemical Carcinogenesis in experimental animals (Sonich-Mullin et al., 2001). As described in that publication, a major impediment to harmonization identified in the consideration of weight of evidence was the evaluation of MOA in animals. Sonich-Mullin et al. (2001) provided a framework for evaluating MOA of chemical carcinogenesis in animals and recognized the importance of moving on to the next step in the overall characterization of cancer hazard and risk in humans: the assessment of relevance of the MOA of animal carcinogenesis to humans. Adoption of the MOA Framework concept is proceeding through its incorporation in the revised United States Environmental Protection Agency (USEPA) Guidelines for Carcinogen Risk Assessment (USEPA, 1999, 2005), and the framework is now commonly used by other regulatory agencies and international organizations. In the United Kingdom, the framework is being used for the assessment of pesticides and industrial chemicals. The United Kingdom

Committee on Carcinogenicity (2004) has noted the framework's value with regard to both harmonization between agencies and internal consistency in its latest guidelines. The framework has also been adopted and is being used by agencies in Australia and in Canada, in the evaluation of Existing Chemicals under the Canadian Environmental Protection Act. The European Union has incorporated the framework into its technical guidance documents on evaluating new and existing industrial chemicals and biocides, including carcinogenicity. With regard to international organizations, of particular note is the use of the framework by the Joint FAO/WHO Meeting on Pesticide Residues (JMPR), for example, in its evaluation of pyrethrin extract and its incorporation into the resulting monograph.

The step to extend the MOA Framework to include consideration of human relevance has been undertaken by IPCS in cooperation with international partners. It was the subject of an IPCS international workshop convened in Bradford, United Kingdom, from 21 to 23 April 2005. This workshop prepared draft text for an IPCS HRF, including updating the 2001 MOA Framework. The draft was published on the Internet for public comment and sent to a number of WHO Collaborating Centres and IPCS Participating Institutions for peer review. An expert meeting convened in London in December 2005 considered the comments received and finalized the framework. The framework text and the steps leading to its development are discussed in detail in the following sections.

### THE 2001 IPCS CONCEPTUAL MOA FRAMEWORK FOR EVALUATING ANIMAL CARCINOGENESIS

### **Purpose of the framework**

The IPCS MOA Framework for evaluating carcinogenesis in animals (Sonich-Mullin et al., 2001) remains a fundamental basis for the IPCS Framework for Analysing the Relevance of a Cancer Mode of Action for Humans. The animal MOA Framework provides a generic approach to the principles commonly used when evaluating a postulated MOA for tumour induction in animals by a chemical carcinogen. Thus, the framework is a tool that provides a structured approach to the assessment of the overall weight of the evidence for the postulated MOA. In this context, a supported MOA would have evidence provided by robust experimental observations and mechanistic data to establish a biologically plausible explanation.

The framework is designed to bring transparency to the analysis of a postulated MOA and thereby promote confidence in the conclusions reached through the use of a defined procedure that encourages clear and consistent documentation supporting the analysis and reasoning and that highlights inconsistencies and uncertainties in the available data. The purpose of the framework is to provide a systematic means of considering the weight of the evidence for an MOA in a given situation; it is not designed to give an absolute answer on sufficiency of the information, as this will vary depending on the circumstance. It is not a checklist of criteria, but rather an analytical approach. However, the process can be greatly aided by the presentation of tabular summaries of comparative data on incidence of key events and tumours.

The animal MOA Framework analysis is an important step in the hazard characterization. It is envisaged that the animal MOA Framework will contribute to risk assessments of chemical

carcinogens across all sectors (drugs, industrial chemicals, pesticides, food additives, etc.). In the resulting risk assessment documentation, the framework analysis would be appropriately positioned within the hazard characterization section. In the absence of adequate epidemiological data, it may be regarded as an essential component in any discussion of human relevance, dose–response relationships, and risk characterization. It is also envisaged that the framework will be useful to both regulators and researchers in identifying research needs based on clear delineation of data gaps and inconsistencies.

MOA analysis can be used to establish either that a compound has an MOA that has been described previously or that it has a novel MOA. Thus, the output of an MOA analysis may serve to support the evaluation of a specific compound or contribute to the generation of a novel MOA. In the former, chemical-specific data play a vital role in the concordance analysis for human relevance. In the latter, it will be important to identify which events are key to the biological processes that represent the MOA.

Thus, an MOA comprising the same set of key events may apply to many different compounds. The evidence necessary to establish that a specific MOA is responsible for a given carcinogenic response will be substantial the first time such an MOA is proposed. As subsequent compounds are found to share this MOA, the "barrier" to acceptance will be lower, although it will always be necessary to establish rigorously that the key events comprising the MOA occur and that they fulfil the criteria described below. It will also be important to exclude other possible MOAs.

Scientific peer participation is a prerequisite for the development and acceptance of a novel postulated MOA. Peer participation includes both peer involvement in the development of an MOA and peer review by scientists who are independent of the process of development of the MOA. Publication in the scientific literature and presentation and discussion at scientific meetings and workshops constitute peer involvement that contributes to acceptance of an MOA by the scientific community.

While acceptance does not necessarily mean unanimity, most of the scientists reviewing an MOA analysis should agree that the relevant scientific information has been identified and appropriately analysed, that "key events" have been identified and are supported by the information presented, that their relationship to carcinogenesis has been clearly established in the hypothesized MOA, and that alternative MOAs have been considered and rejected.

As knowledge advances, the characterization of an MOA will change. Additional key events may be identified, and others may be refined or even dropped. Nevertheless, significant changes to the key events also need some general acceptance, through peer review, such as described above.

### **Update of framework guidelines**

In development of the IPCS HRF, the 2001 animal MOA Framework text has been updated, and this revised version is presented here.

#### Introduction to framework analysis

This section describes the cancer end-point or end-points that have been observed and identifies which of these are addressed in the analysis. Prior to embarking on a framework analysis, there needs to be careful evaluation of the weight of evidence for a carcinogenic response in experimental animals. The nature of the framework is such that only one MOA is analysed at a time; hence, for example, different tumour types associated with chemical treatment, even if recorded in the same animals, will require separate framework analyses to discern each tumour's MOA. However, in considering the pathogenesis of a single type of tumour, it should be recognized that it is possible that a chemical could induce that tumour type by more than one MOA. Hence, it might be necessary to undertake an analysis of more than one MOA for the same tumour type for a single chemical. Consistent with species- and tissue-specific variation in metabolic activation and detoxication, there is often only poor site concordance for genotoxic carcinogens. This will need to be kept in mind when comparing animal and human data. In contrast, consistent with the observation that most carcinogens acting by a non-genotoxic MOA perturb physiological processes that tend to be site specific, site concordance is reasonably assumed, at least as an initial premise in the HRF.

#### 1. Postulated mode of action (theory of the case)

This section comprises a brief description of the sequence of events on the path to cancer for the postulated MOA of the test substance. This explanation of the sequence of events leads into the next section, which identifies the events considered "key" (i.e. necessary and measurable), given the database available for the analysis.

### 2. Key events

This section briefly identifies and describes the "key events"—measurable events that are critical to the induction of tumours as hypothesized in the postulated MOA. To support an association, a body of experiments needs to define and measure an event consistently. Pertinent observations include, for example, tumour response and key events in the same cell type, sites of action logically related to event(s), increased cell growth, specific biochemical events, changes in organ weight and/or histology, proliferation, perturbations in hormones or other signalling systems, receptor–ligand interactions, effects on DNA or chromosomes, and impact on cell cycle. For example, key events for tumours hypothesized to be associated with prolonged regenerative proliferation might be cytotoxicity as measured histopathologically and an increase in labelling index. As another example, key events for induction of urinary bladder tumours hypothesized to be due to formation of urinary solids composed primarily of calcium phosphate might include elevated urinary free calcium, phosphate, and pH and formation of urinary solids, followed by irritation and regenerative hyperplasia of the uro-thelium.

### 3. Concordance of dose–response relationships

This section should characterize the dose–effect/response relationships for each of the key events and for the tumour response and discuss their interrelationships, in the context of the Bradford Hill criteria. Ideally, one should be able to correlate the dose dependency of the increases in incidence of a key event with increases in incidence or severity (e.g. lesion progression) of other key events occurring later in the process, and with the ultimate tumour incidence. Comparative tabular presentation of incidence of key events and tumours is often helpful in examining dose–response. In the case of complex data sets, this is almost essential.

It is important to consider whether there are fundamental differences in the biological response (i.e. dose transitions) at different parts of the dose–response curve for tumour formation (Slikker et al., 2004). If so, key events relevant to the different parts of the dose–response curve will need to be defined and used in the framework analysis.

### 4. Temporal association

This section should characterize the temporal relationships for each of the key events and for the tumour response. The temporal sequence of key events leading to the tumour response should be determined. Key events should be apparent before tumour appearance and should be consistent temporally with each other; this is essential in deciding whether the data support the postulated MOA. Observations of key events at the same time as the tumours (e.g. at the end of a bioassay) do not contribute to considerations of temporal association, but can contribute to analysis in the next section. Most often, complete data sets to address the criterion of temporality are not available.

### 5. Strength, consistency, and specificity of association of tumour response with key events

This section should discuss the weight of evidence linking the key events, precursor lesions, and the tumour response. Stop/recovery studies showing absence or reduction of subsequent events or tumour when a key event is blocked or diminished are particularly important tests of the association. Consistent observations in a number of such studies with differing experimental designs increase that support, since different designs may reduce unknown biases or confounding. Consistency, which addresses repeatability of key events in the postulated MOA for cancer in different studies, is distinguished from coherence, however, which addresses the relationship of the postulated MOA with observations in the broader database (see point 6). Pertinent observations include tumour response and key events in the same cell type, sites of action logically related to event(s), and results from multistage studies and from stop/recovery studies.

#### 6. Biological plausibility and coherence

One should consider whether the MOA is consistent with what is known about carcinogenesis in general (biological plausibility) and also in relation to what is known for the substance specifically (coherence). For the postulated MOA and the events that are part of it to be biologically plausible, they need to be consistent with current understanding of the biology of cancer. However, the extent to which biological plausibility can be used as a criterion against which weight of evidence is assessed may be limited due to gaps in our knowledge. Coherence, which addresses the relationship of the postulated MOA with observations in the broader database-for example, association of MOA for tumours with that for other end-points-needs to be distinguished from consistency (addressed in point 5), which addresses repeatability of key events in the postulated MOA for cancer in different studies. For coherence, likeness of the case to that for structural analogues may be informative (i.e. structure-activity analysis). Information from other compounds that share the postulated MOA may be of value, such as sex, species, and strain differences in sensitivity and their relationship to key events. Additionally, this section should consider whether the database on the agent is internally consistent in supporting the purported MOA, including that for relevant non-cancer toxicities. Some MOAs can be anticipated to evoke effects other than cancer, such as reproductive effects of certain hormonal disturbances that are carcinogenic.

### 7. Other modes of action

This section discusses alternative MOAs that logically present themselves in the case. If alternative MOAs are supported, they need their own framework analysis. These should be distinguished from additional components of a single MOA that likely contribute to the observed effect, since these would be addressed in the analysis of the principal MOA.

### 8. Uncertainties, inconsistencies, and data gaps

Uncertainties should include those related to both the biology of tumour development and those for the database on the compound of interest. Inconsistencies should be flagged and data gaps identified. For the identified data gaps, there should be some indication of whether they are critical as support for the postulated MOA.

### 9. Assessment of postulated mode of action

This section should include a clear statement of the outcome with an indication of the level of confidence in the postulated MOA—for example, high, moderate, or low. If a novel MOA is being proposed, this should be clearly indicated. However, if the MOA is the same as that proposed for other compounds, the extent to which the key events fit this MOA needs to be stated explicitly. Any major differences should be noted, and their implications for the MOA should be discussed.

### ADDRESSING THE ISSUE OF HUMAN RELEVANCE

In 2000, an IPCS Harmonization Project Cancer Planning Work Group convened in Carshalton, United Kingdom (IPCS, 2000). (This initial IPCS working group differed in membership from the subsequent IPCS working group convened to work on the human relevance project.) Among the recommendations of that meeting was the suggestion that IPCS and the International Life Sciences Institute (ILSI) move forward together and in parallel on the development of the extension of the IPCS MOA Framework towards addressing human relevance. It was recognized that ILSI could provide much help in technical workshops. In June 2001, the ILSI Risk Science Institute (RSI) with support from the USEPA and Health Canada formed a working group to examine key issues in the use of MOA information to determine the relevance of animal tumours. These efforts have resulted in several published reports that are described below. An IPCS Cancer Working Group, convened on 3–5 March 2004 in Arlington, Virginia, USA, agreed that these reports should form the starting point for further exploration of the issue of human relevance of animal tumours by IPCS with the goal of developing a unified IPCS HRF for use of MOA information in risk assessment for regulatory and other purposes (IPCS, 2004).

To address the issue of the human relevance of the MOAs determined in animals, ILSI/RSI charged its working group with expanding the IPCS MOA Framework to include evaluation of the human relevance of a cancer MOA determined in animals. The details of the process, the case-studies, and the framework were published as a series of papers in the November 2003 issue of *Critical Reviews in Toxicology* (Cohen et al., 2003; Meek et al., 2003). These articles describe the ILSI/RSI HRF and provide guidance for its application. In addition, references to specific examples on which the framework is based are included. Several iterations of case-studies of chemicals with generally well known MOAs were used to

develop the integrated framework. The intent was to provide guidance for a disciplined, transparent process evaluating the MOA in animals and each key event with respect to human relevance.

The ILSI/RSI HRF is based on three fundamental questions:

- 1. Is the weight of evidence sufficient to establish the mode of action (MOA) in animals?
- 2. Are key events in the animal MOA plausible in humans?
- 3. Taking into account kinetic and dynamic factors, are key events in the animal MOA plausible in humans?

Questions 2 and 3 involve qualitative and quantitative considerations, respectively, in a concordance analysis of human information in relation to the animal MOA and its key events.

These are followed by an explicit description of confidence in the evaluation, identification of specific data gaps, and the implications for risk assessment. It was emphasized by ILSI/RSI that use of this framework would form part of the hazard characterization step of the overall risk assessment process.

## DEVELOPMENT OF AN IPCS HRF GUIDANCE DOCUMENT BASED ON THE IPCS MOA FRAMEWORK AND THE ILSI/RSI HRF

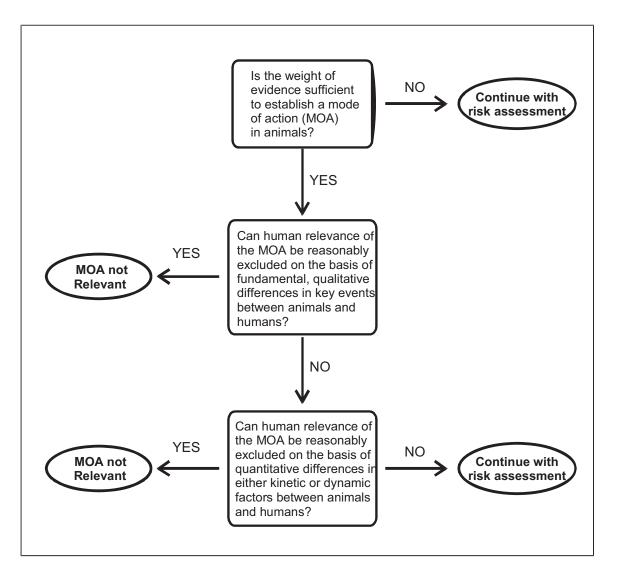

The 2004 IPCS Cancer Working Group discussed the type of document that would be produced as a result of its task to extend the IPCS MOA Framework to address human relevance. It was recognized that one integrated guidance document that worked as a whole would be needed to facilitate uptake and use by regulatory and other risk assessment bodies. The guidance could be supplemented by publication of the other materials generated through the process (e.g. issue papers and case-studies).

There was general agreement among working group members that the questions identified as the critical components of the ILSI/RSI HRF were important and in general appropriate for addressing the human relevance of an MOA determined in animals. However, several issues were identified that could benefit from additional clarification, development, or expansion.

These refinements of the ILSI/RSI HRF were developed through discussions of the IPCS Cancer Working Group and at a workshop convened for this purpose in Bradford, United Kingdom, on 21–23 April 2005 (IPCS, 2005). The resulting IPCS HRF is presented as an approach to answering a series of three questions, leading to a documented, logical conclusion regarding the human relevance of the MOA underlying animal tumours. The application of the guidance results in a narrative with four sections that may be incorporated into the hazard characterization of a risk assessment. The sections are as follows (see Figure 1):

- 1. Is the weight of evidence sufficient to establish a mode of action (MOA) in animals?
- 2. Can human relevance of the MOA be reasonably excluded on the basis of fundamental, qualitative differences in key events between experimental animals and humans?

- 3. Can human relevance of the MOA be reasonably excluded on the basis of quantitative differences in either kinetic or dynamic factors between experimental animals and humans?
- 4. Conclusion: Statement of confidence, analysis, and implications.

**Figure 1. IPCS general scheme illustrating the main steps in evaluating the human relevance of an animal MOA for tumour formation.** The questions have been designed to enable an unequivocal answer *yes* or *no*, but recognizing the need for judgement regarding sufficiency of weight of evidence. Answers leading to the left side of the diagram indicate that the weight of evidence is such that the MOA is not considered relevant to humans. Answers leading to the right side of the diagram indicate either that the weight of evidence is such that the MOA is likely to be relevant to humans or that it is not possible to reach a conclusion regarding likely relevance to humans, owing to uncertainties in the available information. In these cases, the assessment would proceed to risk characterization. It should be noted that only at this stage would human exposure be included in the evaluation.

In applying this framework for a given chemical, tumours of each animal target organ observed are evaluated independently, with the assumption that different MOAs are possible in different organs, although based on this analysis, MOAs in different tissues may be similar. Similarly, an evaluation of the likelihood of congruence between target organ(s) in different species and in humans needs to be made, based on the MOA analysis.

### Is the weight of evidence sufficient to establish a mode of action (MOA) in animals?

Answering this first question in the IPCS HRF requires application of the (updated) IPCS MOA Framework described previously in this document. The steps in the MOA Framework, which are based on the Bradford Hill criteria for causality, are:

- 1. postulated MOA;
- 2. key events; associated critical parameters;
- 3. dose-response relationships;
- 4. temporal association;
- 5. strength, consistency, and specificity of association of key events and tumour response;
- 6. biological plausibility and coherence;
- 7. possible alternative MOAs;
- 8. uncertainties, inconsistencies, and data gaps;
- 9. conclusion about the MOA.

This process incorporates an evaluation of the weight of evidence for possible alternative MOAs at a given site and an evaluation of the overall strength of evidence supporting the MOA under consideration. Ultimately, a decision concerning the weight of evidence supporting the MOA and the level of confidence in that decision must be made. The process also identifies critically important data gaps that, when filled, would increase confidence in the proposed MOA. It is also necessary to establish whether the postulated MOA has already been described for other chemicals, in which case human relevance will already have been evaluated, or whether the proposed MOA is novel, in which case human relevance needs to be assessed de novo.

For a given chemical, the primary sources of information for evaluating an MOA are likely to be data generated for that specific chemical in the animal model in which tumours were produced. Obviously, data from other sources can and should also be used, as appropriate, along with data on chemicals with similar chemical structures, the same or similar MOAs, or both. If the MOA for a chemical is novel, considerably more data will be required to support the conclusion that it is related to the carcinogenic process of the tumours induced by that chemical than for subsequent examples of chemicals acting by the same MOA. The ILSI/RSI working group and the IPCS Bradford workshop did not address the issue of how many data are sufficient to support a specific MOA for a given chemical per se, except by way of example within the case-studies and recognition that acceptance of a novel MOA requires scientific consensus (described above). Consideration at this stage of the MOA analysis of potential variations between animals and humans also facilitates addressing subsequent steps in the framework.

# Can human relevance of the MOA be reasonably excluded on the basis of fundamental, qualitative differences in key events between experimental animals and humans?

The wording of this question was changed from that in the ILSI/RSI HRF, following discussion at the IPCS workshop on the implications of a *yes* or a *no* answer to the original question. In answering the original question, only an unequivocal *no* would be sufficient to

permit the conclusion that the animal MOA was not relevant to humans. Also, it was recognized that translation of the word "plausible" into other languages could be problematic. The question was therefore reworded to enable a *yes/no* answer, but qualified by the descriptor "reasonably", based on recognition that decisions about the adequacy of weight of evidence are not absolute but involve scientific judgement based on transparent analysis of the available data.

This step represents a qualitative assessment of the relevance of the MOA to human cancer potential. Listing the critical specific key events that occur in the animal MOA and directly evaluating whether each of the key events might or might not occur in humans facilitate consideration and transparent presentation of the relevant information. Presentation in tabular form, referred to as a concordance table, can be helpful in delineating the relevant information (for an example, see Meek et al., 2003, case-study 6: kidney and liver tumours associated with chloroform exposure, Table 7; McGregor et al., current document, case-study on formaldehyde, Table 3). The key events (and possibly some of the critical associated processes) are listed with the information regarding these events for the animals in which the tumour was observed. It is intended that the information in these tables be brief, since a narrative explanation is expected to accompany the table. In the right-hand column, the effect on humans for each of the key events is evaluated. An additional column for the results in a different strain, species, sex, or route of administration that does not result in tumours can be useful if information is available for comparison with the model that leads to tumours. In addition, factors may be identified that, while not key themselves, can modulate key events and so contribute to differences between species or individuals. Such factors include genetic differences in pathways of metabolism, competing pathways of metabolism, and cell proliferation induced by concurrent pathology. Any such factors identified should be noted in a footnote to the concordance table.

The evaluation of the concordance of the key events for the MOA for a given chemical in humans is an evaluation of the MOA in humans, rather than an evaluation of the specific chemical. In general, details of the initial key events are likely to be more chemical specific—for example, the enzyme induction response by phenobarbital in rodent liver, or the formation of a cytotoxic metabolite from chloroform by specific cytochrome P-450 enzymes. Later events are more generic to the MOA—for example, pleiotropic stimulation of hepatic proliferation or regenerative hyperplasia. Information that can be utilized to evaluate the key events in humans can come from in vitro and in vivo studies on the substance itself, but also can involve basic information regarding anatomy, physiology, endocrinology, genetic disorders, epidemiology, and any other information that is known regarding the key events in humans. Information concerning an evaluation of the key event in humans exposed directly to the specific chemical is frequently unavailable.

As knowledge concerning the development of cancer evolves, it may become possible to combine some MOAs on the basis of the basic biology of the processes involved, thus relying less on chemical-specific information to reach a conclusion on the human relevance of a given MOA.

In evaluating the concordance of the information in humans to that in animals, a narrative describing the weight of evidence and an evaluation of the level of confidence for the human information need to be provided. Some specific types of information that are useful include the following:

- 1. cancer incidences at the anatomical site and cell type of interest, including age, sex, ethnic differences, and risk factors, including chemicals and other environmental agents;
- 2. knowledge of the nature and function of the target site, including development, structure (gross and microscopic), and control mechanisms at the physiological, cellular, and biochemical levels;
- 3. human and animal disease states that provide insight concerning target organ regulation and responsiveness;
- 4. human and animal responses to the chemical under review or analogues following short-, intermediate-, or long-term exposure, including target organs and effects.

Obviously, a substantial amount of information is required to conclude that the given MOA is not relevant to humans. If such a conclusion is strongly supported by the data, then chemicals producing animal tumours only by that MOA would not pose a cancer hazard to humans, and no additional risk characterization for this end-point is required. Since there is no cancer hazard, there is no cancer risk for the tumour under consideration.

The question of relevance considers all groups and life stages. It is possible that the conditions under which an MOA operates occur primarily in a susceptible subpopulation or life stage—for example, in those with a pre-existing viral infection, hormonal imbalance, or disease state. Special attention is paid to whether tumours could arise from early-life exposure, considering various kinetic and dynamic aspects of development during these life stages. Any information suggesting quantitative differences in susceptibility is identified for use in risk characterization.

# Can human relevance of the MOA be reasonably excluded on the basis of quantitative differences in either kinetic or dynamic factors between experimental animals and humans?

The wording of this question was changed from that in the ILSI/RSI HRF, following discussion at the IPCS workshop on the implications of a *yes* or a *no* answer to the original question. In answering the original question, only an unequivocal *no* would be sufficient to permit the conclusion that the animal MOA was not relevant to humans. The question was therefore reworded to enable a *yes/no* answer, but qualified by the descriptor "reasonably", based on recognition that decisions about the adequacy of weight of evidence are not absolute but involve judgement based on transparent analysis of the available data.

For purposes of human relevance analysis, if the experimental animal MOA is judged to be qualitatively relevant to humans, a more quantitative assessment is required that takes into account any kinetic and dynamic information that is available from both the experimental animals and humans. Such data will of necessity be both chemical and MOA specific and will include the biologically effective doses required to produce the relevant dynamic responses from which neoplasia can arise. Kinetic considerations include the nature and time course of chemical uptake, distribution, metabolism, and excretion, while dynamic considerations include the consequences of the interaction of the chemical with cells, tissues, and organs. On occasion, the biologically effective dose that would be required to create these conditions would not be possible in humans. It may also be that quantitative differences in a biological process involved in a key event-for example, the clearance of a hormone-are so great that the animal MOA is not relevant to humans. However, the IPCS workshop recognized that only infrequently is it likely that it will be possible to dismiss human relevance on the basis of quantitative differences. As with the qualitative assessment, a tabular comparison of quantitative data from the experimental animals and humans can facilitate the evaluation (for example, see Meek et al., 2003, case-study 5, thyroid tumours associated with exposure to phenobarbital, Table 6; Dellarco et al., current document, case-study on thiazopyr, Table 4). Useful comparisons can also be made with key events identified from studies of other compounds believed to induce effects by a similar MOA. For example, in the case of thiazopyr, information on the effects of phenobarbital in humans was particularly informative in evaluating the relevance of the MOA. As molecular and kinetic approaches continue to evolve, understanding of the similarities and differences of responses in animals and humans will be improved. It may become apparent that qualitative differences in a key event between an animal model and humans will be identified as being due to a specific quantitative difference, thus changing the answer to the second question (described above) to no.

As with question 2, if the conclusion to this question is *yes*, then chemicals producing animal tumours only by that MOA would not pose a cancer hazard to humans, and no additional risk characterization for this end-point is required.

### Statement of confidence, analysis, and implications

Following the overall assessment of each of the three questions, a statement of confidence is necessary that addresses the quality and quantity of data underlying the analysis, consistency of the analysis within the framework, consistency of the database, and the nature and extent of the concordance analysis. An evaluation of alternative MOAs, using comparable analyses and rigour, is also essential. A critically important outcome of adequate consideration of the weight of the evidence for an overall MOA and the qualitative and quantitative concordance is the identification of specific data gaps that can be addressed experimentally in future investigations to increase confidence.

Infrequently, there may be conclusive epidemiological data on the cancer risk from a chemical that shares the MOA of the compound under consideration—that is, the compound does or does not cause cancer in humans. Obviously, such data would lend considerable weight to the conclusion of the human relevance evaluation. However, there may be occasions when, despite it being possible to establish an MOA in animals, there is insufficient information on the key events in humans to reach a clear conclusion on human relevance. In such circumstances, it might be possible to bridge this data gap by using epidemiological data. For example, the database on key events in humans for compounds that act like phenobarbital via activation of the constitutively active receptor (CAR) to induce hepatic tumours is incomplete. However, there are robust epidemiological data showing that exposure to phenobarbital for prolonged periods at relatively high doses does not cause cancer in humans. One possibility, therefore, is to "read across" from these findings with phenobarbital to any other compound that shares its MOA in animals in inducing rodent liver tumours and to conclude that the tumours caused by such a compound are not relevant to the risk assessment of the compound in humans (Holsapple et al., 2006). Such a conclusion would be critically dependent on the reliability of the epidemiological data and the similarity between the MOA for the chemical under test to that of the compound for which there are epidemiological data available.

In applying the framework to case-studies, it is apparent that much current research does not address key questions that would facilitate an analysis of an animal MOA or its relevance to humans. Often this has been because of lack of transparent delineation of key data gaps based on consideration of the data in analytical frameworks such as that presented here. Thus, use of the HRF can be very informative to researchers from the outset in the design of their studies.

The output of formal human relevance analysis provides information that is useful for more than just determining whether or not an end-point in animals is relevant to humans. Rather, consideration of the relevant information in a transparent, analytical framework provides much additional information that is critically important in subsequent steps in the risk characterization for relevant effects. Based on a human relevance analysis for a proposed MOA for relevant effects, it may be possible to predict, for example, site concordance or not of observed tumours in animals to humans. Application of the HRF also often provides information on relevant modulating factors that are likely to affect risk, such as hepatitis B and aflatoxin B<sub>1</sub> (see Cohen et al., current document, case-study on 4-aminobiphenyl). Analysis often also provides an indication of those components of a proposed MOA that may operate only over a certain dose range. If a high experimental dose of a given compound is needed to result in an obligatory step in an MOA, then the relevance to human risk becomes a matter of exposure. Thus, the exposure assessment step of the subsequent risk characterization is critical to the proper evaluation of human cancer potential. In addition, information identified during the framework analysis can prove invaluable in hazard quantification based on the key events for the MOA.

Importantly, the human relevance analysis also contributes to identification of any special subpopulations (e.g. those with genetic predisposition) who are at increased risk and often provides information relevant to consideration of relative risk at various life stages. In some cases, this may be based not on chemical-specific information but rather on inference, based on knowledge of the MOA, as to whether or not specific age groups may be at increased or decreased risk.

The data and their analysis using the framework should be reported in a transparent manner, enabling others to determine the basis of the conclusions reached with respect to the key events, the exclusion of other MOAs, and the analysis of human relevance. As the specific form of presentation will vary with the type of data available, it is not helpful to be prescriptive on how the information should be reported. However, presentation should include sufficient details on the context and thought processes to ensure transparency of the conclusions reached. The use of appropriate tables can be helpful in presenting certain data, such as comparative analysis of key events in experimental animals and humans.

#### **Dissemination of the framework**

To assist in the dissemination and application of the IPCS HRF, a database of generally accepted MOAs and informative cases should be constructed and maintained. This would comprise a series of MOAs and their associated key events, for reference by those developing framework analyses for compounds that may act by similar MOAs. The case-studies would comprise worked examples that have been analysed using the framework, to provide an indication of the relevant level of detail of the analyses and nature of the weight of evidence required to support acceptance of a proposed MOA in causing the carcinogenic response. Such cases would be particularly valuable early in the development of a new MOA.

#### Application of the IPCS HRF to DNA-reactive carcinogens

Because of similarities in the carcinogenic process between rodents and humans and the comparable initial interactions with DNA by DNA-reactive carcinogens, it would be expected that, in general, DNA-reactive carcinogens would be assessed as progressing to the step of "yes, the key events in the animal MOA could occur in humans" in the ILSI/RSI HRF, as was the case for ethylene oxide (Meek et al., 2003), and "no" to the equivalent step in the IPCS HRF that asks the question, "Can human relevance of the MOA be reasonably excluded on the basis of fundamental, qualitative differences in key events between experimental animals and humans?", as was the case for 4-aminobiphenyl (Cohen et al., current document). In a recent paper, Preston & Williams (2005) presented a set of key events for tumour development that provided a guide for the use of the ILSI/RSI HRF with DNA-reactive carcinogens. This guide supported the view that for most DNA-reactive chemicals, the animal MOA would be predicted to be relevant to humans. However, it was also argued that there could be exceptions and that the ILSI/RSI HRF would be a valuable tool for identifying these. Use of the ILSI/RSI HRF and the IPCS HRF can also assist in quantifying differences in key events between rodents and humans that may be of value in extrapolating risk to humans. Not all rodent DNA-reactive carcinogens have been established to be human carcinogens, as judged by the International Agency for Research on Cancer (IARC) review process. For some of these exceptions, this human-rodent difference in tumour response is attributable to lower exposure of humans to the agent or to the relative insensitivity of epidemiological studies to detect tumour responses at low exposure levels. However, there are other reasons for such differences that are based on biological considerations. For example, if a DNA-reactive carcinogen induces tumours *only* in a species-specific organ, it is possible that the animal MOA based on key events might not be relevant to humans, although available data on MOA would need to be considered to permit such a conclusion. Similarly, the generally more proficient DNA repair processes that occur in humans compared with rodents (Cortopassi & Wang, 1996; Hanawalt, 2001) or a unique pathway of bioactivation in rodents could result in there being yes answers to the steps in the IPCS HRF that address the queries "Can human relevance of the MOA be reasonably excluded on the basis of fundamental, qualitative differences in key events between experimental animals and humans?" and/or "Can human relevance of the MOA be reasonably excluded on the basis of quantitative differences in either kinetic or dynamic factors between experimental animals and humans?" Alternatively, the IPCS HRF could provide quantitative information on these processes for use later in the risk characterization step.

The need in applying the IPCS HRF for DNA-reactive carcinogens is to develop a set of key events that would clearly describe the cancer process and use these as the guide for establishing the human relevance of a rodent tumour MOA for any particular DNA-reactive carcinogen under consideration.

### The IPCS HRF and risk assessment

Among the strengths of the framework are its flexibility, general applicability to carcinogens acting by any MOA, and the ability to explore the impact of each key event on the carcinogenic response. This includes determination of the nature of the dose–response curve, the identification and location of thresholds for individual key events, and their consequences for the overall tumour response curve. In addition, by considering the kinetic and dynamic factors involved in each key event, it may be possible to reach conclusions regarding the relevance or not of the carcinogenic response to specific subpopulations—for example, in early life, in those with particular diseases, or in those with specific polymorphisms. Alternatively, application of the framework can provide quantitative information on the differences between such groups. Application of the framework can also more generally inform the risk characterization of the chemical, even when it is concluded that the carcinogenic response per se is not relevant to humans.

As stated at the outset, MOA analysis and its human relevance counterpart are aspects of the hazard identification and characterization phases of risk assessment (National Research Council, 1983; Meek et al., 2003). Consistent with this paradigm, the human relevance case-studies referred to in the present report contribute to, but do not complete, a risk assessment for the chemicals under study. This is because a complete risk characterization requires not only evaluation of doses in the range of observations from experimental or occupational hygiene studies but also extrapolation to human exposure levels of interest in daily and lifetime activities.

Hazard characterization—and related MOA analysis—deals with the potential for harm in general terms, while the complete risk assessment puts this potential hazard into context with respect to exposure for decision-makers. Risk characterization seeks to describe the relationship between these effects and the doses to which humans are exposed in order to understand and estimate the nature and likelihood of effects in humans who are generally exposed at lower dose levels.

Understanding dose–response can have a profound effect on hazard characterization and therefore is an important component of the MOA analysis, particularly when non-linear processes or dose transitions are inherent in the relevant biology. Similarly, quantifying hazard in the context of dose informs the process of risk assessment by suggesting extrapolation models that are consistent with our understanding of the biology.

Estimating these generally lower human exposure levels is the task of the exposure analysis component of the risk assessment process. This usually involves extensive analysis of data collected from environmental media and plant and animal tissues, as well as those derived from pharmacokinetic models. This process also depends on analyses of human activity patterns and life stage and lifestyle factors that may bring about exposure. Ideally, based on

this information, a range of exposure scenarios is developed for different groups (men, women, children, infants, special groups, based, for example, on ethnicity or occupation) for use in identifying populations of concern. While hazard characterization, which is largely included in the framework analysis, involves quantification (dose–response analysis), estimating external exposures and contextualizing the hazard with respect to these estimates comprise subsequent steps in the risk assessment process. For example, in the case of melamine (Meek et al., 2003, case-study 7), it was concluded that the animal MOA was potentially relevant to humans. However, recognition that bladder carcinoma formation occurred only at very high doses carried forward to the subsequent stages of the risk assessment, exposure assessment, and risk characterization. The full risk assessment established that human exposures would not achieve levels necessary to produce bladder carcinomas, by a substantial margin.

### CONCLUSIONS

This IPCS HRF has been developed based on experience gained from the original 2001 IPCS MOA Framework and consideration of the 2003 ILSI/RSI human cancer relevance framework. Many aspects of these frameworks have been adopted, but a number of changes have been made to improve clarity and to introduce some elements not previously considered (e.g. sensitive subpopulations). The utility and role of the framework as an analytical tool within hazard characterization and within the overall risk assessment/characterization paradigm—that is, informing human relevance and dose–response extrapolation—have been emphasized. A number of general points and conclusions follow from the development of this framework:

- 1. Prior to embarking on a framework analysis, there needs to be careful evaluation of the weight of evidence for a carcinogenic response in experimental animals.
- 2. Peer involvement and independent review are essential prerequisites for the general acceptance and scientific defensibility of a new MOA.
- 3. The framework is applicable to all MOAs for carcinogens, including DNA reactivity.
- 4. Although human relevance is likely to be assumed for most DNA-reactive carcinogens, the human relevance analysis is a valuable approach to enhance understanding, improve characterization of the hazard and risk, and identify exceptions.
- 5. When dealing with a chemical that may operate through a novel MOA, the analysis is focused on the chemical and entails a detailed evaluation via the HRF. However, when a specific chemical produces a tumour response consistent with an already established and peer-reviewed MOA through which other chemicals have been shown to operate, the analysis is then focused on the established MOA and a determination of whether the chemical produces its carcinogenic effect via the same key events established for the pathway.
- 6. When evaluating the human relevance of a tumour response found in experimental animals, the concordance analysis of key events is for the MOA and is not necessarily a chemical-specific evaluation. Chemical-specific and generic information relevant to the carcinogenic process can be valuable in the analysis. As knowledge advances, MOAs will become less chemical specific and will be based even more on the key biological

processes involved, allowing greater generalization of human relevance from one compound to another.

- 7. The biological understanding and significance of the key events can inform the approach to dose–response extrapolation for cancer risk, and thus understanding of the MOA can have a profound effect on the hazard and risk characterization, particularly when non-linear processes or dose transitions are inherent in the relevant biology.
- 8. It is recommended that a database of generally accepted MOAs and informative casestudies be established and maintained. It should provide examples that add to the existing case-studies developed by ILSI/RSI and IPCS and that are instructive in the application of the framework analysis. This database is particularly important as experience continues to evolve in the development of MOAs of carcinogens.
- 9. It is important to consider potentially susceptible subgroups and different life stages in the analysis.

In conclusion, the IPCS HRF provides a rigorous and transparent approach for judging whether data support a postulated mode of carcinogenic action for a chemical and for evaluating its relevance for humans. The scientific community is encouraged to use this approach as a means to increase the use of mechanistic information in cancer risk assessment and is encouraged to provide feedback, which may lead to additional refinements in the future. The framework is of value to both the risk assessment and research communities in furthering our understanding of carcinogenic processes, in identifying critical data gaps, and in informing the design of studies related to MOAs. When a carcinogenic response is considered potentially relevant to humans, information obtained on the key events during the analysis can prove invaluable in subsequent hazard quantification of the compound. It should be possible to extend the framework to non-cancer end-points, and further work on this is recommended. Thus, application of the IPCS HRF would be an invaluable tool for harmonization across end-points.

### ACKNOWLEDGEMENTS

IPCS and the authors of this paper acknowledge the numerous experts involved in the scientific meetings and workshops leading to the development of this IPCS Human Relevance Framework for Analysing the Relevance of a Cancer Mode of Action for Humans. These were expert meetings and workshops convened and conducted in accordance with procedures of the IPCS/WHO. The outcomes, including this paper, contain the collective views of an international group of experts and do not necessarily represent the decisions or the stated policy of WHO. The work was funded by donations to IPCS from a number of Member States of the World Health Assembly.

### THIAZOPYR AND THYROID DISRUPTION: CASE-STUDY WITHIN THE CONTEXT OF THE IPCS FRAMEWORK FOR ANALYSING THE RELEVANCE OF A CANCER MODE OF ACTION FOR HUMANS<sup>1</sup>

Vicki L. Dellarco, Douglas McGregor, Sir Colin Berry, Samuel M. Cohen, & Alan R. Boobis

Thiazopyr increases the incidence of male rat thyroid follicular cell tumours; however, it is not carcinogenic in mice. Thiazopyr is not genotoxic. Thiazopyr exerts its carcinogenic effect on the rat thyroid gland secondary to enhanced metabolism of thyroxine leading to hormone imbalance. The relevance of these rat tumours to human health was assessed by using the 2006 International Programme on Chemical Safety Human Relevance Framework. The postulated rodent tumour mode of action (MOA) was tested against the Bradford Hill criteria and was found to satisfy the conditions of dose and temporal concordance, biological plausibility, coherence, strength, consistency, and specificity that fits with a well established MOA for thyroid follicular cell tumours. Although the postulated MOA could theoretically operate in humans, marked quantitative differences in the inherent susceptibility for neoplasia to thyroid hormone imbalance in rats allows for the conclusion that thiazopyr does not pose a carcinogenic hazard to humans.

A number of chemical substances have been shown to induce thyroid follicular cell tumours in rats through a mode of action (MOA) that involves perturbation of thyroid hormone homeostasis via reduction of circulating thyroid hormones (Hurley et al., 1998; Capen et al., 1999; IARC, 2001). Homeostatic responses to low thyroid hormone concentrations result in a compensatory increase in the release of thyroid stimulating hormone (TSH) from the pituitary gland, which in turn stimulates the thyroid gland to increase thyroid hormone synthesis and release. Persistent elevation of TSH levels leads to thyroid follicular cell hypertrophy and hyperplasia, which, if maintained (as a result of continuous exposure to the compound), can eventually lead to neoplasia. This neoplastic MOA in rats is well accepted by the scientific community, and both the International Agency for Research on Cancer (Capen et al., 1999; IARC, 2001) and the United States Environmental Protection Agency (USEPA, 1998) have established specific guidance or policies for evaluating the human relevance of rodent thyroid follicular cell tumours.

Thiazopyr, a herbicide that induces rat thyroid follicular cell tumours by its effect on thyroid homeostasis, was the case-study used to illustrate the original 2001 International Programme on Chemical Safety (IPCS) framework for mode of carcinogenic action analysis (Sonich-Mullin et al., 2001). Thiazopyr's MOA is revisited as a case-study here to illustrate the additional guidance provided in the 2006 IPCS Human Relevance Framework (HRF) for evaluation of a neoplastic MOA for humans. This updated case-study highlights how accumulating experience with a particular MOA can make subsequent analyses less difficult. Because this case-study is based on an established MOA in which the key events have been well defined, this analysis will focus on whether thiazopyr produces the biological effects

<sup>&</sup>lt;sup>1</sup> This article, to which WHO owns copyright, was originally published in 2006 in *Critical Reviews in Toxicology*, Volume 36, pages 793–801. It has been edited for this WHO publication and includes corrigenda.

expected of this pathway. This case-study also emphasizes the importance of understanding the basic physiological processes underlying a toxicity pathway in animals and humans. For some compounds, chemical-specific data might be critical in evaluating the key events in humans. For others, the underlying biology is sufficient to allow interpretation of the human relevance of the carcinogenic MOA, both qualitatively and quantitatively. Thiazopyr is an example of the latter. Another MOA case-study of thyroid hormone disruption and the human relevance of rat thyroid follicular cell tumours is available for phenobarbital (Lehman-McKeeman & Hill, in Meek et al., 2003).

The present MOA analysis begins with a brief summary of the available information on the carcinogenicity of thiazopyr, followed by a discussion of the experimental biochemical and histopathological data considered for this thyroid disruption MOA. It is not intended to be a comprehensive assessment of the chemical per se.

### CARCINOGENICITY DATA

Human epidemiological data on the carcinogenicity of thiazopyr are not available. Thiazopyr produces effects on liver and thyroid in various laboratory species, including mice, rats, and dogs. Thiazopyr was found to induce thyroid tumours in male rats only and appears to do so by increasing the hepatic metabolism and excretion of thyroid hormones.

Chronic dietary administration of thiazopyr to mice and rats resulted primarily in thyroid follicular cell tumours in male rats but not in female rats (Naylor & McDonald, 1992; Naylor & Raju, 1992). There were no significant increases in the incidences of any tumours in either sex in the chronic study of mice treated with thiazopyr at up to 800 mg/kg in the diet (128.4 mg/kg body weight [bw] per day in males and 215.9 mg/kg bw per day in females) (Naylor & Raju, 1992). In the rat carcinogenicity study, thiazopyr (technical, 94.8% pure) was administered to male and female Sprague-Dawley (SD) rats (60 per sex per group) at dietary concentrations of 0, 1, 10, 100, 1000, or 3000 mg/kg, providing dose levels of 0, 0.04, 0.4, 4.4, 44.2, or 136.4 mg/kg bw per day for males and 0, 0.06, 0.6, 5.6, 56.3, or 177.1 mg/kg bw per day for females (Naylor & McDonald, 1992). The incidences of thyroid follicular cell adenomas and carcinomas were increased in male rats of the 1000 mg/kg (44.2 mg/kg bw per day) and 3000 mg/kg (136.4 mg/kg bw per day) groups (Table 1). It should be noted that the increase in tumour incidence in male rats is primarily accounted for by benign tumours.

### POSTULATED MOA FOR THE INDUCTION OF THYROID FOLLICULAR CELL TUMOURS IN RATS

The postulated MOA for thiazopyr-induced thyroid follicular cell tumours involves the perturbation of homeostasis of the pituitary–thyroid axis by an extrathyroidal mechanism. Specifically, thiazopyr induces hepatic thyroxine (T4)-uridine diphosphate (UDP) glucurono-syltransferase (UGT) activity, leading to enhanced metabolism of T4 by conjugation and increased biliary excretion of the conjugated hormone. The result of this enhanced liver metabolism is a decrease in serum T4 (and sometimes triiodothyronine, or T3) half-life. The pituitary gland responds to a decrease in circulating serum levels of T4 by enhancing the output and serum level of TSH. Prolonged elevation of circulating TSH levels stimulates the

thyroid gland to deplete its stores of thyroid hormone and continues to induce hormone production. Thus, the thyroid follicular cells enlarge (hypertrophy) and are induced to proliferate at an increased rate and to increase in number (hyperplasia). With chronic exposure, thyroid hyperplasia eventually progresses to neoplasia.

### Table 1. Thyroid follicular cell tumour incidence in Sprague-Dawley male rats(2-year chronic study).

		Dose (mg/kg bw per day) <sup>a</sup>					
	0	0.04	0.4	4.4	44.2	136.4 <sup>b</sup>	
Adenomas	1/50	2/47	0/49	2/47	8/49	12/48	
Carcinomas	1/50	1/47	0/49	0/47	1/49	4/48	
Combined	2/50	3/47	0/49	2/47	9/49	14/48	
%	(2)	(6)	(0)	(4)	(18)	(29)	
Ρ	0.000 <sup>c</sup>	0.470	0.253	0.668	0.024*	0.001**	

Note: Tumour incidences were extracted from data submitted to the USEPA Office of Pesticide Programs (Naylor & McDonald, 1992). Significance: \* P < 0.05; \*\* P < 0.01 (statistical analyses based on Fisher's exact test).

<sup>a</sup> Doses in mg/kg bw per day were estimated.

<sup>b</sup> Two animals in the 136.4 mg/kg bw per day or 3000 mg/kg diet dose group had both benign and malignant tumours.

<sup>c</sup> For trend with dose.

### **KEY EVENTS IN EXPERIMENTAL ANIMALS**

The sequence of key events in thiazopyr's mode of carcinogenic action includes:

- induction of hepatic UGT activity;
- increase in hepatic metabolism and biliary excretion of T4;
- decrease in serum T4 half-life and concentration;
- increase in circulating TSH concentration;
- cellular thyroid hypertrophy and follicular cell hyperplasia.

An evaluation follows to determine whether thiazopyr works via disruption of thyroid– pituitary status by increasing hepatic clearance of circulating thyroid hormone. Thus, based on the key events listed above, biological indicators of thiazopyr's MOA should include changes in liver metabolism, alterations in hormone levels, increases in thyroid growth, and lesion progression in the thyroid. These effects have been observed and measured in male rats in short-term and subchronic studies, and at interim and terminal sacrifices in a chronic study (Hotz et al., 1997). The dose–response and temporal analyses of the key events and tumour response are presented below.

### DOSE-RESPONSE RELATIONSHIP AND CONCORDANCE

A summary of the no-observed-adverse-effect levels (NOAELs) and lowest-observedadverse-effect levels (LOAELs) for the key effects in thiazopyr's MOA are provided in Table 2. In the 56-day study by Hotz et al. (1997), male SD rats (20 per dose) were fed diets containing thiazopyr at 0, 10, 30, 100, 300, 1000, or 3000 mg/kg (doses not measured, but estimated to be 0, 0.5, 1.5, 5, 15, 50, and 150 mg/kg bw per day) for 56 days and evaluated for the effects on liver (weights, T4-hepatic UGT activity, T4 biliary elimination), thyroid (weights, hypertrophy/hyperplasia), and hormones (serum levels of T4, T3, reverse T3, or rT3, and TSH). In this study, the effects on liver, thiazopyr's primary site of action, appear to be the most sensitive indicator of pituitary-thyroid homeostasis perturbation. Statistically significant increases in hepatic T4-UGT activity in the 50 and 150 mg/kg bw per day groups (approximately 3- and 6-fold increases in activity over controls when adjusted for liver weight, respectively) were found at the end of the 56-day treatment period. Consistent with the increase in T4-UGT activity, clearance of T4 from the blood and elimination in bile (40% increase in excretion of <sup>125</sup>I-labelled T4) were increased after 150 mg/kg bw per day of thiazopyr (only dose evaluated). Statistically significant increases in liver weight were found at 15, 50, and 150 mg/kg bw per day of thiazopyr in the 56-day study in male rats by Hotz et al. (1997). In the 2-year rat study (Naylor & McDonald, 1992), absolute liver weights were increased by 122% at 44.2 mg/kg bw per day and by 178% at 136.4 mg/kg bw per day relative to controls. There were also statistically significant increases in the incidence of liver hypertrophy at 44.2 and 136.4 mg/kg bw per day (47/61 and 52/60 versus 0/60 in controls, respectively) in the 2-year rat study.

Effect	NOAEL/LOAEL			
Liver				
Induction of UGT	15/50 mg/kg bw per day (56-day study)			
Increase in T4 biliary elimination	<150/150 mg/kg bw per day (only dose tested in 56-day study)			
Increase in liver weight	5/15 mg/kg bw per day (56-day study)			
	44.2/136.4 mg/kg bw per day (2-year study)			
Hepatocellular hypertrophy	4.4/44.2 mg/kg bw per day (2-year study)			
Hormones				
Decrease in serum T4	50/150 mg/kg bw per day (56-day study)			
Increase in serum TSH	50/150 mg/kg bw per day (56-day study			
Thyroid				
Increase in thyroid weight	15/50 mg/kg bw per day (56-day study)			
	44.2/136.4 mg/kg bw per day (2-year study)			
Increase in thyroid hyperplasia	44.2/136.4 mg/kg bw per day (2-year study)			
Increase in thyroid tumours	4.4/44.2 mg/kg bw per day (2-year study)			

Table 2. Summary of effects on liver, hormones, and thyroid from a 56-day study (Hotz
et al., 1997) and the 2-year chronic study (Naylor & McDonald, 1992) in male rats.

Consistent with the enhanced hepatic clearance of T4 described above, when Hotz et al. (1997) treated male SD rats with doses of thiazopyr, statistically significant ( $P \le 0.05$ ) decreases in serum T4 levels (by 30%) and increases in TSH (by 60%) were found after 56 days of treatment at the highest dose tested (Table 3). T3 serum levels were non-significantly lower at 1.5 mg/kg bw per day and statistically significantly higher at 150 mg/kg bw per day after 56 days of treatment. In general, hepatic microsomal enzyme inducers appear to affect T3 less than T4; thus, T4 and TSH tend to be more reliable indicators of altered pituitary–

thyroid homeostasis (Liu et al., 1995; Hurley et al., 1998; Hood et al., 1999). In the case of thiazopyr, there appears to be a poor correlation between the doses causing the T4 and TSH effects and those causing an increased incidence of thyroid follicular cell tumours. The lowest dose of thiazopyr producing a statistically significant (P < 0.05) increase in thyroid follicular cell tumours in male SD rats was 44.2 mg/kg bw per day in the 2-year study, whereas the NOAEL for effects on T4 and TSH was 50 mg/kg bw per day in the 56-day study (Table 2). Generally, effects on liver enzymes/weight and pituitary-thyroid hormone concentrations would be anticipated to occur at doses at least as low as those that produce thyroid weight changes and increases in thyroid tumour incidence, given that this thyroid disruption MOA is a threshold phenomenon. This apparent discrepancy is probably not real, because neither of the doses quoted is accurate. In the 2-year study, the milligrams per kilogram body weight doses were averaged estimates for the entire study, whereas the relevant doses for comparison with the 56-day mechanistic study are those for rats of 12-20 weeks of age. These doses would have been at least 2-fold higher than those that were readily available (so the real LOAEL for neoplasia would have been about 90 mg/kg bw per day). They would also have been more relevant for neoplasia, because the critical period for hormonal perturbations (e.g. prolonged elevation of TSH) to initiate pathological changes would be early, not late, in the 2-year study. The doses calculated for the 56-day study are also likely to be inaccurate, because food intake information was not available in the publication; the doses are estimates based on assumed intakes. Having acknowledged this uncertainty, it is observed that thyroid weights were increased significantly at 50 mg/kg bw per day and liver weights were increased at 15 mg/kg bw per day, which is consistent with the liver being the initial target in thiazopyr's MOA.

	Dose (mg/kg bw per day) <sup>a</sup>							
	0	0.5	1.5	5	15	50	150	
T4 (µg/dl)	4.1 ± 0.2	4.3 ± 0.3	3.9 ± 0.2	4.1 ± 0.2	4.0 ± 0.2	4.0 ± 0.2	2.9 ± 0.1 <sup>a</sup>	
T3 (ng/dl)	84 ± 3	82 ± 4	68 ± 2	84 ± 3	82 ± 3	91 ± 4	110 ± 6 <sup>a</sup>	
TSH (ng/ml)	2.7 ± 0.2	$3.5 \pm 0.4$	2.7 ± 0.1	3.1 ± 0.4	2.9 ± 0.3	3.1 ± 0.2	$4.3 \pm 0.4^{a}$	

Table 3. Fifty-six-day study in male rats: Hormonal effects (Hotz et al., 1997).

Note: The mg/kg bw per day doses were estimated. Values are mean ± standard error of the mean; 19 or 20 animals per group.

Significantly different from control with Dunnett's test after analysis of variance (ANOVA) ( $P \le 0.05$ ).

As stated above, prolonged TSH stimulation leads to both hypertrophy and hyperplasia of the thyroid. In the 2-year rat study, there was a poor dose correlation between thyroid hyperplasia alone and tumour incidence. While tumour incidence was increased at 44.2 mg/kg bw per day, a statistically significant increase in the incidence of hyperplasia (8/58 versus 1/60 in controls) was found only at 136.4 mg/kg bw per day. Furthermore, in the 56-day rat study, where thyroid histology was reported as follicular cell hypertrophy and hyperplasia combined, there was a significant increase in the incidence of this diagnosis at 150 mg/kg bw per day but not at lower doses (Hotz et al., 1997). There was, however, a good dose correlation between increases in thyroid weights in the 56-day study and tumour incidence in the 2-year study. Statistically significant increases in thyroid weights of 46% were found at 150 mg/kg bw per day and 25% at 50 mg/kg bw per day (Hotz et al., 1997).

### **TEMPORAL RELATIONSHIP**

If an event (or events) is an essential element of tumorigenesis, it must precede tumour appearance. Multiple exposure time data at 7, 14, 28, 56, and 90 days are available in which male SD rats were offered diets containing thiazopyr at 3000 mg/kg (150 mg/kg bw per day) (Hotz et al., 1997). Liver weights and hepatic T4-UGT activity were increased at all observation times from the earliest time of assessment on day 7. Biliary excretion of conjugated T4 was not measured in this experiment; however, serum T4 was reduced at all observation times. Increases in circulating TSH were observed at all sampling times, although the increase was not significant at 14 days after treatment began. Increases in thyroid weight were also observed at all sampling times. Histologically, there was a time-related increase in hypertrophy/hyperplasia beginning at 14 days. In the 2-year rat study, the first thyroid adenoma was observed at week 69 at a dose of 136.4 mg/kg bw per day. Thus, there is a logical temporal response for the key events in thiazopyr-induced thyroid follicular cell tumour formation in which all key events precede tumour formation.

### STRENGTH, CONSISTENCY, AND SPECIFICITY OF ASSOCIATION OF THE TUMOUR RESPONSE WITH KEY EVENTS

Strength, consistency, and specificity of the association can be established from the studies described above. The quantifiable precursor events, fundamental to the proposed MOA, are relatively consistent with the emergence of thyroid follicular cell tumours. Observation of liver weight increase and induction of hepatic T4-UGT in rats receiving the thiazopyr in the diet would be consistent with perturbation of homeostasis of the pituitary-thyroid axis by an extrathyroidal mechanism. An increase in hepatic T4-UGT activity is a step occurring before the other key biochemical changes and before thyroid follicular cell hypertrophy and hyperplasia. Thiazopyr treatment clearly results in a decrease in circulating T4 and an increase in TSH following enhanced liver metabolism of T4. Furthermore, in subchronic studies, the increases in thyroid weight and the development of hypertrophy/hyperplasia were shown to appear to a statistically significant degree under the same conditions of dose and time as the appearance and reversal of changes in thyroid hormone levels and thyroid hormone metabolism. Stop/recovery studies (Hotz et al., 1997) showed that cessation of thiazopyr dosing was followed by a return of hormone levels to control values, as well as a reduction in liver and thyroid weights and reversal of hyperplasia of thyroid follicular cells. Early dosing withdrawal would be expected to result in a reversal of hypothyroidism and of lesion progression for this non-genotoxic MOA. The only sign that was slow to reverse was the increase in thyroid weight after the longest dosing period.

### **BIOLOGICAL PLAUSIBILITY AND COHERENCE**

There are considerable data from studies in laboratory rodents demonstrating the relationship between sustained perturbation of the hypothalamic–pituitary–thyroid axis, prolonged stimulation of the thyroid gland by TSH, and the progression of thyroid follicular cells to hypertrophy, hyperplasia, and eventually neoplasia (McClain, 1995; Hard, 1998; Hurley et al., 1998; Capen et al., 1999; IARC, 2001). Increased secretion of TSH may result via several mechanisms, including increased hepatic clearance of T4, as is the case with thiazopyr.

Circulating levels of T4 are monitored by the thyrotropic cells of the pituitary gland that are responsible for the synthesis of TSH. In the pituitary gland, T4 is metabolized by 5'-deiodinase type II to T3, which then binds to specific receptors in the cell nucleus. A decrease in T3 receptor occupancy results in stimulation of TSH synthesis and secretion. Studies in vivo have shown that injection of rats with TSH leads to reductions in thyroid follicular cell nuclear statin, a non-proliferation-specific nuclear antigen, indicating that these cells were leaving the non-dividing state to resume the cell cycle (Bayer et al., 1992). This study showed that low, repeated doses of TSH (0.25 IU per rat twice daily) produced a cumulative response in nuclear statin levels over 10 days, which returned to normal resting levels within 5 days of cessation of TSH injections. Reduction in nuclear statin is also an early event that parallels the earliest known pinocytotic response to TSH. These data are consistent with increased TSH concentrations alone causing thyroid follicular cells of rats to enter a state of preproliferation. Therefore, the suggestion that thiazopyr causes thyroid follicular cell neoplasms in rats by initially inducing hepatic T4-UGT is coherent with the known physiology of the hypothalamus-pituitary-thyroid dynamic control system, at least to the stage of hypertrophy and hyperplasia.

Lastly, the tumour response elicited by thiazopyr is typical of a rodent thyroid carcinogen, in that thyroid follicular cell tumours are found in male rats but not in female rats or mice. Rats tend to be more sensitive to thyroid carcinogenesis than mice, and male rats are frequently found to be more sensitive than female rats with respect to the proportion of chemicals that induce thyroid tumours (Hurley et al., 1998). In keeping with this, TSH levels are typically higher in male rats than in females (Hill et al., 1989). In addition, male rats are sometimes more prone to hepatic enzyme induction than females of the same strain, but this depends on the enzyme in question, the dose of the inducing compound, and the age of the animals (Sundseth & Waxman, 1992; Agrawal & Shapiro, 1996; Oropeza-Hernandez et al., 2003).

# OTHER MODES OF ACTION

Mutagenesis is always one possible MOA to consider, but no genetic toxicity has been demonstrated for thiazopyr in the following tests:

- mutation in four strains of *Salmonella typhimurium* (Bakke, 1989a);
- mutation at the *hgpt* locus of Chinese hamster ovary cells (Li & Myers, 1989);
- micronucleus induction in bone marrow cells of mice treated in vivo (Flowers, 1990);
- unscheduled DNA synthesis induction in hepatocytes of rats treated in vivo (Bakke, 1989b).

Therefore, the available evidence indicates that mutagenesis is not an alternative MOA for thiazopyr.

Additional effects on the hypothalamic–pituitary–thyroid axis and disruption of other pathways of thyroid hormone metabolism are other possibilities for altering thyroid homeostasis. These variations would not differ in any fundamental way from the one that has been proposed for thiazopyr, in that all would lead to prolonged TSH stimulation with continuous exposure.

# UNCERTAINTIES, INCONSISTENCIES, AND DATA GAPS

There appears to be a lack of dose concordance for thyroid tumours and hormone changes, but this is likely to be due to inaccuracies in the milligrams per kilogram body weight doses compared—which either were estimated (versus calculated on the basis of food consumption and body weight data) and cover an early period in the life of rats or were averages for the whole duration of the experiment—as well as experimental variability.

# ASSESSMENT OF POSTULATED MODE OF ACTION

The data presented are judged, with a moderately high degree of confidence, to be adequate to explain the development of thyroid follicular cell tumours in male rats following chronic dietary exposure to thiazopyr. Thiazopyr clearly increased liver weights (i.e. the initial target organ) at doses lower than those causing tumours and enhanced thyroid growth (i.e. increased thyroid weights) at the lowest tumorigenic dose.

#### Human applicability of the proposed MOA

The IPCS HRF, which was developed from the Risk Science Institute/International Life Sciences Institute "Human Relevance Framework" (Meek et al., 2003) and modified based on discussions by the IPCS Cancer Working Group (Boobis et al., current document), presents a four-part approach to addressing a series of three questions and leading to a documented, logical conclusion regarding the human relevance of the MOA underlying animal tumours.

1. Is the weight of evidence sufficient to establish a mode of action (MOA) in animals? As described in detail above, there is clear evidence that thiazopyr alters thyroid homeostasis by UGT induction, by reducing serum T4 levels and consequently elevating serum TSH.

2. Can human relevance of the MOA be reasonably excluded on the basis of fundamental, qualitative differences in key events between experimental animals and humans? The current understanding of the regulation of thyroid hormone homeostasis in humans and of the role of increased TSH levels (as a result of altered thyroid homeostasis) as a risk factor for thyroid cancer was considered in order to assess the human relevance of the key events in thiazopyr's animal mode of carcinogenic action. Although there are substantial quantitative dynamic differences (discussed below), the fundamental mechanisms involved in the function and regulation of the hypothalamic-pituitary-thyroid axis in rats are qualitatively similar to those in humans (Bianco et al., 2002). Therefore, an agent that decreases T4 levels in rats could likewise reduce T4 in humans; this, in turn, could potentially lead to an increase in TSH levels. There are data showing that rodents and humans respond in a similar fashion to perturbations of pituitary-thyroid function. For example, it is well known that iodine deficiency, which readily leads to decreased thyroid hormone levels, stimulates thyroid cell proliferation in humans, leading to goitre. If left untreated, iodine deficiency may lead to tumour formation, albeit rarely (Thomas & Williams, 1999). Although there is no evidence of increased susceptibility to thyroid cancer, a number of pharmaceuticals (e.g. propylthiouracil, lithium, amiodarone, iopanoic acid) that disrupt thyroid homeostasis by acting directly on the thyroid gland (e.g. by inhibiting hormone synthesis or release or by blocking the conversion

of T4 to T3) are known to lead to hypothyroidism and increases in TSH in humans (Ron et al., 1987).

In contrast to rats, no increases in TSH levels have been found in humans following exposure to agents that induce hepatic microsomal enzymes and reduce circulating T4 levels (discussed in Lehman-McKeeman & Hill, in Meek et al., 2003). For example, the pharmaceutical compounds phenytoin, rifampin, and carbamazepine induce hepatic microsomal enzymes, including UGT, and reduce circulating T4 levels, but TSH levels are unchanged (Curran & DeGroot, 1991); agents that produce thyroid tumours in rats by increasing glucuronidation and biliary excretion of T4 at high experimental doses (e.g. omeprazole, lansoprazole, and pantoprazole) produce no changes in thyroid hormones at clinical doses in humans (Masubuchi et al., 1997). Thus, there appears to be a substantial difference in the dose–response relationship for altered homeostasis of the pituitary–thyroid axis in rats compared with humans. As discussed below, this observation is due to quantitative dynamic differences between rats and humans in the basic physiological processes underlying pituitary–thyroid function.

3. Can human relevance of the MOA be reasonably excluded on the basis of quantitative differences in either kinetic or dynamic factors between experimental animals and humans? Thiazopyr does not target the thyroid directly. Rather, its primary effect is on hepatic metabolizing enzymes, and the increase in metabolic activity indirectly increases the systemic clearance of T4, leading to the hypothyroid state and the compensatory increase in TSH found in rats. Although there are no chemical-specific data on the potential for thiazopyr to disrupt thyroid hormone homeostasis in humans, a number of other microsomal enzyme inducers have been extensively studied, such as phenobarbital (Lehman-McKeeman & Hill, in Meek et al., 2003). As discussed above, agents that produce hypothyroidism by altering hepatic clearance of T4 do not appear to result in elevated TSH levels in humans. Presumably, TSH is not increased because a critical reduction of T4 is not reached.

There are several important physiological and biochemical differences between rats and humans related to thyroid function. Rats have a smaller reserve capacity of thyroid hormones when compared with humans. The rat has a much shorter thyroid hormone half-life than humans. The half-life of T4 is about 12 h in rats compared with 5–9 days in humans (Dohler et al., 1979). The shorter half-life in rats is likely related to the absence of a high affinity binding globulin for T4 that is present in humans (Hill et al., 1989). In rats, the increased clearance contributes to the need for a higher rate of production of T4 (per unit of body weight) to maintain normal levels of T4. In contrast, in humans, the binding of thyroid hormone to this globulin accounts for a slower metabolic degradation and clearance, which in turn result in the thyroid gland being less active than in rats. The constitutive TSH levels are approximately 25 times higher in rats to agents that reduce T4 and lead to elevated TSH. There is no increased risk of thyroid tumour development if TSH is not elevated.

Another difference of rats compared with humans is the histological appearance of the thyroid. This histological difference is related to the higher rate of production of T4 to

maintain a consistent serum concentration, thus making the rat thyroid more "functionally active" than that of primates, including humans (McClain, 1995). More of the follicular epithelium in the rat is stimulated to synthesize thyroglobulin, and therefore more of the follicular cells are tall cuboidal and appear to be active in synthesis. In contrast, more of the follicular cells in humans tend to be short cuboidal or almost squamous in appearance, suggesting they are quiescent. Because rat follicular cells are already generally active, under stimulation from TSH, they will respond with hyperplasia more readily than human follicular cells. Because of the greater storage capability of the human thyroid and the greater numbers of cells in a quiescent state, human thyroid follicular cells will be roused from their quiescent state to synthesize and secrete additional thyroid hormone without the need for a hyperplastic response to re-establish homeostasis. Therefore, the primary response in the human thyroid gland would be thyroglobulin reabsorption and cellular hypertrophy rather than hyperplasia. In short, there is much greater buffering capacity in the biochemistry of the human than the rat thyroid.

Even though certain agents can cause a reduction in thyroid hormone levels in humans, there is no clear evidence that these agents increase susceptibility to thyroid cancer (Ron et al., 1987). For example, epidemiological studies with phenobarbital do not show any increased risk of thyroid cancer (Olsen et al., 1993). Studies of individuals with conditions that would lead to elevated TSH (patients with Graves disease or goitre) indicate that the occurrence of thyroid cancer is rare in these circumstances (e.g. Mazzaferri, 2000; Gabriele et al., 2003). A study of environmental and heritable causes of cancer among 9.6 million individuals, using the nationwide Swedish Family-Cancer Database, found that the environment did not appear to play a principal causative role in thyroid cancer (Lichtenstein & Hemminki, 2002). The only known human thyroid carcinogen is radiation, a mutagenic exposure.

As summarized in Table 4, there is sufficient evidence in the general literature on the biochemical and physiological differences in thyroid function to indicate differences in tumour susceptibility between rats and humans. In contrast to humans, rats are very susceptible to thyroid neoplasia secondary to hypothyroidism. In particular, modest changes in thyroid hormone homeostasis will promote tumour formation in rats. Thus, thyroid tumours induced by thiazopyr involving increased hepatic clearance of hormone and altered homeostasis of the pituitary–thyroid axis in rodents are considered not relevant to humans, based on quantitative dynamic differences.

4. Conclusion: statement of confidence, analysis, and implications. There is sufficient experimental evidence to establish a thyroid disruption MOA for thiazopyr-induced thyroid follicular cell tumours in rats. Although thiazopyr may potentially result in hypothyroidism in humans, there is sufficient quantitative evidence on the basic physiological processes in the general literature to conclude that thyroid tumours induced by a process involving increased hepatic clearance of thyroid hormone and altered homeostasis of the pituitary–thyroid axis in rodents is not likely to lead to an increase in susceptibility to tumour development in humans. Although there are no human data on thiazopyr, clinical data on other hepatic microsomal enzyme inducers were critical to this human relevance analysis. The general literature provided sufficient evidence to show that unlike in the rat, decreased T4 levels typically show no evidence of compensatory increases in TSH levels in humans. There is also cellular and biochemical evidence that the rat pituitary-thyroid axis is much more sensitive than that in humans to such perturbations. This sensitivity is likely the result of the rapid turnover of T4 in rats coupled with the higher demand for TSH to maintain thyroid activity.

Key event	Evidence in rats	Evidence in humans
Increased hepatic clearance of T4	In short-term and chronic rat studies, the liver is found to be the most sensitive target, and evidence of increased T4 hepatic clearance is provided by studies on T4-hepatic UGT activity, T4 half-life, T4 biliary elimination, liver weights, and hypertrophy.	No data available for thiazopyr, but microsomal enzyme induction is plausible.
Decreased serum T4	Direct experimental evidence.	No data available for thiazopyr, but plausible given that other microsomal enzyme inducers have been shown to reduce T4 in humans.
Increased TSH levels	Direct experimental evidence.	No data available for thiazopyr, but other microsomal enzyme inducers have not been shown to increase TSH levels even when T4 is decreased.
Increased TSH increases thyroid cell proliferation and tumour formation	Direct experimental evidence.	Induction of thyroid follicular cell tumours secondary to hypothyroidism is remote in humans, given the quantitative differ- ences in thyroid function/homeostasis. Occurrence of thyroid cancer is rare even in severely hypothyroid individuals.

#### Table 4. A comparison of key events in rats and humans.

# **IMPLICATIONS OF THE IPCS HRF**

The thiazopyr example is an illustration of an induced tumour response consistent with an MOA that has been previously defined and established. Thus, addressing the first question in the framework analysis, "Is the weight of evidence sufficient to establish a mode of action (MOA) in animals?", became a determination of whether the data set on the chemical conforms to the same key events defined for the pathway of interest. This example further demonstrates how data on the basic understanding of the biological processes involved in the MOA provide an important means to compare the rodent and human key events. Thus, this generic human information was essential to evaluating the qualitative and quantitative differences between experimental animals and humans in addressing the plausibility of the cancer MOA for humans (i.e. questions 2 and 3 in the HRF).

# 4-AMINOBIPHENYL AND DNA REACTIVITY: CASE-STUDY WITHIN THE CONTEXT OF THE IPCS FRAMEWORK FOR ANALYSING THE RELEVANCE OF A CANCER MODE OF ACTION FOR HUMANS<sup>1</sup>

# Samuel M. Cohen, Alan R. Boobis, M.E. (Bette) Meek, R. Julian Preston, & Douglas B. McGregor

The International Programme on Chemical Safety (IPCS) Human Relevance Framework (HRF) was evaluated for a DNA-reactive (genotoxic) carcinogen, 4-aminobiphenyl, based on a wealth of data in animals and humans. The mode of action (MOA) involves metabolic activation by *N*-hydroxylation, followed by *N*-esterification leading to the formation of a reactive electrophile, which binds covalently to DNA, principally to deoxyguanosine, leading to an increased rate of DNA mutations and ultimately to the development of cancer. In humans and dogs, the urinary bladder urothelium is the target organ, whereas in mice, it is the bladder and liver; in other species, other tissues can be involved. Differences in organ specificity are thought to be due to differences in metabolic activation versus inactivation. Based on qualitative and quantitative considerations, the MOA is possible in humans. Other biological processes, such as toxicity and regenerative proliferation, can significantly influence the dose–response of 4-aminobiphenyl-induced tumours. Based on the IPCS HRF, 4-aminobiphenyl would be predicted to be a carcinogen in humans, and this is corroborated by extensive epidemiological evidence. The IPCS HRF is useful in evaluating DNA-reactive carcinogens.

4-Aminobiphenyl is carcinogenic when administered to several species by a variety of routes (IARC, 1972, 1986, 1987). It was selected as a chemical for a case-study for the International Programme on Chemical Safety (IPCS) Human Relevance Framework (HRF) as a representative DNA-reactive carcinogen because of its established mode of action (MOA) in animal models, based on substantial data available evaluating its metabolic activation, DNA reactivity, genotoxicity, and carcinogenicity. It is also similar to numerous known animal and human carcinogens belonging to the chemical class of aromatic amines (structure–activity relationships), and there are extensive epidemiological, metabolic, and biochemical data in humans. This case-study illustrates the nature of data that are helpful in delineating MOAs for DNA-reactive carcinogens. Distinction between modulating factors and key events in an MOA analysis is also presented.

Based on the strong animal evidence and extensive epidemiological data, the International Agency for Research on Cancer (IARC) has classified 4-aminobiphenyl as a known human carcinogen (IARC, 1972, 1987). Although initially identified as a human urinary bladder carcinogen in individuals exposed to high levels occupationally, it has subsequently been demonstrated as a major component of cigarette smoke, leading to an increased risk of urinary bladder cancer in cigarette smokers (Del Santo et al., 1991; Curigliano et al., 1996). Additional research has shown that it is a ubiquitous environmental chemical occurring naturally when organic material containing nitrogen undergoes combustion.

<sup>&</sup>lt;sup>1</sup> This article, to which WHO owns copyright, was originally published in 2006 in *Critical Reviews in Toxicology*, Volume 36, pages 803–819. It has been edited for this WHO publication and includes corrigenda.

### **CARCINOGENICITY OF 4-AMINOBIPHENYL IN ANIMALS**

Experimental studies indicate that 4-aminobiphenyl is carcinogenic in mice, rats, rabbits, and dogs, although significant target tissue differences and susceptibility have been observed (IARC, 1972). By most routes of exposure, 4-aminobiphenyl is primarily a carcinogen of the liver and, to a lesser extent, the urinary bladder in mice, whereas in dogs (and humans), the urinary bladder appears to be the target organ. Many of the studies were conducted a number of years ago, and published accounts include only limited details. In addition, potential precursor lesions at interim periods were rarely documented, and none of the studies included protocols, such as stop/recovery, which might be informative in the context of MOA. Nonetheless, results indicate clear species and individual differences in response (e.g. Block et al., 1978), characteristic of MOAs entailing competing metabolic activation and deactivation processes (Table 1).

Species	Route/dose	Incidence	Comment	Reference
Mice	Gavage; 1 mg/week for 38 weeks	Bladder carcinomas in 2/12 mice surviving to 90 weeks		Clayson et al. (1965)
Mice	Gavage; 0 or 1.5 mg/week for 52 weeks	Bladder carcinomas in 1/21 exposed males vs 0/19 in controls; increased incidence of hepatomas in males and females		Clayson et al. (1967)
Mice	Subcutaneous injection of 200 µg for up to 52 weeks	Hepatomas in 19/20 males and 6/23 females after 48–52 weeks		Gorrod et al. (1968)
Mice	0–220 mg/l in	Significant increases in	Hyperplasia of the	Schieferstein

Rats	Subcutaneous injection in arachis oil of total dose of 3.6–5.8 g/kg bw	Mammary and intestinal tumours		Walpole et al. (1952)

#### Table 1. Carcinogenicity studies of 4-aminobiphenyl in various species.

Species	Route/dose	Incidence	Comment	Reference
Rabbits	Oral administra- tion of unspecified dose	Bladder papillomas in 1 animal and carcinomas in 3 animals	Earliest carcinoma observed 4 years after start of treat- ment	Bonser (1962)
Dogs (2)	Gelatin capsules 6 times weekly for life for a total dose of 30 or 34 g	Carcinoma of the bladders appeared in 33 months		Walpole et al. (1954)
Dogs	Gelatin capsules 0.3 g 3 times weekly (total dose: 94.5–144 g per dog)	Bladder carcinomas after 21–34 months		Deichmann et al. (1958)
Dogs (6)	1.0 mg/kg bw 5 times weekly for 34 or 37 months (total dose 5.5–7.0 g per dog)	3 bladder papillomas and 3 bladder carcinomas (transitional cell type)		Deichmann et al. (1965)
Dogs	Single dose	Ineffective in inducing bladder tumours over a 5-year period		Deichmann & MacDonald (1968)
Dogs (24 beagles)	Oral administra- tion 5 days/week for 3 years	Negative or minimal disease in 4 dogs, with no neoplasia in 2; neoplasia developed slowly in 11 dogs, while a rapidly progressive pattern was observed in the remaining 9 dogs		Block et al. (1978)

#### Table 1 (Contd)

bw, body weight

Following its oral administration by gavage (1 mg per mouse per week for 38 weeks), 2/12 mice surviving to 90 weeks developed bladder carcinoma (Clayson et al., 1965). In a separate but similar experiment, dosing mice with 1.5 mg of 4-aminobiphenyl for 52 weeks resulted in bladder carcinoma in 1/21 male mice as compared with 0/19 in controls. In this experiment, the frequency of hepatomas in both male and female mice was significantly higher than that in the controls (Clayson et al., 1967). Three subcutaneous injections of mice with 200 µg of 4-aminobiphenyl produced hepatomas in 19/20 males and 6/23 females after 48–52 weeks (Gorrod et al., 1968). Oral administration of 4-aminobiphenyl in drinking-water at concentrations of up to 220 and 300 mg/l to male and female BALB/cStCrlfC3Hf/Nctr mice, respectively, for up to 96 weeks induced dose-related, significant increases in angiosarcomas (males only). Hyperplasia of the bladder was observed in most of the mice of both sexes in groups of about 118 receiving concentrations of 75 mg/l (females) and 55 mg/l (males) or greater, whereas none was reported in the control groups of similar size (Schieferstein et al., 1985). In a number of experiments, newborn B6C3F1 mice were primarily susceptible to

liver carcinogenesis following 4-aminobiphenyl administration (Dooley et al., 1988, 1992; Von Tungeln et al., 1996; Parsons et al., 2005).

Daily subcutaneous injection of rats with 4-aminobiphenyl in arachis oil to a total dose of 3.6–5.8 g/kg body weight (bw) resulted in significant increases in the incidence of mammary gland and intestinal tumours (Walpole et al., 1952).

Among seven rabbits given commercial 4-aminobiphenyl orally (dose unstated), bladder papillomas were found in one and carcinomas in three animals. The earliest carcinoma was observed 4 years after the start of treatment (Bonser, 1962).

Two dogs fed 4-aminobiphenyl in gelatin capsules 6 times weekly for life (total dose per dog: 30, 34 g) developed carcinoma of the bladder in 33 months (Walpole et al., 1954). This was confirmed by similarly feeding capsules containing 4-aminobiphenyl (0.3 g per dog) 3 times weekly. Bladder carcinomas were observed after 21–34 months (total dose: 94.5–144.0 g per dog) (Deichmann et al., 1958). When the dose of 4-aminobiphenyl was reduced to 1.0 mg/kg bw and given to six dogs 5 times weekly for 34 months or 37 months (total dose: 5.5–7.0 g per dog), three bladder papillomas and three bladder carcinomas (transitional cell type) were observed (Deichmann et al., 1965). A single dose was not effective in inducing bladder tumours over a period of 5 years (Deichmann & MacDonald, 1968). Among 24 beagles that received 4-aminobiphenyl orally 5 days per week for 3 years, three basic patterns of bladder carcinogen responses were seen. Negative or minimal disease was seen in four dogs, of which two remained completely free of neoplasia. Neoplasia developed slowly in 11 dogs, while a rapidly progressive pattern was observed in the remaining 9 dogs (Block et al., 1978).

# IS THE WEIGHT OF EVIDENCE SUFFICIENT TO ESTABLISH A MODE OF ACTION (MOA) IN ANIMALS?

The first question of the IPCS HRF is an evaluation of the animal MOA itself. This is based on the process delineated by the MOA Framework developed by IPCS and published in 2001 (Sonich-Mullin et al., 2001), which evolved from the Bradford Hill criteria for causality in epidemiology studies (Hill, 1965).

#### A. Postulated mode of action

4-Aminobiphenyl is metabolized by hepatic enzymes to *N*-hydroxy-4-aminobiphenyl, which can be *N*-esterified (*N*-acetylated, *N*-glucuronidated, or *N*-sulfated) in hepatic and other tissues (Miller et al., 1961; Kadlubar et al., 1977, 1991; Miller & Miller, 1977; Delclos et al., 1987; Chou et al., 1995) (Figure 1). *O*-Esterification and ring hydroxylation are competing enzymatic reactions leading to detoxification. Tissue and species differences in the activity of these reactions dictate, at least in part, variations in susceptibility to the carcinogenic effects of 4-aminobiphenyl and differences in organ specificity in the development of tumours. Ultimately, a reactive electrophilic nitrenium ion is formed in the target tissue following *N*-esterification, and this is capable of forming DNA adducts. The principal DNA adduct is *N*-(deoxyguanosin-8-yl)-4-aminobiphenyl (Talaska et al., 1990; Kadlubar et al., 1991; Flammang et al., 1992; Hatcher & Swaminathan, 1995, 2002). As a consequence of the

mutations that can result from these reactions at critical sites of critical genes, neoplastic cells eventually develop.

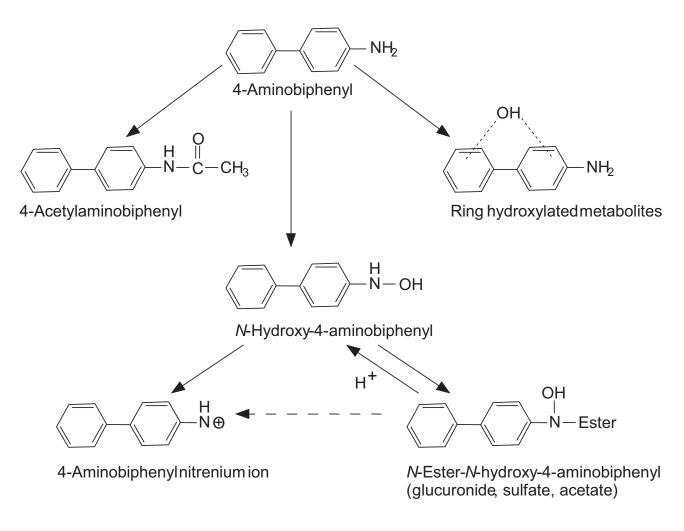

Figure 1. Metabolism of 4-aminobiphenyl

# **B. Key events**

The major route of hepatic activation of 4-aminobiphenyl begins with its *N*-hydroxylation, catalysed, the balance of evidence indicates, by CYP1A2, at least in rats and humans (Butler et al., 1989b). In mice, there is evidence that CYP1A2 is not the only, or even the primary, form of cytochrome P-450 involved (Kimura et al., 1999). The *N*-hydroxylamine can also be produced by reaction with a variety of oxidases and peroxidases, such as by the prostaglandin synthase component of cyclo-oxygenase (Kadlubar et al., 1982). Whether any of these non-cytochrome P-450 reactions occur in vivo and are of toxicological significance remains unclear. The *N*-hydroxylamine undergoes *N*-acetylation by *N*-acetyltransferase-1 (NAT1) (Flammang & Kadlubar, 1986; Oda, 2004), resulting in an *N*-acetoxy ester that is unstable in acidic conditions, forming an arylnitrenium ion that can react directly with DNA, forming a DNA adduct at the C-8 position of guanine (Hammons et al., 1985; Flammang & Kadlubar, 1986; Hatcher & Swaminathan, 2002). Additionally, the *N*-hydroxylamine generated in liver can serve as a substrate for uridine diphosphate (UDP) glucuronosyltransferase (UGT),

yielding an *N*-glucuronide conjugate that is transported to the urinary bladder (Kadlubar et al., 1977). The glucuronide can either be excreted in urine or, under acidic conditions, serve as an additional source of the *N*-hydroxylamine in the urinary bladder, following hydrolysis. There are a number of reactions that can compete with this reaction scheme, including *N*-acetylation of 4-aminobiphenyl by *N*-acetyltransferase-2 (NAT2), but the resulting arylacetamide is a poor substrate for CYP1A2, and it is considered to be primarily a detoxification reaction. As a consequence, *N*-acetylation of the parent amine is considered a deactivating process. Rates of acetylation can thus affect the balance between activation and deactivation. Humans phenotypically are either rapid or slow acetylators (Lower et al., 1979). Mouse strains exist that are analogous to human slow and rapid acetylators. Thus, C57BL/6 is a rapid acetylator strain, while A/J is a slow acetylator (Hein, 1988). Interest in these differences in response. As a consequence of the DNA adducts formed, mutations can be produced. The key events are summarized in Table 2.

#### Table 2. Key events in the carcinogenicity of 4-aminobiphenyl in animals.

- 1. Metabolic activation
  - a) N-Hydroxylation
  - b) N-Esterification (glucuronide, acetyl, sulfate)
  - c) Hydrolysis to nitrenium ion
- 2. DNA adduct formation (dG-C8, dA-C8, dG-N2) in pluripotential cell of target organ
- 3. DNA mutation in critical gene(s) leading to cancer
- 4. Cancer

dA, deoxyadenosine; dG, deoxyguanosine

# C. Dose-response relationship

In view of the fact that many of the relevant studies were conducted a number of years ago, data on concordance of dose-response for precursor lesions for tumours are restricted to hyperplasia in the mouse urinary bladder. Dogs do not develop bladder tumours after a single dose of 4-aminobiphenyl (Deichmann & MacDonald, 1968), and there do not appear to have been studies of dose-response relationships in this species following multiple exposures. In the only study in which information on the incidence of precursor lesions was reported, male BALB/c mice were treated with drinking-water containing 4-aminobiphenyl at concentrations of 0, 7, 14, 28, 55, 110, or 220 mg/l for up to 96 weeks (Schieferstein et al., 1985). These treatments were associated with bladder carcinoma incidences of 0/116, 1/117, 1/118, 0/118, 6/115, 5/118, and 23/118, respectively. The incidences in the 55 mg/l group and higher were statistically significantly higher than in controls. Female mice were exposed to drinkingwater concentrations of 4-aminobiphenyl of 0, 7, 19, 38, 75, 150, and 300 mg/l. The corresponding incidences of bladder carcinomas were 0/118, 0/118, 0/119, 1/118, 0/118, 5/117, and 1/117. Incidences of hyperplasia were much higher, although severity was not indicated. In males, the incidences of hyperplasia were 0/116, 4/117, 9/118, 71/118, 108/115, 107/118, and 102/118 for doses of 0, 7, 14, 28, 55, 110, and 220 mg/l, respectively, and for females, 0/118, 0/118, 3/119, 53/119, 106/118, 97/117, and 83/117 for doses of 0, 7, 19, 38, 75, 150, and 300 mg/l, respectively. Thus, the dose-response curves for tumours and hyperplasia were sigmoidal or hockey stick-shaped. In contrast, steady-state levels of urothelial C-8 guanine DNA adducts showed a linear dose–response (Poirier et al., 1995).

In this same study (Schieferstein et al., 1985), there was no increase in the incidence of liver tumours in the males, whereas in the females, the incidences of liver tumours (adenomas and carcinomas combined) were 0/117, 0/120, 2/120, 4/119, 11/119, 17/118, and 10/117 at doses of 0, 7, 19, 38, 75, 150, and 300 mg/l, respectively. The incidence of angiosarcomas of various tissues combined was also increased at the three highest doses in males and females, although the incidences were somewhat higher in females than in males.

### **D. Temporal relationship**

Establishing time sequences for events in a carcinogenic process is partially, but to an important extent, dependent upon the sensitivity of the available methods for their measurement. Thus, tumours must attain a size allowing their histological detection, while the measurement of mutations and DNA adducts requires not only time but sufficient tissue. Consequently, the latter are more usually studied in liver than in urinary bladder, where the paucity of tissue available in the urothelium, particularly in rodents, causes technical difficulties that have no connection with the frequency of the biochemical and biological events. The metabolism and formation of DNA adducts are early events, which can be observed within a few minutes or hours in vitro and within a day following in vivo treatment with 4aminobiphenyl (e.g. Kadlubar et al., 1991; Swaminathan & Reznikoff, 1992; al-Atrash et al., 1995; Hatcher & Swaminathan, 1995; Doerge et al., 1999; Tsuneoka et al., 2003). Many in vivo experiments, however, continue exposure for 3-4 weeks to allow an accumulation of adducts, achieve steady-state levels, and facilitate their detection (e.g. Talaska et al., 1990; Flammang et al., 1992; Poirier & Beland, 1992; Poirier et al., 1995; Underwood et al., 1997). Mutations can also be detected within a short time in vitro, but have generally not been detected in vivo in target tissues until after several weeks or months of exposure (e.g. H-ras in mouse liver; Parsons et al., 2002), although this comparatively long period may not be a true reflection of when mutations first arise. In one study, mutations were detected in a Muta<sup>TM</sup>Mouse urinary bladder assay 14 days after a single dose of 4-aminobiphenyl (Fletcher et al., 1998). Carcinomas and hyperplasia of the urinary bladder are apparently late-occurring lesions in mice and dogs; however, time course changes have not been systematically evaluated. Although mice were killed at intervals beginning at 13 weeks in one 2-year study, and hyperplastic lesions were induced in the urinary bladder, their incidences at different times were not presented (Schieferstein et al., 1985). Tumours in the urinary bladder are commonly not discovered until after about 2 years in mice (Schieferstein et al., 1985) and longer in dogs (Walpole et al., 1954; Deichmann et al., 1958, 1965). However, neoplastic transformation of human urothelial cells (infected with SV40) treated in vitro with 4aminobiphenyl followed by in vitro culture for 6 weeks was demonstrated upon their inoculation into nude mice (Bookland et al., 1992b).

# **E.** Strength, consistency, and specificity of association of the tumour response with key events

Evidence in support of the association of the tumour response with key events comes only in part from studies on bladder; considerable evidence is provided by studies on liver. DNA adduct formation has been demonstrated in both tissues.

There is an abundance of studies that demonstrate that 4-aminobiphenyl is a mutagen, including positive mutagenicity with certain frameshift mutation and base pair substitutionsensitive strains (TA1538, TA98, and TA100) of Salmonella typhimurium, but only in the presence of rodent liver S9 metabolic activating preparations. The requirement for S9 metabolic activation clearly demonstrates the lack of DNA reactivity and mutagenicity of the parent amine. In addition, 4-aminobiphenyl induces unscheduled DNA synthesis in rat liver cells in vitro (United States Environmental Protection Agency Genetic Activity Profiles). These in vitro studies provide evidence that 4-aminobiphenyl can cause genetic damage following metabolic activation. Bacterial mutation studies have also been conducted comparing metabolic activation systems based on liver homogenates from Aroclor 1254-induced male Sprague-Dawley rats and C57BL/6 mice, using S. typhimurium TA100 tester strains that expressed different levels of N- and O-acetyltransferase (OAT) activity (Dang & McQueen, 1999). TA100 has a single copy of the NAT/OAT gene; YG1029 has multiple copies of the NAT/OAT gene, and TA100/1,8DNP<sub>6</sub> is NAT/OAT-deficient. Effects with mouse and rat S9 were similar (but the effects of Aroclor 1254 treatment were not examined). Using either 4aminobiphenyl or 4-acetylaminobiphenyl as substrates, considerably more mutations were induced in YG1029 than in TA100 or TA100/1,8DNP<sub>6</sub>, in which mutation induction was similar. This supports a role for high acetylation activity in mutation induction by the Nhydroxylamine in these bacteria.

The non-enzymatic step to an arylnitrenium ion in the mechanism of mutagenesis in vivo is supported by the observation that *N*-hydroxy-4-aminobiphenyl mutagenesis in the high OAT-expressing *S. typhimurium* TG1024 strain is dependent on the pH of the medium, with an inverse relationship between mutant numbers and pH over the range 4.0–8.0 (Sarkar et al., 2002).

Administration of 4-aminobiphenyl in the drinking-water of BALB/c mice for 28 days resulted in higher levels of DNA adducts in liver than in urinary bladder of females, while the reverse occurred in males. Thus, in each sex, the DNA adduct level correlated with the susceptibility of the tissue to tumour induction by 4-aminobiphenyl (Poirier et al., 1995). However, the shape of the dose–response curve was linear for DNA adducts in both tissues (although it appears to saturate and is relatively flat in female mice), whereas the tumour dose–response curve was sigmoidal (Poirier et al., 1995).

Adduct levels were also highest in the urinary bladder of female Hsd:ICR(Br) mice that were dosed topically (the more usual exposure route in occupational settings) with 50 nmol 4-aminobiphenyl for 21 weeks. The principal adduct in all tissues examined (bladder, liver, lung, and skin) co-chromatographed with *N*-(deoxyguanosin-8-yl)-4-aminobiphenyl (Underwood et al., 1997).

One study of mutagenesis in male Muta<sup>TM</sup>Mouse transgenic mice (i.e. transgenic CD2F, [BALB/c × DBA/2]) treated orally with 4-aminobiphenyl at 10 mg/kg bw per day for 10 days reported that the mutation frequencies in urinary bladder, liver, and bone marrow were increased by 13.7-, 4.8-, and 2.4-fold, respectively (Fletcher et al., 1998).

Newborn B6C3F1 (C57BL/6 × C3H) mice responded to treatment with 4-aminobiphenyl by developing a high frequency of liver tumours, many of which carried H-*ras* codon 61 CAA  $\rightarrow$  AAA mutations (Parsons et al., 2005). In vivo, the level of one major DNA adduct [*N*-(deoxyguanosin-8-yl)-4-aminobiphenyl] was present at 5 adducts/10<sup>6</sup> nucleotides in newborn mice treated with 0.3 µmol 4-aminobiphenyl 24 h earlier. After 8 months, the CAA  $\rightarrow$  AAA mutation was detected in 67% of the treated mice and 50% of the vehicle (dimethyl sulfoxide, or DMSO) controls, but the average mutant fraction in treated mice was 45 × 10<sup>-5</sup> compared with only 2 × 10<sup>-5</sup> in controls. After 12 months, liver tumours had developed in 79% of the treated mice and in 8% of the controls. These tumours are not those of the human target organ, but the results of this study support the general MOA proposed for bladder carcinogenesis (i.e. DNA adduct formation, followed by mutation in a key gene and the subsequent emergence of tumours).

Dogs (sex not stated) killed 24 h after a single oral dose of 4-aminobiphenyl (5 mg/kg bw) had 5.4 fmol DNA adducts/µg liver DNA and 4.8 fmol DNA adducts/µg urinary bladder DNA, whereas no DNA adducts were detected in either the liver or bladder of a dog whose bladder had been instilled with 4-aminobiphenyl. In contrast, a dog bladder instilled with the reactive intermediate N-hydroxy-4-aminobiphenyl had 3.9 fmol DNA adducts/µg bladder DNA and no detectable adducts in liver DNA. Quantification was by an immunochemical method (Roberts et al., 1988). Examination of bitches treated with tritium-labelled 4aminobiphenyl (per os, intravenously, or intraurethrally), N-hydroxy-4-aminobiphenyl (intravenously or intraurethrally), or *N*-hydroxy-4-aminobiphenyl *N*-glucuronide (intravenously) demonstrated (1) the presence of 4-aminobiphenyl-haemoglobin adducts in blood erythrocytes; (2) that after per os dosing with 4-aminobiphenyl, the major portion of total Nhydroxy-4-aminobiphenyl entering the bladder lumen was free N-hydroxy-4-aminobiphenyl (0.7%), with lower concentrations of the acid-labile *N*-glucuronide (0.3%); (3) that urothelial DNA adducts following intraurethral instillation of N-hydroxy-4-aminobiphenyl were 60 times higher than after intraurethral instillation of 4-aminobiphenyl; and (4) that exposure to N-hydroxy-4-aminobiphenyl and subsequent 4-aminobiphenyl-DNA adduct formation are directly dependent on the frequency of urination and, to a lesser extent, on urinary pH (Kadlubar et al., 1991). The urinary pH of dogs may vary from about 4.5 to 7.5, depending upon the diet (Merck, 1998), time after eating, time of day, and amount of water consumed; these are factors that might influence the carcinogenic response (Cohen, 1995). Studies in vitro with microsomal preparations from dog liver and bladder have shown the presence of transacetylation activities in both organs, so that N-hydroxy-4-aminobiphenyl binding to RNA and DNA occurs in the presence of 4-acetylaminobiphenyl, N-hydroxy-4-acetylaminobiphenyl, or acetyl coenzyme A (CoA) as acetyl donors, although the levels of binding were less with bladder than with hepatic microsomes (Hatcher & Swaminathan, 1992).

Examination of urothelial cells exfoliated into urine of dogs treated with 4-aminobiphenyl showed that DNA adducts were identical to those from DNA modified in vitro with *N*-hydroxy-4-aminobiphenyl and from dog bladder urothelial DNA isolated from 4-aminobiphenyl-dosed dogs at autopsy. A dose-related increase in 4-aminobiphenyl–DNA adduct formation was demonstrated (Talaska et al., 1990).

#### F. Biological plausibility and coherence

The observations that 4-aminobiphenyl can form adducts with DNA and that it is mutagenic in organs in which tumours develop indicate, in general terms, that the proposed MOA is plausible (Fletcher et al., 1998). In addition, *N*-hydroxy-4-aminobiphenyl is able to cause neoplastic transformation of non-tumorigenic SV40-immortalized human urothelial cells (Bookland et al., 1992b). The findings with 4-aminobiphenyl are also consistent with the vast literature regarding the metabolic activation, DNA adduct formation, mutagenesis, and urinary bladder carcinogenesis in several species (including humans) of several related aromatic amine chemicals (Kadlubar et al., 1977; Miller & Miller, 1977; Delclos et al., 1987). The lack of DNA adduct formation and mutagenicity of the parent amine in various in vitro systems without metabolic activation clearly demonstrates the requirement for metabolic activation. The same DNA adducts are identified in tissues after administration of the amine or following exposure to the *N*-hydroxyl metabolite, with the structure of the adducts having been chemically confirmed. The mutagenic potential of the specific C-8 guanine DNA adduct has also been demonstrated, although the specific biophysical aspects have been better demonstrated for structurally related aromatic amines such as 2-aminofluorene (Kriek, 1992).

### **G. Other modes of action**

Alternatives of components of the already described MOA have been suggested. However, they do not detract from the overall described MOA but suggest either alternative specific aspects (such as other activating enzymes) or associative processes that could affect quantitative aspects. 4-Aminobiphenyl is oxidized by hepatic enzymes other than CYP1A2 (Kimura et al., 1999) to the *N*-hydroxylated metabolite that causes liver and urinary bladder toxicity and carcinogenesis, possibly including oxidases and peroxidases (Kadlubar et al., 1982, 1991). Although the specific enzymes involved in metabolic activation may vary, the ultimate sequence of generation of a reactive electrophile, DNA adduct formation, mutagenesis, and carcinogenesis is consistent. Furthermore, it is reasonable to believe that from this point in the MOA, the same sequence occurs as that involving CYP1A2-mediated activation, regardless of the activating enzyme.

In addition to bulky adducts, there is evidence to suggest that *N*-hydroxy-4-aminobiphenyl causes oxidative damage in urothelial DNA, possibly involving endogenous peroxidases (Burger et al., 2001). The relevance of this for the carcinogenic activity of 4-aminobiphenyl is unknown.

*N*-Hydroxy-4-aminobiphenyl and its further activated forms are cytotoxic to urothelial and other cells in vitro (Reznikoff et al., 1986), but the role that this plays in its carcinogenic effects is unclear (see below for discussion of a potentiating role in urothelial carcinogenesis, rather than causative role). It is likely that this process alters the dose–response relationship, but does not alter the fundamental MOA described above.

#### H. Assessment of the postulated mode of action

The early steps in the proposed MOA are well supported by the available evidence, and it has been judged that there is good and sufficient evidence that 4-aminobiphenyl is a urinary bladder carcinogen in dogs and mice, and in other tissues (primarily the liver) in rodents. Thus, it is metabolized to products that can form DNA adducts in the liver and in other target organs, and mutations have been demonstrated to arise. Although other organs can also be targets for 4-aminobiphenyl-induced neoplasia, the urinary bladder is the main target in dogs and in some strains of mice. Evidence for the intervening steps between general genotoxicity and the emergence of neoplasia is lacking. There is a notable lack of study of the effects of 4-aminobiphenyl on cell proliferation in the urinary bladder, but information on related aromatic amines and amides is available, particularly the analysis of the interaction between DNA reactivity (and mutagenesis) and cell proliferation induced by 2-acetylaminofluorene in mouse urinary bladder utilizing data from a megamouse, ED-01 study (Cairns, 1979; Gaylor, 1979; Littlefield et al., 1979). The reliance for mutagenicity on cell proliferation can provide an explanation for the sigmoidal shape of the tumour dose–response despite a linear dose–response for DNA adducts (Cohen & Ellwein, 1990). This link has significant implications for assessing potency and dose–response for 4-aminobiphenyl-induced urinary bladder cancer (see discussion below).

# I. Uncertainties, inconsistencies, and data gaps

Bacterial mutation studies of 4-aminobiphenyl with metabolic activation have shown that most mutations are frameshifts, whereas a single study of sequence analysis of 4-aminobiphenyl-induced mutations in the *lacZ* gene in single-stranded DNA from a bacterio-phage M13 cloning vector revealed exclusively base pair substitutions, with over 80% occurring at G sites:  $G \rightarrow T$  transversions predominated, followed by  $G \rightarrow C$  transversions and  $G \rightarrow A$  transitions. The major DNA adduct, *N*-(deoxyguanosin-8-yl)-4-aminobiphenyl, was then inserted within the M13 genome, and the mutational frequency and specificity were measured after in vivo replication. The targeted mutational efficiency was approximately 0.01%, and the primary mutation was  $G \rightarrow C$  transversion. Thus, the observations are consistent with in vivo observations, but the mutagenic activity was weak (Verghis et al., 1997).

Most in vivo investigations have been in mice. Dogs, for understandable reasons, have received less attention, although this is the species that is more sensitive to bladder carcinogenesis. Mouse strain differences in response are evident: B6C3F1 and female BALB/cStCrlfC3Hf/Nctr are more susceptible to liver carcinogenesis, whereas male BALB/cStCrlfC3Hf/Nctr mice develop bladder tumours after exposure to 4-aminobiphenyl (Schieferstein et al., 1985; Dooley et al., 1988, 1992). Nevertheless, mouse strain effects have received relatively little attention in the available studies.

The enzyme considered as fundamental for the metabolism of 4-aminobiphenyl to a product that forms adducts with DNA in liver and bladder is CYP1A2 (Butler et al., 1989a, 1989b). However, comparison of responses in CYP1A2(+/+) wild-type mice with CYP1A2(-/-) knockout mice showed that, contrary to expectations, CYP1A2 expression was not associated with 4-aminobiphenyl-induced oxidative stress or with 4-aminobiphenyl–DNA adduct formation. Furthermore, prior treatment with 2,3,7,8-tetrachlorodibenzo-*p*-dioxin (TCDD), which increased hepatic CYP1A2 protein expression 5-fold along with expression of other phase I and phase II enzymes, either did not change or actually decreased the level of adducts in liver. The specific quantitative effects of such induction will depend on the balance of the enzymes induced. These results suggest either that CYP1A2 is not the major metabolic activator of 4-aminobiphenyl or that other enzymes in mice activate the compound in the absence of CYP1A2 (Tsuneoka et al., 2003). Based on studies with other aromatic amines,

additional activating enzymes might include other P-450 enzymes, oxidases, or peroxidases (Lakshmi et al., 1990; Smith et al., 1991; Hughes et al., 1992).

Another reaction considered to be important for carcinogenesis induced by 4-aminobiphenyl is acetylation. Acetylation plays several roles in 4-aminobiphenyl carcinogenesis. *O*-Acetylation and *N*,*O*-acetyltransfer of *N*-hydroxy-4-aminobiphenyl are expected to increase risk in humans, whereas *N*-acetylation of 4-aminobiphenyl should reduce risk (Lower et al., 1979). Acetylation can be catalysed by NAT1 or NAT2, with the latter exhibiting a marked polymorphism within the population (Hein et al., 2000; Cascorbi et al., 2001). It is predicted that a slow acetylation phenotype will increase the risk of bladder cancer, since acetylation of the parent amine, 4-aminobiphenyl, is considered to be a detoxification process in humans, whereas a rapid acetylation phenotype should be associated with a decreased risk.

However, studies of acetylator phenotype in mice have produced conflicting results. In one study, male and female homozygous rapid acetylator or homozygous slow acetylator mice that were apparently identical in every other respect were administered 4-aminobiphenyl·HCl (55-300 mg/l) in drinking-water for 28 days. The levels of hepatic DNA adducts increased with dose in both sexes, with the levels being higher in females, but were independent of the mouse acetylator phenotype. In the urinary bladder, DNA adducts increased to a plateau at 100 mg/kg in male mice and were again independent of acetylator phenotype. In female mice, the DNA adduct levels were lower than in males and decreased at the highest dose; the DNA adduct levels were higher in the rapid acetylator phenotype, contrary to expectations (Flammang et al., 1992). These results were interpreted as suggesting that acetyltransferase activities are not rate determining for DNA adduct formation in mice. A similar conclusion that there was no correlation between murine NAT2 alleles and 4-aminobiphenyl-DNA adduct levels was reached by McQueen et al. (2003), using C57BL/6, B6.A, and A/J mouse strains and the transgenic strains hNAT1:A/J and hNAT1:C57, which carry the human NAT1 transgene. However, the differences in murine NAT2 activity were modest and probably not sufficient to affect 4-aminobiphenyl genotoxicity. Recent studies suggest that in humans, NAT1, not NAT2, is responsible for the O-acetylation of N-hydroxy-4-aminobiphenyl (Oda, 2004).

There are also mouse strain-specific mutations that require explanation. Thus, in B6C3F1, 4aminobiphenyl induces predominantly  $C \rightarrow A$  mutations (reflecting  $G \rightarrow T$  transversions in the non-coding strand) in H-*ras* codon 61, whereas in CD-1 mice, the predominant mutation in H-*ras* codon 61 was  $A \rightarrow T$  transversion (Manjanatha et al., 1996).

Cell proliferation is also required for neoplasia, but there have been few studies that have investigated cell proliferation at an early stage of the carcinogenic process of 4-aminobiphenyl. It is also notable that in the carcinogenicity experiment described previously (Schieferstein et al., 1985), although urinary bladder carcinomas developed only in males, a high prevalence of hyperplasia was reported in both males and females. Apparently this observation has not been investigated further (discussed below).

In summary, the evidence is strong for the sequence of key events including metabolic activation, DNA adduct formation, and gene mutation as the MOA for 4-aminobiphenyl-induced urinary bladder carcinogenesis. It is further strengthened by data from studies with structurally related aromatic amines. However, data gaps remain concerning details of the specific enzymes involved, the basis for differing organ specificity between species and details regarding potency, and the shape of the dose–response curve in humans. This is, perhaps, not unexpected in view of the complexity of the relevant competing metabolic pathways. While available data are considered sufficient to support the hypothesized MOA, the impact of these uncertainties needs to be considered quantitatively in the overall assessment (Table 3).

#### Table 3. Modulating factors affecting 4-aminobiphenyl urinary bladder carcinogenesis.

- 1. Competing activities of esterification enzymes
- 2. Genetic polymorphisms affecting enzymatic activation or inactivation (e.g. slow and fast acetylators)
- 3. Urinary pH (mainly affected by diet) and possibly other urinary constituents
- 4. Urothelial cell proliferation (induced by high doses of 4-aminobiphenyl or by co-administration with some other agent affecting urothelial proliferation)

# CAN HUMAN RELEVANCE OF THE MOA BE REASONABLY EXCLUDED ON THE BASIS OF FUNDAMENTAL, QUALITATIVE DIFFERENCES IN KEY EVENTS BETWEEN EXPERIMENTAL ANIMALS AND HUMANS?

There is considerable evidence in humans and human cell systems supporting each of the key events for 4-aminobiphenyl-induced urinary bladder cancer. Metabolic activation to the *N*-hydroxylamine has been demonstrated, with several different enzymes being suggested for activation and several others that might potentiate or reduce the effects of *N*-hydroxylation, such as *N*-acetylation. Genetic polymorphisms significantly affect activities of these enzymes, producing variations in the population that can affect susceptibility to the urinary bladder carcinogenesis response to 4-aminobiphenyl exposures. DNA adducts identical to those detected in DNA from mice and dogs have been identified in human urothelial cells, and consequently they have a similar mutagenic potential. Furthermore, extensive epidemiological evidence demonstrates the urinary bladder carcinogeneity of 4-aminobiphenyl in humans.

Bladder cancer is associated with smoking and occupational exposures to 4-aminobiphenyl. 4-Aminobiphenyl was manufactured in the United States of America from 1935 to 1955 (Melick et al., 1955) and was used as a highly efficient rubber antioxidant, but it is apparently no longer commercially produced. In epidemiological studies, which were confined to one series of workers occupationally exposed to commercial 4-aminobiphenyl, a high incidence of bladder carcinomas was reported (Melick et al., 1955, 1971; Melamed et al., 1960; Koss et al., 1965, 1969). Among 503 workers, 59 cases with positive cytology were identified, among which 35 cases of carcinoma of the urinary bladder were histologically verified; 7 remained cytologically positive at the time of publication, while 7 died from other causes and 10 were lost to follow-up (Koss et al., 1969). In addition to cigarette smoke, there also appear to be other, ill-defined environmental sources of exposure, possibly from other sources of combustion of substances containing carbon and nitrogen (Skipper et al., 2003). Cigarette smoking accounts for between 40% and 70% of the bladder cancer cases in the United States and Europe (IARC, 1986; Castelao et al., 2001). Black (air-cured) tobacco is a greater source of 4-aminobiphenyl than is blonde (flue-cured) tobacco (Bryant et al., 1988).

The key events demonstrated for 4-aminobiphenyl bladder carcinogenesis in mice and dogs have also been specifically evaluated for 4-aminobiphenyl in humans, primarily in individuals exposed to 4-aminobiphenyl in cigarette smoke, but also utilizing in vitro methods with human urothelial cells (see Table 4).

Table 4. Concordance evaluation of key events of 4-aminobiphenyl-induced urinary
bladder carcinogenesis between species.

Key event	Mouse	Dog	Human
1. Metabolic activation to reactive electrophile	+	+	+
2. DNA adduct formation	+	+	+
3. Mutagenesis	+	+	+
4. Carcinoma	+	+	+

Absorbed 4-aminobiphenyl is *N*-oxidized in the liver by CYP1A2, which, in spite of its rather high homology with CYP1A1, has an essentially different substrate specificity and is found only in liver (Lang & Pelkonen, 1999). Other enzymes have been suggested to be capable of supporting metabolic activation to the *N*-hydroxylamine.

NAT1 and NAT2 each catalyse three types of acetylation: the N-acetylation of arylamines, the O-acetylation of N-hydroxylamines, and the N,O-acetyltransfer of arylhydroxamic acids (Flammang & Kadlubar, 1986; Mattano et al., 1989; Fretland et al., 1997; Hein et al., 2000). It is believed that N-acetylation by N-acetyltransferases has a protective effect regarding bladder carcinogenicity, primarily because the acetamide of 4-aminobiphenyl formed is significantly less potent as a substrate for N-hydroxylation compared with the amine. Two genes, NAT1 and NAT2, code for the NAT isoforms, and allelic variation has been associated with susceptibility to urinary bladder cancer in humans (Hein et al., 2000). Most studies suggest that NAT2 slow acetylators are at increased risk of developing bladder cancer, whereas the contribution of the NAT1 genotype to aromatic amine bladder carcinogenesis is less clear (Cartwright et al., 1982; Hein et al., 2000). Among smokers, there is a higher level of 4-aminobiphenyl-haemoglobin adducts associated with the slow acetylator phenotype (Vineis et al., 1990). Interactions of NAT1 and NAT2 have been suggested (Cascorbi et al., 2001). In a study of 425 German bladder cancer patients, Cascorbi et al. (2001) found that there is (1) a partial linkage of the NAT1\*10 genotype to the NAT2\*4 genotype, (2) a clear underrepresentation of NAT1\*10 genotypes among rapid NAT2 genotypes in the cases studied, and (3) a gene-gene-environment interaction in that NAT2\*slow/NAT1\*4 genotype combinations with a history of occupational exposure were 5.96 (2.96-12.0) times more frequent in cancer cases than in controls without a risk from occupation (P < 0.0001). Hence, the data suggest that individuals with NAT2\*4 and NAT1\*10 are at a significantly lower risk for bladder cancer, particularly when exposed to environmental risk factors.

Polymorphisms in *CYP1A2* (Oscarson et al., n.d.) and *NAT2* (Hein et al., 2000) genes are associated with variations in the activities of these enzymes in human populations, although the extent to which variation in CYP1A2 activity is due to genetic factors has yet to be determined (Sachse et al., 2003). Moreover, expression of the *CYP1A2* gene is induced in cigarette smokers, leading to even higher CYP1A2 enzyme activities (Sesardic et al., 1988; Eaton et al., 1995). An individual exposed to 4-aminobiphenyl and expressing high levels of CYP1A2 and slow NAT2 activity would be expected to have increased levels of *N*-hydroxy-4-aminobiphenyl and, therefore, higher levels of 4-aminobiphenyl–haemoglobin adducts and 4-aminobiphenyl–DNA adducts in liver and urinary bladder than an individual expressing low levels of CYP1A2 and rapid NAT2 activity.

The tumour suppressor genes *RB1* and *TP53* appear to be involved in bladder cancer, especially high-grade urothelial carcinomas rather than low-grade papillary tumours. Both genes are involved in the regulation of the cell cycle. In addition, TP53 plays a role in response to DNA damage, cell death, and neovascularization (Hickman et al., 2002), and its gene product regulates the expression of multiple genes (Vousden & Lu, 2002). A strong association has been found between RB1 inactivation and muscle invasion (Cairns et al., 1991; Ishikawa et al., 1991; Presti et al., 1991; Primdahl et al., 2000). In one study of 45 bladder cancers, seven of nine TP53 mutations occurred in grade 3 tumours (i.e. invasion includes perivesicular tissue) (Martone et al., 1998). Inactivation of RB1 occurs in 30-80% of muscle-invasive bladder cancers (Cairns et al., 1991; Logothetis et al., 1992; Wright et al., 1995; Ioachim et al., 2000), most frequently as a consequence of heterozygous 13q deletions in combination with mutation of the remaining allele (Cordon-Cardo & Reuter, 1997). In studies investigating at least 30 tumours, TP53 mutations occurred in 40-60% of invasive bladder cancers (Tiguert et al., 2001; Lu et al., 2002). Although no specific mutational hotspots were identified, more than 90% of the mutations occurred in exons 4-9. In a study of the binding spectrum of N-hydroxy-4-aminobiphenyl in DNA fragments containing exons 5, 7, and 8 of TP53, preferential binding was identified at codon 285, a non-CpG site, and at codons 175 and 248, which are CpG sites, but only after C5 cytosine methylation had occurred (Feng et al., 2002). The authors concluded that the mutational spectrum in TP53 in bladder cancer strongly suggests a role of 4-aminobiphenyl in the etiology of this neoplasm.

Exposure to tobacco smoke, an environmental source of 4-aminobiphenyl, is associated with increased levels of 4-aminobiphenyl-haemoglobin adducts, in both adults and fetuses. In a study of smoking (n = 14) and non-smoking (n = 38) women, 4-aminobiphenyl-haemoglobin levels were  $183 \pm 108$  pg/g haemoglobin in smokers and  $22 \pm 8$  pg/g haemoglobin in non-smokers, whereas the levels in their respective fetuses were  $92 \pm 54$  pg/g haemoglobin and 17  $\pm 13$  pg/g haemoglobin (Coghlin et al., 1991), a difference that has also been observed in adults in studies of tumour tissue DNA (Curigliano et al., 1996). Haemoglobin adduct levels (used as a surrogate for exposure levels and indicator for DNA adduct potential) have been associated with levels of exposure to tobacco as a source of 4-aminobiphenyl (black tobacco > blonde tobacco > non-smokers) in a male study population from Turin, Italy; the risk of bladder cancer followed the same pattern (Bryant et al., 1988). There is a substantial gap in information linking the presence of adducts, primarily an indication of exposure, and the emergence of cancer.

In humans, 4-aminobiphenyl has been associated only with urinary bladder cancer, whereas in mice, liver and urinary bladder tumours are induced. Although the specific reasons for these species differences in organ specificity are not known, they appear to be due to variations in competing N-esterification enzymatic activations. Sulfation appears to be primarily associated with liver carcinogenesis by aromatic amines, whereas N-glucuronidation appears to be more associated with bladder carcinogenesis. Acetylation has mixed effects, but in humans appears to be principally a detoxification process that can be influenced significantly by N-acetyltransferase polymorphisms that result in fast versus slow acetylation. Human tissues have been studied for their possible involvement in the metabolism of 4aminobiphenyl and its metabolites. CYP1A2 is responsible for the metabolism of 4-aminobiphenyl to N-hydroxy-4-aminobiphenyl by human hepatic microsomal fraction (Butler et al., 1989b). N-Hydroxy-4-aminobiphenyl can be metabolized to a product that binds covalently to calf thymus DNA by cytosolic sulfotransferases from human liver and, to a lesser extent, colon, but not from pancreas or urinary bladder. In view of this lack of sulfotransferase activity in bladder, it has been suggested that hepatic sulfotransferase may actually decrease the bioavailability of N-hydroxy-4-aminobiphenyl in extrahepatic tissues and serve as a detoxification mechanism for the urinary bladder (Chou et al., 1995). On the other hand, Nacetyltransferases that are present in human urothelial cells (Frederickson et al., 1992; Swaminathan & Reznikoff, 1992) can metabolize N-hydroxy-4-aminobiphenyl, as well as the acetylated compounds N-hydroxy-4-acetylaminobiphenyl and N-acetoxy-4-acetylaminobiphenyl, to a DNA-reactive material. The major adduct co-chromatographs with N-(deoxyguanosin-8-yl)-4-aminobiphenyl. <sup>32</sup>P-postlabelling analysis of the DNA from cytosolmediated binding of N-hydroxy-4-aminobiphenyl revealed four radioactive spots. Five adducts were found when intact human urothelial cells were used, two of which were the same as two found using cytosol. This suggests the possibility of an activation pathway or pathways in addition to acetylation.

Experiments similar to those performed with dog tissues have shown that human urothelial cell microsomes possess transacetylation activity, so that *N*-hydroxy-4-aminobiphenyl binding to RNA and DNA occurs in the presence of 4-acetylaminobiphenyl, *N*-hydroxy-4-acetylaminobiphenyl, or acetylCoA as acetyl donors (Hatcher et al., 1993). These authors also found that <sup>32</sup>P-postlabelling of DNA adducts formed after reaction with *N*-hydroxy-4-aminobiphenyl, *N*-hydroxy-4-acetylaminobiphenyl, and *N*-acetoxy-4-aminobiphenyl showed similar profiles, suggesting that the arylnitrenium ion, arising from *N*-acetoxy-4-aminobiphenyl, might be the common reactive species. The structures of the adducts have been identified as the 3',5'-bisphospho derivatives of *N*-(deoxyguanosin-8-yl)-4-aminobiphenyl) (dG-C8-aminobiphenyl), *N*-(deoxyadenosin-8-yl)-4-aminobiphenyl (dA-C8-aminobiphenyl) (Frederickson et al., 1992; Hatcher & Swaminathan, 1995), and *N*-(deoxyguanosin-*N*(2)-yl)-4-azobiphenyl (Hatcher & Swaminathan, 2002).

The results available comparing tobacco smokers with non-smokers support the relevance to humans of the hypothesized MOA. In a study of 46 T1 bladder cancer cases, mean relative staining intensity for 4-aminobiphenyl–DNA adducts was significantly higher in current smokers ( $275 \pm 81$ , n = 24) than in non-smokers ( $113 \pm 71$ , n = 22) (Curigliano et al., 1996). Similar results have been reported for laryngeal tissue (Flamini et al., 1998) and for mammary tissue (Faraglia et al., 2003). Using 4-aminobiphenyl–haemoglobin adducts as an

indicator of exposure, it was found that bladder carcinoma patients had higher levels than controls (Del Santo et al., 1991), whereas lung cancer patients did not (Weston et al., 1991). The basis for this difference is unknown.

In addition to the evidence of genotoxicity generated with non-human test systems, 4-aminobiphenyl can be metabolized by human urothelial cell microsomal preparations to a mutagen in *S. typhimurium* YG1024 (a derivative of TA98 with elevated *O*-acetyltransferase activity) but not in strain TA98 itself (Hatcher et al., 1993). No other species or other human tissues were examined in this study.

6-Thioguanine-resistant mutants can be induced in a non-tumorigenic, SV40-immortalized human urothelial cell line by exposure to 4-aminobiphenyl itself or exposure to N-hydroxy-4aminobiphenyl, N-hydroxy-4-acetylaminobiphenyl, or N-acetoxy-4-acetylaminobiphenyl (Bookland et al., 1992a). No exogenous metabolic activation system was required for the observed activity. The lowest effective concentrations to produce a statistically significant increase in the mutant fraction were as follows: *N*-acetoxy-4-acetylaminobiphenyl, 2 µmol/l; *N*-hydroxy-4-acetylaminobiphenyl, 5 µmol/l; *N*-hydroxy-4-aminobiphenyl, 20 µmol/l; and 4aminobiphenyl, 100 µmol/l. Three of these substances were also tested for tumorigenic transformation using the same human immortalized urothelial cells in an in vitro-in vivo assay in which the end-point was carcinoma development when treated cells were injected subcutaneously into nude mice (Bookland et al., 1992b). Transformation was demonstrated after all treatments, the lowest concentrations being as follows: N-hydroxy-4-acetylaminobiphenyl, 0.5 µmol/l; N-hydroxy-4-aminobiphenyl, 0.5 µmol/l; and 4-aminobiphenyl, 20 µmol/l. The lower concentrations required for transformation in comparison with those for mutation are noted, but how this should be interpreted is not clear. It is consistent with the transformation being independent of mutation and with the transformation assay having a higher sensitivity, or it could merely reflect a difference in sensitivity of the methods.

In summary, on a qualitative basis, the key events in the MOA are the same in mice, dogs, and humans: metabolic activation to the *N*-hydroxylamine with subsequent formation of a reactive electrophile (presumably the nitrenium ion), formation of guanine adducts, gene mutation, and the ultimate formation of cancer. The intervening events between gene mutation and cancer, such as which genes are mutated and how cancer is induced, are not known. The MOA, nevertheless, has been clearly demonstrated and is the same in the animal models and in humans.

### CAN HUMAN RELEVANCE OF THE MOA BE REASONABLY EXCLUDED ON THE BASIS OF QUANTITATIVE DIFFERENCES IN EITHER KINETIC OR DYNAMIC FACTORS BETWEEN EXPERIMENTAL ANIMALS AND HUMANS?

As described in detail above, the metabolic activation, DNA adducts, and mutagenicity of 4aminobiphenyl are qualitatively the same in mice, dogs, and humans, leading to the induction of urothelial tumours of the urinary bladder in these three species and other tumours in mice, rats, and rabbits. Although detailed aspects of absorption, distribution, and excretion have not been reported, similarity in the levels of DNA adduct formation in the urothelium occurring in mice, dogs, and humans suggests that kinetic differences are not significant between these three species. Although similar enzymatic processes occur in the three species, quantitative differences are evident. These differences may explain some of the variations seen in target organ specificity among the species and might suggest possible quantitative differences in generation of the DNA adducts. Nevertheless, these differences do not negate the overall MOA for any of the species or the different target organs and are consistent with the complexity of the competing pathways for metabolic activation and deactivation.

Presumably there is a potential for repair of the different adducts, and quantitative differences might exist among species and even among tissues. However, the detection of relatively high numbers of adducts in all three species indicates that significant numbers of stable adducts are produced.

The target tissue common among mice, dogs, and humans, the urinary bladder urothelium, is similar morphologically (Pauli et al., 1983). The urothelium has a characteristic asymmetric unit membrane at the luminal surface that provides a major part of the barrier function to urine. It is composed of urothelium-specific proteins, the uroplakins, the sequence of which is highly conserved among species (Wu et al., 1994). In addition, the urothelium is metabolically active in all three species.

Modulating urinary factors have also been identified that can quantitatively affect the ultimate formation of urothelial DNA adducts, such as pH and frequency of urination (Cohen, 1995; Sarkar et al., 2002). Although the range of pH varies among species, the pH in mice, dogs, and humans readily reaches acidic and alkaline levels as well as neutral. Again, although quantitative differences occur, these do not preclude the existence of this MOA in humans.

There is no evidence implicating another MOA besides DNA reactivity. However, significant quantitative differences exist between species with regard to apparent potency of 4aminobiphenyl with respect to urinary bladder carcinogenesis. It is clear, however, that metabolites of 4-aminobiphenyl interact with proteins (e.g. haemoglobin) as well as with DNA and that metabolites of 4-aminobiphenyl are cytotoxic (Schieferstein et al., 1985; Reznikoff et al., 1986; Kadlubar et al., 1991). Interaction with urothelial cellular proteins might be responsible for the cytotoxicity and regenerative proliferation seen in the mouse bladder at higher doses of 4-aminobiphenyl. The interaction of DNA reactivity and consequent mutagenicity and cell proliferation provide an explanation for the sigmoidal shape of the dose-response curve for tumours despite a linear dose-response for DNA adducts (Cohen & Ellwein, 1990). The high concentrations of 4-aminobiphenyl found in the urine of mice that can produce urothelial cytotoxicity are generally not attained in humans exposed to cigarette smoke. However, other (unknown) substances appear to produce urothelial hyperplasia in cigarette smokers (Auerbach & Garfinkel, 1989). This increased cell proliferation significantly potentiates the effects of 4-aminobiphenyl on the bladder, providing a significantly greater number of DNA-replicating cell targets on which to act in comparison with the small number present in the normal, slowly replicating urothelium. Thus, the apparent greater potency of 4-aminobiphenyl in humans compared with mice is unlikely, but represents the synergy of DNA reactivity and cell proliferation produced by a single substance, 4-aminobiphenyl, in mice, but by different substances in the complex mixture of cigarette smoke.

Occupational exposure to 4-aminobiphenyl presumably resulted in greater doses of 4-aminobiphenyl than did exposure to cigarette smoke, since the incidence of bladder cancer in such populations was considerably higher than in smokers. However, quantitative measurements of metabolite concentrations or DNA adduct levels in urothelial cells could not be determined at the time these occupational exposures occurred, and cigarette smoking history in those individuals was not assessed (Koss et al., 1965, 1969).

In summary, although quantitative differences among species exist, they do not exclude the same MOA in mice and dogs occurring in humans.

# CONCLUSION: STATEMENT OF CONFIDENCE, ANALYSIS, AND IMPLICATIONS

The early steps in the proposed MOA are well supported by the available evidence, indicating that the key events of metabolic activation, DNA adduct formation, and mutation are the same qualitatively in mice, dogs, and humans. There is strong and sufficient evidence that 4-aminobiphenyl is a human urinary bladder carcinogen. Evidence for the intervening steps between mutation and cancer development is lacking. The associations described for adduct levels and *TP53* mutations are not compelling because these particular genetic alterations appear late in tumour progression and are often the result of endogenous causes (e.g. spontaneous depurination at methylated CpG sites). This aspect of *TP53* mutations in bladder cancer has been studied in a case–control study (Schroeder et al., 2003). In addition, most urothelial tumours in humans are low-grade papillary lesions, which generally do not have *TP53* mutations.

The mutational spectrum of N-hydroxy-4-acetylaminobiphenyl has been studied in embryonic fibroblasts of the Big Blue mouse (Besaratinia et al., 2002). Treatment of these cells for 24 h resulted in a dose-dependent increase in mutation frequency of the *cII* transgene of up to 12.8-fold over background. Single-base substitutions comprised 86% of the mutations in the treated cells and 74% of the mutations in the controls. Of these mutations, 63% and 36%, respectively, occurred at guanine residues along the *cII* gene. Whereas  $G \rightarrow T$  transversions accounted for 47% of the mutations in the treated *cII* gene, the most common mutations in untreated cells were insertions, which accounted for 19% of the mutations. Mapping of the induced adducts established five preferred DNA adduction sites, of which four were major mutation sites for N-hydroxy-4-acetoxyaminobiphenyl, especially  $G \rightarrow T$  transversions. In the TP53 gene in human bladder cancer, however,  $G \rightarrow A$  transitions predominate (53%) and are prevalent at all of its five mutational hotspots (codons 175, 248, 273, 280, and 285), three of which are at methylated CpG hotspots (175, 248, and 273). In cII, neither the preferred adduction sites nor the induced mutational hotspots are biased towards methylated CpG dinucleotides. It is concluded from this study that there is a serious discordance between the mutation pattern induced by N-hydroxy-4-acetoxyaminobiphenyl in the cII gene and the mutational pattern observed in TP53 in human bladder cancer. However, the role of methylation status and transcriptional activity on the mutation spectrum induced by 4aminobiphenyl has yet to be determined. It is also to be noted that the TP53 mutation spectrum is a reflection of a selection process during tumour development.

Based on the preceding analysis, it is clear that the MOA for 4-aminobiphenyl carcinogenesis is known in the animal model, and the MOA is relevant to humans both qualitatively and quantitatively. The conclusion based on this evaluation, even without epidemiological evidence, is that 4-aminobiphenyl poses a cancer hazard to humans.

To perform a full risk assessment requires additional information regarding the doseresponse and human exposures. Based on the information described above, it is clear that the data predict a cancer hazard for humans at expected exposures, at least for occupational (historical) and cigarette smoking exposures. Further analysis is required regarding the potential risk at ambient exposures in those who are not cigarette smokers. The MOA analysis provides the basis and foundation for such an assessment. The epidemiological evidence on 4-aminobiphenyl supports the conclusions suggested by the MOA HRF.

#### 4-AMINOBIPHENYL AND THE HUMAN RELEVANCE FRAMEWORK

4-Aminobiphenyl was evaluated using the proposed IPCS HRF based on an MOA analysis. The defined key events for this DNA reactivity MOA—metabolic activation, DNA adduct formation, mutagenicity, and cancer induction—clearly are the same in humans as in the animal (mice, dogs) models, indicating that 4-aminobiphenyl presents a cancer hazard for humans. The information for this MOA analysis provides a substantive foundation on which to build a complete cancer risk assessment for humans. For this chemical, there is also substantial epidemiological evidence to verify the conclusions derived from the HRF analysis.

The additional key events for this MOA—which genes are mutated and how do these genetic alterations lead to cancer—are not known for 4-aminobiphenyl. However, this does not detract from the conclusions, given the strength of evidence for the proposed MOA, based on the framework analysis presented here.

What data are necessary to conclude that a chemical produces cancer by a DNA-reactive MOA? Our suggestion is that at the very least there be a demonstration that DNA adducts are produced, preferably in the target tissue, and that the chemical is mutagenic (either with or without metabolic activation). Mutagenicity is used here in a more specific, restricted sense than the broader term genotoxicity. Demonstration of DNA adducts and mutagenicity in the target tissue after in vivo exposure increases confidence in the proposed MOA. Identification of the specific metabolic pathway and specific DNA adducts induced provides a significantly better basis for extrapolating between the animal model and humans.

This case demonstrates the potential utility of data on surrogate compounds in MOA analysis. However, the relevance of data on related compounds, whether in vivo or in vitro, needs to be adequately justified. Weight-of-evidence analysis of structure–activity relationships, which have been well developed for DNA reactivity and mutagenicity, should also contribute to framework analysis.

#### ACKNOWLEDGEMENTS

This paper has been reviewed in accordance with United States Environmental Protection Agency (USEPA) guidance but does not necessarily reflect USEPA policy. We thank Drs. Andrew Kligerman and Doug Wolf for their careful review of this paper.

#### FORMALDEHYDE AND GLUTARALDEHYDE AND NASAL CYTOTOXICITY: CASE-STUDY WITHIN THE CONTEXT OF THE IPCS FRAMEWORK FOR ANALYSING THE RELEVANCE OF A CANCER MODE OF ACTION FOR HUMANS<sup>1</sup>

Douglas McGregor, Hermann Bolt, Vincent Cogliano, & Hans-Bernhard Richter-Reichhelm

Formaldehyde and glutaraldehyde cause toxicity to the nasal epithelium of rats and mice upon inhalation. In addition, formaldehyde above certain concentrations induces dose-related increases in nasal tumours in rats and mice, but glutaraldehyde does not. Using the 2006 International Programme on Chemical Safety (IPCS) human framework for the analysis of cancer mode of action (MOA), an MOA for formaldehyde was formulated and its relevance tested against the properties of the non-carcinogenic glutaraldehyde. These compounds produce similar patterns of response in histopathology and in genotoxicity tests (although formaldehyde has been much more extensively studied). The MOA is based on the induction of sustained cytotoxicity and reparative cell proliferation induced by formaldehyde at concentrations that also induce nasal tumours upon long-term exposure. Data on dose dependency and temporal relationships of key events are consistent with this MOA. While a genotoxic MOA can never be ruled out for a compound that is clearly genotoxic, at least in vitro, the non-genotoxic properties fundamental to the proposed MOA can explain the neoplastic response in the nose and may be more informative than genotoxicity in risk assessment. It is not yet fully explained why glutaraldehyde remains non-carcinogenic upon inhalation, but its greater inherent toxicity may be a key factor. The dual aldehyde functions in glutaraldehyde are likely to produce damage resulting in fewer kinetic possibilities (particularly for proteins involved in differentiation control) and lower potential for repair (nucleic acids) than would be the case for formaldehyde. While there have been few studies of possible glutaraldehyde-associated cancer, the evidence that formaldehyde is a human carcinogen is strong for nasopharyngeal cancers, although less so for sinonasal cancers. This apparent discrepancy could be due in part to the classification of human nasal tumours with tumours of the sinuses, which would receive much less exposure to inhaled formaldehyde. Evaluation of the human relevance of the proposed MOA of formaldehyde in rodents is restricted by human data limitations, although the key events are plausible. It is clear that the human relevance of the formaldehyde MOA in rodents cannot be excluded on either kinetic or dynamic grounds.

#### INTRODUCTION

Formaldehyde and glutaraldehyde are aliphatic mono- and dialdehydes, respectively, that undergo reactions typical of aldehydes to form acetals, cyanohydrins, oximes, hydrazones, and bisulfite complexes. They are highly reactive chemicals and produce covalently crosslinked complexes with DNA and proteins. Their metabolism has some commonality in that they are both oxidized by aldehyde dehydrogenases. Several studies have demonstrated that inhalation exposure to formaldehyde causes nasal tumours in rats, whereas no nasal tumours were observed in the only 2-year inhalation study of rats exposed to glutaraldehyde.

<sup>&</sup>lt;sup>1</sup> This article, to which WHO owns copyright, was originally published in 2006 in *Critical Reviews in Toxicology*, Volume 36, pages 821–835. It has been edited for this WHO publication and includes corrigenda.

#### Formaldehyde

Formaldehyde has been tested for carcinogenicity by the inhalation route in mice, rats, and Syrian hamsters, by oral administration (drinking-water) in rats, by skin application in mice, and by subcutaneous injection in rats. There is conclusive evidence from the inhalation studies that formaldehyde is a carcinogen in rats.

There is considerable evidence that prolonged inhalation exposure to formaldehyde induces highly non-linear dose-related increases in the incidence of tumours of the anterior and posterior lateral meatus of rats (Morgan et al., 1986; Feron et al., 1988; Woutersen et al., 1989; Monticello et al., 1996; Kamata et al., 1997; CIIT, 1999). There are sharp increases in tumour incidence at formaldehyde concentrations equal to and greater than 7.2 mg/m<sup>3</sup>. Exposure to concentrations of 2.4 mg/m<sup>3</sup> and lower induced no malignant nasal tumours. Table 1 combines the data from two published rat studies (Kerns et al., 1983a; Monticello et al., 1996) conducted at the same laboratory and some additional information from one of these studies on a number of rats that had not been examined at the time of the publications (Schlosser et al., 2003). The majority of formaldehyde-induced neoplasms were squamous cell carcinomas.

Formaldehyde concentration (mg/m <sup>3</sup> )	Number of rats at risk <sup>a</sup>	Actual number of tumours <sup>b</sup>
0	122	0
0.84	27	0
2.4	126	0
7.2	113	3

18	182	157

Table 1. Combined incidence of nasal squamous cell carcinomas in rats exposed to
formaldehyde.

Note: Adapted from Schlosser et al. (2003).

<sup>a</sup> Rats at risk are those that survived to 2 years and were examined at that time plus those that died before 2 years in which tumours were found.

<sup>b</sup> Rats in which tumours were found at or before 2 years.

In contrast, inhalation studies in Syrian hamsters showed no carcinogenic effect at a single dose of 12.3 mg/m<sup>3</sup> (Dalbey, 1982), and one of two inhalation studies in mice showed no effect in females and squamous cell carcinomas in 2/17 males killed at 2 years at a high-dose concentration of 17.6 mg/m<sup>3</sup> (Kerns et al., 1983a, 1983b), whereas the other was inadequate for evaluation (Horton et al., 1963).

Studies on rats using other routes of exposure produced no significant results in two of four drinking-water studies (Takahashi et al., 1986; Tobe et al., 1989), forestomach papillomas in one study (Til et al., 1989), and leukaemia and gastrointestinal tract tumours in another (Soffritti et al., 1989), but the interpretation of the last study has been questioned (Feron et al., 1990). Mouse skin application and subcutaneous injection studies were not suitable for evaluation. In no study in rodents was there a significant increase in nasal tumours other than in the five inhalation exposure studies in rats—that is, at the entry portal.

#### Glutaraldehyde

Glutaraldehyde has been tested for carcinogenicity by the inhalation route in mice and rats and by oral administration (drinking-water) in rats. Inhalation studies showed no carcinogenic effect in either B6C3F1 mice exposed to a single concentration of 400  $\mu$ g/m<sup>3</sup> for 78 weeks (Zissu et al., 1998) or multiple concentrations up to 1000  $\mu$ g/m<sup>3</sup> for 2 years (NTP, 1999) or F344 rats exposed to concentrations of up to 3000  $\mu$ g/m<sup>3</sup> for 2 years (NTP, 1999). In a drinking-water study in which male and female F344 rats were exposed to glutaraldehyde concentrations of up to 4000 mg/m<sup>3</sup> for 2 years, increased incidences of large granular cell lymphatic leukaemia were found in the spleen of females at all exposure concentrations (Ballantyne, 1995; Van Miller et al., 1995).

## 1. IS THE WEIGHT OF EVIDENCE SUFFICIENT TO ESTABLISH A MODE OF ACTION (MOA) IN ANIMALS?

#### A. Postulated mode of action

Prolonged exposure to formaldehyde above a critical concentration induces sustained cytotoxicity and cell proliferation. As a result of genetic changes within this proliferating cell population, neoplasia emerges. The genetic changes are postulated to be secondary to the cytotoxicity, metaplasia, and hyperplasia that are clearly induced by formaldehyde. Formal-dehyde is a genotoxic substance in vitro and forms DNA–protein cross-links (DPX). DPX are a well established indicator of formaldehyde exposure, but it is not clear whether they are premutational lesions required to produce neoplasia (by initiating DNA replication errors, resulting in mutation). Apart from the abundance of DPX observations in rats, there is little evidence that formaldehyde is mutagenic to mammalian cells in vivo.

This postulated MOA is mainly based on observations of consistent, non-linear dose–response relationships for all three key events (sustained cell proliferation, DPX, and tumours) and concordance of incidence of these effects across regions of the nasal passages.

#### **B. Key events**

#### Formaldehyde

Limitation of damage to the entry portal following exposure to formaldehyde is clearly important, with metabolism playing a significant role in the process. The importance of the entry portal for formaldehyde-induced nasal tumours is supported by the observation that the principal non-neoplastic effect in rats exposed orally to formaldehyde solutions is the development of histological changes within the forestomach and glandular stomach (Til et al., 1989; Tobe et al., 1989).

Formaldehyde is an endogenous metabolic product of *N*-, *O*-, and *S*-demethylation reactions within cells (Hardman et al., 2001), and circulating concentrations of about 2.0–2.6  $\mu$ g/g blood are normal in unexposed mammals (Heck et al., 1982, 1985; Casanova et al., 1988). Exogenous formaldehyde is rapidly detoxified upon absorption. It has a half-life in plasma of about 1 min in rats exposed intravenously (Rietbrock, 1965), and it readily and spontaneously combines with reduced glutathione to form *S*-hydroxymethylglutathione, the substrate for alcohol dehydrogenase 3 (ADH3, also known as glutathione-dependent formaldehyde

dehydrogenase) (Uotila & Koivusalo, 1974; Koivusalo et al., 1989), to form S-formylglutathione, which is further metabolized to formic acid and reduced glutathione by S-formylglutathione hydrolase (Uotila & Koivusalo, 1997). The  $K_M$  for initial binding of hydroxymethylglutathione with ADH3 is about 0.004 mmol/l, and the concentration of free formaldehyde is likely to be even lower (Uotila & Koivusalo, 1997; Hedberg et al., 1998). It may be toxicologically significant that formaldehyde also combines with thiols such as cysteine and cysteinylglycine (Holmquist & Vallee, 1991). In addition to this efficient metabolic detoxification mechanism, the mucociliary apparatus provides protection of the underlying epithelium from gases and vapours. Thus, in order to attain free formaldehyde concentrations that may be cytotoxic to the target tissue, relatively high concentrations of formaldehyde vapour must be delivered to the target site to overcome these protective mechanisms. Mechanistic events of clear significance for carcinogenicity occur at dose levels where formaldehyde detoxification mechanisms are saturated in rats (Casanova & Heck, 1987).

The predominant non-neoplastic and preneoplastic events that have been measured and associated with nasal cancer formation following inhalation exposure of the nasal epithelium to formaldehyde include cytotoxicity, DPX formation, nasal epithelial cell regenerative proliferation, squamous metaplasia, and inflammation, which are site-specific, highly non-linear response processes in concordance with the incidence of nasal tumours.

The relative magnitude of an increase in cell proliferation is dependent upon the size of the target cell population within specific regions of the nasal cavity and not always directly related to the length of exposure, or total cumulative exposure (Swenberg et al., 1983, 1986; Monticello et al., 1991, 1996; Monticello & Morgan, 1994). These factors have been well defined and measured in a number of studies in rat, monkey, and human epithelial cells. In a 24-month carcinogenicity assay with interim sacrifices at 3, 6, 12, and 18 months, cell proliferation was demonstrated in rats exposed to 7.2, 12, and 18 mg/m<sup>3</sup> at all times (Monticello et al., 1991, 1996).

An immunohistochemical technique was used to assess the presence of p53 protein, a marker of cell proliferation (proliferating cell nuclear antigen, or PCNA), and tumour growth factor (TGF)- $\alpha$  in the histopathological sections of the same tumours. In addition to the p53-positive immunostaining in squamous cell carcinomas, especially in cells with keratinization, p53-positive immunostaining was observed in preneoplastic hyperkeratotic plaques, while normal nasal mucosa did not stain. A correlation was found between the distribution of immunostaining of PCNA and that of p53 (Wolf et al., 1995).

The formation of DPX in rats is a non-linear function of concentration (Casanova & Heck, 1987; Casanova et al., 1989, 1994; Heck & Casanova, 1995) and correlates with the site specificity of tumours (Casanova et al., 1994). Cross-links were not detected in the olfactory mucosa or in the bone marrow of rats (Casanova-Schmitz et al., 1984; Casanova & Heck, 1987). DPX have been found in rhesus monkeys following inhalation exposure to formal-dehyde, with the highest concentrations in the middle turbinates, followed by the anterior lateral wall septum and nasopharynx (Casanova et al., 1991).

Studies of rats, mice, Syrian hamsters, and rhesus monkeys exposed to formaldehyde for 13 (mice) or 26 weeks found that squamous metaplasia in the nasal turbinates developed in rats and rhesus monkeys at 3.7 mg/m<sup>3</sup>, but not in Syrian hamsters or, at 4.9 mg/m<sup>3</sup>, in mice (Rusch et al., 1983; Maronpot et al., 1986). Cell replication is also a feature of the more tumour-susceptible areas of the nasal epithelium of rats (Casanova et al., 1994).

#### Glutaraldehyde

Inhalation exposure to glutaraldehyde at 400  $\mu$ g/m<sup>3</sup> for 78 weeks resulted in non-neoplastic lesions in the nasal vestibule of female mice, consisting of hyperplasia of the squamous epithelium lining the dorsal wall and the lateral aspect of the atrioturbinate (Zissu et al., 1998).

In the United States National Toxicology Program (NTP) studies of glutaraldehyde, the nasal changes observed in male and female rats included the following:

- 1. In the squamous epithelium in the most rostral part of the nasal passage, behind the external nares, there were increased incidences of hyperplasia and inflammation. The hyperplasia was a minimal to marked change characterized by variable thickening of the epithelium due to an increase in the number of cell layers and, in the more severe cases, varying degrees of keratin accumulation.
- 2. In the respiratory epithelium, there was hyperplasia, minimal goblet cell hyperplasia (primarily along the nasal septum and ventral meatus), inflammation, and squamous metaplasia, with accumulation of keratin on the epithelial surface in the more severe cases.
- 3. In the olfactory epithelium of the dorsal meatus, there were slightly increased incidences of hyaline degeneration.

The glutaraldehyde-associated inflammation that was observed in the squamous epithelial and respiratory epithelial regions was a minimal to marked change consisting of multifocal to locally extensive infiltrates of neutrophils, lymphocytes, and plasma cells. Occasionally, there were a few macrophages within the lamina propria and, in severe cases, within the epithelium itself. In male and female mice of this same study, the lesions were qualitatively similar to those found in rats. Females were more severely affected than male mice.

Glutaraldehyde induced DPX in a TK6 human lymphoblast cell line (St. Clair et al., 1991). In vivo, glutaraldehyde induced cell proliferation (S-phase nuclei) in nasal cells in rats and mice exposed by inhalation (Gross et al., 1994) and nasal instillation (St. Clair et al., 1990). In a parallel nasal instillation study by the same authors, formaldehyde induced the same level of cell proliferation at 20-fold higher molar concentrations.

#### C. Dose-response relationship

#### Formaldehyde

Available data from rats exposed to formaldehyde show a highly non-linear dose–response pattern for the key events, with no observed effects at 2.4 mg/m<sup>3</sup>, a minimal response at 7.2 mg/m<sup>3</sup>, and a sharp increase at 12 and 18 mg/m<sup>3</sup>.

79

In rats exposed to formaldehyde, no increases in cell turnover or DNA synthesis were found in the nasal mucosa after subchronic or chronic exposure to concentrations of  $\leq 2.4 \text{ mg/m}^3$ (Rusch et al., 1983; Zwart et al., 1988; Monticello et al., 1991; Casanova et al., 1994). Small, site-specific increases in the rate of cell turnover were noted at 3.7 mg/m<sup>3</sup> (6 h/day, 5 days/week, for 13 weeks) in Wistar rats (Zwart et al., 1988) and in the rate of DNA synthesis at 7.2 mg/m<sup>3</sup> in Fischer 344 rats exposed for a similar period (Casanova et al., 1994). At these concentrations, however, an adaptive response would seem to occur in rat nasal epithelium, since cell turnover rates after 6 weeks (Monticello et al., 1991) or 13 weeks (Zwart et al., 1988) are lower than those after 1–4 days of exposure. The unit length labelling index (ULLI) method was used to establish the proliferation in male Fischer 344 rats exposed to formaldehyde concentrations of 0, 0.84, 2.4, 7.2, 12, or 18 mg/m<sup>3</sup> for 6 h/day, 5 days/week, for 3, 6, 12, 18, or 24 months. Significant increases in ULLI were present only in the 12 and 18 mg/m<sup>3</sup> groups, with the greater increases on the anterior lateral meatus and the medial maxilloturbinate. Elevated ULLI in the anterior dorsal septum developed later in the course of the exposure. This belated elevation of ULLI may have been secondary to changes in airflow patterns and thus local formaldehyde concentrations associated with growth of lesions and distortion of the airspace in those areas of the nose more susceptible to neoplasia (Monticello et al., 1996).

The non-linear relationships for formaldehyde-induced DPX formation, epithelial cell proliferation, and subsequently nasal tumours are demonstrated in Table 2. It is arguable that the designations of high- and low-tumour areas proposed by Casanova et al. (1994) are not the most appropriate, and consequently the truly high tumour incidence region DPX response may have been diluted by that of the intermediate tumour incidence (posterior lateral meatus) region.

Other studies showed that Fischer 344 rats exposed to 1.2 mg/m<sup>3</sup> (22 h/day, 7 days/week, for 26 weeks) developed no detectable nasal lesions, whereas at 3.6 mg/m<sup>3</sup>, the only histological change was squamous metaplasia in the nasal turbinates (Rusch et al., 1983). The development of mild squamous metaplasia was similarly demonstrated in the nasal turbinates of Fischer 344 rats exposed to 2.4 mg/m<sup>3</sup> (6 h/day, 5 days/week, for 24 months) (Kerns et al., 1983b). Epithelial dysplasia and rhinitis were also observed in these rats. The occurrence of squamous metaplasia appears to be the histological feature requiring the lowest formaldehyde concentration of any of the in vivo responses reported.

A rat, anatomically accurate computational fluid dynamics model was used to test whether the distribution of formaldehyde-induced squamous metaplasia was related to the location of high-flux regions posterior to the squamous epithelium. Squamous metaplasia was considered present when  $\geq$ 50% of a subsection was lined by squamous epithelium. No squamous metaplasia was present in sections of nose from rats exposed to 2.4 mg/m<sup>3</sup> or less. Squamous metaplasia was present on the lateral meatus after exposure to 7.2 mg/m<sup>3</sup> or more and on the lateral and medial walls of the airway after exposure to 12 or 18 mg/m<sup>3</sup> (Kimbell et al., 1997).

There is evidence that glutathione-mediated detoxification of formaldehyde within nasal tissues becomes saturated in rats at inhalation exposures above  $4.8 \text{ mg/m}^3$ . This saturation of

formaldehyde metabolism may contribute to the non-linearity of the dose–response relationships for DPX, cell proliferation, and tumour incidence at exposures above this level (Casanova & Heck, 1987).

Formalde- hyde	Cell proliferation ([ <sup>3</sup> H]thymidine-labelled . cells/mm basement membrane) <sup>a</sup>		DNA–protein cross-link formation (pmol [ <sup>14</sup> C]- formaldehyde bound/mg DNA) <sup>b</sup>		Incidence of nasal carcinoma <sup>c</sup>

### Table 2. Comparative effects of formaldehyde exposure upon cell proliferation, DNA– protein cross-linking, and tumour incidence.

<sup>a</sup> Cell proliferation measured in three locations of the nasal epithelium in male F344 rats exposed to the indicated concentrations of formaldehyde, 6 h/day, 5 days/week, for 3 months (Monticello et al., 1996).

<sup>b</sup> Extent of DNA-protein cross-link formation measured in two regions of the nasal cavity (respiratory mucosa) in male F344 rats exposed to the indicated concentrations of formaldehyde, 6 h/day, 5 days/week, for about 12 weeks; the complete lateral meatus was designated the "high-tumour region"; the "low-tumour region" comprised the medial aspects of naso- and maxilloturbinates, posterior lateral wall, posterior dorsal septum excluding olfactory region, and nasopharyngeal meatuses (Casanova et al., 1994). Data were derived from graphical representations in the reference cited.

<sup>c</sup> Incidence of nasal tumours within the entire nasal cavity or the anterior lateral meatus, posterior lateral meatus, or anterior mid-septum in male F344 rats exposed to the indicated concentrations of formaldehyde, 6 h/day, 5 days/week, for 24 months (Monticello et al., 1996).

#### Glutaraldehyde

A series of repeated-dose experiments with rats and mice exposed to glutaraldehyde has been summarized by NICNAS (1994). Among these, the lowest concentration producing lesions of the nasal cavity of rats was 1000  $\mu$ g/m<sup>3</sup> (6 h/day, 5 days/week, for 13 weeks) (NTP, 1993). The most severe lesions occurred in the anterior portions of the nasal passages and involved both the respiratory and olfactory epithelium. Hyperplasia and squamous metaplasia were most commonly noted on the lateral wall of the nasal cavity and on the tips of the nasoturbinates. Lesions were most extensive in rats exposed to 4000  $\mu$ g/m<sup>3</sup>, but were also noted in the 1000 and 2000  $\mu$ g/m<sup>3</sup> groups and in one male exposed to 500  $\mu$ g/m<sup>3</sup> delivered for 14 weeks (Bushy Run, 1983).

Mice appeared to be more sensitive to glutaraldehyde inhalation in a 13-week study, with inflammation of the nasal cavity being observed in female mice even at the lowest concentration of 250  $\mu$ g/m<sup>3</sup> and in male mice at 1000  $\mu$ g/m<sup>3</sup>. The species difference in

sensitivity is probably due to the smaller airways of mice being more prone to blockage by debris (NTP, 1993). Histopathological lesions in the respiratory tract were most severe in mice in the 4000  $\mu$ g/m<sup>3</sup> group and consisted of minimal to mild squamous metaplasia of the laryngeal epithelium, suppurative inflammation in the anterior parts of the nasal cavity, and minimal squamous metaplasia on the tips of the nasoturbinates. Necrosis and inflammation were noted at lower concentrations, primarily in the anterior portion of the nasal passage.

In the NTP (1993) 13-week studies with glutaraldehyde, there were significant, exposurerelated increases in ULLI in the squamous epithelium of the nasal vestibule and, to a lesser extent, the respiratory epithelium of the atrioturbinate of the dorsal meatus. The exposurerelated increase in cell replication was generally greater in rats than in mice. Upon examining the results in individual mice, it was found that there was an increased rate of cell replication in the squamous epithelium of the nasal vestibule only of those mice in which there was also neutrophilic infiltration of the mucosa; however, the severity of the infiltrate did not correlate with the degree of cell proliferation. These observations were clearest at 13 weeks, particularly in female mice. In rats, in addition to increased replication in the squamous epithelium of the dorsal atrioturbinate, whereas in mice, the response in this area was weak.

#### **D. Temporal association**

#### Formaldehyde

A number of short-, medium-, and long-term studies of the effect of formaldehyde exposure on cell proliferation within the respiratory epithelium of rats have indicated a sustained increase in proliferation of nasal epithelial cells following exposure to concentrations greater than 2.4 mg/m<sup>3</sup>, irrespective of the exposure period. Cell proliferation was observed in rats exposed to formaldehyde for periods from as short as 3 days. In the ULLI study already described, the magnitude of increased cell proliferation generally decreased over time but remained significantly increased by approximately 2- to 10-fold over controls, for certain nasal locations, up to and including the 18-month observation period when this effect was last examined (Monticello et al., 1996).

Data relating to temporal associations for DPX are limited, as most formaldehyde inhalation studies of DPX formation are of short duration (i.e. exposure duration up to 1 day). Formaldehyde-induced DPX in the nasal epithelium of rats and rhesus monkeys was shown consistently in these studies (Casanova et al., 1991). However, a well conducted study investigating both acute and cumulative DPX yields in rats exposed to formaldehyde for about 12 weeks (Casanova et al., 1994) found that the acute DPX yield in the lateral meatus (a high tumour yield site) of previously exposed rats was about half that in naive rats at concentrations greater than 7.2 mg/m<sup>3</sup>, while there were no differences in the medial and posterior meatuses (low tumour yield sites). No significant accumulation of DPX occurred in previously exposed rats.

Regenerative cell proliferation following formaldehyde-induced cytotoxicity increases the number of DNA replications and thus increases the probability of DPX-initiated DNA

replication errors, resulting in mutations. This hypothesis is supported by the observed inhibition of DNA replication in the rat nose at elevated concentrations (Heck & Casanova, 1995) and increased p53 expression in preneoplastic lesions (Wolf et al., 1995). In 5 of 11 squamous cell carcinomas from rats exposed to 18 mg/m<sup>3</sup> for up to 2 years, there were point mutations at the GC base pairs in the p53 complementary DNA (cDNA) sequence (Recio et al., 1992).

#### Glutaraldehyde

The study of cell replication in the 13-week rat and mouse inhalation studies with glutaraldehyde (NTP, 1993) showed that, in contrast to the results obtained for mice, the increased cell replication (ULLI) in the nasal vestibule of rats occurred early (within a few days) and either remained elevated or decreased slightly through the course of the study. Increases in ULLI in the nasal vestibule of mice tended to develop with time. In an inhalation study with mice (Zissu et al., 1994), the earliest lesions were observed in the respiratory epithelium of the septum and the naso- and maxilloturbinates after 4 days of exposure to 1.2 mg/m<sup>3</sup>. Severe histopathological changes were still observed 2 weeks after the end of the exposure to 4.0 mg/m<sup>3</sup>. No exposure-related histological abnormalities were detected in the trachea and lungs.

### **E.** Strength, consistency, and specificity of association of tumour response with key events

#### Formaldehyde

There are extensive studies investigating formaldehyde-induced neoplasia. Available data revealed formaldehyde-induced DPX formation and increased epithelial cell proliferation within the upper respiratory tract in a range of species including rats and monkeys and a variety of rat and human cells in vitro. It was found that at similar levels of exposure, concentrations of DPX were approximately an order of magnitude lower in rhesus monkeys than in rats. Increased human epithelial cell proliferation following in situ exposure to formaldehyde was reported in a model system in which rat tracheae populated with human tracheobronchial epithelial cells were xenotransplanted into athymic mice.

There is good correlation between key events and regional tumour incidence and tumour sites. Cell proliferation, metaplasia, and increased DPX were seen in the regions of the nasal cavity where tumours have been observed. The highly non-linear dose–response relationships for DPX, cytotoxicity, cell proliferation, metaplasia, and tumours are consistent, with significant increases in metaplasia occurring at 2.4 mg/m<sup>3</sup> in one study and all end-points being observed at concentrations of greater than 4.8 mg/m<sup>3</sup>. This is also in good correlation with the concentration at which mucociliary clearance is inhibited and glutathione-mediated metabolism is saturated—that is, 4.8 mg/m<sup>3</sup>. The study by Morgan et al. (1986) examining effects of inhaled formaldehyde on the nasal mucociliary apparatus in male rats also included 18-h recovery groups following days 1, 9, and 14 of exposure to concentrations of 2.4 mg/m<sup>3</sup>, 7.2 mg/m<sup>3</sup>, and 18 mg/m<sup>3</sup>. Inhibition of mucociliary clearance was progressively more extensive with increasing duration of exposure, but showed little or no evidence of recovery 18 h after cessation of exposure.

Mice appear to be less susceptible than rats to the development of nasal tumours following exposure to a given concentration of formaldehyde. However, it is well known that mice decrease their minute volume in response to inhalation of noxious chemicals (Brown et al., 1986, in CIIT, 1999).

#### Glutaraldehyde

In comparison with formaldehyde, the glutaraldehyde-induced lesions were located in a more anterior part of the nose, involving the squamous epithelium. Also, they were of a different character, with none of the focal hyperkeratosis and hyperplasia with cellular atypia and dysplasia found in animals receiving formaldehyde for 13 weeks (Monticello, 1990; Morgan & Monticello, 1990).

#### F. Biological plausibility and coherence

#### Formaldehyde

Evidence supporting the hypothesis that prolonged regenerative cell proliferation can be a causal mechanism in chemical carcinogenesis continues to accumulate (IPCS, 2002). This proposed MOA for formaldehyde-induced nasal tumours in animals exposed by inhalation is consistent with biological plausibility and the available data. Sustained increased cell proliferation has been observed in the nasal cavity in extensive short- and medium-term toxicity studies in rats and a few studies in other species. Histopathological effects in the nasal cavity (epithelial cell dysplasia and metaplasia) were consistent in a range of sub-chronic and chronic animal studies. It should be noted, however, that the respective roles of DPX, mutation, and cellular proliferation in the induction of nasal tumours in the rat have not been fully elucidated.

#### Glutaraldehyde

Effects of inhaled glutaraldehyde have not been as extensively studied as those of formaldehyde. In inhalation studies, glutaraldehyde did not induce nasal tumours in rats and mice. However, the same key events that are considered key events in the nasal carcinogenicity of formaldehyde—cytotoxicity and cell proliferation—have been demonstrated in rats and mice exposed to glutaraldehyde. This might appear to reduce the plausibility of these processes being important for formaldehyde.

#### G. Possible alternative modes of action

#### Formaldehyde

There is the possibility that mutagenicity could play a role in the development of formaldehyde-induced tumours. Evaluation of the available data indicates that formaldehyde is genotoxic in vitro, but is generally not genotoxic in standard in vivo assays, although there are many studies demonstrating that it produces DPX.

Formaldehyde has been extensively studied for genotoxicity in vitro, with positive results in studies with bacterial and mammalian cells (Ames test, gene mutation), and produced DNA single-strand breaks and DPX (reviewed in IARC, 2005). In vivo, formaldehyde has reproducibly induced mutations in *Drosophila*, but there is no convincing evidence of its genotoxic activity in rodent bone marrow cell tests. There is limited evidence that formaldehyde expo-

sure is associated with increased chromosomal aberration and micronucleus frequencies in human nasal and buccal cells and peripheral blood lymphocytes (reviewed in IARC, 2005; see Appendix).

It is unclear to what extent DPX contributes to the mutagenesis and carcinogenicity of formaldehyde (Recio, 1997; Merk & Speit, 1998; Speit et al., 2000; Liteplo & Meek, 2003). The presence of DPX has been considered mainly as an indicator of exposure, although some have also seen these lesions as premutagenic in character and therefore evidence of a direct genotoxic mechanism. DPX are, however, potentially damaging to the afflicted cell, and cell death is a likely outcome should they occur at high frequency. They also indicate that protein–protein cross-linkage (PPX) may occur, with potentially less serious effects for the cell. Should key proteins be involved in the PPX formation, this could have consequences on the regulatory machinery of the cell, including the regulation of differentiation. Such a change clearly occurs in the nasal epithelium of rats exposed to formaldehyde, since areas of metaplasia emerge. Neoplasia could be viewed as simply a different kind of metaplasia, unless there is compelling evidence for a genotoxic mode of action.

A different interpretation of the data has been offered by Gaylor et al. (2004), who analysed the concentration–response relationship for formaldehyde-induced cell proliferation in rats using statistical methods designed to identify J-shaped concentration curves. Cell proliferation data were used because there were insufficient quantal data on cancer incidence to perform the analysis. Their analysis supports the hypothesis that the threshold-type dose–response for nasal tumour incidence is the result of a minor genotoxicity at low dose that is superimposed by a J-shaped dose–response for cell proliferation at high cytotoxic dose levels (Lutz, 1998). At low doses, the effect of incremental DNA damage may be cancelled out by a reduction in cell proliferation; therefore, in spite of the apparent threshold, the data remain consistent with a genotoxic mechanism.

In rats exposed to formaldehyde, point mutations at GC base pairs in the cDNA sequence of the evolutionarily conserved regions II–V of the p53 gene were found in 5 of 11 primary nasal squamous cell carcinomas (Recio et al., 1992). This observation may be interpreted to indicate genotoxic processes induced by formaldehyde in the carcinogenic process; however, the presence of specific mutations in the emergent tumour is not evidence that they were present in the early stages of neoplasia or that they were directly induced by the chemical. While there is the possibility of a direct mutagenic event occurring, it is also possible that these mutations arose indirectly of exposure as a result of functional changes in chromatin proteins induced by the chemical. At what stage in the life history of the tumour these observed mutations occurred is also open to speculation: they are relatively common events, it is clear, but it is also clear that they are not essential events (since they do not occur in all tumours that are apparently of the same type). The occurrence of these mutations indicates that a genotoxic mechanism has not been excluded, but this evidence does not necessarily support one.

Specific changes in gene expression have also been observed in vivo. The results indicated that exposure to formaldehyde can cause alteration in the expression levels of genes involved in several functional categories, including xenobiotic metabolism, cell cycle regulation, DNA synthesis and repair, oncogenes, and apoptosis (Hester et al., 2003). It is not clear at present

how specific these changes are to formaldehyde or what their role is, if any, in carcinogenicity.

#### Glutaraldehyde

Glutaraldehyde has been less extensively tested than formaldehyde for genotoxicity in vitro and in vivo. It produces weak and inconsistent positive findings in tests in vitro and is not active in the vast majority of in vivo studies. The genetic toxicity of glutaraldehyde has been recently reviewed (Zeiger et al., 2005).

Glutaraldehyde induced DNA repair systems in bacterial cells and was a weak mutagen in *Salmonella* and *Escherichia coli*. Unscheduled DNA synthesis (UDS), DPX, and double-strand breaks were seen in human cell lines, but not in primary rat cells. There were weak and inconsistent responses in chromosomal aberration and sister chromatid exchange (SCE) studies with mammalian cells, and glutaraldehyde did not induce transformation in cultured Syrian hamster embryo (SHE) cells.

In vivo, glutaraldehyde induced S-phase DNA synthesis in nasal cells in rats and mice following direct nasal administration. Glutaraldehyde did not produce DNA damage in rat liver or cross-links in rat testes DNA or sperm cells. Tests for induction of chromosomal aberration in bone marrow cells in rats and mice were generally negative. Glutaraldehyde did not induce micronuclei in bone marrow cells or dominant lethal mutations in mice. Thus, glutaraldehyde does possess genotoxic potential, and, although the database is not as extensive as it is for formaldehyde, it might be anticipated that site of contact genotoxicity would occur. Consequently, if genotoxicity is a major carcinogenic MOA for formaldehyde, it remains to be explained why glutaraldehyde is not active.

#### H. Uncertainties, inconsistencies, and data gaps

#### Formaldehyde

In most of the cancer bioassays for formaldehyde, data on intermediate end-points such as proliferative response as a measure of cytotoxicity and DPX are limited. Consequently, direct comparison of the incidence of intermediate lesions and tumours is restricted. Additionally, information on a direct relationship between DPX and mutation induction and the probability of converting a DPX into a mutation is desirable, while the mode by which regenerative cell proliferation is involved in the production of mutations required for tumour development needs to be determined.

Studies on the *hprt* mutation spectrum in formaldehyde-exposed human cells revealed that 50% of the mutations are deletions, whereas 50% are due to point mutation at the A:T base pair (Crosby et al., 1988; Liber et al., 1989). The finding of deletions as part of the formaldehyde mutation spectrum may explain the homozygous nature of base pair mutations observed in p53 in formaldehyde-induced squamous cell carcinomas. However, there is an inconsistency with regard to the base pair that is mutated. It was found to be A:T in *hprt* in human and mammalian cell lines and G:C at p53 in formaldehyde-induced squamous cell carcinomas are induced by formaldehyde in vitro, these types of mutation may not be fundamental to its carcinogenicity.

#### Glutaraldehyde

Glutaraldehyde is clearly much more cytotoxic than formaldehyde, perhaps because it is a bifunctional alkylating agent. Intranasal instillation studies have demonstrated that, on a molar basis, glutaraldehyde is 10- to 20-fold more toxic than formaldehyde when delivered to the nasal mucosa as a single treatment in aqueous solution (St. Clair et al., 1990). Comparison of results from a 13-week inhalation study of glutaraldehyde (NTP, 1993) with similar inhalation studies with formaldehyde (Heck et al., 1990; Monticello, 1990; Monticello et al., 1991) shows that glutaraldehyde is about 20-fold more toxic than formaldehyde by this route also. Pulmonary damage and mortality occur at much higher glutaraldehyde concentrations. Cytotoxicity is manifest closer to the external nares in the case of inhaled glutaraldehyde. This difference in the site of toxic action may be particularly important because, if the only difference was toxic potency, then glutaraldehyde would be expected to produce effects similar to those of formaldehyde, although only at lower doses.

#### I. Assessment of postulated mode of action

#### Formaldehyde

From a weight-of-evidence point of view, the hypothesized MOA for formaldehyde-induced nasal tumours satisfies several criteria, including consistency, concordance of dose–response relationships across all key events, and biological plausibility and coherence of the database. Given the extensive experimental data that address and are consistent with the proposed MOA of formaldehyde in the induction of tumours in the nasal cavity, a high degree of confidence may be ascribed to it.

#### Glutaraldehyde

The key events of cytotoxicity, cell proliferation, and DPX formation (in vitro) have been demonstrated with exposure to glutaraldehyde. However, glutaraldehyde has not produced nasal tumours in rats and mice. Therefore, if the proposed MOA for formaldehyde is to be maintained, an explanation for this discrepancy is necessary. A reason for the difference has not been identified, but a hypothesis can be proposed. The dialdehyde function of glutaraldehyde is an important factor that may inhibit the macromolecules with which it reacts from further reaction within the cellular environment. Should these macromolecules be proteins involved in the maintenance of survival, then their immobility perhaps more likely leads to cell death than to a change in differentiation state. This immobilization of macromolecules by glutaraldehyde is the property that makes it a better fixative for high-resolution microscopy (e.g. electron microscopy) than formaldehyde. It almost certainly contributes to the very much higher toxicity of the dialdehyde. The monoaldehyde function of formaldehyde also causes cellular damage, but a proportion of proteins involved in cellular differentiation may be able to continue in that role, although with an altered outcome that may be the beginning of a path to neoplasia. If, on the other hand, these aldehydes react with nucleic acids (the evidence for glutaraldehyde reacting in this way is not substantial), then the repair of the alkylated nucleotides may be more difficult or even impossible in the case of glutaraldehyde, whereas repair does occur following formaldehyde interaction with DNA. Thus, irrespective of whether the mode of formaldehyde action in carcinogenicity is as proposed or is primarily due to genetic toxicity, the different response to glutaraldehyde exposure can be explained.

#### 2. CAN HUMAN RELEVANCE OF THE MOA BE EXCLUDED ON THE BASIS OF FUNDAMENTAL, QUALITATIVE DIFFERENCES IN KEY EVENTS BETWEEN EXPERIMENTAL ANIMALS AND HUMANS?

#### A. Formaldehyde

In rhesus monkeys exposed to formaldehyde at 7.2 mg/m<sup>3</sup> for between 1 and 6 weeks, formaldehyde-induced lesions were associated with increases in cell proliferation rates of up to 18-fold over controls and remained significantly elevated after 6 weeks of exposure. Histological lesions and increases in cell proliferation were most extensive in the nasal passages and were minimal in the lower airways, whereas the maxillary sinuses showed no evidence of a response to formaldehyde exposure. Based on the extent of lesions and cell proliferation data, it appeared that rhesus monkeys are more sensitive than rats to the acute and subacute effects of formaldehyde at 7.2 mg/m<sup>3</sup> (Monticello et al., 1989). The absence of response in the maxillary sinuses in rhesus monkeys is an observation deserving special attention in the design of epidemiological studies (or, perhaps, in the reporting of tumour sites). Most epidemiological studies of sinonasal cancer have not distinguished tumours arising in the nose from those developing in the nasal sinuses. Thus, the risk for nasal cancer specifically would tend to be diluted if there was no corresponding risk for cancer in the sinuses and could go undetected through lack of statistical power.

Many epidemiological studies have investigated formaldehyde exposure and cancer of the respiratory tract. The strongest evidence of an association has been observed for nasopharyngeal cancers. A statistically significant excess of deaths from nasopharyngeal cancer has been observed in the largest cohort study of industrial workers (Hauptmann et al., 2004), with statistically significant exposure–response relationships for peak and cumulative exposure. An excess of deaths from nasopharyngeal cancer was observed in a proportionate mortality analysis of the largest cohort of embalmers in the United States (Hayes et al., 1990). An excess of cases of nasopharyngeal cancer was observed in a Danish study of proportionate cancer incidence among workers at companies that manufactured or used formaldehyde (Hansen & Olsen, 1995). Other cohort studies reported fewer cases of nasopharyngeal cancer than expected (Walrath & Fraumeni, 1983; Coggon et al., 2003; Pinkerton et al., 2004). Of seven case–control studies of nasopharyngeal cancer, five found elevations of risk for exposure to formaldehyde.

Several case–control studies have investigated the association between exposure to formaldehyde and sinonasal cancer. A pooled analysis of 12 studies showed an increased risk of adenocarcinoma in men and women thought never to have been exposed to wood dust or leather dust, with an exposure–response trend for an index of cumulative exposure (Luce et al., 2002). One other case–control study (Olsen & Asnaes, 1986) and a proportionate incidence study (Hansen & Olsen, 1995) showed an increased risk of sinonasal cancer, particularly squamous cell carcinoma. However, the three most informative cohort studies of industrial workers showed no excesses of sinonasal cancer (Coggon et al., 2003; Hauptmann et al., 2004; Pinkerton et al., 2004).

In evaluating this body of evidence, the International Agency for Research on Cancer (IARC) concluded that there was sufficient epidemiological evidence that formaldehyde causes

nasopharyngeal cancer in humans; only limited epidemiological evidence that formaldehyde causes sinonasal cancer in humans; and strong but not sufficient evidence for a causal association between leukaemia and occupational exposure to formaldehyde (Cogliano et al., 2005).

There are no publications describing DPX in nasal cells from formaldehyde-exposed personnel. Assessment of DPX in peripheral lymphocytes from formaldehyde-exposed workers demonstrated an association with overall exposure (Shaham et al., 2003). The single DPX study involved 399 workers from 14 hospital pathology departments, and formaldehyde exposure categories were low-level (mean 0.5 mg/m<sup>3</sup>, range 0.05–0.8 mg/m<sup>3</sup>) and high-level (mean 2.7 mg/m<sup>3</sup>, range 0.86–6.7 mg/m<sup>3</sup>). Adjusted mean DPX were significantly higher in the exposed groups. There appear to be some doubts regarding the sensitivity and reproducibility of the physical separation method used in this study (Heck & Casanova, 2004).

Some studies have investigated the histological changes within the nasal epithelium of workers occupationally exposed to formaldehyde; however, the extent to which nasal epithelial cell regenerative proliferation occurs is unresolved because the results are mixed and there was co-exposure to wood dust in some studies (Berke, 1987; Edling et al., 1988; Holmström et al., 1989; Boysen et al., 1990; Ballarin et al., 1992).

Mucociliary clearance in the anterior portion of the nasal cavity was reduced following exposure of volunteers to formaldehyde at  $0.30 \text{ mg/m}^3$  (Andersen & Mølhave, 1983).

The concordance of animal and human key events for formaldehyde is summarized in Table 3.

Evidence in animals	Evidence in humans
Positive in vivo (target cells)	Plausible
Positive in vivo (target cells)	Plausible (some evidence but confounded by co-exposure)
DPX (target cells in vivo)	DPX (non-target cells, i.e. lymphocytes)
Positive in vitro; unconvincing in vivo	Positive (? cells)
Positive (mainly anterior lateral meatus)	Positive (nasopharyngeal) ? (sinonasal)
	Positive in vivo (target cells) Positive in vivo (target cells) DPX (target cells in vivo) Positive in vitro; unconvincing in vivo Positive (mainly anterior lateral

Table 3. Formaldehyde concordance table	
---	--

#### **B. Glutaraldehyde**

There are few epidemiological studies for exposure to glutaraldehyde and human cancer. No increase in the number of cancer deaths was observed among 186 male glutaraldehyde production workers. The average time since first exposure to glutaraldehyde was 20.6 years, and the period of exposure was 3–7 years. During periods of monitoring exposure, glutaraldehyde concentrations in air ranged from 0.04 to 1.4 mg/m<sup>3</sup> (NICNAS, 1994). Studies of embalmers, pathologists, and members of the American Association of Anatomists for possible effects of glutaraldehyde have all shown increases in risk of cancer; however, all of

these groups were also exposed to formaldehyde (Walrath & Fraumeni, 1983; Consensus Workshop on Formaldehyde, 1984; Stroup et al., 1986).

There are no studies examining glutaraldehyde exposure and DPX formation, cytotoxicity, and cell proliferation in human nasal tissues.

The concordance of animal and human key events for glutaraldehyde is summarized in Table 4.

Key event	Evidence in animals	Evidence in humans
Cytotoxicity	Positive	Plausible
Proliferation	Positive in vivo	Plausible
Genotoxicity	DPX in vitro	Unknown
Mutations	Positive in vitro	Unknown
Nasal tumours	Negative (no evidence at any site)	Unknown

#### 3. CAN HUMAN RELEVANCE OF THE MOA BE EXCLUDED ON THE BASIS OF QUANTITATIVE DIFFERENCES IN EITHER KINETIC OR DYNAMIC FACTORS BETWEEN EXPERIMENTAL ANIMALS AND HUMANS?

#### A. Formaldehyde

Quantitative differences between experimental animals and humans for the postulated MOA will be a function of the concentration of formaldehyde at the target tissue. It is formaldehyde per se, and not its metabolites, that causes cytotoxicity. Exogenous inhaled formaldehyde is rapidly metabolized upon absorption, to formate, by a number of widely distributed cellular enzymes, particularly formaldehyde dehydrogenase. In addition to this efficient metabolic detoxification mechanism, the mucociliary apparatus provides protection of the underlying epithelium from gases and vapours. Thus, in order to attain free formaldehyde concentrations that may be cytotoxic to the target tissue, relatively high concentrations of formaldehyde vapour must be delivered to the target site to overcome these protective mechanisms. Mechanistic events of clear significance for carcinogenicity occur at dose levels where formaldehyde detoxification mechanisms are saturated in rats (Casanova & Heck, 1987).

It is critical to take dosimetry into consideration when considering quantitative species differences for formaldehyde-induced toxicity in the respiratory tract. Inhaled formaldehyde is predominantly deposited and readily absorbed in the regions of the upper respiratory tract with which it comes into initial contact, owing to its high reactivity with biological macromolecules (Heck et al., 1983; Swenberg et al., 1983). A complex relationship between nasal anatomy, ventilation, and breathing patterns (nasal or oronasal) determines where in the upper respiratory tract formaldehyde absorption occurs in species. In rodents, which are obligate nasal breathers, deposition and absorption occur primarily in the nasal passage. In contrast, primates are oronasal breathers; although absorption and deposition are likely to occur primarily in the oral mucosa and nasal passages, they can also occur in the trachea and bronchus (Monticello et al., 1991). This hypothesis is supported by effects (histopathological changes, increased epithelial cell proliferation, and DPX formation) being observed farther along within the upper respiratory tract in monkeys.

Species differences in dosimetry have been taken into account in a two-stage clonal growth model that has been developed to predict the nasal carcinogenic risk of formaldehyde in humans (Conolly et al., 2004). The model also incorporates data on normal growth curves for rats and humans, cell cycle times, and cells at risk in the different regions of the respiratory tract.

Mice are better able to reduce both their respiratory rate and tidal volume upon repeated exposures; therefore, mice have less formaldehyde available for deposition than rats, resulting in less tissue damage and a lower rate of cell turnover in the nasal epithelium (Chang et al., 1981, 1983). These are characteristics that may help explain the lack of neoplastic response in the nose of mice.

Although there are likely to be quantitative differences between animal species and humans due to differences in dosimetry in the respiratory tract, there do not appear to be fundamental differences that would indicate that the proposed MOA does not occur in humans.

#### **B. Glutaraldehyde**

Much less is known of the kinetics of glutaraldehyde in experimental animals compared with formaldehyde. Inhalation studies do not appear to have been conducted. The terminal halflives for elimination are long for both intravenous injection (rat 10 h, rabbit 15–30 h) and dermal application (rat 40–110 h, rabbit 20–100 h), probably due to the binding of glutaraldehyde to protein and the slow excretion of metabolites. The metabolites have not been identified, but it has been proposed that the metabolism of glutaraldehyde probably involves initial oxidation to the corresponding carboxylic acids by aldehyde dehydrogenase. The glutaric acid formed by oxidation is probably further metabolized by reaction with coenzyme A (CoA) to give glutaryl CoA, which is then oxidized by glutaryl CoA dehydrogenase to glutaconyl CoA, leading to its eventual degradation to carbon dioxide via acetate (Beauchamp et al., 1992; NTP, 1993; NICNAS, 1994; Ballantyne, 1995).

Glutaraldehyde reacts readily with proteins as a cross-linking agent, mainly between amino groups. The reaction is rapid and pH dependent (rate increases at pH >9), to give Schiff bases. Further reaction occurs to give a number of complex reaction products, with the mechanism of the cross-linking process not yet fully understood.

Little information is available on the interaction between glutaraldehyde and DNA, but it has been reported (Hopwood, 1975) that glutaraldehyde reacts with DNA only at >60 °C (summarized by NICNAS, 1994), and there are data implying that there is no reaction under physiological conditions (Sewell et al., 1984; Douglas & Rogers, 1998; Vock et al., 1999).

#### 4. STATEMENT OF CONFIDENCE, ANALYSIS, AND IMPLICATION

#### A. Formaldehyde

Sustained cytotoxicity and cell proliferation are key events in the proposed MOA for the induction of several types of animal tumours. There are substantial data to support this postulated MOA for formaldehyde-induced nasal tumours in rats. Cytotoxicity, DPX formation, nasal epithelial cell regenerative proliferation, squamous metaplasia, and inflammation have been measured in rat studies and are site-specific, highly non-linear concentration–response processes in concordance with the incidence of nasal tumours.

Based on the weight of evidence, it is likely that the MOA is relevant to humans, at least qualitatively. Increased cell proliferation and DPX formation within epithelia of the upper respiratory tract have been observed in monkeys exposed to formaldehyde vapour. Increased human epithelial cell proliferation following in situ exposure to formaldehyde has also been observed in a model system in which rat tracheae populated with human tracheobronchial epithelial cells were xenotransplanted into athymic mice. Limited evidence on histopathological lesions in the nose of humans exposed primarily to formaldehyde in the occupational environment is consistent with a qualitatively similar response of the upper respiratory tract in experimental animals. In addition, several epidemiological studies have indicated an increased risk of nasal cancers with formaldehyde exposure.

Therefore, the MOA is considered relevant to humans, and animal nasal tumour and other supporting data should be taken forward to evaluate human risk. This process would include consideration of the data suggesting that formaldehyde induces tumours in a non-linear, dose-dependent manner. There may also be quantitative differences in response between species for the proposed MOA due to differences in dosimetry.

#### **B.** Glutaraldehyde

The epidemiological studies for glutaraldehyde are very limited and do not show an association with nasal tumours. In animal studies, glutaraldehyde has been shown to cause cytotoxicity, cell proliferation, and DPX production, but not nasal tumours, in inhalation studies in rats and mice. The fact that glutaraldehyde is clearly more toxic than formaldehyde should not constitute a reason for the difference in carcinogenic potential. Although, dose for dose, glutaraldehyde exposure may tend to result in more cell death than formaldehyde exposure, if glutaraldehyde is a carcinogen, this should be demonstrable at doses lower than those used for formaldehyde.

The MOA postulated for formaldehyde—that is, sustained cytotoxicity and cell proliferation—would appear to be relevant to glutaraldehyde, but tumour formation has not been demonstrated. It has been tentatively suggested here that the difference in pathological responses to these aldehydes is due to formaldehyde being a monoaldehyde whereas glutaraldehyde is a dialdehyde. This difference may result in a different form of cross-linking so that glutaraldehyde cross-link products are neither likely to retain any biological function nor likely to be repairable. The case-study highlights the difficulties in applying the HRF when the animal tumour data are inadequate.

### IPCS FRAMEWORK FOR ANALYSING THE RELEVANCE OF A NON-CANCER MODE OF ACTION FOR HUMANS

#### PREFACE

Following completion of the IPCS Framework for Analysing the Relevance of a Cancer Mode of Action for Humans (see Part 1), an expert meeting was convened in Geneva in 2006 to explore the question as to whether the IPCS framework could be applied in chemical risk assessment generally (i.e. to develop a non-cancer framework). The participants at this expert meeting concluded that the framework should be applicable to all end-points and proceeded to author a draft publication out of session. The draft was sent for peer review by the members of the Harmonization Project Steering Committee and subsequently revised by the authors, taking into account the peer review comments received.

# IPCS FRAMEWORK FOR ANALYSING THE RELEVANCE OF A NON-CANCER MODE OF ACTION FOR HUMANS<sup>1</sup>

Alan R. Boobis, John E. Doe, Barbara Heinrich-Hirsch, M.E. (Bette) Meek, Sharon Munn, Mathuros Ruchirawat, Josef Schlatter, Jennifer Seed, & Carolyn Vickers

Structured frameworks are extremely useful in promoting transparent, harmonized approaches to the risk assessment of chemicals. One area where this has been particularly successful is in the analysis of modes of action (MOAs) for chemical carcinogens in experimental animals and their relevance to humans. The International Programme on Chemical Safety (IPCS) recently published an updated version of its MOA Framework in animals to address human relevance (cancer Human Relevance Framework, or HRF). This work has now been extended to noncancer effects, with the eventual objective of harmonizing framework approaches to both cancer and non-cancer end-points. As in the cancer HRF, the first step is to determine whether the weight of evidence based on experimental observations is sufficient to establish a hypothesized MOA. This comprises a series of key events causally related to the toxic effect, identified using an approach based on the Bradford Hill criteria. These events are then compared qualitatively and, next, quantitatively between experimental animals and humans. The output of the analysis is a clear statement of conclusions, together with the confidence, analysis, and implications of the findings. This framework provides a means of ensuring a transparent evaluation of the data, identification of key data gaps and of information that would be of value in the further risk assessment of the compound, such as on dose-response relationships, and recognition of potentially susceptible subgroups, for example, based on life stage considerations.

The framework described in this paper, a non-cancer Human Relevance Framework (HRF), was prepared by the International Programme on Chemical Safety (IPCS) (WHO/ILO/UNEP) project on the Harmonization of Approaches to the Assessment of Risk from Exposure to Chemicals. This global "Harmonization Project" aims to harmonize global approaches to chemical risk assessment through both increased consistency of risk assessment methodologies and development of international guidance documents. The project enables the achievement of commitments on harmonization of chemical risk assessment methodologies agreed by the United Nations Conference on Environment and Development (United Nations, 1992), the Intergovernmental Forum on Chemical Safety (1994), the World Summit on Sustainable Development (UNEP, 2002), and the Strategic Approach to International Chemicals Management (WHO, 2006). The project involves experts from the different sectors where chemicals are assessed, and hence the documents produced can be applied in the assessment of industrial chemicals, biocides, pesticides, veterinary chemicals, pharmaceuticals, cosmetics, natural toxicants, food additives, and environmental contaminants in food, water, air, and consumer products.

A main outcome of the Harmonization Project is the IPCS Conceptual Framework for Evaluating a Mode of Action for Chemical Carcinogenesis (Sonich-Mullin et al., 2001) and

<sup>&</sup>lt;sup>1</sup> This article, to which WHO owns copyright, was published in 2008 in *Critical Reviews in Toxicology*, Volume 38, pages 87–96. It has been edited for this WHO publication.

its subsequent development into an IPCS Framework for Analysing the Relevance of a Cancer Mode of Action for Humans (IPCS cancer HRF) (Boobis et al., 2006; see also Part 1 of this document). The mode-of-action (MOA) analysis utilizes a weight-of-evidence approach based on the Bradford Hill criteria for causality (Hill, 1965). It aims to determine whether it is possible to establish an MOA for a carcinogenic response observed in an experimental animal study, through application of a weight-of-evidence approach that requires identification of key events along the causal pathway to cancer. When an MOA has been established in experimental animals, the cancer HRF provides an analytical tool to enable the transparent evaluation of the data in order to consider the human relevance of the MOA.

Following on from this, IPCS decided to consider whether the framework for cancer could be applied, with modifications, if necessary, to other end-points and their associated MOAs. Recognizing the work that the Risk Science Institute (RSI) of the International Life Sciences Institute (ILSI) had conducted in parallel to develop a similar framework and apply it to non-cancer risk assessment, IPCS convened an international meeting in Geneva in March 2006 to review and consider the ILSI publication (Seed et al., 2005), along with the IPCS cancer HRF (Boobis et al., 2006; see also Part 1 of this document), in order to explore the question as to whether the IPCS framework could be applied in chemical risk assessment generally. In summary, this IPCS meeting recognized that the framework should be applicable to all endpoints, both cancer and non-cancer, and recommended further work to put this into practice, including documenting the rationale for application of the framework more generally, which appears in the present paper, and steps to facilitate uptake and use of the framework.

The IPCS meeting recognized that the non-cancer HRF would have multiple uses in chemical risk assessment:

- It would provide an internationally harmonized approach to the establishment of an MOA in experimental animals and its relevance to humans.
- It would generate criteria for the MOA against which subsequent cases could be considered—that is, to show whether a compound shares an established MOA.
- It would enable clarification of key information relating to the human relevance of the MOA, and this would inform the assessment of other chemicals that share the MOA.
- In general, application of the framework would enable critical data deficiencies and research needs to be identified and inform qualitative and quantitative assessment.

# THE NEED FOR A NON-CANCER HUMAN RELEVANCE FRAMEWORK

The non-cancer HRF is a tool that provides a structured approach to the assessment of human relevance of a postulated MOA in animals in a weight-of-evidence context. Subsequently, it includes explicit consideration of the relevance of the proposed MOA to humans, often based on consideration of more generic information, such as anatomical, physiological, and biochemical variations among species. In this manner, the framework encourages maximum use of both chemical-specific and more generic information in a transparent and analytical fashion.

Pivotal to transparency in determining human relevance using the framework are the delineation and consideration of the nature of evidence in various species of key events—that is, those in a postulated MOA that are measurable and critical to the induction of the toxicological response. Evaluation of the concordance of key events based on explicit consideration of variations between experimental animals and humans constitutes the principal basis of transparency in consideration of weight of evidence for human relevance.

While principally relevant to hazard characterization, the non-cancer HRF additionally contributes more generally to transparency in risk assessment through explicit delineation and consideration of data on appropriate key events that are also relevant to subsequent dose–response analysis for MOAs deemed relevant to humans. If the MOA in experimental animals is judged to be qualitatively relevant to humans, a more quantitative assessment is required that takes into account any kinetic and dynamic information that is available from both the experimental animals and humans in order to determine whether human relevance might be precluded on this basis.

These same data are critical to subsequent dose–response analysis for MOAs considered relevant in considering the adequacy of, for example, available information as a basis for replacement of default uncertainty factors in the development of chemical-specific adjustment factors (CSAFs) (IPCS, 2005). This information could, for example, constitute an adequate basis to consider interspecies variation in rates of formation of reactive metabolites in the target tissue, for replacement of the default subfactor for interspecies differences in toxicokinetics with a CSAF (IPCS, 2005).

Use of this non-cancer HRF also promotes harmonization of approaches to risk assessment for all end-points, bridging previously distinct approaches on, for example, cancer and noncancer effects. Harmonization in this context refers to a biologically consistent approach to risk assessment for all end-points, for which exploration of biological linkages is critical to ensuring maximal use of relevant information. Often, for example, organ toxicity is a critical key event in postulated MOAs for induction of tumours at the same site. The non-cancer HRF, then, sets the stage for identification of critical precursor non-cancer key events for which subsequent quantification of interspecies differences and interindividual variability in dose–response analysis is relevant. In other cases, a postulated MOA may lead to toxic effects in multiple organs, and these would be considered in the same non-cancer HRF analysis.

In addition, consideration in a transparent framework may identify factors that, while not themselves essential for the toxicological effect (and hence not key events), may modulate key events and, as a result, contribute to differences between species or individuals. Such factors include genetic differences in pathways of metabolism, competing pathways of metabolism, and cell proliferation induced by concurrent pathology.

Such an analysis may also provide an indication of those components of a proposed MOA that may operate only over a certain dose range. If a high experimental dose of a given compound is needed to result in an obligatory step in an MOA, then the relevance to human

risk becomes a matter of exposure. Thus, the exposure assessment step of the risk assessment is critical to a comprehensive evaluation.

Importantly, then, application of the non-cancer HRF contributes to identification of any specific subpopulations (e.g. those with genetic predisposition) who are at increased risk and provides information relevant to consideration of relative risks at various life stages. In many cases, this is based not on chemical-specific information but rather on inference, based on knowledge of the MOA, as to whether specific age groups may be at increased or decreased risk. This requires explicit consideration of comparative developmental and ageing processes and events in humans and animal models. These considerations are critical to determination of focus in the remaining stages of risk assessment, such as dose–response analysis.

The transparent delineation of the weight of evidence for postulated MOAs and their relevance to humans (requiring explicit consideration of the strengths and weaknesses of the available database, as well as highlighting qualitative and quantitative similarities and differences among species and related uncertainties) also identifies any inconsistencies in the available data and defines critical data gaps and research needs. This derives from the requirement in each step to explicitly assess confidence in the quality and quantity of data underlying the analysis, consistency of the analysis within the framework, consistency of the database—that is, that studies are not contradictory of each other—and the nature and extent of the concordance analysis.

Iterative application of the non-cancer HRF, even before all of the data are available, to the analysis of a postulated MOA and its relevance to humans are beneficial as a basis for developing and refining research strategies as additional information becomes available. In this context, the framework should prove helpful in facilitating discussion between risk assessors and research scientists in jointly understanding the nature of data that would support human relevance analysis of a postulated MOA in animals and defining next steps in data acquisition. Iterative consideration of MOA in designing research strategies is also expected to increase efficiency by focusing resources in critical areas in more tiered and targeted approaches.

As knowledge advances, MOAs will become less chemical specific and based even more on the key biological processes involved, allowing greater generalization of human relevance from one compound to another. The need for chemical-specific data for established MOAs will be less, although it will always be necessary to establish rigorously that the key events comprising the MOA occur.

The transparency in the human relevance of a postulated MOA that results from application of the non-cancer HRF should promote confidence in the conclusions reached, through the use of a defined procedure that encourages clear and consistent documentation supporting the analysis and reasoning, highlights inconsistencies and uncertainties in the available data, and identifies critically important data gaps that, when filled, would increase confidence in outcome. This transparency not only is anticipated to facilitate discussion between the risk assessment and research communities, but may also contribute to greater convergence among different regulatory agencies. The non-cancer HRF also provides the basis for improved process and content for scientific peer input and peer review, specifying minimum criteria of clarity and transparency as a basis to acquire input and acceptance of postulated MOAs and their relevance to humans. Adherence to these criteria enables others to determine the basis of the conclusions reached with respect to the key events, the exclusion of other MOAs, and the analysis of human relevance.

# WHEN WOULD THE NON-CANCER HRF BE APPLIED?

The non-cancer HRF provides a valuable tool to assess an MOA, but it requires significant amounts of effort and experimental work, so it is not something that would be used during the course of the assessment of every chemical. Its main purpose would be to determine whether to apply the default assumption that all effects seen in animals are relevant to humans. This question increases in importance when the application of the default assumption during the course of a risk assessment indicates that adverse effects are likely to occur—for example, where there is a low margin of exposure between the point of departure for the effect under consideration and the estimated human exposure, especially if the human exposure estimate has already been refined. It then becomes important to know whether risk management measures will be required. This is of most concern when new data emerge, such as those identifying a new effect, additional data on the dose–response relationship of the chemical, or changes in use pattern or exposure estimation, which change the risk assessment of a chemical that is already in use.

Use of the non-cancer HRF may also be of value in the situation where the effects in animals would have potentially serious consequences if they occurred in humans, such as neuro-toxicity or teratogenesis. These effects are subject to very rigorous risk assessment procedures, so they comparatively frequently suggest the need for risk management measures.

Another situation in which use of the non-cancer HRF should be considered is where there are interspecies differences in either the type of effect or the dose levels at which an effect occurs. In these cases, it will be important to understand which species is the most appropriate upon which to base extrapolation to humans. This indication would also apply to differences between sexes or strains in the same species.

These situations indicate that further consideration is required, and the non-cancer HRF provides a way of doing this. The framework can be applied at any stage in the process of considering an effect. It should be applied in an iterative way during the course of investigating an effect to help guide the scientist. When an effect has first been observed and gives rise to concern, the framework allows the investigator to structure the work programme by prompting the questions to be addressed. As the investigation develops, it guides the investigator in assessing the data as they are generated and provides pointers in deciding whether and what other data would be required.

In situations where there is a large body of data, the framework allows the evaluator to weight the evidence according to its significance as well as its volume.

The non-cancer HRF can also be useful when a chemical is observed to cause an effect suspected of being caused by an MOA that has already been established using the framework or shares structural similarity to a chemical or class of chemicals with an established MOA. The earlier use of the non-cancer HRF to establish this MOA will have identified the key steps that need to be investigated in order to ascribe the MOA to the new chemical. This will prove valuable both in a prospective way in designing new research or testing programmes and retrospectively in evaluating a data set.

# **CONSIDERATION OF THE NON-CANCER HRF**

The non-cancer HRF is an analytical tool that enables a structured approach to the assessment of the overall weight of the evidence for the postulated MOA and its relevance to humans. The framework is not designed to provide an absolute answer on sufficiency of the information, as this will vary, depending on the circumstance. It must be emphasized that it is not a checklist of criteria but an approach to data evaluation and presentation. The output from the application of the framework serves as the basis for the continuation of the risk assessment of the compound.

It is envisaged that the non-cancer HRF will be applicable to a wide range of toxicological end-points, encompassing changes in structure and function of organs, tissues, and cells, including physiological and neurobehavioural effects. The types of toxicity that could be addressed using the framework include, but are not limited to:

- *Organ toxicity*: Examples include benzene-induced haematotoxicity (aplastic anaemia), paraquat-induced lung toxicity, chloroquine-induced ocular toxicity.
- *Reproductive toxicity*: Examples include phthalate-induced male infertility, dioxininduced dysregulation of female fertility.
- *Developmental toxicity*: Examples include methylmercury-induced developmental neurotoxicity, retinoid-induced teratogenesis.
- *Neurotoxicity*: Examples include lead-induced peripheral neuropathy, acrylamide-induced axonopathy, 1-methyl-4-phenyl-1,2,3,6-tetrahydropyridine (MPTP)-induced Parkinson disease.
- *Immunotoxicity*: Examples include organotin-induced immunosuppression, isoniazidinduced systemic lupus erythematosus (SLE)-like syndrome, contaminated L-tryptophaninduced eosinophilia-myalgia syndrome (EMS).

# **Introduction to MOA**

Prior to embarking on a non-cancer HRF analysis, there needs to be careful evaluation of the weight of evidence for a toxicological response on exposure to a chemical in experimental animals. The nature of the non-cancer HRF is such that only one MOA is analysed at a time; hence, for example, different toxicological effects associated with chemical administration, even if observed in the same animals, will require separate framework analyses to discern the MOA for each effect. Consistent with species- and tissue-specific variation in metabolic activation and detoxication, there may be poor site concordance for some toxicants. This will need to be kept in mind when comparing animal and human data.

# Postulated mode of action (theory of the case)

This comprises a brief outline of the sequence of events in the MOA postulated to be responsible for the toxicological effect of the test substance. This description leads into the next section, which identifies the events considered "key" (i.e. necessary and measurable) in the MOA.

## Key events

The "key events" in the MOA are briefly identified and described. Key events are those events that are critical to the induction of the toxicological response as hypothesized in the postulated MOA and are also measurable. To support an event as key, there needs to be a body of experimental data in which the event is characterized and consistently measured. The types of information that might be relevant include, for example, toxicological response and relevant key events in the same cell type, sites of action logically related to the event(s), specific biochemical events, changes in the expression or activity of enzymes, receptor–ligand interactions, effects on cofactor levels, specific changes in histology, changes in cell proliferation (increased or decreased), perturbations in hormone homeostasis or other signalling pathways (either intracellular or extracellular), second messengers, or ion fluxes, increased degradation of macromolecules, and changes in membrane permeability or integrity.

# Concordance of dose–response relationships

The dose–response relationships for each of the key events and for the toxicological response should be characterized and their interrelationships discussed with respect to the Bradford Hill criteria (Hill, 1965). Ideally, it should be possible to correlate the dose dependency of the increases in the magnitude (or frequency) of a key event with increases in the severity (e.g. lesion progression) of other key events occurring later in the process and with the ultimate toxicological response. Comparative tabular presentation of the magnitude of changes in key events and toxicological response is often helpful in examining dose–response concordance.

It is important to consider whether there are fundamental differences in the biological response (i.e. dose transitions) at different parts of the dose–response curve (Slikker et al., 2004). If so, key events relevant to the different parts of the dose–response curve will need to be defined and used in the framework analysis.

## Temporal association

The temporal relationships for each of the key events and for the toxicological response should be characterized. Key events should be observable before toxicity is apparent and should be consistent temporally with each other; this is an essential step in deciding whether the data support the postulated MOA. Observations of key events at the same time as the toxicological response (e.g. at the end of a study) do not permit conclusions as to temporal association, but can contribute to the analysis described in the next section.

# Strength, consistency, and specificity of association of toxicological response with key events

The weight of evidence linking the key events, any precursor lesions, and the toxicological response should be addressed (see Weed [2005] for a discussion of what is meant by weight of evidence). Stop/recovery studies showing absence or reduction of toxicity when a key

event is blocked or reduced are particularly useful tests of the association. Consistent observations in a number of studies, with different experimental designs, increase support for the MOA, since different designs can reduce any unknown bias or confounding. Consistency, which is the repeatability of the key events in the postulated MOA in different studies, is distinct from coherence, however, which addresses the relationship of the postulated MOA with observations more broadly (see next point). Observations that may be of value here include toxicological response and relevant key events in the same cell type, sites of action logically related to event(s), and results from stop/recovery studies.

## Biological plausibility and coherence

One should consider whether the MOA is consistent with what is known about the biology of the target process/site in general (biological plausibility) and also in relation to what is known specifically about the overall biological effects of the substance (coherence). For the postulated MOA and its associated key events to be biologically plausible, they need to be consistent with current understanding of biology. However, when using biological plausibility as a criterion against which weight of evidence is assessed, it is important to consider the potential for gaps in our knowledge. Coherence, which addresses the relationship of the postulated MOA for the toxicological response with that for other end-points—needs to be distinguished from consistency (addressed in the preceding point). In assessing coherence, information on structural analogues may be of value (i.e. structure–activity analysis). Information from other compounds that share the postulated MOA may also be helpful, such as sex, species, and strain differences in sensitivity and their relationship to key events. Additionally, this section should consider whether the database on the agent is internally consistent in supporting the proposed MOA.

## Other modes of action

Alternative MOAs that logically present themselves should be considered. If alternative MOAs are supported, they will need a separate non-cancer HRF analysis. These should be distinguished from additional components of a single MOA, since these would be addressed as part of the MOA under consideration.

# Uncertainties, inconsistencies, and data gaps

Uncertainties should be stated fully and explicitly. They should include those related to the biology of the toxicological response and those for the database on the compound being evaluated. Any inconsistencies should be noted and data gaps identified. It should be clearly stated whether the identified data gaps are critical in supporting the postulated MOA.

# Assessment of postulated mode of action

There should be a clear statement of the outcome of the analysis, indicating the level of confidence in the postulated MOA—for example, high, moderate, or low. If a novel MOA is being proposed, this should be clearly indicated. However, if the MOA is the same as one previously described, the extent to which the key events fit this MOA needs to be stated explicitly. Any major differences should be noted and their implications for acceptance of the MOA discussed.

# Life stage considerations

Since the response of an organism to a chemical exposure may vary through its lifespan, consideration of life stage is important for the MOA analysis of all toxic end-points. This is particularly true for effects that result from developmental exposures, since organ susceptibility may be restricted to critical periods of development, may depend on the ontogeny of key metabolic enzymes, or may depend on the interaction of the developing organism with its mother (see Zoetis & Walls, 2003). In addition, disruption of developmental processes may have downstream consequences.

Consideration of the ageing process is also important, for several reasons. First, developmental exposures can result in toxicities that are not detected until much later in life. In addition, there can be species-specific patterns of ageing for different organ systems. For example, reproductive senescence has a different etiology in rodents and humans and can even differ among different strains of rodents.

## Human relevance

If it is possible to establish an MOA in animals for a toxicological effect, the next stage is to evaluate its relevance to humans. The IPCS non-cancer HRF is presented as an approach to answering a series of three (or four) questions, leading to a documented, logical conclusion regarding the human relevance of the MOA underlying the toxicological effect. The application of the guidance results in a narrative with four (or five) sections, which may be incorporated into the hazard characterization of a risk assessment.

1. Is the weight of evidence sufficient to establish a mode of action (MOA) in animals? This question is addressed by performing an MOA analysis as described above, the steps of which are based on the Bradford Hill criteria for causality (Hill, 1965). The weight of evidence for possible alternative MOAs needs to be considered and a conclusion reached on the overall strength of evidence supporting the MOA under consideration. The approach also identifies any critically important data gaps that, when filled, would increase confidence in the proposed MOA. If the postulated MOA has already been described for other chemicals, its human relevance will already have been evaluated. If the proposed MOA is novel, human relevance will need to be assessed de novo.

2. Can human relevance of the MOA be reasonably excluded on the basis of fundamental, qualitative differences in key events between experimental animals and humans? This step involves a qualitative assessment of the relevance of the MOA to humans. Listing the critical key events that occur in the animal MOA and directly evaluating whether or not each of the key events might occur in humans facilitate the evaluation and increase the transparency of the process. Presentation in tabular form, referred to as a concordance table, can be particularly useful. The information in such tables should be relatively brief, as a narrative explanation should always accompany the table. In one column, the effect on humans for each of the key events is evaluated. Another column for the results in a different strain, species, or sex or for a different route of administration that does not result in toxicity can be useful for comparative purposes. Factors may be identified that, while not key themselves, can modulate key events and so contribute to differences between species or individuals. Examples include genetic differences in pathways of metabolism, competing pathways of

metabolism, and effects induced by concurrent pathology. Any such factors identified should be noted in a footnote to the concordance table.

The evaluation of the concordance of the key events for the MOA for a given chemical in humans is an evaluation of the MOA in humans, rather than an evaluation of the specific chemical. In general, details of the initial key events are likely to be more chemical specific. Later events will be more generic to the MOA. While information for evaluating the key events in humans can come from in vitro and in vivo studies on the substance itself, basic information on anatomy, physiology, endocrinology, genetic disorders, epidemiology, and any other information that is known regarding the key events in humans can be of value.

In answering this question, a narrative describing the weight of evidence and an evaluation of the level of confidence for the human information should be prepared. Examples of specific types of information that can be useful include:

- where appropriate, background incidences of the effect at the anatomical site and cell type of interest, including age, sex, ethnic differences, and risk factors, including chemicals and other environmental agents;
- knowledge of the nature and function of the target site, including development, structure (gross and microscopic), and control mechanisms at the physiological, cellular, and biochemical levels;
- human and animal disease states that provide insight concerning target organ regulation and responsiveness;
- human and animal responses to the chemical under review or structural analogues following short-, intermediate-, or long-term exposure, including target organs and effects.

Obviously, a substantial amount of information is required to conclude that a given MOA is not relevant to humans. If such a conclusion is strongly supported by the data, exposure to chemicals producing toxicity only by that MOA would not pose a risk to humans, and no additional risk characterization for this end-point is required.

The question of relevance considers all groups and life stages. It is possible that the conditions under which an MOA operates occur primarily in a susceptible subpopulation or life stage—for example, in those with a pre-existing viral infection, hormonal imbalance, or disease state. Any information suggesting qualitative or quantitative differences in susceptibility is highlighted for use in risk characterization.

There are several aspects relating to life stage that should be considered in the non-cancer HRF analysis. First, the analysis should consider the comparative developmental processes and events that occur in humans and the animal model(s) (see Zoetis & Walls, 2003). This comparison will demonstrate the extent to which developmental processes are similar in humans and the animal model(s). In general, development is highly conserved; where this is the case, it would lead to a conclusion that the MOA in animals is also plausible in humans. However, there are some developmental processes that are unique to some species, which may therefore lead to a species-specific MOA that will not be plausible in humans.

Second, the analysis should consider the phase specificity or relative timing of the developmental processes or events in humans and the animal model(s). Critical developmental events may occur at different times during ontogeny. Some developmental events may occur early during the prenatal development of the animal and relatively late in human prenatal development. Other developmental events may occur prenatally in humans and postnatally in the animal, or vice versa. Differences in timing of the developmental events can have an impact on the dose metrics if there are substantial differences in placental versus lactational transfer. Similarly, a comparison of the ontogeny of key metabolic enzymes relative to the key developmental process may reveal substantial differences between humans and the animal model. Such considerations may lead to a conclusion that the animal MOA is not plausible in humans.

3. Can human relevance of the MOA be reasonably excluded on the basis of quantitative differences in either kinetic or dynamic factors between experimental animals and humans? If the MOA in experimental animals cannot be judged to be qualitatively irrelevant to humans (no to question 2), a more quantitative assessment is undertaken, taking into account any kinetic and dynamic information that is available from experimental animals and humans. Such data will of necessity be both chemical and MOA specific and where possible should include the biologically effective doses required to produce the dynamic effects giving rise to the toxicity. Kinetic considerations include the rate and extent of absorption, tissue distribution, metabolism, and excretion. Differences in ontogeny can result in substantial species differences in placental and lactational transfers, which will affect the dose metrics. This may therefore result in a quantitative difference in the MOA between humans and experimental animals. Similarly, the differential ontogeny of key metabolic enzymes can result in substantial quantitative differences between humans and experimental animals. Dynamic considerations include the consequences of the interaction of the chemical with cells, tissues, and organs. Only infrequently is it likely that it will be possible to dismiss human relevance on the basis of quantitative differences. Since quantitative exposure assessment is part of the subsequent risk characterization rather than the HRF, the difference would have to be of such a magnitude that human exposure could not possibly be envisaged to reach such levels. In most cases, it will not be possible to reach such a conclusion without undertaking formal exposure assessment in the subsequent risk characterization. Hence, the answer to the question will be no, but it may still be concluded that the risk is negligible in the subsequent risk characterization. Melamine-induced urinary bladder carcinogenesis provides a useful case-study illustrating this point (Meek et al., 2003). Again, tabular comparison of the data from experimental animals and humans can help in the evaluation. Information from studies of other compounds acting by the same or a similar MOA can be of value. As understanding of the basis for differences in responses between experimental animals and humans improves, differences in key events thought to be qualitative may be shown to be due to specific quantitative differences.

While it may not be possible to conclude that the MOA for toxicity is not relevant to humans on the basis of quantitative differences, during the evaluation it may become apparent that the magnitude of those differences is sufficient to impact markedly on the risk assessment. Hence, it is particularly important that the narrative for the answer to this question be comprehensive and capture as much quantitative information as possible. As with question 2, if the response to this question is *yes*, then exposure to chemicals producing toxicity only by this MOA would not pose a risk to humans, and no additional risk characterization is required.

The preceding three questions comprise a decision tree (see Figure 1).

		Is the weight of evidence sufficient to establish a mode of action (MOA) in animals?	NO →	Continue with risk assessment
		$\downarrow$ YES		
MOA not relevant	YES ←	Can human relevance of the MOA be reasonably excluded on the basis of fundamental, qualitative differences in key events between experimental animals and humans?		
		$\downarrow$ NO		
MOA not relevant	YES ←	Can human relevance of the MOA be reasonably excluded on the basis of quantitative differences in either kinetic or dynamic factors between experimental animals and humans?	$\mathbf{NO}$ $\rightarrow$	Continue with risk assessment

Figure 1. Decision tree for determining human relevance of an MOA for toxicity observed in experimental animals.

## Potential implications for dose-response assessment

Should it not be possible to exclude human relevance of the MOA for toxicity prior to proceeding with the risk assessment, a further question should be addressed. This is: *4. Are there any quantitative differences in the key events such that default values for uncertainty factors for species or individual differences could be modified?* Such information, on either kinetics or dynamics, could be used to calculate a CSAF, in which one or more of the default values for species or interindividual differences in kinetics or dynamics are replaced by a value based on chemical-specific information (IPCS, 2005). The other components of the adjustment factor would retain their default values. Such information may lead to either an increase or a decrease in the adjustment factor relative to the normal default.

## **Published case-studies**

In developing a framework for assessing the human relevance of MOAs for non-cancer endpoints, ILSI/RSI also developed a series of illustrative case-studies. These were on molinateinduced inhibition of spermatogenesis (Kavlock & Cummings, 2005a), renal and developmental effects of ethylene glycol (Corley et al., 2005), developmental neurotoxicity of nicotine (Slikker et al., 2005), phthalate ester effects on male reproductive development (Foster, 2005), vinclozolin-induced malformations (Kavlock & Cummings, 2005b), developmental effects of valproic acid (Wiltse, 2005), haemoglobin-based oxygen carriers (HBOC)-related congenital malformations (Holson et al., 2005), developmental effects of angiotensinconverting enzyme (ACE) inhibitors (Tabacova, 2005), developmental ototoxicity of polyhalogenated aromatic hydrocarbons (Crofton & Zoeller, 2005), and propylthiouracilinduced effects on neurological development (Zoeller & Crofton, 2005). While these cases covered a range of end-points, most involved effects during development. Hence, there is a need for additional case-studies on other end-points, such as those indicated above. As experience is obtained in using this framework, some of the published cases could be further refined to provide valuable illustrative examples for training in the application of the framework.

In general, the cases have been very useful in highlighting a number of the key issues on which this non-cancer HRF is based. Examples include the importance of the concordance analysis, the value of quantitative information identified during the application of the framework when it is not possible to exclude human relevance, the need for a transparent and comprehensive narrative when reporting the conclusions of a framework analysis, the importance in identifying key data gaps (e.g. case-study on molinate and HBOC), identification of research needs (e.g. case-study on vinclozolin), the importance of understanding the formation of a specific metabolite, and the importance of establishing a robust MOA through the application of the Bradford Hill criteria (Hill, 1965) to the key events.

# Statement of confidence, analysis, and implications

Following application of the non-cancer HRF and answering the three (or four) questions, a statement of confidence should be provided that addresses the quality and quantity of data underlying the analysis, the consistency of the analysis within the framework, the consistency of the database, and the nature and extent of the concordance analysis. Alternative MOAs should have been evaluated, when appropriate, with the same rigor. A critical outcome is the identification of specific data gaps that could be addressed experimentally to increase confidence in the analysis.

The output of the non-cancer HRF provides information that is useful for more than just determining whether or not the MOA for toxicity in experimental animals is relevant to humans. It can also provide much information that is critically important in subsequent steps in the risk characterization for relevant effects. For example, it may be possible to develop CSAFs on the basis of the information provided. Application of the framework can also provide information on relevant modulating factors that are likely to affect risk. In addition, it can identify those elements of a proposed MOA that operate only over a certain dose range. Where an obligatory step in an MOA occurs only following a high experimental dose of a compound, the relevance of the MOA to human risk is determined by the exposure. Thus, effective exposure assessment is particularly important to the evaluation of human risk from such toxicity.

The analysis also contributes to the identification of any specific subpopulations (e.g. those with genetic predisposition) who may be at increased risk and often provides information useful in considering relative risk at various life stages. This may be based not always on chemical-specific information but rather on inference, on the basis of knowledge of the MOA, as to whether the risk in specific age groups might be expected to differ.

The data and their analysis using the non-cancer HRF should be reported in a clear and comprehensive manner, so that others can determine the basis of the conclusions reached.

Although the specific form of presentation will vary with the type of data available, a structured report, including the key headings from the framework, should be provided where possible. Presentation should include sufficient details on the context and thought processes to ensure transparency of the conclusions reached. The inclusion of concordance tables is strongly encouraged. This increases transparency and facilitates peer engagement.

# **USE OF THE FRAMEWORK AND ITS OUTPUTS**

The IPCS non-cancer HRF, which is based principally on robust concordance analysis of key events in postulated MOAs, is envisaged to be of value to both the risk assessment and research communities as a basis to contribute to harmonization in several areas, including:

- adequacy and nature of weight of evidence for postulated MOAs in animals and their relevance to humans;
- MOA integration across end-points;
- criteria for transparency to ensure sufficiency of peer input and review.

Among the strengths of the non-cancer HRF are its flexibility, transparency, and general applicability across end-points. This includes determination of the nature and shape of the dose–response curve, the identification and location of biological thresholds for individual key events, and their consequences. In addition, consideration of the kinetic and dynamic factors involved in each key event is informative regarding the relevance or not to specific subpopulations—for example, in early life, in those with particular diseases, or in those with specific polymorphisms. Alternatively, application of the framework can provide quantitative information on the differences between such groups. Human relevance analysis may also indicate that a species is inappropriate for evaluating a potentially relevant end-point because of dose limitations.

# NEXT STEPS

To ensure effective adoption of the non-cancer HRF, there will be a need to train individuals in its application and in the interpretation of its outputs. Experience is being gained in the use of the cancer HRF, and the expertise gained would be applicable in the training of others in the use of the non-cancer HRF. Training would be facilitated by the availability of a number of suitable case-studies. Those published to date would be a sound basis for further development for this purpose (Seed et al., 2005). In addition, cases on a wider range of end-points need to be developed. It would be helpful if organizations with experience in non-cancer HRF analysis could develop courses and make the materials available to others with suitable expertise to help in training.

A database of generally accepted MOAs should be compiled and maintained, together with informative case-studies. Such a database would be of particular importance as experience continues to evolve in the development of MOAs and in determining whether the MOA for a compound is novel or has been described previously for other compounds.

The current non-cancer HRF, which arose out of the IPCS cancer HRF, is focused on noncancer end-points. However, there are marked similarities in the philosophy and strategy to evaluating cancer and non-cancer effects. It is strongly recommended that one of the next steps in harmonization of risk assessment of chemicals should be the preparation of a unified HRF that is applicable to all toxicological end-points, including cancer. The integration of framework approaches into the risk assessment process should be further elaborated, in which illustrative examples would be of value. Some guidance on problem formulation before embarking on an HRF analysis should be included in such a framework document, as should guidance on the use of the outputs of HRF analysis in risk assessment. For example, during application of the framework, a much deeper understanding of dose–response relationships is often developed, which should be taken forward into hazard characterization. As indicated above, knowledge of any dose transitions is invaluable in interpreting exposure data. Identification of key events in the MOA can provide insight into the sources and magnitude of interspecies and interindividual differences.

ハーモナイゼーションプロジェクト文書とは、国際化学物質安全性計画(IPCS)(WHO/ILO/UNEP) のもと世界保健機関(WHO)によって出版された出版物群である。ハーモナイゼーションプロジ ェクト文書は、化学物質のリスク評価方法に関する正式な文書として、環境保健クライテリア (EHC)の方法論シリーズ(黄表紙)を補完するものである。

有害化学物質の評価と管理に関する現在の国際的、地域的及び各国内の協調的な取り組みの主 なきっかけは、1992年の国連環境開発会議(UNCED)にあった。UNCEDアジェンダ21の第19 章において、有害化学物質の環境的に健全な管理のための「青写真」が示されている。各国政府 によるこのコミットメントは、2002年の持続可能な開発に関する世界首脳会議で、さらに2006年 の国際的な化学物質管理のための戦略的アプローチ(SAICM)でも再確認された。化学物質への ばく露によるリスク評価のアプローチの調和に関する IPCS プロジェクト(ハーモナイゼーショ ンプロジェクト)は、このアジェンダ21第19章の下で実施されており、SAICMの実施に貢献し ている。特に、本プロジェクトは、SAICMの目標である「リスク低減」とSAICM世界行動計画 の活動である「リスク評価のための新たな調和された手法の開発と利用」に対応している。

IPCS ハーモナイゼーションプロジェクトの目的は、共通の原則とアプローチを追求することに よって化学物質のリスク評価を世界的に改善し、持続可能性というフレームワークの中でヒトの 健康と環境をより良く保護するための国内及び国際的な管理手法を強化することである。ハーモ ナイゼーションプロジェクトは、特定の問題に関する国際的なガイダンス文書を作成することを 含め、化学物質リスク評価に対する世界各国のアプローチを調和させることを目的としている。 このガイダンスは、化学物質のリスク評価を実施する際に各国や国際機関で採用され、使用する ことを目的としている。このガイダンスは、世界中の専門家の協力を得て作成されている。本プ ロジェクトは、まず各国の手法や慣行について情報を共有し、理解を深め、異なるアプローチの 統一化が有益となる分野を特定した上で、調和のとれたアプローチの実施を可能にするガイダン スを作成するという段階的アプローチを用いて採用している。本プロジェクトでは、アプローチ の調和を図る上で、特に重要なリスク評価の側面に焦点を当てたビルディングブロック法を採用 している。

このプロジェクトにより、国際的に認められた手法を用いてリスク評価(またはその構成要素) を実施することを可能にし、これらの評価を共有することで重複を避け、リスク管理のための貴 重な資源を最適に利用することが可能となる。また、リスク管理の意思決定の基礎となる健全な 科学を促進し、リスク評価の透明性を高め、不必要な化学物質の試験を減らすことができる。ま た、科学的知識の発展が新たな調和のとれた手法の開発へとつながりうる。

この進行中のプロジェクトは、各地域の代表的なハーモナイゼーションプロジェクト運営委員 会と、詳細な作業を管理するいくつかの特別作業部会によって監督されている。最終的には、国 際的なピアレビュー及びパブリックコメントといった厳格なプロセスが含まれている。

第1部

発がん MOA のヒトへの関連性を解析するための IPCS フレームワーク及び事例研究

#### 序文

国際化学物質安全性計画(IPCS)の(動物における)<sup>1</sup>「化学物質の発がん作用機序の評価に関 する概念的フレームワーク」の公表を受けて、2004年3月3日から5日に米国バージニア州アー リントンで IPCS がんワーキンググループが開催された。このワーキンググループは、規制やその 他の目的でリスク評価において作用機序に関する情報を利用するための統一された IPCS ヒト関 連性フレームワークを開発することを目標に、動物における腫瘍のヒトへの関連性の問題をさら に検討する必要性があることに合意し、この作業のための初期のガイダンスを提供した。このワ ーキンググループのメンバーは、事務局サポートと経済協力開発機構(OECD)の代表者を含めて 以下の通りである。

Hermann Bolt 教授(ドイツ・生理学研究所)

Alan R. Boobis 教授(インペリアル・カレッジ・ロンドン、健康毒性学部門、英国)

John Bucher 博士(国立環境衛生科学研究所、米国)

Vincent Cogliano 博士(国際がん研究機関 発がん物質同定・評価ユニット、フランス)

Samuel M. Cohen 博士(病理学・微生物学、ハヴリック・ウォール腫瘍学教授、ネブラス

カメディカルセンター大学、米国)

William Farland 博士(環境保護庁研究開発局、米国)

Jun Kanno 博士(独立行政法人国立医薬品食品衛生研究所 細胞分子毒性学研究部門、日本)

Lois D. Lehman-McKeeman 博士 (ブリストル・マイヤーズ スクイブ、米国)

Bette Meek 氏(カナダ保健省環境衛生センター、カナダ)

Laurence Musset 氏(経済協力開発機構 環境安全衛生部門、フランス)

Jerry Rice 博士 (コンサルタント、米国)

Cindy Sonich-Mullin 氏(世界保健機関 国際化学物質安全性計画、米国)

Carolyn Vickers 氏(世界保健機関 国際化学物質安全性計画、スイス)

Deborah Willcocks 氏(国家工業化学品届出・評価スキーム(NICNAS)、既存化学品担当、

オーストラリア)

2005 年 4 月 21 日から 23 日に英国のブラッドフォードで開催された IPCS 国際ワークショップ においてアーリントン会議のガイダンスを考慮し、MOA フレームワークに人間への関連性を考慮 した内容に拡張することが検討された。このワークショップでは、2001 年の MOA フレームワー クの更新を含む IPCS ヒト関連性フレームワークの草案が作成された。

<sup>&</sup>lt;sup>1</sup> Sonich-Mullin C, Fielder R, Wiltse J, Baetcke K, Dempsey J, Fenner-Crisp P, Grant D, Hartley M, Knaap A, Kroese D, Mangelsdorf I, Meek E, Rice J, Younes M (2001) IPCS conceptual framework for evaluating a mode of action for chemical carcinogenesis. *Regulatory Toxicology and Pharmacology*, **34**:146–152.

ワークショップの参加者は、事務局サポート、欧州食品安全局と欧州化学品局の代表者を含め、 以下の通りである。 Peter Abbott 博士(オーストラリア・ニュージーランド食品基準、科学的リスク評価局、 オーストラリア) Antero Aitio 博士(世界保健機関、国際化学物質安全性計画、スイス) Diana Anderson 博士(ブラッドフォード大学、生物医学科、イギリス) Colin Berry 教授(イギリス) Hermann Bolt 教授(生理学研究所、ドイツ) Alan R. Boobis 教授(インペリアル・カレッジ・ロンドン、健康毒性学部門、英国) Susy Brescia 博士 (イギリス健康安全局、英国) John Bucher 博士(国立環境衛生科学研究所、米国) Vincent Cogliano 博士(国際がん研究機関 発がん物質同定・評価部門、フランス) Samuel M. Cohen 博士(病理学・微生物学、ハヴリック・ウォール腫瘍学教授、ネブラ スカメディカルセンター大学、米国) Vicki Dellarco 博士(環境保護庁、農薬プログラム部、米国) Christine Dove 氏(ブラッドフォード大学 生命科学部、英国) Jun Kanno 博士(独立行政法人国立医薬品食品衛生研究所 細胞分子毒性学研究部門、日 本) Janet Kielhorn 博士(フラウンホーファー毒物実験医学研究所 化学リスク評価部、ドイ ツ Sandra Kunz 氏(世界保健機関、国際化学物質安全性計画、スイス) Christian Laurent 博士 (欧州食品安全機関、科学的専門家サービス、イタリア) Douglas McGregor 博士(毒性評価コンサルタント、英国) Bette Meek 氏(カナダ保健省、環境衛生センター、カナダ) Sharon Munn 氏(欧州化学機関、毒物・化学物質担当、イタリア) Julian Preston 博士(環境保護庁、環境発がん部門国立健康・環境影響研究所、米国) Jerry Rice 博士 (コンサルタント、米国) Hans-Bernhard Richter-Reichhelm 博士(連邦リスク評価研究所(BfR)、ドイツ) Carolyn Vickers 氏(世界保健機関、国際化学物質安全性計画、スイス) Deborah Willcocks 氏(国家工業化学品届出・評価スキーム(NICNAS)既存化学品担当、 オーストラリア) William P. Wood 博士(環境保護庁、リスクアセスメントフォーラム、米国) Zheng Yuxin 博士(労働衛生·毒物管理機関、中華人民共和国疾病管理予防局、WHO 労 働衛生協力センター、中国)

草案はパブリックコメントのためにインターネット上で公開され、ピアレビューのために多く のWHO協力機関とIPCS参加機関に送付された。2005年12月にロンドンで開催された専門家会 議では、寄せられたコメントを検討し、最終的にフレームワークが決定された。専門家会議の参 加者は以下の通りである。

Alan R. Boobis 教授(インペリアル・カレッジ・ロンドン、英国)(報告者)
Samuel M. Cohen 博士(病理学・微生物学、ハヴリック・ウォール腫瘍学教授、ネブラ スカメディカルセンター大学、米国)
Vicki Dellarco 博士(環境保護庁、農薬プログラム部、米国)
William Farland 氏(環境保護庁、研究開発局、米国)(座長)
Douglas McGregor 博士(毒性評価コンサルタント、英国)
Carolyn Vickers 氏(世界保健機関、国際化学物質安全性計画、スイス)
Deborah Willcocks 氏(国家工業化学品届出・評価スキーム(NICNAS)、既存化学品担当、 オーストラリア)

### 貢献者リスト

Colin Berry 名誉教授(クイーン・メアリー、ロンドン、英国)

Hermann Bolt (産業生理研究所、ドイツ)

Alan R. Boobis (実験薬理学・毒性学、医学部、インペリアル・カレッジ・ロンドン、英国)

Vincent Cogliano (国際がん研究機関 発がん物質同定・評価部門、フランス)

Samuel M. Cohen (病理学・微生物学、エプリーがん研究所、ネブラスカメディカルセンター大学、米国)

Vicki Dellarco (環境保護庁、農薬プログラム部、米国)

William Farland (環境保護庁、研究開発局、米国)

Douglas McGregor (毒性評価コンサルタント、英国)

M.E. (Bette) Meek (カナダ保健省、安全環境計画、既存物質部門、カナダ)

R. Julian Preston (環境保護庁、米国)

Hans-Bernhard Richter-Reichhelm (連邦リスク評価研究所 (BfR)、ドイツ)

Carolyn Vickers(世界保健機関、国際化学物質安全性計画、スイス)

Deborah Willcocks (国家工業化学品届出・評価スキーム (NICNAS)、既存化学品担当、オー ストラリア)

# 発がん MOA のヒトへの関連性を解析するための

# IPCS フレームワーク

## Alan R. Boobis, Samuel M. Cohen, Vicki Dellarco, Douglas McGregor, M.E. (Bette) Meek, Carolyn Vickers, Deborah Willcocks, & William Farland

体系化されたフレームワークの利用は、化学物質のリスク評価における調和を促進する上で非常 に重要である。したがって、国際化学物質安全性計画(International Programme on Chemical Safety: IPCS)は、実験的研究で観察された発がん性反応のヒトへの関連性の問題に対処するために、発が ん Mode of Actioin (MOA) フレームワークを更新し、拡張した。第一段階は、MOA を確立する ことが可能かどうかを判断することである。MOA は、Bradford Hill 基準に基づいたエビデンスの 重み付けアプローチを用いて特定された発がんの原因経路に沿った一連の key events で構成され ている。次に、実験動物とヒトの間で key events を定性的に、次に定量的に比較する。最後に、信 頼性、解析的検討及び意義についての明確な報告書が作成される。IPCS 発がん性ヒト関連性フレ ームワークは、データの透明性のある評価、重要なデータギャップの特定及び関連性が排除できな い場合であっても、化合物のさらなるリスク評価において価値のある情報の体系的な提示を可能 にする解析ツールを提供するものである。この価値ある情報には、用量反応曲線の形状に関するデ ータ、閾値の特定及び遺伝的またはライフステージの違いなどに基づいた潜在的に感受性の高い 集団を認知することが含まれる。

過去 30 年間のがんリスク評価の発展の基礎となったのは、がんの生物学的理解の深まりと発が んにおける key events の特定である。1980 年代半ばまでは、ヒトにおけるがんのハザードとリス クに関する国内及び国際的な評価は、主に発がん性のある物質のげっ歯類を用いた生涯試験に依 存していた。後ろ向きがん研究の基礎となるに十分なヒトにおけるエビデンスが存在する薬剤は ほとんどなく、職場や環境における一般的なばく露に対する現代の規制を考えれば、将来的に発 がん性が検出される薬剤はさらに少ないと予想される。げっ歯類を用いた評価において、実験動 物で観察された腫瘍は、潜在的にヒトに対して発がん性を有する物質を特定するために意味のあ る外挿が可能であり、数学的モデルを用いて規制上重要となるヒトにおけるリスクの上限推定値 を提供することができるという前提があった。同時期に、発がんにおいて変異原性が重要な意義 を有する可能性があるということが科学界に受け入れられつつあった。その後、かなりの数の化 学物質が、DNA との直接的な相互作用を伴わないプロセスによって実験動物にがんを引き起こす ことが次第に明らかになってきた。実験動物とヒトの両方における発がんの生物学的基盤に関す る我々の理解を深めることは、発がん性が疑われる薬剤の薬物動態及び薬理作用に関するより多 くのデータを提供することにより、リスク評価の過程を有益なものとした。特定の化合物の発が んに関与する生物学的プロセスを考察することは、Mode of action(以下、MOA)の概念につなが っている。

<sup>&</sup>lt;sup>1</sup> この論文は、WHO が著作権を有するものであり、元々は 2006 年に Critical Reviews in Toxicology, Volume 36, pages 781-792 に掲載されたものです。この論文は WHO の出版物のために編集されたもので、正誤表が含まれています。

#### IPCS Framework for Analysing the Relevance of a Cancer Mode of Action for Humans and Case-Studies

推定される発がん MOA とは、試験で観察された影響につながる生物学的に妥当な key events の 一連の流れであり、堅牢な実験観察とメカニズムデータに裏付けられ、重要な細胞学的及び生化 学的事象、すなわち、観察された発がん性に必要かつ測定可能な事象を論理的なフレームワーク で記述している。MOA は作用機序 (mechanism of action)とは対照的であり、作用騎乗では一般的 に、効果の分子的基盤を十分に理解し、その詳細を記述することで、分子的観点から因果関係を 確立することができる。

2001 年に、リスク評価手法の調和の一環として、国際化学物質安全性計画(International Programme on Chemical Safety: IPCS)(WHO/ILO/UNEP)は、因果関係に関する Bradford Hill 基準 に基づいた実験動物の発がん MOA(動物 MOA)評価のためのフレームワークを発表した。本文 書書で紹介している IPCS ヒト関連性フレームワーク(HRF)は、この MOA フレームワークを更 新し、ヒトとの関連性を考慮するために拡張したものである。これは、化学物質の特定の発がん 性について利用可能なデータを透明性のある方法で体系的に評価する手段を提供する解析ツール である。フレームワークは、規制当局の内外のリスク評価者にとって価値のあるものであると同 時に、研究者にとっても貴重なツールとなることを想定している。フレームワークを利用する理 由には、以下のようなものがある。

- データ解析の一般的なアプローチを提供し、調和の推進に貢献する。
- 利用可能なデータの検討と使用及び導き出された結論の論拠の透明性を促進する。
- データの提示におけるガイダンスを提供する。
- 重要なデータの不足と必要な追加データを特定する。
- ヒトに対する発がん性リスクの定量的評価において情報を提供する。

これら及びその他のトピックについて、以下でより詳細に議論する。

# 発がん MOA のヒトへの関連性を解析するためのフレームワークを開発する上での IPCS の役割

IPCS は、化学物質へのばく露によるリスク評価のアプローチの調和に関するより大きなプロジェクトの一環として、発がんリスク評価への手法を調和させる取り組みを主導してきた。この作業の第一段階では、実験動物における化学物質の発がん MOA を評価するための「IPCS の概念的なフレームワーク」の公表につながった(Sonich-Mullin ら, 2001 年)。この出版物に記載されているように、エビデンスの重み付けを検討する際にみられる調和への障害は、主に動物 MOA の評価であった。Sonich-Mullin ら(2001 年)は、動物における化学物質の発がん MOA を評価するためのフレームワークを提供し、ヒトにおけるがんのハザードとリスクの総合的な判定の次のステップ、すなわち、動物における発がん MOA のヒトへの関連性の評価に進むことの重要性を認識した。MOA フレームワークの概念は、米国環境保護庁(USEPA)発がん物質リスク評価ガイドライン改訂版(USEPA、1999 年、2005 年)に盛り込まれており、MOA フレームワークは現在、他の規制当局や国際機関でも一般的に用いられている。英国では、このフレームワークが農薬や工業用化学物質の評価に利用されている。

英国発がん性委員会(2004年)は、機関間の調和と最新のガイドラインにおける内部の整合性の 両方の点でフレームワークの価値を指摘している。このフレームワークは、オーストラリアの機 関でも採用され、カナダではカナダ環境保護法の下での既存化学物質の評価に用いられている。 欧州連合(EU)は、新規及び既存の工業用化学物質及び殺生物剤のの評価について、発がん性を 含む技術ガイダンス文書に本フレームワークを組み込んでいる。国際機関では、FAO/WHO 合同 残留農薬専門家会議(JMPR)が、例えばピレスリン抽出物の評価やその結果として得られた研究 論文に、このフレームワークを組み入んでいることが。特筆される。

MOA フレームワークを拡張し、ヒトへの関連性の考慮を含めるためのステップは、IPCS が国際的なパートナーと協力して実施されてきた。これは 2005 年 4 月 21 日から 23 日まで英国ブラッドフォードで開催された IPCS の国際ワークショップの議題であった。このワークショップでは、2001 年の MOA フレームワークの更新を含む IPCS HRF の草案が作成された。この草案はパブリックコメントのためにインターネット上で公開され、また、ピアレビューのために多くの WHO 協力機関と PCS 参加機関に送付された。2005 年 12 月にロンドンで開催された専門家会議では、受け取ったコメントが検討され、フレームワークが最終決定された。フレームワークの内容とその発展へとつながるステップについては、以下のセクションで詳述する。

#### 2001年の動物における発がん性評価のための IPCS 概念的 MOA フレームワーク

#### フレームワークの目的

動物における発がん性評価のための IPCS MOA フレームワーク (Sonich-Mullin ら, 2001 年) は 今もなお発がん MOA のヒトとの関連性を解析するための IPCS フレームワークの基本原理とな っている。動物 MOA フレームワークは、発がん性化学物質による動物の腫瘍誘発に対して、想 定される MOA を評価する際に一般的に適用される原則への汎用的アプローチを提供するもので ある。したがって、このフレームワークは想定される MOA に対する総合的なエビデンスの重み 付けの評価に際して体系的なアプローチを提供するツールである。すなわち、この文脈では支持 された MOA は、生物学的に妥当な説明を確立するためにしっかりとした実験的観察とメカニズ ムデータのエビデンスを持つことになる。

このフレームワークは、推定される MOA の解析に透明性をもたらし、その結果、明確にされ た手法(解析と推論を裏付ける明確で一貫性のある文書化を促し、利用可能なデータの矛盾と不 確実性を明らかにする手法)を用いることにより到達した結論の信頼性が増すように設計されて いる。フレームワークの目的は、特定の状況における MOA のエビデンスの重み付けを検討する 体系的な手段を提供することであり、情報が十分か否かに関して絶対的な回答を与えるようには 設計されていない。なぜなら情報は状況によって異なるためである。このフレームワークは基準 のチェックリストではなく、むしろ解析的なアプローチである。しかし、key events 及び腫瘍の発 生に関する比較データの表形式の要約はこのプロセスの大きな助けとなる。

動物 MOA フレームワーク解析は、ハザードの特性評価の重要なステップである。動物 MOA フレームワークは、すべての分野(医薬品、工業用化学物質、農薬、食品添加物など)にわたる発がん化学物質のリスク評価に貢献することが想定されている。

#### IPCS Framework for Analysing the Relevance of a Cancer Mode of Action for Humans and Case-Studies

結果として得られるリスク評価文書では、フレームワーク解析はハザードの特性評価のセクショ ン内に適切に配置されるであろう。適切な疫学データがない場合には、ヒトとの関連性、用量反 応関係、リスクの特性を議論する上で、フレームワーク解析は不可欠な要素とみなされるかもし れない。また、このフレームワークは、データギャップや矛盾の明確な定義に基づいて研究の必 要性を特定する上で規制当局と研究者の双方にとって有用であると考えられる。

MOA 解析は、化合物が以前に記述されている MOA を有すること、または新規の MOA を有す ることを確認するために用いることができる。したがって、MOA 解析の結果は、特定の化合物の 評価に役立つこともあれば、新規の MOA の確立に貢献することもある。前者において、化学物 質に特有のデータが、ヒトへの関連性を考慮した一致解析において重要な役割を果たす。後者に おいては、どのような事象が MOA を表す生物学的プロセスの鍵となるのかを特定することが重 要になる。

このように、同様の一連の key events で構成された MOA は、多くの異なる化合物にも適用でき る可能性がある。ある MOA が特定の発がん作用の原因であることを立証するために必要なエビ デンスは、そのような MOA が初めて提示される場合には重要である。後発の化合物がこの MOA を共有することが発見される場合に、受け入れに対する「障壁」は低くなるが、MOA を構成する key events が発生すること、また、以下に説明する基準を満たしていることを厳密に立証する必要 がある。また、他の可能性のある MOA を除外することも重要である。

科学的な専門家の関与は、新規に想定される MOA の確立と承認のための必要条件である。「専 門家の関与」には、MOA の確立への専門家の関与と、MOA の研究プロセスから独立した科学者 によるピアレビューの両方が含まれる。科学雑誌への発表、科学会議やワークショップでの発表 や議論も、科学界が MOA を受け入れるための「専門家の関与」を意味する。

容認は必ずしも科学者全員が合意したことを意味するわけではないが、容認されたということ は、MOA をレビューした科学者の大部分が、提示された MOA に関して関連する科学的情報が特 定され適切に解析されていること、「key events」が特定され提示された情報によって支持されてい ること、発がんとの関係が仮説の MOA において明確に説明されていること及びその代替 MOA が 検討され、それらが除外されていることに合意したということである。

知識の向上につれて MOA は変化するだろう。追加の key events が特定され、他の事象は見直されるか、あるいは取り除かれるかもしれない。しかしながら、key events に関する大きな変更は、 上記のようなピアレビューを通してある程度一般に認められることも必要である。

#### フレームワークガイドラインの更新

IPCS HRF の発展において、2001 年の動物 MOA フレームワークの内容が更新されたので、その 改訂版を以下に提示する。

## 序文

このセクションでは、観察された発がんエンドポイントまたはその他エンドポイントについて 記述し、これらのうちのどれが解析で扱われているかを特定する。フレームワーク解析に着手す る前に、実験動物における発がん性反応のエビデンスの重み付けを慎重に評価する必要がある。 フレームワークの性質上、一度に1つの MOA のみが解析される。したがって、例えば、化学物 質の投与に関連した異なる種類の腫瘍は、かりに同じ動物で記録されていても、各腫瘍の MOA を 識別するために別々のフレームワーク解析が必要となる。しかしながら、あるひとつの腫瘍の病 態を検討する際には、化学物質が複数の MOA によってそのタイプの腫瘍を誘発する可能性があ ることを認識しておくべきである。したがって、ある化学物質におけるひとつの腫瘍について複 数の MOA の解析を行う必要があるかもしれない。遺伝毒性発がん物質の場合、代謝活性化と解 毒における種や組織特異的な違いと同様に、発がん部位が異なることも多い。動物とヒトのデー タを比較する際にはこのことについて留意する必要がある。対照的に、非遺伝毒性 MOA に則っ て作用するほとんどの発がん物質は、特異的な傾向のある生理学的プロセスに影響を及ぼすとい う観察結果から、少なくとも HRF の初期の前提として、部位の一致が合理的に想定されている。

### 1. 推定される MOA (事例における仮説)

このセクションでは、被験物質において推定される MOA について、腫瘍になるまでの一連の 事象を簡単に説明している。この一連の事象の説明は、次のセクションにつながり、解析に利用 可能なデータベースから、「鍵」と考えられる事象(すなわち、必要かつ測定可能な事象)を特定 する。

#### 2. Key events

このセクションでは、「key events」一推定される MOA において仮定された腫瘍の誘発に極めて 重要な測定可能な事象について簡潔に特定し、説明する。関連性を裏付けるためには、一連の実 験で事象を定義し、それを一貫して測定する必要がある。関連する観察項目には、例えば、同じ 種類の細胞における発がん性と key events、事象に論理的に関連する作用部位、細胞増殖の増加、 特定の生化学的事象、臓器重量や組織学的変化、増殖、ホルモンや他のシグナル伝達系の変動、 受容体-リガンド相互作用、DNA や染色体への影響、細胞周期への影響などが含まれる。例えば、 再生性増殖の延長と関連していると推定される腫瘍の発生における key events は、病理組織学的 検索における細胞毒性の検出と標識指標の上昇であるかもしれない。別の例として、リン酸カル シウムを主成分とする尿固形物の形成が原因であると推定される膀胱腫瘍の誘発の key events に は、尿中の遊離カルシウム、リン酸塩、pH の上昇と尿固形物の形成、それに続く尿路上皮への刺 激及び再生性過形成が含まれる。

#### 3. 用量反応関係の一致性

このセクションでは Bradford Hill 基準の観点から、それぞれの key events と発がんの用量-効果/ 反応関係を特徴づけ、それらの相互関係について議論するべきだろう。理想的には、key events の 発生率の増加の用量依存性と、その後に発生する他の key events の発生率または重症度(病変の 進行など)の増加及び最終的な腫瘍の発生率とを相関させることができるようにすべきである。 Key events と腫瘍の発生率を表形式で比較表示することは、しばしば用量反応性を検討する上で しばしば有用である。複雑なデータセットの場合、これはほぼ必須である。 腫瘍形成に対する用量反応曲線の異なる部分において、生物学的反応(すなわち線量推移)に基本的な相違があるか否かを検討することが重要である(Slikker ら, 2004 年)。もしそうであれば、 用量反応曲線の異なる部分に関連する key events を明らかにし、フレームワーク解析に用いる必要がある。

# 4. 時間的関連性

このセクションでは、それぞれの key events と腫瘍反応の時間的関係の特徴について述べなけ ればならない。腫瘍反応に至る key events を時系列的に明らかにすべきである。key events は腫瘍 の発現前に明らかにしなければならず、互いに時間的な整合性が取れていなければならない。す なわち、時間的関連性についてはデータが想定される MOA を支持しているかどうかを判断する 上で不可欠である。腫瘍と同時に key events が観察された場合(例えば、バイオアッセイの終了時 など)は、時間的関連性の検討には役立たないが、次のセクションに述べる解析に役立てること ができる。多くの場合、時間的関連性についての基準を満たす完全なデータセットは入手できな い。

# 5. 腫瘍反応とkey events との関連性の強さ、一貫性、特異性

このセクションでは、key events、前がん病変及び腫瘍反応を結び付けるエビデンスの重み付け について議論しなければならない。Key events を遮断または低減した場合に、その後の事象または 腫瘍が発生しない、または減少することを示す中止/回復試験は、関連性を検証する上で特に重要 である。デザインが異なることによって未知のバイアスや交絡因子を減少させると考えられるた め、異なる実験デザインの研究において一貫した結果が観察されることは、key events と腫瘍の関 連性をより強く裏付けることになる。しかし、さまざまな研究で推定される MOA の key events の 再現性で示される一貫性 (consistency) は、より広範なデータベースでの結果と推定 MOA の相関 性で示される整合性 (coherence) とは区別される (6 参照)。関連する観察項目には、同じ種類の 細胞における腫瘍反応と key events、事象に論理的に関連する作用部位並びに多段階試験及び中止 /回復試験の結果が含まれる。

# 6. 生物学的妥当性及び整合性

その MOA が、一般的にがんの発生について一般的に知られていることと一致している(生物 学的に妥当である)かどうか、また、その物質について知られていることと関連している(理論 的な整合性がある)かどうかを検討しなければならない。推定される MOA とその一部である事 象が生物学的に妥当であるとするためには、それらが現在のがんについての生物学的理解と一致 している必要がある。しかしながら、我々の知識には限りがあるために生物学的妥当性について エビデンスの重み付けを評価する際の基準として用いることができる範囲は限られているであろ う。推定される MOA とより広範なデータベースの観測値との関係 ―例えば、発がん MOA と他 のエンドポイントの MOA との関連性―を扱う「整合性」は、異なる研究における推定される発 がん MOA における key events の再現性を扱う「一貫性」(ポイント5参照)とは区別される必要 がある。理論的な整合性については、構造的アナログにおける事例との類似性が参考になるかも しれない(すなわち、構造-活性解析)。推定される MOA を共有する他の化合物からの情報、たと えば、感度における性差、種差及び系統差や key events との関係に関するような情報は重要とな るだろう。さらに、このセクションでは、その薬剤に関するデータベースが内部で一貫して関連 している発がん以外の毒性を含めた MOA を支持しているかどうかを検討しなければならない。 MOA の中には、発がんにつながるホルモン障害による生殖への影響のような、発がん以外の影響 を引き起こすことが予想されるものがある。

## 7. その他のMOA

このセクションでは、事例の中で論理的に提示された代替 MOA について議論する。代替 MOA が支持されている場合は、それ自体のフレームワーク解析が必要である。これら代替 MOA は観察された影響に寄与していると考えられる推定される MOA の追加的な構成要素とは区別し、異なる独立した MOA として解析しなければならない。さもなくば、代替 MOA ではなく、元々の解析の対象であった MOA に関する解析になってしまう。

## 8. 不確実性、矛盾、データギャップ

不確実性には、腫瘍発生の生物学的知見に関連するものと、対象の化合物のデータベースに関 連するものの両方を含まなければならない。矛盾点にはフラグを立て、データギャップについて 特定しなければならない。特定されたデータギャップについては、推定される MOA の裏付けと して重要か否かを示すべきである。

## 9. 推定される MOA の評価

このセクションには、推定される MOA の信頼度を示す指標と共に(例えば、高、中、低など) 結果に関する明確な記述を含まなければならない。新規の MOA が推定されている場合は、新規 であることを明確に示すべきである。しかし、MOA が他の化合物について提示されているものと 同じである場合には、key events がこの MOA にどの程度合致しているかを明示する必要がある。 大きな違いがあれば、それを明記し、MOA に対するその違いの意味合いについて議論すべきであ る。

## ヒトへの関連性の問題

2000 年に、英国のカーシャルトンで IPCS ハーモナイゼーションプロジェクトがん計画ワーキ ンググループが招集された(IPCS、2000 年)(この最初の IPCS ワーキンググループは、ヒト関連 性プロジェクトの作業のために招集されたその後の IPCS ワーキンググループとはメンバーが異 なっていた)。この会議において、ヒトへの関連性への対応に向けて IPCS MOA フレームワークの 拡張を IPCS と国際生命科学研究機構(ILSI)が協力して並行して進めていくことが提案された。 ILSI は技術ワークショップにおいて多くの支援を提供できることが認識された。2001 年 6 月、 ILSI リスクサイエンス研究所(RSI)は、USEPA とカナダ保健省の支援を受けて、動物における 腫瘍とヒトとの関連性を判断するための MOA 情報の使用における重要な問題を検討するための ワーキンググループを結成した。これらの努力の結果、以下に記載されているいくつかの報告書 が公表された。2004 年 3 月 3 日から 5 日に米国バージニア州アーリントンで開催された IPCS が んワーキンググループは、これらの報告書を出発点として、規制目的やその他の目的で MOA 情 報をリスク評価に使用するための統一的な IPCS HRF を作成することを目標に、動物における腫 瘍のヒトへの関連性の問題を IPCS がさらに調査することに合意した(IPCS、2004 年)。

動物で決定された MOA のヒトへの関連性の問題に対処するために、ILSI/RSI は同ワーキング グループに、動物で決定された発がん MOA のヒトへの関連性の評価を含めるために IPCS MOA フレームワークを拡張することを求めた。このプロセス、事例研究及びフレームワークの詳細は、 Critical Reviews in Toxicology 誌の 2003 年 11 月号に一連の論文として発表された(Cohen ら, 2003 年)。これらの論文では ILSI/RSI HRF を説明し、その適用のための指針を提供している。さらに、 フレームワークが基づいた具体的な例への参照も含まれている。統合フレームワークを開発する ために、一般的によく知られている MOA を有する化学物質を複数回にわたって繰り返し検討し た事例研究が使用された。その意図は、動物での MOA と各 key event についてヒトへの関連性を

#### IPCS Framework for Analysing the Relevance of a Cancer Mode of Action for Humans and Case-Studies

評価する規律ある透明なプロセスの指針を提供することであった。

ILSI/RSI HRF は3つの基本的な問いかけに基づいている:

- 1. 動物における Mode of action (動物 MOA) を確立するのにエビデンスの重み付けは十分か?
- 2. 動物の MOA に含まれる key events はヒトにおいて妥当であるか?
- 3. 動態的、薬力学的要因を考慮した上でも、動物の MOA における key events はヒトにおいて妥当か?

問 2 と 3 に関して、動物の MOA とその key events に関連したヒトでの情報の一致解析において、それぞれ定性的な検討と定量的な検討が必要となる。

これらに続いて、ILSI/RSI HRF は評価の信頼性、特異的なデータギャップの特定、それらのリ スク評価の意味合いを明確に記述している。ILSI/RSI では、このフレームワークの利用が全体的 なリスク評価プロセスのハザードの特性評価ステップの一部を形成することを強調した。

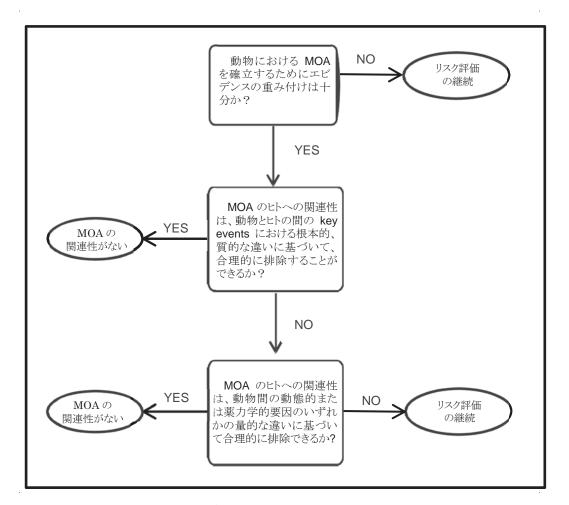

#### IPCS MOA フレームワークと ILSI/RSI HRF に基づく IPCS HRF ガイダンス文書の開発

2004年の IPCS がんワーキンググループでは、ヒトへの関連性に対処するために IPCS MOA フレームワークを拡張する作業の報告書として作成される文書のタイプについて議論された。規制 当局や他のリスク評価機関による採用と利用を促進するためには、全体を一つに統合されたガイ ダンス文書が必要であると認識された。ガイダンスは、発行論文や事例研究といったプロセスを 経て作成された他の公表資料を追加することができる。

ワーキンググループのメンバー間では、ILSI/RSI HRF の重要な構成要素として特定された問い かけは重要であり、動物で決定された MOA のヒトへの関連性に対処するのに適切であるという 点で概ね合意されていた。しかし、フレームワークの補足説明、進展、または拡大が有効と思わ れるいくつかの課題が明らかとなった。

ILSI/RSI HRF のこれらの改良は IPCS がんワーキンググループの議論と、2005 年 4 月 21 日から 23 日に英国ブラッドフォードで開催されたワークショップでの議論を経て進められた(IPCS、 2005 年)。結果として得られた IPCS HRF は、動物の腫瘍における MOA のヒトへの関連性に関す る文書化された論理的な結論へとつながる一連の 3 つの問いかけに答えるためのアプローチとし て提示されている。このガイダンスを適用すると、リスク評価のハザードの特性評価に組み入れ ることができる 4 つのセクションからなるストーリーができあがる。これらのセクションは以下 の通りである(図1を参照)。

- 1. 動物における Mode of action (動物 MOA) を立証するためにエビデンスの重み付けは十分か?
- 2. 実験動物とヒトとの間の key events の根本的、質的な違いに基づいて、MOA のヒトへの関連性 を合理的に排除できるか?
- 3. 実験動物とヒトとの間の動態的または薬力学的要因のいずれかの量的な違いに基づいて、MOA のヒトへの関連性を合理的に排除できるか?
- 4. 結論:信頼性、解析的検討及び帰結の記述。

# 図 1. IPCS の一般的なスキーム:腫瘍形成に対する動物 MOA のヒトへの関連性を評価す る際の主なステップを示す

質問は、Yes か No かを明確に答えられるように設計されているが、エビデンスの重み付けが十分 であるかどうかを判断する必要がある。図の左側に示された回答は、エビデンスに十分な重みがあ り MOA がヒトに関連するとは考えられないことを示している。図の右側の回答は、MOA がヒト に関連する可能性が高いと考えられるという十分に重みのあるエビデンスの存在を示しているか、 利用可能な情報に不確実性があるため、ヒトへの関連性の可能性についての結論を出すことができ ないことを示している。このような場合、評価はリスクの判定に進むことになる。この段階でのみ、 ヒトへのばく露評価が含まれることに留意すべきである。

このフレームワークをある化学物質に適用する場合、観察された各動物の標的臓器の腫瘍は、 異なる臓器では異なる MOA が存在しうるという仮定の下、独立して評価される。しかし、この 解析手法に基づいたとしても、異なる組織での MOA が類似している可能性はある。同様に、異 なる種とヒトにおいて、標的臓器における MOA が一致する可能性についての評価も MOA 解析 に基づいて行う必要がある。

# 動物における Mode of action (動物 MOA)を確立するのにエビデンスの重み付けは十分か

IPCS HRF のこの最初の問いかけに答えるためには、上述の(更新された) IPCS MOA フレーム ワークを適用する必要がある。因果関係を説明するための Bradford Hill 基準に基づいた MOA フ レームワークのステップは、次のとおりである:

- 1. 推定される MOA
- 2. Key events; 関連する重要なパラメータ
- 3. 用量反応関係
- 4. 時間的関連性
- 5. Key events と腫瘍反応との関連の強さ、一貫性、特異性
- 6. 生物学的妥当性と整合性
- 7. 可能性のある代替 MOA
- 8. 不確実なこと、矛盾すること及びデータギャップ
- 9. MOA に関する結論

このプロセスには、状況に応じた考え得る代替 MOA のエビデンスの重み付けの評価と、検討 中の MOA を支持するエビデンスの全体的な強度の評価が組み込まれている。最終的には、MOA を支持するエビデンスの重み付けと、それに対する信頼度について決定しなければならない。ま た、このプロセスは、ギャップを満たすことで推定される MOA の信頼性を高めるであろう決定 的に重要なデータギャップを特定する。また、推定される MOA が他の化学物質において既に記 述された MOA であり、ヒトへの関連性について既に評価されているかどうか、または、新規の MOA であり、ヒトへの関連性について新たに評価する必要があるかどうかを確認することも必要 である。

ある化学物質について、MOA を評価するための主な情報源は、腫瘍が発生した動物モデルにお けるデータである可能性が高い。当然、類似の化学構造を持つ化学物質に関するデータや、同じ または類似の MOA に関するデータ、もしくはその両方のデータといった他の情報源からのデー タも必要に応じて利用することができるし、利用すべきである。ある化学物質の MOA が新規で ある場合、その化学物質が誘発された腫瘍の発がんプロセスに関連しているという結論を裏付け るためには、同じ MOA で作用する後続の化学物質よりもかなり多くのデータが必要である。 ILSI/RSI ワーキンググループと IPCS ブラッドフォードワークショップでは、対象の化学物質の MOA を支持するのに十分なデータの数はどのくらいかという問題に関して、事例研究の中で例を 示し、新しい MOA を受け入れるには科学的コンセンサスが必要であるとの認識(上述)を示し てはいるが、それら以外についての方針等は何ら表明していない。この段階における動物とヒト との間の潜在的な違いについての MOA 解析の検討は、フレームワークにおける次のステップの 対応を容易にする。

# 実験動物ととトとの間の key events の根本的、質的な違いに基づいて、MOA のとトとの関連性を合理的に排除することができるか

この質問の文言は、IPCS ワークショップにおける質問に対する回答の意味合いについての議論 を受けて、ILSI/RSI HRF に記載されていた文言から変更された。元の質問への回答では、動物 MOA がヒトへの関連性を持たないという結論を出すには、はっきりとした「No」しか許容されていな かった。また、「plausible」という単語が他の言語に翻訳する際に問題になる可能性があることも 認識された。そのため、質問は Yes/No の回答を可能にするように書き換えられたが、エビデンスの重み付けの妥当性に関する決定は絶対的なものではなく、利用可能なデータの透明性のある解析に基づいた科学的判断が必要であるという認識に基づき、「合理的に」という語句が付け加えられた。

このステップでは、ヒトにおける発がんの可能性と MOA の関連性を定性的に評価することで ある。動物 MOA で発生する重要な特定の key events をリストアップし、それぞれの key events が ヒトで発生するか否かを直接評価することで、関連する情報の検討と透明性のある提示が容易に なる。一致表 (concordance table) と呼ばれる表形式での提示は、関連情報を明確にするのに役立 つ (例として、事例研究 6:クロロホルムばく露に伴う腎臓及び肝臓の腫瘍、Meek ら、2003 年、表 7;本書、ホルムアルデヒドに関する事例研究、McGregor ら、表 3 を参照)。腫瘍が観察された動 物におけるこれらの事象に関する情報とともに、key events (及び重要と思われるいくつかの関連 プロセス) がリストアップされる。これらの表の情報は簡潔にすることが意図されており、表に は説明文が添付されることが予想される。右側の列では、各 key events についてヒトへの影響を 評価している。追加の列として、腫瘍が発生しない別の系統、種、性、または投与経路での結果 についての情報は、腫瘍が発生するモデルとの比較情報が得られる場合に有用である。さらに、 それ自体は key events ではないが、key events を変化させ、種差または個体差に寄与する因子が同 定されることがある。そのような因子には、代謝経路の遺伝的差異、競合する代謝経路及び同時 進行する病態によって誘導される細胞増殖が含まれる。特定されたそのような要因はすべて、一 致表の脚注に記載されるべきである。

ヒトにおけるある化合物の MOA の key events の一致性の評価は、その特定の化学物質の評価と いうよりは、ヒトにおける MOA の評価である。一般的に、初期の key events の詳細は化学物質に 特異的である可能性が高い。例えば、げっ歯類の肝臓におけるフェノバルビタールによる酵素誘 導反応や、特定のチトクローム P-450 酵素によるクロロホルムからの細胞毒性代謝物の生成など である。その後の事象は MOA においてより一般的なものであり、例えば、多面的な肝増殖刺激 や再生性過形成などである。ヒトにおける key events の評価に利用できる情報は、化学物質の in vitro 及び in vivo 試験に由来するもののほか、解剖学、生理学、内分泌学、遺伝学、疫学、その他 ヒトの key events に関する既知の情報などの基本的な情報が含まれる。特定の化学物質に直接ば く露されたヒトにおける key events の評価に関する情報は、入手できないことが多い。

がんの発生・進行に関する知見が蓄積されるにつれて、関与するプロセスの基本的な生物学的 知見に基づいていくつかの MOA を組み合わせることが可能になるかもしれない。それにより、 MOA のヒトへの関連性について結論付ける際に、その化学物質の特異的な情報への依存度が低く なるかもしれない。

20

ヒトの情報と動物の情報との一致性を評価する際には、エビデンスの重み付けを説明し、ヒト の情報の信頼度の評価をする必要がある。有用な情報の具体的な種類としては、以下のようなも のがある。

- 1. 対象の解剖学的部位及び細胞の種類におけるがんの発生率:年齢、性別、人種及び化学物質や その他の環境因子などのリスク因子を含む。
- 2. 標的部位の性質と機能に関する知見:生理的、細胞的、生化学的レベルでの発生、構造(肉眼 的、顕微鏡的)、制御機構を含む。
- 3. ヒト及び動物の疾患状態:標的臓器の調節及び応答性に関する洞察を提供する。
- 短期、中期、または長期ばく露後の、対象となる化学物質または類似物質に対するヒト及び動物の反応:標的臓器及び影響を含む。

当然、対象の MOA がヒトに関連していないと結論づけるには、相当量の情報が必要である。 そのような結論がデータによって強く支持されているならば、その MOA によってのみ動物の腫 瘍を誘発される化学物質は、ヒトに対するがんに関するハザードを有さず、このエンドポイント に対するリスク判定を追加で行う必要はない。がんに関するハザードがないため、検討中の腫瘍 に対する発がんリスクはない。

関連性の質問は、すべての集団とライフステージを考慮している。MOA が作用する状況は、例 えばすでにウイルスに感染しているヒト、ホルモンバランスの不均衡のあるヒト、または病を患 っているヒトなど、主に感受性の高い集団またはライフステージで起こる可能性がある。ライフ ステージの早期における発達に関する様々な動態的及び薬力学的側面を考慮して、腫瘍がライフ ステージの早期におけるばく露から発生するかどうかに特別な注意が払われている。感受性の量 的な違いを示唆するいかなる情報も、リスク判定に用いるために特定される。

# 実験動物ととトとの間の動態的または薬力学的要因のいずれかの量的差異に基づいて、 MOAのとトへの関連性を合理的に排除することができるか

この質問の文言は、IPCS ワークショップにおける質問に対する回答の意味合いについての議論 を受けて、ILSI/RSI HRF に記載されていた文言から変更された。元の質問への回答では、動物 MOA がヒトへの関連性を持たないという結論を出すには、はっきりとした「No」しか許容されていな かった。そのため、質問は Yes/No の回答を可能にするように書き換えられたが、エビデンスの重 み付けの妥当性に関する決定は絶対的なものではなく、利用可能なデータの透明性のある解析に 基づいた科学的判断が必要であるという認識に基づき、「合理的に」という語句が付け加えられた。

ヒトへの関連性解析の目的では、実験動物の MOA がヒトに定性的に関連性があると判断され る場合には、実験動物とヒトの両方から得られるあらゆる動態的及び薬力学的情報を考慮して、 より定量的な評価が必要である。このようなデータは、必然的に化学物質及び MOA に特有のも のであり、腫瘍形成を起こしうる薬力学的反応を引き起こすために必要な生物学的影響を及ぼす 用量を含むものである。動態的考察には、化学物質の取り込み、分布、代謝及び排泄の性質及び 経時的変化が含まれ、一方、薬力学的考察には、化学物質と細胞、組織及び器官との相互作用の 結果が含まれる。 時折、これらの条件を作り出すために必要とされる生物学的に影響を及ぼす用量が、ヒトにおい て不可能であることがある。また、ホルモンのクリアランスなど key events に関与する生物学的 プロセスにおける定量的な違いが大きすぎるため、動物の MOA がヒトには関連しないというこ ともあり得る。しかし、量的な差異に基づいて MOA のヒトへの関連性を否定することが可能に なるのは、ごくまれであると IPCS ワークショップでは認識されている。定性評価と同様に、実験 動物とヒトの定量データを表形式で比較することで、評価を容易にすることができる(例えば、 事例研究 5、フェノバルビタールばく露に伴う甲状腺腫瘍、Meek ら、2003 年、表 6;チアゾピル に関する事例研究、Dellarco ら、本書、表 4 参照)。同様の MOA によって効果を誘導すると考え られている他の化合物の研究から同定された key events との比較も有用である。例えば、チアゾ ピルの場合、ヒトにおけるフェノバルビタールの効果に関する情報は、MOA の関連性を評価する 上で特に有用であった。分子学的及び動態学的アプローチが進化し続けるにつれ、動物及びヒト における反応の類似性及び相違点の理解が向上するであろう。動物モデルとヒトとの間の key events における定性的な違いが、特定の定量的な違いによるものであることが明らかになるかも しれない。その場合、第 2 の問いかけ(上述)への回答を「No」に変更する。

問2と同様に、この問いかけへの結論が「Yes」であれば、その MOA によってのみ動物に腫瘍 を誘発させる化学物質はヒトにがんに関するハザードをもたらさず、このエンドポイントにおけ る追加のリスク判定は必要ない。

#### 信頼性、解析及び帰結の記述

3つの問いかけのそれぞれの総合評価に続いて、解析の基礎となるデータの質と量、フレームワ ーク内での解析の一貫性、データベースの一貫性、一致解析の性質と程度についての信頼性につ いての記述が必要である。また、同等の解析法や厳密な評価を用いた代替的な MOAs の評価も不 可欠である。全体的な MOA と質的・量的一致のエビデンスの重み付けを十分に考慮し、その結 果として、MOA の信頼性を高めることができる将来の研究で実験的に特異的なデータギャップを 特定することが極めて重要である。

まれに、検討中の化合物と共通する MOA を有する化学物質の発がんリスクに関する決定的な 疫学的データ、すなわち、その化合物がヒトに発がん性を有するか否かのデータが存在すること がある。当然、そのようなデータは、ヒトへの関連性評価の結論にかなりの重みを与えるであろ う。しかし、動物では MOA を確立することが可能であるにもかかわらず、ヒトでの key events に 関する情報が不十分であり、ヒトへの関連性について明確な結論を出すことができない場合があ る。そのような場合には、疫学データを利用することで、このデータギャップを埋めることがで きるかもしれない。例えば、構成的活性化受容体(CAR)の活性化を介してフェノバルビタール と同様の作用をして肝腫瘍を誘発する化合物のヒトでの key events に関するデータベースは不完 全である。しかし、比較的高用量のフェノバルビタールに長期間ばく露しても、ヒトでは発がん しないことを示す確固たる疫学的データがある。したがって、1 つの可能性としては、これらのフ ェノバルビタールに関する知見から、げっ歯類に肝腫瘍を誘導する動物 MOA を共有する他の化 合物について「類推」し、そのような化合物によって引き起こされる腫瘍は、ヒトにおける化合 物のリスク評価には関係ないと結論づけることである(Holsapple ら、2006 年)。

22

このような結論は、疫学的データの信頼性及び試験対象の化学物質の MOA と疫学的データが利用可能な化合物の MOA との類似性に極めて依存している。

このフレームワークを事例研究に適用すると、現在の研究の多くは、動物 MOA の解析及びヒトとの関連性の解析を容易にするような重要な問いに対処していないことは明らかである。多くの場合、このことは、ここで紹介したような解析フレームワークでのデータの検討に基づいて、主要なデータギャップを透明性をもって記述していないことが原因である。このように、HRF を用いることは試験設計の初期段階から研究者にとって非常に有益である。

統一された形式のヒト関連性解析の結果は、動物のエンドポイントがヒトに関連するかどうか を判断するだけでなく、それ以上に有用な情報を提供してくれる。むしろ、透明性のある解析的 フレームワークの中で関連情報を検討することで、関連する影響のリスク判定における次の段階 で多くの極めて重要な追加情報が提供される。推定される関連影響に関する MOA のヒト関連性 解析に基づくことで、例えば、動物で観察された腫瘍がヒトにおいて発生部位が一致するかどう かを予測することが可能である。また、HRF を適用することで、B型肝炎やアフラトキシン B<sub>1</sub>な どのように、リスクに影響を与える可能性のある関連する調節因子に関する情報が得られること が多い (4- Aminobiphenyl に関する事例研究、Cohen ら、本書を参照)。解析はまた、推定される MOA の構成要素のうち、一定の用量以上でのみ作用する可能性のあるものについての指標を提供 することが多い。MOA に必須なステップを引き起こすために対象の化合物の実験的高用量のばく 露が必要とされる場合、ヒトのリスクとの関連性はばく露の問題となる。このように、その後の リスク判定におけるばく露評価ステップは、ヒトでの発がん性を適切に評価するために重要であ る。さらに、フレームワーク解析で特定された情報は、MOA の key events に基づくハザードの定 量化において非常に貴重なものとなりうる。

重要なことだが、ヒト関連性解析は、リスクが増大している特別な集団(遺伝的素因を持つ集団など)を特定することにも寄与し、しばしば、様々なライフステージにおける相対リスクの検討に関連する情報を提供してくれる。場合によっては、これは化学物質固有の情報に基づくのではなく、特定の年齢層のリスクが増加しているか減少しているかについて、MOAの知識に基づいている場合もある。

フレームワークを用いたデータ及びその解析は、透明性のある方法で報告され、他の者が key events、他の MOA の除外及びヒトとの関連性の解析に関して到達した結論の根拠を判断できるよ うにすべきである。具体的な提示形式は利用可能なデータの種類によって異なるため、情報がど のように報告されるべきかを規定することに意味はない。しかし、到達した結論の透明性を確保 するために、文脈や考察のプロセスに関して十分な詳細情報が含まれていなければならない。実 験動物とヒトにおける key events の比較解析など、特定のデータを提示する際には、適切な表を 使用することが有用である。

## フレームワークの普及

IPCS HRF の普及と適用を支援するために、一般的に受け入れられている MOA と有益な事例の データベースを構築し、維持する必要がある。これは、類似の MOAs で作用する可能性のある化 合物のフレームワーク解析を進めている人が参照できるよう一連の MOAs とそれに関連した key events で構成されている。事例研究は、実際の事例で構成されており、それらは発がん性反応を引 き起こす推定 MOA の受入れを支持するために必要な解析の詳細の関連度とエビデンスの重み付 けの性質を示すために、フレームワークを用いて解析されている。そのような事例研究は、新し い MOA を開発する初期段階では特に貴重であろう。

#### DNA 反応性発がん物質への IPCS HRF の適用

げっ歯類とヒトの発がんプロセスに類似性があり、DNA 反応性発がん物質による DNA との初 期相互作用が類似しているため、一般的に DNA 反応性発がん物質は、エチレンオキサイドの場合 (Meek ら、2003 年)のように ILSI/RSI HRF の「動物の MOA の key events はヒトで起こりうる」 という質問に対し「Yes」のステップに進むと評価され、IPCS HRF における上記質問に相当する 「実験動物とヒトとの間の key evants の根本的、質的な違いに基づいて、MOA のヒトとの関連性 を合理的に排除することができるか」の質問に対し 4-Aminobiphenyl の場合(Cohen ら、本書) 「No」のステップへと進むと評価されると予想される。最近の論文では、Preston & Williams (2005 年)は、DNA 反応性発がん物質に対する ILSI/RSI HRF の使用の指針となる腫瘍発生の key events のセットを提示した。この指針は、ほとんどの DNA 反応性化学物質について、動物 MOA はヒト に関連すると予測されるという見解を支持した。しかし、例外がある可能性があり、ILSI/RSI HRF はこれらを特定するための貴重なツールになるとも指摘された。ILSI/RSI HRF と IPCS HRF を使 用することは、ヒトへのリスクを外挿する際に価値があるであろうげっ歯類とヒトの間の key eventsの違いを定量化するのにも役立つ。国際がん研究機関(IARC)のレビュープロセスで判断 されたように、すべてのげっ歯類における DNA 反応性発がん物質がヒトの発がん物質であると 確立されているわけではない。これらの例外のいくつかについては、発がん性におけるこのヒト-げっ歯類間の違いは、ヒトがその化合物へのばく露量が少ないこと、または低ばく露レベルでの 発がん性を検出する疫学研究の相対的な感度の低さに起因している。しかしながら、このような 違いの理由は他にも生物学的考察に基づくものがある。例えば、DNA 反応性発がん物質が種特異 的な器官でのみ腫瘍を誘発する場合、MOA に関する利用可能なデータを考慮する必要があるが、 この key events に基づく動物 MOA はヒトには関連がない可能性もある。同様に、ヒトではげっ歯 類と比較して一般的に DNA 修復プロセスが発達している (Cortopassi & Wang、1996 年; Hanawalt、 2001 年)、あるいはげっ歯類に特有の生体内活性化の経路があることから、IPCS HRF における「実 験動物とヒトの間の key events の根本的、質的な違いに基づいて、MOA のヒトとの関連性は合理 的に排除できるか」及び/または「実験動物とヒトの間の動態的または薬力学的な要因のいずれ かの量的な違いに基づいて、MOA のヒトとの関連性は合理的に排除できるか」という問いに対し 「Yes」のステップへと進む可能性がある。あるいは、IPCS HRF はこれらのプロセスに関するそ の後のリスク判定の段階で利用可能な定量的な情報を提供しうる。

DNA 反応性発がん物質に IPCS HRF を適用する際に必要なことは、発がん過程を明確に説明する一連の key events を開発し、検討中の DNA 反応性発がん物質に対するげっ歯類における発がん MOA のヒトへの関連性を確立するための指針としてこれらを使用することである。

#### **IPCS HRF** 及びリスク評価

このフレームワークの強みは、柔軟性、あらゆる MOA によって作用する発がん物質への広範 な適用性及び発がん性反応における各 key event の影響を探索する能力といった点である。これに は、用量反応曲線の性質の決定、個々の key event の閾値の存在の特定やその値の特定及びそれら の腫瘍の反応曲線全体への影響の特定が含まれる。さらに、各 key event に関与する動態的及び薬 力学的な因子を考慮することで、特定の集団、例えば、幼若な人々、特定の疾患を持つ人々、ま たは特定の遺伝子多型を持つ人々に対する発がん性反応の関連性の有無に関する結論に到達する ことが可能になるかもしれない。あるいは、フレームワークを適用することで、そのようなグル ープ間の違いに関する定量的な情報を得ることができる。フレームワークの適用はまた、発がん 性反応自体がヒトには関連性がないと結論づけられた場合でも、化学物質のリスク評価に概ね有 益なものになりうる。

冒頭で述べたように、MOA 解析とヒトへの関連性の解析は、リスク評価におけるハザードの特定と特性評価の段階の一側面である(National Research Council、1983 年; Meek ら、2003 年)。このフレームワークに沿って、本文書で言及しているヒトへの関連性に関する事例研究は、完全なものではないが、研究対象の化学物質のリスク評価に貢献する。これは、完全なリスク評価を行うためには、実験的研究や職業衛生研究で設定された範囲の用量を評価するだけでなく、日常生活や生涯の活動における対象化学物質のヒトへのばく露レベルへの外挿を必要とするからである。

ハザードの特性評価及び関連する MOA 解析は、一般的な用語で危害の可能性を扱うのに対し、 完全なリスク評価は、意思決定者に対してこの潜在的なハザードをばく露に関する文脈で説明す るものである。リスク評価は、一般的に低用量レベルで被ばくしているヒトにおける影響の性質 と発生する可能性を理解し、推定するために、これらの影響とヒトへのばく露量との関係を記述 しようとするものである。

用量反応関係を理解することは、ハザードの特性評価に大きな影響を及ぼす可能性があるため、 MOA 解析の重要な要素であり、生物学的に非線形的なプロセスや種間における閾値の差が内在し ている場合には特に重要な要素である。同様に、用量に関連したハザードを定量化することは、 生物学的理解と整合性のある外部モデルを提示することで、リスク評価のプロセスに役立つ。

これらの一般的に低いヒトばく露レベルを推定することは、リスク評価におけるばく露解析の 課題である。これには通常、環境媒体、動植物組織、薬物動態モデルから得られたデータの広範 な解析が含まれる。このプロセスはまた、ヒトの活動パターン、ライフステージや生活様式とい ったばく露をもたらす可能性のある要因の解析にも依存する。 理想は、この情報に基づいて懸念される集団を特定するために、異なる集団(男性、女性、子供、 乳幼児、民族性や職業などに基づく特別な集団)を対象としたそれぞれのばく露量の範囲に関す るシナリオが作成されることである。その大部分がフレームワーク解析に含まれているハザード の特性評価には定量化(用量反応解析)が含まれているが、外部ばく露量の推定及びこれらの推 定ばく露量におけるハザードの説明は、リスク評価に含まれるその次のステップにおいて行われ る。例えば、メラミンの場合(事例研究7、Meek ら、2003年)では、動物の MOA はヒトとの関 連性が高いと結論づけられた。しかし、膀胱がんの形成は非常に高用量でしか起こらないという 認識により、リスク評価、ばく露評価、リスク判定の次の段階へと解析が進められた。リスク評 価全体として、メラミンのヒトへのばく露は膀胱がんの発生に必要なレベルを大きく下回るとい う評価が下された。

## 結論

この IPCS HRF は、2001 年の IPCS MOA フレームワークから得られた経験と 2003 年の ILSI/RSI ヒト発がん性関連フレームワークの検討に基づいて作成された。これらのフレームワークにおけ る概念の多くが採用されているが、明確性を向上させ、これまで考慮されていなかった要素(例 えば、感受性の高い集団)を導入するために、多くの変更が加えられている。ハザードの特性評 価及び全体的なリスク評価/判定のフレームワークにおける解析ツールとしてのフレームワークの 有用性と役割、すなわちヒトへの関連性と用量反応性の外挿に役立つことが強調されている。こ のフレームワークの開発から得られた、多くの要点と結論は以下のとおりである。

- 1. フレームワーク解析に着手する前に、実験動物における発がん性反応のエビデンスの重み付け を慎重に評価する必要がある。
- 2. 専門家の関与及び第三者によるレビューは、新しい MOA が一般に受け入れられるため、また、 科学的な正当性を得るための必須条件である。
- 3. フレームワークは、DNA 反応性を含むすべての発がん MOA に適用できる。
- ほとんどの DNA 反応性発がん物質についてはヒトへの関連性が想定されると思われるが、ヒ ト関連性解析は、理解を深め、ハザードとリスクの特性評価/判定を改善し、例外を特定するた めの重要なアプローチである。
- 5. 新規の MOA を介して作用する可能性のある化学物質を扱う場合、解析はその化学物質に焦点 を当て、HRF を介して詳細な評価を行うことが必要となる。しかし、ある化学物質が他の化学 物質において既に確立され、専門家のピアレビューを経た MOA と一致した腫瘍反応をもたら す場合、解析は確立されている MOA と、その化学物質がその MOA の一連の流れにおいて確 立されている key events と同じ key events を介して発がん作用を生み出すか否かに焦点を当て て行われる。
- 6. 実験動物で発見された腫瘍反応のヒトへの関連性を評価する場合、key events の一致解析は MOA に対するものであり、必ずしも化学物質に焦点を当てた評価ではない。発がんプロセス に関連する化学物質特有の情報や化学物質一般の情報は、解析において貴重なものとなり得る。 知識の進歩に伴い、MOA は化学物質特有のものではなくなり、関連する重要な生物学的プロ セスにより一層依拠することとなり、それにより、ある化合物におけるヒトとの関連性を別の 化合物へと一般化することが可能になるであろう。

- 7. Key events の生物学的理解と生体における重要性は、発がんリスクの用量反応性の外挿性に関する解解析に情報を提供することができる。そのため MOA の理解はハザードとリスクの判定に大きな影響を与えうる。特に非線形性のプロセスや種間の閾値の差が、関連する生物学的性質に内在する場合に顕著である。
- 8. 一般的に受け入れられている MOA と有益な事例研究のデータベースを構築し、維持すること が推奨される。このデータベースは、ILSI/RSI 及び IPCS によって行われた既存の事例研究に 加え、フレームワーク解析の適用において有益な事例を提供するものでなければならない。こ のデータベースは、発がん物質の MOA の研究において知見が蓄積し続ける中で特に重要であ る。
- 9. 解析において、潜在的に感受性の高い集団やさまざまなライフステージを考慮することが重要 である。

結論として、IPCS HRF は、推定される化学物質の発がん MOA をデータが裏付けるかどうかを 判断し、ヒトへの関連性を評価するための厳格で透明性のあるアプローチを提供している。科学 界において発がんリスク評価における作用機序に関する情報の利用を増やす手段として、このア プローチを利用し、フィードバックを行うことが奨励されており、このことが将来的な更なる改 良につながるだろう。このフレームワークは、発がんプロセスの理解を深め、重要なデータギャ ップを特定し、MOA に関連した研究の設計に有益な情報をもたらすという点で、リスク評価と研 究の両方のコミュニティにとって価値がある。発がん反応がヒトに関連する可能性があると考え られる場合、解析中に key events について得られた情報は、その後の化合物のハザードの定量化 において極めて貴重なものとなりうる。このフレームワークは発がん以外のエンドポイントにま で拡張できるようにするべきであり、このことに関する更なる研究が推奨される。したがって、 IPCS HRF の適用は、エンドポイント間の調和のための貴重なツールとなるであろう。

## 謝辞

IPCS と本論文の著者らは、この発がん MOA のヒトとの関連性を解析するための IPCS フレー ムワークの開発につながった科学的な会議やワークショップに関与した多くの専門家に謝意を表 します。これらは IPCS/WHO の手順に従って招集され、実施された専門家会議及びワークショッ プです。本文書を含む成果物は、国際的な特別作業部会の意見を集約したものであり、必ずしも WHO の決定や表明された方針を代表するものではありません。本事業は、世界保健総会の多くの 加盟国からの IPCS への寄付金により資金提供された。

# チアゾピルと甲状腺障害:

# 発がん MOA のヒトへの関連性を解析するための

# IPCS フレームワークを用いた事例研究2

#### Vicki L. Dellarco, Douglas McGregor, Sir Colin Berry, Samuel M. Cohen, & Alan R. Boobis

チアゾピルは雄ラットの甲状腺濾胞細胞腫瘍の発生率を増加させるが、マウスに対して発がん性 はないとされている。チアゾピルに遺伝毒性はない。チアゾピルは、チロキシンの代謝亢進により ホルモンバランスが崩れることにより二次的にラット甲状腺に発がん作用を及ぼす。これらのラ ットにおける腫瘍とヒトの健康への関連性は、2006年の国際化学物質安全性計画ヒト関連性フレ ームワーク(IPCS HRF)を用いて評価された。推定されたげっ歯類における発がん MOA を Bradford Hill 基準に照らして検証したところ、用量と時間の一致、生物学的妥当性、整合性、強度、一貫性、 特異性の条件を満たしており、甲状腺濾胞細胞腫瘍について確立されている MOA に適合している ことがわかった。推定された MOA はヒトでも理論的には作用する可能性はあるが、甲状腺ホルモ ンの不均衡に対するラットの発がん性の感受性がヒトとは量的に顕著に異なることから、チアゾ ピルはヒトに対する発がんに関するハザードを有さないという結論が導き出された。

多くの化学物質が、循環甲状腺ホルモンの減少を介した甲状腺ホルモンのホメオスタシスのか く乱を伴う作用機序(MOA)を介してラットの甲状腺濾胞細胞腫瘍を誘発することが示されてい る(Hurley ら、1998年; Capen ら、1999年; IARC、2001年)。甲状腺ホルモンの低下に対しホメ オスタシスを保とうとする反応は、下垂体からの甲状腺刺激ホルモン(TSH)の放出の代償的な増 加をもたらし、その結果、甲状腺を刺激して甲状腺ホルモンの合成及び放出を増加させる。TSH レベルの持続的な上昇は、甲状腺濾胞細胞の肥大及び過形成へとつながり、(化合物への持続的な ばく露の結果)高いTSH レベルが維持された場合、最終的には腫瘍形成へとつながる。ラットに おけるこの腫瘍形成 MOA は、科学界では十分に受け入れられており、国際がん研究機関(Capen ら、1999年; IARC、2001年)及び米国環境保護庁(USEPA、1998年)は、げっ歯類における甲 状腺濾胞細胞腫瘍のヒトへの関連性を評価するための独自のガイダンスまたは方針を確立してい る。

除草剤であるチアゾピルは、甲状腺ホルモンのホメオスタシスへ影響することによりラット甲 状腺濾胞細胞腫瘍を誘発するが、これは発がん MOA 解析のための 2001 年の国際化学物質安全性 計画(International Programme on Chemical Safety: IPCS)のオリジナルフレームワークを示すため に用いられた事例である(Sonich-Mullin ら、2001 年)。ここではチアゾピルの MOA を、事例研究 としてここで再検討し、2006 年の IPCS ヒト関連性フレームワーク(HRF)で提供されたヒトの 腫瘍形成 MOA 評価のための追加ガイダンスを説明した。この更新された事例研究では、ある特 定の MOA での経験の蓄積が、その後の解析の難易度をどの程度下げられるのかについて強調し ている。この事例研究は、key events が十分に定義されている確立された MOA に基づいているた め、この解析では、チアゾピルがこの経路で期待されている生物学的効果をもたらすか否かに焦

<sup>&</sup>lt;sup>2</sup> この論文は、WHO が著作権を有するものであり、元々は 2006 年に Critical Reviews in Toxicology, Volume 36, pages 793-801 に掲載されたものです。この論文は、WHO の出版物のために編集されており、正誤表が含まれています。

#### IPCS Framework for Analysing the Relevance of a Cancer Mode of Action for Humans and Case-Studies

点を当てている。この事例研究はまた、動物及びヒトにおける毒性発現の経路の基礎となる生理 学的プロセスを理解することの重要性を強調している。いくつかの化合物では、化学物質特有の データがヒトでの key events を評価する上で重要な場合があるかもしれないが、その他の化合物 については、基礎となる生物学的知見があれば、発がん MOA のヒトへの関連性を定性的にも定 量的にも解釈できる場合がある。チアゾピルは後者の例である。甲状腺ホルモンのかく乱とラッ ト甲状腺濾胞細胞腫瘍のヒトへの関連性に関する他の MOA 事例研究としてフェノバルビタール についての事例研究がある(Lehman-McKeeman & Hill, in Meek ら、2003 年)。

本 MOA 解析は、チアゾピルの発がん性に関する利用可能な情報の簡単な要約から始まり、続いて、この甲状腺ホルモンかく乱 MOA で考察された生化学的及び病理組織学的な実験データの 議論が行われる。本解析は化学物質そのものの包括的な評価を意図したものではない。

## 発がん性データ

チアゾピルの発がん性に関するヒトの疫学的データは得られていない。チアゾピルは、マウス、 ラット及びイヌを含む様々な実験動物種において、肝臓及び甲状腺に影響を及ぼす。チアゾピル は雄ラットにおいてのみ甲状腺腫瘍を誘発することが確認されており、甲状腺ホルモンの肝代謝 及び排泄を増加させることによってこれを引き起こすようである。

チアゾピルはマウス及びラットへの慢性的な混餌投与により、主に雄ラットに甲状腺濾胞細胞 腫瘍を誘発したが、雌ラットでは誘発しなかった(Naylor & McDonald、1992 年; Naylor & Raju、 1992 年)。チアゾピルを最大 800 mg/kg まで混餌投与したマウスの慢性試験(雄では 1 日あたり 128.4 mg/kg 体重[bw]、雌では 1 日あたり 215.9 mg/kg bw)では、いずれの性においても腫瘍の発 生率に有意な増加は認められなかった(Naylor & Raju、1992 年)。ラット発がん性試験では、チア ゾピル(原体、純度 94.8%)を雄及び雌の Sprague-Dawley ラット(SD ラット)(各群雌雄 60 匹ず つ)に 0、1、10、100、1000 または 3000 mg/kg の濃度で混餌投与し、雄では 1 日あたり 0、0.04、 0.4、4.4、44.2、136.4 mg/kg bw、雌では 1 日あたり 0、0.06、0.6、5.6、56.3 または 177.1 mg/kg bw の用量を与えた(Naylor & McDonald、1992)。甲状腺濾胞細胞腺腫及びがんの発生率は、1000 mg/kg (1 日あたり 44.2 mg/kg bw)及び 3000 mg/kg(1 日あたり 136.4 mg/kg bw)投与群の雄ラットで増 加した(表 1)。なお、雄ラットにおける腫瘍発生率の増加は主に良性腫瘍によるものであったこ とに留意すべきである。

## ラットにおける甲状腺濾胞細胞腫瘍の誘発において推定される MOA

チアゾビル誘発性甲状腺濾胞細胞腫瘍において推定される MOA は、甲状腺外における機序に よる下垂体-甲状腺軸のホメオスタシスの乱れを含むものであった。具体的な流れを以下に述べる。 チアゾビルは肝臓におけるチロキシン(T4)-ウリジン二リン酸(UDP)グルクロン酸転移酵素(UGT) 活性を誘導し、抱合による T4 の代謝を促進し、ホルモンの抱合体の胆汁排泄を増加させる。この 肝臓代謝の促進の結果として、血清 T4 及び時にはトリヨードサイロニン(T3)の半減期が減少す る。下垂体は、TSH の放出及び血清レベルを高めることにより、T4 の循環血清レベルの低下に対 応する。循環 TSH レベルの長期的な上昇は、甲状腺を刺激して甲状腺ホルモンの貯蔵を枯渇させ、 ホルモン産生を誘導し続ける。 その結果、甲状腺濾胞細胞は大きくなり(肥大)、高い増殖率で細胞数を増やす(過形成)ように 誘導される。慢性的なチアゾピルのばく露により、甲状腺過形成は最終的には腫瘍へと進行する。

・投与量に従ってP値が低下した。

# 実験動物における key events

チアゾピルの発がん MOA における一連の key events には、以下のものが含まれる。

- 肝 UGT 活性の誘導
- T4の肝臓での代謝及び胆汁排泄の増加
- 血清 T4 の半減期及び濃度の低下
- 循環 TSH 濃度の上昇
- 甲状腺濾胞細胞肥大及び濾胞細胞過形成

次に、チアゾピルが、循環甲状腺ホルモンの肝クリアランスを増加させて甲状腺-下垂体軸を乱 すことによって作用するかどうかを評価する。上記の key events に基づき、チアゾピルの MOA の 生物学的指標は、肝臓代謝の変化、ホルモンレベルの変化、甲状腺の成長の増加及び甲状腺の病 変の進行が挙げられることになる。これらの影響は、短期及び亜慢性試験さらに慢性試験におけ る中間及び計画殺において、雄ラットで観察され、測定されている(Hotz ら、1997 年)。Key events 及び腫瘍反応の用量反応性を以下に示す。

# 用量反応関係及び一致性

チアゾピルの MOA における主要な影響について、無毒性量(NOAEL)及び最小毒性量(LOAEL) の概要を表2に示す。Hotzら(1997)による56日間の試験では、雄SD ラット(各群20匹)に、 チアゾピルを0、10、30、100、300、1000、または3000 mg/kgの濃度で(測定されていないが、 チアゾピルの摂取量は1日あたり0、0.5、1.5、5、15、50及び150 mg/kg bwと推定される)を56 日間混餌投与し、肝臓(重量、肝T4-UGT活性、T4胆汁排泄)、甲状腺(重量、肥大/過形成)及 びホルモン(T4、T3、リバースT3(rT3)及びTSHの血清レベル)に対する影響を評価した。こ の試験では、チアゾピルの主要作用部位である肝臓への影響が、下垂体-甲状腺のホメオスタシス のかく乱の最も敏感な指標であると考えられる。50 mg/kg bw/day 投与群及び150 mg/kg bw/day 投

#### IPCS Framework for Analysing the Relevance of a Cancer Mode of Action for Humans and Case-Studies

与群では、肝 T4-UGT 活性が 56 日間の投与期間終了時に統計学的に有意に増加した(肝重量で標準化したところ、対照群と比較してそれぞれ約3倍と6倍に活性が増加した)。T4-UGT 活性の増加と一致して、血中からの T4 のクリアランス及び胆汁中への排泄(125I 標識 T4 の排泄量)は、 チアゾピルを150 mg/kg bw/day 投与後に40%増加した(150 mg/kg bw/day が評価された唯一の投 与量)。Hotz ら(1997年)による雄ラットを対象とした56日間の試験では、チアゾピルを1日あたり15、50及び150 mg/kg bw 投与した場合に、肝重量の統計学的に有意な増加が認められた。 ラット2年間の試験(Naylor & McDonald、1992年)では、絶対肝重量は対照群と比較して、44.2 mg/kg bw/day 投与群で122%、136.4 mg/kg bw/day 投与群で肝肥大の発生率が統計的に有意に増加した (対照群の0/60に対してそれぞれ47/61及び52/60)。

影響	NOAEL/LOAEL
肝臓

# 表 2. 雄ラットを対象とした 56 日間の試験(Hotz ら、1997)及び 2 年間の慢性試験(Naylor & McDonald、1992)から得られた肝臓、ホルモン及び甲状腺に対する影響の概要

Hotz ら(1997) が雄 SD ラットにチアゾピルを投与したとき、上述した T4 の肝クリアランスの 亢進と同様に、最高用量の投与 56 日後に血清 T4 濃度の統計学的に有意な (P $\leq 0.05$ ) 減少 (30%減 少)と TSH の増加(60%増加)が認められた(表 3)。T3 の血清レベルは、1.5 mg/kg bw/day では 56 日投与後に統計学的に有意ではないものの低下し、150 mg/kg bw/day では有意に上昇した。一 般に、肝ミクロソーム酵素誘導剤による影響は T4 よりも T3 に影響を与えにくいようである。し たがって、T4 及び TSH は、下垂体-甲状腺のホメオスタシスの変化の指標としてはより信頼性の 高い傾向がある (Liu ら、1995 年、Hurley ら、1998 年、Hood ら、1999 年)。

チアゾピルの場合、T4 及び TSH に影響を及ぼす用量と、甲状腺濾胞細胞腫瘍の発生率の増加を 引き起こす用量との間には、相関関係が乏しいようである。雄 SD ラットにおいて甲状腺濾胞細 胞腫瘍の統計学的に有意(P<0.05)な増加をもたらしたチアゾピルの最低用量は、2年間の試験で は1日当たり44.2 mg/kg bw であったが、T4 及び TSH に対する影響の NOAEL は56 日間の試験 では1日当たり50mg/kg bwであった(表2)。一般的に、肝酵素/肝重量及び下垂体-甲状腺ホル モン濃度への影響は、この甲状腺ホルモンかく乱 MOA が閾値を有する現象であることを考える と、少なくとも甲状腺の重量変化及び甲状腺腫瘍発生率の増加をもたらす用量と同程度の低用量 で起こると予想される。引用された投与量のどちらも正確ではないので、この見かけの不一致は おそらく真ではない。2年間の試験における体重1kg当たりの投与量は、試験期間全体の平均的 な推定値であったのに対し、比較に用いられた 56 日間のメカニズム試験での投与量は、12~20 週 齢のラットにおけるものである。これらの投与量は、容易に算出可能な投与量よりも少なくとも 2 倍高かったと考えられる(したがって、腫瘍に対する実際の LOAEL は1日あたり約 90 mg/kg bw であったはずである)。また、ホルモンのかく乱(例えば TSH の長期上昇)が病理学的変化を もたらし始める臨界期は、2年間の試験において後期ではなく早期であったため、これらの投与 量は腫瘍に対する関連性も高かったと考えられる。56日間の試験で計算された投与量は公表され た論文からは摂餌量の情報が入手できなかったため、摂餌量の推定値に基づいて計算された。そ のためこれについても不正確である可能性が高い。この不確実性を認識した上で、1日あたり 50 mg/kg bw で甲状腺重量が有意に増加し、1日あたり15 mg/kg bw で肝臓重量の増加が認められた が、これはチアゾピルの MOA では最初のターゲットが肝臓であることと一致している。

	Dose (mg/kg bw per day) <sup>a</sup>						
	0	0.5	1.5	5	15	50	150
T4 (μg/dL)	$4.1\pm0.2$	$4.3\pm0.3$	$3.9\pm 0.2$	$4.1\pm0.2$	$4.0\pm0.2$	$4.0\pm0.2$	$2.9\pm0.1^a$
T3 (ng/dL)	$84\pm3$	$82\pm4$	$68 \pm 2$	$84\pm3$	$82\pm3$	$91\pm 4$	$110 \pm 6^a$
TSH (ng/mL)	$2.7\pm0.2$	$3.5\pm 0.4$	$2.7\pm0.1$	$3.1\pm 0.4$	$2.9\pm0.3$	$3.1\pm 0.2$	$4.3\pm0.4^a$

表 3. 雄ラットにおける 56 日間の試験:ホルモン作用(Hotz ら、1997 年)

注: 投与量 mg/kg bw/day は推定値である。値は平均値±標準誤差で表している;1 群あたり19 または20 匹。 <sup>a</sup> 分散分析 (ANOVA) 後の Dunnett の検定で対照群と統計学的に有意に異なる (*P*≦0.05)。

上述のように、長期の TSH 刺激は甲状腺の肥大と過形成の両方を引き起こす。ラットの2年間の試験では、甲状腺肥大のみと腫瘍発生率との間には用量相関性は見られなかった。腫瘍発生率は44.2 mg/kg bw/day 投与群で増加したが、過形成の発生率の統計学的に有意な増加(対照群 1/60 に対し 8/58)は136.4 mg/kg bw/day 投与群でのみ認められた。さらに、ラットの56日間の試験では、組織学的に甲状腺濾胞細胞肥大と過形成が併発しており、150 mg/kg bw/day 投与群での発生率は統計学的に有意に増加したが、それ以下の用量では増加しなかったと報告されている(Hotz ら、1997年)。しかし、56日間の試験での甲状腺重量の増加と2年間の試験での腫瘍発生率との間には良好な用量相関性があった。150 mg/kg bw/day 投与群で 46%、50 mg/kg bw/day 投与群で 25%の統計学的に有意な甲状腺重量の増加が認められた(Hotz ら、1997年)。

34

## 時間的関連性

ある事象が腫瘍形成の必須要素である場合、それは腫瘍の発生に先行して発現しなければなら ない。雄 SD ラットに 3000 mg/kg (1日あたり 150 mg/kg bw)のチアゾピルを混餌投与した7、14、 28、56 及び 90 日後といった複数のタイミングにおけるデータが利用可能である(Hotz ら、1997 年)。肝重量増加及び肝 T4-UGT 活性上昇は、最も早く測定した7日目から全ての測定時期におい て認められた。この実験では抱合化 T4 の胆汁排泄は測定されなかったが、血清 T4 はすべての観 察時期において減少した。循環 TSH の増加は、投与開始後 14 日目においては有意ではなかった が、すべてのサンプリング時期で観察された。甲状腺重量の増加もすべてのサンプリング時期で 観察された。組織学的には、14 日目から肥大/過形成の経時的な増加が認められた。2 年間のラッ ト試験では、1 日あたり 136.4 mg/kg bw を投与した 69 週目に最初の甲状腺腺腫が観察された。こ のように、チアゾピル誘発性甲状腺濾胞細胞腫瘍形成においては、すべての key events が腫瘍形 成に先行するという論理的な経時的反応が認められた。

# 腫瘍反応と key events との関連性の強さ、一貫性及び特異性

この関連性の強さ、一貫性、特異性は、上述の試験から確立できる。推定される MOA の基礎と なる定量可能な前駆事象は、甲状腺濾胞細胞腫瘍の発現と比較的一致している。チアゾピルを混 餌投与されたラットにおいて、肝重量の増加及び肝 T4-UGT の誘導が観察されることから、甲状 腺外の機序による下垂体-甲状腺軸のホメオスタシスのかく乱と一致しているようである。肝 T4-UGT 活性の上昇は、他の重要な生化学的変化や甲状腺濾胞細胞の肥大及び過形成の前に起こる段 階である。チアゾピルの投与は肝臓における T4 の代謝が促進されるため、循環 T4 の減少及び TSH の増加が明らかである。さらに、亜慢性試験では、甲状腺重量の増加及び肥大・過形成の発 生は、甲状腺ホルモン濃度及び甲状腺ホルモン代謝の変化の出現や回復と同じ用量及び時間の条 件下で統計学的に有意な程度で現れることが示された。中止/回復試験(Hotz ら、1997 年)では、 チアゾピルの投与中止後、ホルモン値がコントロール値に戻り、肝臓と甲状腺の重量が減少し、 甲状腺濾胞細胞の過形成が回復することが示された。早期に投与を中止することで、この非遺伝 毒性 MOA における甲状腺ホルモンの低下と病変の進行が回復することが期待された。唯一回復 が遅くなったのは、最も長い投与期間の後の甲状腺重量の増加であった。

# 生物学的妥当性及び整合性

実験用のげっ歯類を用いた研究から、視床下部-下垂体-甲状腺軸の持続的なかく乱、TSH による甲状腺への長期的な刺激及び甲状腺濾胞細胞の肥大、過形成、最終的な腫瘍への進行との関係を示すデータが数多く存在する(McClain、1995年; Hard、1998年; Hurley ら、1998年; Capen ら、1999年; IARC、2001年)。チアゾピルの場合と同様に、TSH の分泌増加は、T4 の肝クリアランスの増加を含むいくつかのメカニズムを介して生じる可能性がある。

T4の循環レベルは、TSH の合成を担う下垂体の甲状腺刺激細胞によってモニターされている。 下垂体では、T4 は、5-dried-deio-dinase (ヨウ素ペルオキシダーゼ) II 型により T3 に代謝され、T3 は細胞核内の特定の受容体に結合する。T3 受容体の占有率が低下すると、TSH 合成と分泌が刺激 される。ラットへの TSH の注射が、非増殖細胞特異的核抗原である甲状腺濾胞細胞核スタチンが 減少し、これらの細胞が非分裂状態を脱して細胞周期を再開していることが生体内での研究で示 されている (Bayer ら、1992 年)。この試験では、低用量の TSH を反復投与(ラット1 匹あたり 0.25 IU を1日2回) すると、核内スタチンレベルが 10 日間にわたって累積反応が生じ、TSH の 注射を中止してから5 日以内に正常な安静時のレベルに戻ることが示された。核内スタチンの減 少もまた、TSH に対する最も早い反応として知られているピノサイトーシスと類似した初期の事 象である。これらのデータは、TSH 濃度の増加だけでラットの甲状腺濾胞細胞を増殖前の状態に なることと矛盾しない。したがって、チアゾピルが最初に肝 T4-UGT を誘導することでラットの 甲状腺濾胞細胞腫瘍を引き起こすという指摘は、少なくとも肥大と過形成の段階までは視床下部-下垂体-甲状腺の動的な制御システムに関する既知の生理学的知見と一致している。

最後に、チアゾピルにより誘発される腫瘍反応はげっ歯類の甲状腺発がん物質の典型的なもの であり、甲状腺濾胞細胞腫瘍は雄ラットにはみられるが、雌のラットやマウスには認められない。 ラットはマウスよりも甲状腺発がん物質に対し感受性が高い傾向があり、さらに、雄ラットは雌 ラットよりも甲状腺腫瘍を誘発する化学物質の割合が大きいことがよくみられている (Hurley ら、 1998 年)。このことと一致して、TSH レベルは通常雄ラットの方が雌よりも高い (Hill ら、1989 年)。さらに、雄ラットは時に同系統の雌よりも肝酵素が誘導されやすいことがあるが、これは酵 素の種類、酵素誘導を起こす化合物の用量や動物の年齢に依存する (Sundseth & Waxman、1992 年; Agrawal & Shapiro、1996 年; Oropeza-Hernandez ら、2003 年)。

# その他の MOA

変異原性は常に考慮すべき可能性のある MOA の 1 つであるが、以下の試験においてチアゾピルの遺伝毒性は示されていない。

- ネズミチフス菌 (Salmonella typhimurium) の4つの菌株を用いた突然変異試験 (Bakke、1989 年 a)。
- チャイニーズハムスター卵巣細胞を用いたの突然変異試験(hgpt 座位)(Li & Myers、1989年)。
- マウスの骨髄細胞を用いた In vivo 小核試験(Flowers、1990年)。
- ラットの肝細胞を用いた In vivo 不定期 DNA 合成試験(Backke、1989 年 b)。

したがって、利用可能なエビデンスは、突然変異誘発がチアゾピルの代替 MOA ではないこと を示している。

その他の視床下部-下垂体-甲状腺軸への影響及び甲状腺ホルモン代謝における他の経路のかく 乱は、甲状腺のホメオスタシスを変化させる可能性がある。しかし、これらの変化は、チアゾピ ルについて推定されているものと根本的には変わらず、すべて継続的なばく露による TSH 刺激の 長期化につながっているであろう。

# 不確実性、矛盾、データギャップ

甲状腺腫瘍とホルモンの変化には用量の一致がみられないが、これは比較に用いられた体重 1 kg 当たりのミリグラム投与量(摂餌量と体重値から算出された)が不正確であること、比較した 投与量が一方は若齢期のラットにおける平均値であり、もう一方が試験全体の平均値であったこ と、また、試験間のばらつきなどに起因している可能性がある。

# 推定される MOA の評価

提示されたデータは、中程度に高い信頼度で、チアゾピルの混餌投与による慢性ばく露後の雄 ラットにおける甲状腺濾胞細胞腫瘍の発生を説明するのに十分であると判断される。チアゾピル は、腫瘍を引き起こす用量よりも低い用量で明らかに肝臓重量を増加させ(すなわち、肝臓が最 初の標的臓器である)、腫瘍を誘発させる中で最も低い用量で甲状腺の成長(すなわち、甲状腺重 量の増加)を促進させた。

## 推定される MOA のヒトへの適用可能性

IPCS HRF はリスクサイエンス研究所/国際生命科学研究機構の「ヒト関連性フレームワーク」 (Meek ら、2003 年)をもとに開発され、「IPCS がんワーキンググループ」の議論をもとに修正さ れたものであり(Boobis ら,本書)、一連の3つの問いかけに対処し、動物の腫瘍における MOA のヒトへの関連性に関する文書化された論理的な結論を導くための4つの部分からなるアプロー チを提示している。

1. 動物 MOA を確立するのにエビデンスの重み付けは十分か?上で詳述したように、チアゾピルは UGT 誘導により血清 T4 レベルを低下させ、その結果として血清 TSH を上昇させることで、 甲状腺ホルモンのホメオスタシスを変化させるという明確なエビデンスがある。

実験動物とヒトとの間のkey events の根本的、質的な違いに基づいて、MOA のヒトとの関連 2. <u>性を合理的に排除することができるか?ヒトにおける甲状腺ホルモンのホメオスタシスの調節に</u> 関する現在の理解と、(甲状腺ホルモンのホメオスタシスの変化の結果としての) TSH レベルの上 昇が甲状腺がんのリスク因子として果たす役割について、チアゾピルの動物における発がん MOA の key events のヒトへの関連性を評価するために検討がなされた。ラットにおける視床下部-下垂 体-甲状腺軸の機能と調節に関与する基本的なメカニズムは、量的な薬力学的差異(後述)はある が、定性的にはヒトのそれと類似している(Bianco ら、2002 年)。したがって、ラットで T4 レ ベルを低下させる薬剤は、ヒトでも同様に T4 を低下させる可能性があり、その結果、TSH レベル の上昇につながる可能性がある。げっ歯類とヒトは、下垂体-甲状腺機能のかく乱に対して同様の 反応を示すデータがある。例えば、甲状腺ホルモンのレベルを容易に低下させるヨウ素欠乏症は、 ヒトでは甲状腺細胞の増殖を刺激して甲状腺腫を引き起こすことが知られている。ヨウ素欠乏症 を放置すると、まれではあるが腫瘍形成につながることがある(Thomas & Williams、1999 年)。甲 状腺がんになりやすいというエビデンスはないが、甲状腺に直接作用して(例えば、ホルモン合 成や放出を阻害する、T4からT3への変換を阻害する)甲状腺ホルモンのホメオスタシスを乱す 多くの医薬品(プロピルチオウラシル、リチウム、アミオダロン、イオパノ酸など)は、ヒトでは 甲状腺ホルモンの低下及び TSH の上昇につながることが知られている(Ron ら、1987 年)。

ラットとは対照的に、ヒトでは、肝ミクロソーム酵素が誘導され、循環 T4 レベルを低下させる 薬剤にばく露されても TSH レベルの上昇は認められていない(Lehman-McKeeman & Hill, in Meek ら、2003 年)。例えば、医薬品のフェニトイン、リファンピン、カルバマゼピンは、UGT を含む 肝ミクロソーム酵素を誘導し、血中の T4 レベルを低下させるが、TSH レベルは変化しない(Curran & DeGroot、1991 年)。同様に、実験的に高用量で T4 のグルクロン酸抱合及び胆汁排泄を増加さ せることによりラットに甲状腺腫瘍を発生させる薬剤(例えば、オメプラゾール、ランソプラゾ ール、パントプラゾール)は、ヒトにおいて臨床用量では甲状腺ホルモンに変化をもたらさない (Masu-buchi ら、1997 年)。このように、ラットにおける下垂体-甲状腺軸のホメオスタシスの変 化の用量反応関係には、ヒトと比較してかなりの違いがあるように思われる。後述するように、 この現象は、ラットとヒトでは下垂体-甲状腺機能の基礎となる生理学的プロセスの量的な薬力学 的差異に起因している。

3. 実験動物とヒトとの間の薬力学的または動態的要因のいずれかの量的差異に基づいて、MOA のヒトへの関連性を合理的に排除することができるか?チアゾピルは甲状腺を直接標的とするものではない。むしろ、その主な作用は肝代謝酵素に対するものであり、代謝活性の亢進は間接的にT4の全身クリアランスを増加させ、ラットでみられるような甲状腺機能低下状態とTSHの代償性の増加をもたらす。チアゾピルがヒトにおける甲状腺ホルモンの恒常性を乱す可能性については、チアゾピル特有のデータはないが、フェノバルビタール(Lehman-McKeeman & Hill, in Meekら、2003 年)のような他の多くのミクロソーム酵素誘導剤で広く研究されている。上述したように、T4の肝クリアランスを変化させることで甲状腺機能減退症下を引き起こす薬剤は、ヒトではTSHレベルの上昇をもたらさないようである。おそらく、T4の減少が閾値まで達していないので、TSH は上昇しないのではないかと考えられる。

甲状腺機能に関連して、ラットとヒトの間にはいくつかの重要な生理学的及び生化学的相違が ある。ラットはヒトに比べて甲状腺ホルモンの予備容量が小さい。ラットはヒトに比べて甲状腺 ホルモンの半減期が非常に短く、T4の半減期は、ヒトの5~9日に対し、ラットでは約12時間で ある(Dohler ら、1979年)。ラットの半減期が短いのは、ヒトに存在するT4の高親和性結合グロ ブリンが存在しないことに関係していると考えられる(Hill ら、1989年)。ラットでは、クリアラ ンスの増加によって正常なT4レベルを維持するために、より高い体重あたりのT4産生率を必要 とする。対照的に、ヒトではこのグロブリンへ甲状腺ホルモンが結合することによって、ラット と比較して代謝的分解及びクリアランスが遅く、その結果、甲状腺はラットよりも活性が低い。 恒常的なTSHレベルは、ラットではヒトよりも約25倍高く、ラットでは下垂体-甲状腺軸の活性 が高いことを反映している(Dohler ら、1979年; McClain、1992年)。したがって、ヒトは、T4を 減少させTSHの上昇をもたらす薬剤に対して、ラットよりも定量的に感受性が低い。TSH が上昇 していなければ、甲状腺腫瘍発生のリスクが高まることはない。

ヒトとの比較においてラットのもう一つの違いは、甲状腺の組織像にある。この組織学的な相 違は、ラットでは安定した一定の血清 T4 濃度を維持するための T4 のより高い産生速度と関連し ており、これによりラットの甲状腺は、人間を含む霊長類のそれよりも"機能的に活性化"した状 態となっている(McClain、1995 年)。

38

ラットの濾胞上皮の多くは、刺激を受けてサイログロブリンを合成するため、濾胞細胞の多くは 背の高い立方体状をしており、活発にホルモン合成しているように見える。対照的に、ヒトの濾 胞細胞の多くは、短い立方体状またはほぼ扁平な外観を呈し、静止状態のように見える傾向があ る。ラットの濾胞細胞はすでに全体的に活性化しているので、TSHによる刺激を受けると、ヒト の濾胞細胞よりも容易に反応し過形成を生じる。ヒトの甲状腺は貯蔵能力が高く、休止状態にあ る細胞の数が多い。そのため、ヒトの甲状腺濾胞細胞は恒常性を回復するための過形成反応を必 要とせずに、休止状態から覚醒して追加の甲状腺ホルモンを合成・分泌する。したがって、ヒト 甲状腺における主要な反応は、過形成ではなくサイログロブリンの再吸収と細胞の肥大であろう。 要するに、ラット甲状腺よりもヒト甲状腺の方が、生化学的な面においてははるかに大きな緩衝 能力を持っているということである。

ある薬剤がヒトにおいて甲状腺ホルモンレベルの低下を引き起こす可能性があるとしても、こ れらの薬剤が甲状腺がんの感受性を高めるという明確なエビデンスはない(Ron ら、1987 年)。例 えば、フェノバルビタールを用いた疫学研究では、甲状腺がんのリスクの増加は示されていない (Olsen ら、1993 年)。TSH が上昇するような状態にある人々(バセドウ病または甲状腺腫の患者) を対象とする研究は、このような状況においても甲状腺がんの発生はまれであることを示してい る (例えば、Mazzaferri、2000 年;Gabriele ら、2003 年)。全国規模のスウェーデンの家族がんデ ータベースを用いた 960 万人のがんの環境的及び遺伝的原因を調査した結果、環境が甲状腺がん の主な原因となる役割を果たしているようには見えないことが明らかにされた(Lichtenstein & Hemminki、2002 年)。唯一知られているヒト甲状腺の発がん物質は放射線であり、すなわち変異 原性物質のばく露である。

表4に要約されているように、甲状腺機能の生化学的及び生理学的差異に関する一般的な文献 には、ラットとヒトの間で腫瘍に対する感受性に違いがあることを示す十分なエビデンスがある。 ヒトとは対照的に、ラットは甲状腺ホルモンの低下症に続発する甲状腺腫瘍に対して非常に感受 性が高い。特に、甲状腺ホルモンの恒常性にわずかでも変化があるとラットでは腫瘍形成が促進 される。したがって、げっ歯類におけるホルモンの肝クリアランスの増加と下垂体-甲状腺軸のホ メオスタシスの変化を伴うチアゾピルによって誘発される甲状腺腫瘍は、量的な動態の違いから ヒトへの関連性はないと考えられる。

4. 結論:信頼性、解析及び帰結の記述。ラットにおけるチアゾピル誘発性甲状腺濾胞細胞腫瘍に関 して、甲状腺ホルモンかく乱 MOA を確立するのに十分な実験的エビデンスが存在する。チアゾピル はヒトにおいて甲状腺機能減退症を引き起こす可能性があるが、一般的な文献には、げっ歯類におけ る甲状腺ホルモンの肝クリアランスの増加と下垂体-甲状腺軸のホメオスタシスの変化を伴うプロセ スによって誘発される甲状腺腫瘍は、ヒトの腫瘍発生に対する感受性の増加にはつながらないと結論 づけるのに十分な基本的な生理学的プロセスに関する定量的エビデンスがある。チアゾピルに関する ヒトでのデータはないが、他の肝ミクロソーム酵素誘導剤に関する臨床データは、チアゾピルのヒト への関連性の解析には不可欠であった。一般的な文献からは、ラットとは異なりヒトでは T4 レベルの 低下が代償的に TSH レベルを上昇させることを示すエビデンスはないことを示すのに十分なエビデ ンスが得られた。また、ラットの下垂体-甲状腺軸がこのようなホルモンのかく乱に対してヒトよりも はるかに感受性が高いという細胞学的及び生化学的エビデンスもある。 この感受性の高さは、甲状腺の活動を維持するための TSH の需要が高いことと相まって、ラット における T4 の急速なターンオーバーが早いことに起因すると思われる。

## IPCS HRF の結果

チアゾピルの例は、過去に明確にされ、確立された MOA と一致する誘発された腫瘍反応について示したものである。したがって、フレームワーク解析の最初の質問である「動物 MOA を確立するのにエビデンスの重み付けは十分か」に対応することは、その化学物質に関するデータセットが対象となる経路に対して定義にされた同じ key events に適合しているか否かを判断する必要があった。この例は、MOA に関与する生物学的プロセスの基本的な理解に関するデータが、どのようにげっ歯類とヒトの key events を比較するための重要な手段となるかを示している。このように、実験動物とヒトの間の質的及び量的な差異を評価し、ヒトに対する発がん MOA の妥当性(すなわち、HRF の問 2 と 3)評価するためには、このヒトに関する一般的な情報は、不可欠であった。

# 4-AminobiphenylとDNAの反応性: 発がん MOA のヒトへの関連性を解析するための IPCS フレームワークを用いた事例研究1

# Samuel M. Cohen, Alan R. Boobis, M.E. (Bette) Meek, R. Julian Preston, & Douglas B. McGregor

DNA 反応性(遺伝毒性)発がん物質である 4-Aminobiphenyl を例に、動物とヒトにおける豊富なデ ータに基づいて国際化学物質安全性計画(International Programme on Chemical Safety: IPCS)のヒト 関連性フレームワーク(Human Relevance Framework: HRF)を評価した。この Mode of action (MOA) は、N-水酸化による代謝的活性化、N-エステル化による反応性親電子物質の生成を経て、この親電 子物質が DNA(主にデオキシグアノシン)と共有結合し、DNAの突然変異を促進させ、最終的に はがんの発生につながると考えられている。ヒトとイヌでは、膀胱が標的臓器であるのに対し、マ ウスでは膀胱と肝臓が標的臓器であり、他の種では他の組織が関与することもある。臓器特異性の 違いは、代謝的活性化と不活性化の違いによるものと考えられている。定性的及び定量的な考察か ら、ヒトの MOA が可能である。毒性や再生性増殖などの他の生物学的プロセスは、4-Aminobiphenyl 誘発性腫瘍の用量反応に大きく影響する可能性がある。IPCS HRF によれば、4-Aminobiphenyl はヒ トにおいて発がん物質であると予測され、これは広範な疫学的エビデンスによって裏付けられて いる。IPCS HRF は DNA 反応性発がん物質の評価に有用である。

4-Aminobiphenyl は、様々な経路で複数の種において発がん性が確認されている(IARC、1972 年、1986年、1987年)。4-Aminobiphenyl は、代謝的活性化、DNA 反応性、遺伝毒性、発がん性を 評価した多くのデータに基づき、動物モデルにおける MOA が確立されていることから、代表的 な DNA 反応性発がん物質として、国際化学物質安全性計画(International Programme on Chemical Safety: IPCS)のヒト関連性フレームワーク(Human Relevance Framework: HRF)の事例研究対象 化学物質に選定された。また、芳香族アミンに属する既知の動物及びヒト発がん物質と類似して おり(構造活性相関)、ヒトにおける疫学的、代謝学的、生化学的データが豊富に存在している。 この事例研究は、DNA 反応性発がん物質の MOA を明確にするのに役立つデータの性質を示して いる。MOA 解析における調節因子と key events の区別についても示されている。

動物における有力なエビデンスと広範な疫学的データに基づいて、国際がん研究機関(IARC) は 4-Aminobiphenyl を既知のヒト発がん物質として分類した(IARC、1972 年、1987 年)。4-Aminobiphenyl は最初、職業的に高レベルにばく露されたヒトの膀胱発がん物質として同定された。 その後、タバコの煙の主成分として実証され、喫煙者の膀胱がんのリスク増加につながるといわ れている(Del Santo ら、1991 年; Curigliano ら、1996 年)。追加研究では、窒素を含む有機物が燃 焼する際に自然に発生し、至る所に存在する環境化学物質であることが示されている。

<sup>&</sup>lt;sup>1</sup> この論文は、WHO が著作権を有するものであり、元々は 2006 年に Critical Reviews in Toxicology, Volume 36, pages 803-819 に掲載 されたものである。この論文は WHO の出版物のために編集されたもので、正誤表が含まれている。

# 動物における 4-Aminobiphenyl の発がん性

実験的研究では、標的組織と感受性には有意な差が認められているものの、4-Aminobiphenylは マウス、ラット、ウサギ、イヌにおいて発がん性があることが示されている(IARC、1972年)。4-Aminobiphenylは、ほとんどのばく露経路において、マウスでは主に肝臓と、低頻度で膀胱に対し て発がん性が認められるが、イヌ(及びヒト)では膀胱が標的臓器であると考えられる。これら の研究の多くが数年前に行われたものであり、詳細な情報は限られたものしか公表されていない。 さらに、試験途中における潜在的な前駆病変はほとんど記録されておらず、どの研究にも MOA で 参考となる中止/回復などの研究計画書は含まれていなかった。それにもかかわらず、研究結果に は競合する代謝的活性化及び不活性化プロセスが競合する MOA に特徴的な反応における影響の 種及び個体差(例えば、ブロックら、1978年)が示されている(表1)。

hw 休重						

#### bw, 体重

経口投与(マウス1週あたり1 mg、38週間)の後、90週まで生存した2/12のマウスに膀胱がんが発生した(Clayson ら、1965年)。別の実験では、マウスに1.5 mgの4-Aminobiphenylを52週間投与したところ、対照群では0/19匹であったのに対し、1/21匹の雄マウスで膀胱がんが発生した。この実験では、雄マウスと雌マウスの両方で肝臓がんの頻度が対照群よりも有意に高かった(Clayson ら、1967年)。4-Aminobiphenyl 200 µgをマウスに3回皮下注射したところ、48~52週後に19/20匹の雄及び6/23匹の雌で肝臓がんが生じた(Gorrod ら、1968年)。4-Aminobiphenylを、BALB/cStCrlfC3Hf/Netrマウスの雄と雌に、それぞれ220 mg/Lと300 mg/Lまでの濃度で飲水投与すると、投与量に相関して、血管肉腫(雄と雌)、膀胱がん(雄のみ)、肝細胞がん(雌のみ)の有意な増加が認められた。膀胱の過形成は、75 mg/L(雌)及び55 mg/L(雄)以上の濃度の投与を受けた約118匹の群では、両性のマウスのほとんどで観察されたが、対照群では報告されていない(Schieferstein ら、1985年)。多くの実験において、新生児B6C3F1マウスは、4-Aminobiphenyl投与後に、主に肝発がんに感受性があった(Dooley ら、1988年、1992年; Von Tungeln ら、1996年; Parsons ら、2005年)。

#### IPCS Framework for Analysing the Relevance of a Cancer Mode of Action for Humans and Case-Studies

ピーナッツオイル中に 4-Aminobiphenyl を混入して合計 3.6~5.8 g/kg 体重(bw)の用量をラットに毎日皮下注射すると、乳腺及び腸の腫瘍の発生率が有意に増加した(Walpole ら、1952 年)。

市販の4-Aminobiphenylを経口投与(用量は記載なし)した7匹のウサギのうち、1匹に膀胱乳 頭腫が、3匹に膀胱がんが認められた。最も早い発がんは投与開始から4年後に観察された(Bonser、 1962年)。

4-Aminobiphenyl をゼラチンカプセルで週6回投与し続けた2匹のイヌ(1匹あたりの総投与量: 30、34g)は、33ヶ月で膀胱がんを発症した(Walpole ら、1954年)。同様に4-Aminobiphenylを含むカプセル(イヌ1匹あたり0.3g)を週3回与えても、21~34ヶ月後に膀胱がんが観察された(総投与量:イヌ1匹あたり94.5~144.0g)(Deichmann ら、1958年)。4-Aminobiphenylを1.0 mg/kg bwに減量し、6匹のイヌに週5回、34ヶ月または37ヶ月間投与したところ(総投与量:1匹当たり5.5~7.0g)、それぞれ3例で膀胱乳頭腫及び膀胱がん(移行上皮型)が観察された(Deichmann ら、1965年)。単回投与では、5年間で膀胱腫瘍は誘発されなかった(Deichmann & MacDonald、1968年)。4-Aminobiphenylを週5日、3年間経口投与した24匹のビーグル犬では、膀胱発がん物質の反応の基本的な3つのパターンが認められた。陰性または最小限の病変は4匹にみられ、そのうちの2匹には腫瘍が発生しなかった。腫瘍は11匹のイヌでゆっくりと進行したが、残りの9匹では急速に進行するパターンが観察された(Block ら、1978年)。

## 動物 MOA を立証するのにエビデンスの重み付けは十分か

IPCS HRF の最初の問いかけは、動物 MOA そのものの評価である。これは、疫学研究における 因果関係を説明するための Bradford Hill 基準 (Hill、1965 年)から発展し、IPCS が開発した、2001 年発表の MOA フレームワーク (Sonich-Mullin ら、2001 年)に示されている手順に基づいている。

## A. 推定される MOA

4-Aminobiphenyl は、肝酵素によって *N*-hydroxy-4-aminobiphenyl に代謝され、肝及び他の組織に おいて *N*-エステル化 (*N*-アセチル化、*N*-グルクロン化、または *N*-硫酸化) される (Miller ら、1961; Kadlubar ら、1977 年、1991 年; Miller & Miller、1977 年; Delclos ら、1987 年; Chou ら、1995 年) (図 1)。*O*-エステル化及び環状水酸化は、無毒化につながる競合する酵素反応である。これらの 反応の活性における組織差や種差により、少なくとも部分的には、4-Aminobiphenyl の発がん作用 に対する感受性の違いや、腫瘍の発生における臓器特異性に違いを生じさせる。最終的には、*N*-エステル化の後、反応性親電子ニトレニウムイオンが標的組織に形成され、これが DNA 付加体を 形成しうる。主な DNA 付加体は、*N*- (deoxyguanosin-8-yl)-4-aminobiphenyl である (Talaska ら、1990 年; Kadlubar ら、1991 年; Flammang ら、1992 年; Hatcher & Swaminather、1995 年、2002 年)。 これらの反応が重要な遺伝子の重要な部位で起こることにより突然変異がおこり、その結果、最終的に腫瘍細胞が発生する。

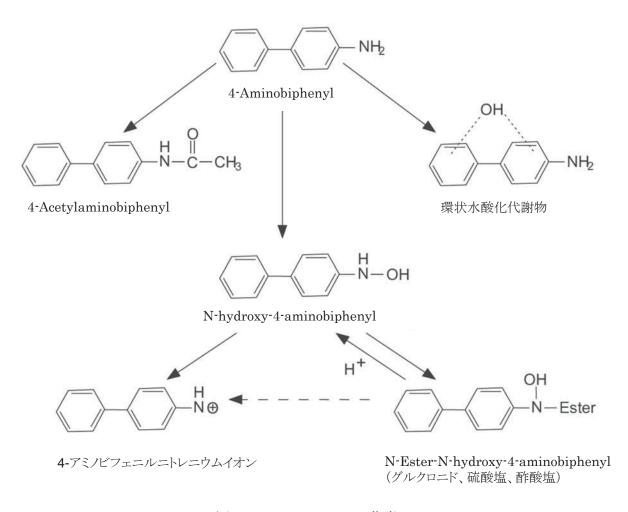

図 1.4-Aminobiphenyl の代謝

#### **B.** Key events

4-Aminobiphenylの肝活性化の主要経路は、少なくともラットとヒトでは CYP1A2 によって触媒 される 4-Aminobiphenylの *N*-水酸化から始まる(Butler ら、1989 年 b)。マウスでは、CYP1A2 や チトクローム P-450 が唯一もしくは主要に関与しているわけではないという報告がある(Kimura ら、1999 年)。また、*N*-hydroxylamine はシクロオキシゲナーゼのプロスタグランジン合成酵素 (Kadlubar ら、1982 年)のような様々なオキシダーゼ及びペルオキシダーゼとの反応によって生 成される。これらの非チトクローム P-450 反応のいずれかが生体内で起こるが、毒性学的に意義 があるかは不明なままである。*N*-hydroxylamine は、*N*-アセチルトランスフェラーゼ 1(NAT1) (Flammang & Kadlubar、1986 年; Oda、2004 年)による *N*-アセチル化を受け、酸性条件下では不 安定な *N*-アセトキシエステルを生じ、DNA と直接反応し得るアリルニトレニウムイオンを形成 し、グアニンの C-8 位に DNA 付加体を形成する(Hammons ら、1985 年; Flammang & Kadlubar、 1986 年; Hatcher & Swaminathan、2002 年)。さらに、肝臓で生成された N-hydroxylamine は、ウリ

ジンニリン酸(UDP)グルクロン酸転移酵素(UGT)の基質として機能し、N-グルクロニド抱合体を生じ、これが膀胱に運ばれる(Kadlubarら、1977年)。グルクロニドは尿中に排泄されるか、酸性条件下において、加水分解後に膀胱内の N-hydroxylamineの追加供給源として機能する。N-ア セチルトランスフェラーゼ-2(NAT2)による 4-Aminobiphenylの N-アセチル化など、この反応と

#### IPCS Framework for Analysing the Relevance of a Cancer Mode of Action for Humans and Case-Studies

競合する反応が多数存在するが、得られるアリルアセトアミドは、CYP1A2 にとって貧弱な基質 であり、主に解毒反応であると考えられている。その結果、親アミンの N-アセチル化は不活性化 反応と考えられている。アセチル化の速度は、活性化と不活性化のバランスに影響を与える。ヒ トの表現型には、rapid acetylators と slow acetylators が存在する(Lower ら、1979 年)。ヒトのそれ ぞれのアセチレーターに類似したマウスの系統が存在し、C57BL/6 は rapid acetylators 系統であり、 A/J は slow acetylators 系統である(Hein、1988)。これらの違いに対する研究は、種間、系統間、 個体間での反応の違いを説明しうる。形成された DNA 付加体により、突然変異が生じる可能性が ある。key events を表 2 にまとめた。

## 表 2. 動物における 4-Aminobiphenyl の発がん性における key events

- 1. 代謝的活性化
  - a) N-ヒドロキシル化
  - b) N-エステル化 (グルクロニド、アセチル、硫酸塩)
  - c) 加水分解してニトレニウムイオンにする
- 2. 標的職器の多能性細胞における DNA 付加体形成(dG-C8, dA-C8, dG-N2)
- 3. がんにつながる重要な遺伝子の DNA 突然変異
- 4. 発がん
- dA、デオキシアデノシン;dG、デオキシグアノシン

## C. 用量反応関係

関連する研究の多くが何年も前に実施されたという事実を考慮すると、腫瘍の前駆病変に対す る用量反応の一致に関するデータは、マウスの膀胱過形成に限定されている。イヌでは、4-Aminobiphenylの単回投与後に膀胱腫瘍が発生することはなく(Deichmann & MacDonald、1968 年)、 複数回投与後の用量反応関係の研究は行われていない。前駆病変の発生率に関する情報が報告さ れている唯一の研究では、雄の BALB/c マウスに 0、7、14、28、55、110、220 mg/Lの濃度の 4-Aminobiphenyl を含む飲料水を介して 96 週間まで処置したものがある (Schieferstein ら、1985 年)。 これらの処置後の膀胱がん発生率は、それぞれ 0/116、1/117、1/118、0/118、6/115、5/118 及び 23/118 であった。55 mg/L 以上の群の発生率は、対照群に比べて統計的に有意に高かった。雌マウスに 4-Aminobiphenyl を濃度 0、7、19、38、75、150 及び 300 mg/Lの飲料水を介してばく露させると、 膀胱がんの発生率は、0/118、0/118、0/119、1/118、0/118、5/117及び1/117であった。重症度は示 されていなかったが、過形成の発生率ははるかに高かった。雄では、0、7、14、28、55、110及び 220 mg/L の投与量で、過形成の発生率は 0/116、4/117、9/118、71/118、108/115、107/118 及び 102/118 であった。雌では、それぞれ 0、7、19、38、75、150 及び 300 mg/L の用量で 0/118、0/118、3/119、 53/119、106/118、97/117 及び 83/117 であった。このように、腫瘍及び過形成の用量反応曲線は、 シグモイド型またはホッケースティック型であった。対照的に、尿路上皮細胞のC-8 グアニンDNA 付加体の平衡レベルは直線的な用量反応関係を示した(Poirier ら、1995年)。

同研究(Schieferstein ら、1985年)では、雄では肝腫瘍の発生率の増加は認められなかったが、 雌では、それぞれ0、7、19、38、75、150及び300mg/Lの投与量で、肝腫瘍(腺腫及びがんを合 わせたもの)の発生率は0/117、0/120、2/120、4/119、11/119、17/118及び10/117であった。様々 な組織を合わせた血管肉腫の発生率は、雄と雌の高い3用量で増加したが、発生率は雄よりも雌 の方がやや高かった。

## D. 時間的関連性

発がん過程における事象の順序を確立することは、その測定方法の感度に部分的ではあるが大 いに依存する。したがって、腫瘍は組織学的に検出できる大きさに達していなければならず、一 方で突然変異や DNA 付加体の測定には時間だけでなく十分な量の組織が必要である。その結果、 後者は膀胱よりも肝臓で研究されるのが一般的だが、特にげっ歯類では尿道の組織が少ないため、 生化学的・生物学的事象の頻度とは関係のない技術的な困難が生じている。DNA 付加体の代謝及 び形成は初期の事象であり、4-Aminobiphenyl による in vitro 処理後、数分または数時間以内及び 1 日以内に観察される(Kadlubar ら、1991年; Swaminathan & Reznikoff、1992年; al-Atrash ら、1995 年; Hatcher & Swaminathan、1995年; Doerge ら、1999年; Tsuneoka ら, 2003年)。しかしながら、 多くの in vivo 実験では、付加体を蓄積させ、平衡レベルに達し、検出を容易にするために、3~4 週間ばく露を継続する(例えば、Talaska ら、1990年; Flammang ら、1992年; Poirier & Beland、 1992 年; Poirier ら、1995 年; Underwood ら、1997 年)。また、突然変異は in vitro では短時間で検 出され得るが、生体内では数週間または数ヶ月のばく露後でないと検出されない(例えば、マウ ス肝臓における H-ras; Parsons ら、2002 年)。この期間は、突然変異が最初に生じた時期を正確に 反映しているとは限らない。ある研究では、4-Aminobiphenyl の単回投与から 14 日後に Muta™Mouse 膀胱アッセイで突然変異が検出された(Fletcher ら、1998 年)。膀胱のがんや過形成 は、マウスやイヌでは明らかに遅発性の病変であるが、時間経過の変化は体系的に評価されてい ない。ある2年間の研究では、マウスを13週から一定間隔で安楽殺し、膀胱に過形成病変を誘導 したが、異なる時期の発生率は示されていない(Schieferstein ら、1985)。膀胱の腫瘍は、一般的 に、マウスでは約2年後(Schieferstein ら、1985年)、イヌではそれより長い時間が経過するまで 発見されない(Walpole ら、1954 年; Deichmann ら、1958 年、1965 年)。しかし、ヒトの(SV40 に感染した)尿道粘膜細胞を 4-Aminobiphenyl で in vitro 処理し、6 週間 in vitro 培養した後、ヌー ドマウスに接種した場合、腫瘍性の形質転換が認められた(Bookland ら、1992 年 b)。

## E. 腫瘍反応と key events との関連性の強さ、一貫性、特異性

腫瘍反応と key events との関連性を支持するエビデンスは、膀胱に関する研究から得られたものがあるが、肝臓に関する研究からも有力なエビデンスが得られている。DNA 付加体の形成は両 組織で実証されている。

4-Aminobiphenyl が変異原性物質であることを示す研究は豊富にあり、S. typhimurium 菌の特定 のフレームシフト型突然変異及び塩基対置換感受性株(TA1538、TA98 及び TA100)に対する陽性 反応が、げっ歯類肝 S9 代謝的活性化製剤の存在下でのみ認められている。S9 による代謝的活性 化が必要であるということは、親アミンの DNA 反応性及び変異原性の欠如を示している。さら に、4-Aminobiphenylは、in vitro でラット肝細胞において不定期 DNA 合成を誘導する(米国環境 保護庁遺伝的活性プロファイル)。これらの in vitro 研究は、4-Aminobiphenyl が代謝的活性化後に 遺伝的損傷を引き起こす可能性があるというエビデンスを示している。また、細菌を用いた突然 変異試験でも代謝的活性化システムの解析が行われている (Dang & McQueen、1999)。Aroclor 1254 誘発雄 Sprague-Dawley ラット及び C57BL/6 マウスの肝臓ホモジネート及び、異なるレベルの N-及び O-アセチルトランスフェラーゼ (OAT) 活性を発現する S. typhimurium TA100 試験菌株が使 用された。TA100 は NAT/OAT 遺伝子のシングルコピーを有し、YG1029 は NAT/OAT 遺伝子のマ ルチコピーを有し、TA100/1.8DNP6 は NAT/OAT 欠損株である。マウス及びラット S9 を用いた効 果は類似していた(ただし、Aroclor 1254 処理の効果は調べなかった)。4-Aminobiphenyl または 4-Acetylaminobiphenyl を基質とした場合、YG1029 では TA100 または TA100/1,8DNP6 よりも多く突 然変異が誘発された。このことは、これらの細菌における N-hydroxylamine による突然変異誘発に は、高いアセチル化活性が関与していることを示唆している。

生体内での突然変異誘発機構におけるアリルニトレニウムイオンへの非酵素的ステップは、高 OAT-発現 *S. typhimurium* TG1024 株における *N*-hydroxy-4-aminobiphenyl の突然変異誘発が培地の pH に依存し、4.0~8.0 の範囲で突然変異体数と pH との間に逆相関の関係が観察されたことによ って支持される (Sarkar ら、2002 年)。

BALB/c マウスに 4-Aminobiphenyl を 28 日間飲水投与したところ、雌では膀胱よりも肝臓の方 が DNA 付加体の量が多かったのに対し、雄では逆の結果が得られた。このように、各性におい て、DNA 付加体のレベルは、4-Aminobiphenyl による腫瘍誘導に対する組織の感受性と相関して いた(Poirier ら、1995 年)。しかしながら、用量反応曲線の形状は、両組織の DNA 付加体では直 線的であった(雌マウスでは飽和して比較的平坦)のに対し、腫瘍の用量反応曲線はシグモイド 型であった(Poirier ら、1995 年)。

付加体の量は、50 nmol の 4-Aminobiphenyl を 21 週間にわたって局所投与した Hsd:ICR(Br)マウスの雌マウスの膀胱で最も高かった (一般的な職業的ばく露経路)。検査した全組織 (膀胱、肝臓、肺、皮膚)の主な付加体は、*N*-(deoxyguanosin-8-yl)-4-aminobiphenyl とのコクロマトグラフィーを用いて検査した (Under-wood ら、1997 年)。

雄の Muta<sup>™</sup>Mouse トランスジェニックマウス(すなわち、トランスジェニック CD2F、 [BALB/c×DBA/2]) に 10 mg/kg bw/日の 4-Aminobiphenyl を 10 日間経口投与した突然変異誘発の研 究では、膀胱、肝臓及び骨髄における突然変異頻度がそれぞれ 13.7 倍、4.8 倍及び 2.4 倍に増加し たことが報告されている(Fletcher ら、1998 年)。

新生児 B6C3F1(C57BL/6×C3H)マウスは、4-Aminobiphenyl の投与に反応して高頻度の肝腫瘍を 発症し、その多くは *H-ras* 遺伝子のコドン 61 における CAA→AAA 突然変異であった(Parsons ら, 2005 年)。in vivo では、0.3 µmol の 4-Aminobiphenyl を 24 時間前に投与した新生児マウスに おいて、主要な DNA 付加 *N*-(deoxyguanosin-8-yl)-4-aminobiphenyl 量は、5 adducts /10<sup>6</sup> ヌクレオチ ドであった。8 ヶ月後、CAA→AAA 突然変異は、投与マウスの 67%及び対照(ジメチルスルホキ シド、または DMSO)の 50%で検出されたが、投与マウスの平均突然変異率は 45×10<sup>-5</sup> であったの に対し、対照ではわずか 2×10<sup>-5</sup> であった。12 ヵ月後には、投与マウスの 79%、対照マウスの 8% に肝腫瘍が発生していた。これらの腫瘍はヒトの標的臓器の腫瘍ではないが、本研究の結果は、 膀胱がんの発生において提示されている一般的な MOA(すなわち、DNA 付加体の形成、重要な 遺伝子の突然変異、その後の腫瘍の出現)を支持するものである。

4-Aminobiphenyl (5 mg/kg bw) を単回経口投与してから 24 時間後に死亡したイヌ (性別は明記 されていない)の DNA 付加体は、肝臓で 5.4 fmolDNA adducts/µg、膀胱で 4.8 fmolDNA adducts/µg であった。しかし、4-Aminobiphenyl を膀胱に投与したイヌの肝臓と膀胱では DNA 付加体は検出 されなかった。一方、反応性中間体である *N*-hydroxy-4-aminobiphenyl を膀胱に投与したイヌの膀 胱では、3.9 fmol DNA adducts/µg の DNA 付加体が検出され、肝臓では付加体は検出されなかった。 免疫化学的方法で定量を行った (Roberts ら、1988 年)。トリチウム標識された 4-Aminobiphenyl (経 口、静脈内、または尿道内)、*N*-hydroxy-4-aminobiphenyl (静脈内、または尿道内)、*N*-hydroxy-4aminobiphenyl *N*-glucuronide (静脈内)を投与された雌イヌの試験では以下のことが実証された。

(1) 血中赤血球中の 4-aminobiphenyl -ヘモグロビン付加体の存在(2) 4-aminobiphenyl 投与後、膀胱内腔に入る *N*-hydroxy-4-aminobiphenyl の大部分は遊離 *N*-hydroxy-4-aminobiphenyl (0.7%) であり、酸溶性 *N*-グルクロニドは低濃度(0.3%) であること(3) *N*-hydroxy-4-aminobiphenyl を尿道内に注入した後の DNA 付加体量は、4-Aminobiphenyl を尿道内に注入した後と比較して 60 倍多かったこと、(4) *N*-hydroxy-4-aminobiphenyl へのばく露及びそれに続く 4-Aminobiphenyl-DNA 付加体の形成は、排尿の頻度及び尿の pH に依存すること(Kadlubar ら、1991 年)。

イヌの尿中 pH は、食事内容(Merck、1998年)、食後からの時間、時間帯及び消費水量に依存 して、約 4.5 から 7.5 まで変化することがあり、これらは発がん性に影響を及ぼす可能性のある因 子である(Cohen、1995)。イヌの肝臓及び膀胱からのミクロソーム調製物を用いた in vitro の研究 では、両臓器においてトランスアセチル化活性が存在することが示されており、そのため、4-Acetylaminobiphenyl、*N*-hydroxy-4-acetyl-aminobiphenyl、またはアセチルコエンザイム A(CoA)が アセチル供与体として存在する場合には、*N*-hydroxy-4-aminobiphenyl の RNA 及び DNA への結合 が起こるが、結合量は肝臓ミクロソームよりも膀胱ミクロソームの方が少なかった(Hatcher & Swaminathan、1992 年)。

4- Aminobiphenyl を投与したイヌの尿に含まれる尿膜細胞を調べたところ、*N*-hydroxy-4aminobiphenyl で in vitro で修飾した DNA や、4-aminobiphenyl を投与したイヌの剖検時に単離した イヌの膀胱尿路上皮細胞の DNA と同一の DNA 付加体が検出された。4- aminobiphenyl-DNA 付加 体形成の用量依存的増加が示された(Talaska ら、1990 年)。

# F. 生物学的妥当性及び整合性

4-Aminobiphenyl が DNA と付加体を形成し、腫瘍が発生する器官で変異原性を示すという結果 は、一般的に提案されている MOA の妥当性を示している(Fletcher ら、1998 年)。さらに、*N*hydroxy-4-aminobiphenyl は、腫瘍化していない SV40 不死化ヒト尿細管細胞の腫瘍化を引き起こす ことができる(Bookland ら、1992 年 b)。また、4-Aminobiphenyl に関する知見はいくつかの関連 芳香族アミンの代謝的活性化、DNA 付加体形成、突然変異誘発及びいくつかの種(ヒトを含む) における膀胱発がんに関する膨大な文献と一致している(Kadlubar ら、1977 年; Miller & Miller、 1977 年; Delclos ら、1987 年)。代謝的活性化を伴わない様々な in vitro 系での親アミンの DNA 付 加体形成及び変異原性の欠如は、代謝的活性化の必要性を明確に示している。アミンの投与後、 または *N*-ヒドロキシル代謝物へのばく露後に組織内で同じ DNA 付加体が確認され、付加体の構 造が化学的に確認されている。特定の生物物理学的側面は 2-aminofluorene のような構造的に関連 する芳香族アミンの方がより明らかにされているが、C-8 グアニン DNA 付加体の変異原性につい ても明らかにされている、(Kriek、1992 年)。

# G. その他の MOA

既に記載されている MOA の構成要素の代替的なものが提案されている。しかし、それらは MOA の全体的な説明を損なうものではなく、限局的側面(他の活性化酵素など)、または定量的側面に 影響を与える可能性のある過程のいずれかを示唆している。4-Aminobiphenyl は、CYP1A2 以外の 肝酵素(Kimura ら、1999年)によって N-水酸化代謝物に酸化され、肝臓及び膀胱の毒性及び発が んを引き起こすが、これには酸化酵素及びペルオキシダーゼが関与している可能性がある (Kadlubar ら、1982年、1991年)。代謝的活性化に関与する酵素は異なるかもしれないが、反応 性親電子物質の生成、DNA 付加体の形成、変異原性、発がんという順序は一貫している。さらに、 MOA のこの時点から、活性化酵素にかかわらず、CYP1A2を介した活性化と同じ順序で起こると 考えるのが妥当である。

巨大な付加体に加えて、*N*-hydroxy-4-aminobiphenylは、内因性ペルオキシダーゼが関与している可能性があり、尿道粘膜DNAに酸化的損傷を引き起こすことを示唆するエビデンスがある(Burger ら、2001 年)。このことと 4-Aminobiphenyl の発がん活性との関連性は不明である。

N-hydroxy-4-aminobiphenyl 及びその活性型は、in vitro で尿道粘膜及び他の細胞に対して細胞毒性を示す(Reznikoff ら、1986年)が、これが発がん作用に果たす役割は不明である(原因ではなく、尿道粘膜発がんにおける増強的な役割については以下を参照のこと)。この過程で用量反応関係は変化するが、上述の基本的な MOA は変化しないと考えられる。

# H. 推定される MOA の評価

推定される MOA の初期段階は、利用可能なエビデンスによって十分に裏付けられており、4-Aminobiphenyl はイヌやマウスでは膀胱発がん物質であり、げっ歯類では他の組織(主に肝臓)で の発がん物質である十分なエビデンスがあると判断されている。このように、肝臓や他の標的臓 器では DNA 付加体を形成しうる生成物に代謝され、突然変異が生じることが実証されている。 他の臓器も 4-Aminobiphenyl 誘発性腫瘍の標的となりうるが、イヌやマウスの一部の系統では膀 胱が主な標的となっている。一般的な遺伝毒性と腫瘍発生との間の段階についてのエビデンスは 十分ではない。4-Aminobiphenyl の膀胱の細胞増殖への影響についての研究は著しく不足している が、関連する芳香族アミンやアミドについての情報は入手可能であり、特にメガマウス ED-01 実 験(Cairns、1979年; Gaylor、1979年; Littlefield ら、1979年)のデータを用いたマウスの膀胱に おける 2-acetylaminofluorene によって誘導される DNA 反応性(及び変異原性)と細胞増殖との間 の相互作用の解析が行われている。変異原性が細胞増殖に依存していることは、DNA 付加体の用 量反応が直線的であるにもかかわらず、腫瘍の用量反応がシグモイド型であることの説明を提供 することができる(Cohen & Ellwein、1990年)。この関連性は、4-Aminobiphenyl 誘発性膀胱がん の発生と用量反応性を評価する上で重要な意味を持つ(以下の議論を参照)。

# I. 不確実性、矛盾、データギャップ

4-Aminobiphenyl の代謝的活性化を伴う細菌を用いた突然変異試験では、ほとんどの変異がフレ ームシフトであることが示されているが、バクテリオファージ M13 クローニングベクターから得 た一本鎖 DNA 中の lacZ 遺伝子の 4-Aminobiphenyl 誘発突然変異の配列解析を行ったところ、80% 以上が G 部位で生じる塩基対置換が明らかになった。G→T トランスバージョンが優勢で、次に G→C トランスバージョン、G→A トランジションが続いた。次に、主要な DNA 付加体である *N*-(deoxyguanosin-8-yl)-4-aminobiphenyl を M13 ゲノム内に挿入し、生体内複製後に変異頻度と特異性 を測定した。目標とする突然変異率は約 0.01%であり、一次突然変異は G→C トランスバージョ ンであった。このように、in vitro での観察結果は in vivo での観察結果と矛盾しないが、変異原性 は弱いものであった (Verghis ら、1997 年)。

in vivo での研究のほとんどはマウスで行われている。無理からぬ理由ではあるが、イヌは膀胱 発がんに対して感受性が高い種であるにもかかわらず、あまり注目されていない。反応における マウスの系統の違いは明らかである。B6C3F1及び雌のBALB/cStCrlfC3Hf/Netrマウスは、肝臓発 がんに対してより感受性が高く、一方、雄のBALB/cStCrfC3Hf/Netrマウスは、4-Aminobiphenylへ のばく露後に膀胱腫瘍を発症する(Schieferstein ら、1985 年; Dooley ら、1988 年、1992 年)。そ れにもかかわらず、利用可能な研究では、マウスの系統差による影響はあまり注目されていない。

4-Aminobiphenyl が代謝され、肝臓や膀胱で DNA と付加体を形成する基本的な酵素と考えられ ているのは CYP1A2 である(Butler ら、1989 年 a、1989 年 b)。しかし、CYP1A2(+/+)野生型マウ スと CYP1A2(-/-)ノックアウトマウスの影響を比較すると、予想に反して、CYP1A2 の発現は、4-Aminobiphenyl 誘発性酸化ストレスまたは 4-Aminobiphenyl-DNA 付加体形成とは関連していない ことが示された。さらに、他の第1相及び第2相反応の酵素の発現とともに肝 CYP1A2 タンパク 質の発現を5倍に増加させた 2,3,7,8-テトラクロロジベンゾ-p-ジオキシン(TCDD)は、肝臓にお ける付加体量を変化させないか、または実際に減少させた。このような誘導の定量的効果は、誘 導された酵素のバランスに依存するであろう。これらの結果は、CYP1A2 が 4-Aminobiphenyl の主 要な代謝的活性化因子ではないか、CYP1A2 の非存在下でもマウスの他の酵素がこの化合物を活 性化させていることを示唆している(Tsuneoka ら, 2003 年)他の芳香族アミンを用いた研究に基 づくと、活性化酵素は他にも、P-450 酵素、酸化酵素、またはペルオキシダーゼを含むかもしれな い(Lakshmi ら、1990 年; Smith ら、1991 年; Hughes ら、1992 年)。 4-Aminobiphenyl によって誘導される発がんにおいて重要であると考えられている別の反応は、 アセチル化である。アセチル化は 4-Aminobiphenyl の発がんにいくつかの役割を果たしている。*N*hydroxy-4-aminobiphenyl の *O*-アセチル化及び *N*,*O*-アセチル化は、ヒトではリスクを増加させると 予想されるが、4-Aminobiphenyl の *N*-アセチル化はリスクを減少させるはずである(Lower ら、 1979年)。アセチル化は、NAT1 または NAT2 によって触媒され、後者は集団内で顕著な多型が存 在する(Hein ら、2000年; Cascorbi ら、2001年)。親アミンである 4-Aminobiphenyl のアセチル化 はヒトでは解毒過程と考えられているため、アセチル化が遅い表現型は膀胱がんのリスクを増加 させると予測されている。それゆえ、アセチル化が速い表現型はリスクの減少と関連しているは ずである。

しかし、マウスの acetylator の表現型の研究では、相反する結果が得られている。ある研究では、 他のすべての点で明らかに同一であると思われるホモ接合性の rapid acetylator マウスまたはホモ 接合性の slow acetylator マウスの雄雌に、4-Aminobiphenyl 塩酸(55-300 mg/L)を 28 日間飲水投与 した。肝 DNA 付加体のレベルは雌雄ともに投与量の増加とともに増加したが、acetylator の表現 型とは無関係であった。膀胱では、DNA 付加体は雄マウスでは 100 mg/kg でプラトーに到達し、 acetylator の表現型とは無関係であった。雌マウスでは、DNA 付加体量は雄マウスよりも低く、最 高用量で減少したが、予想に反して rapid acetylator 表現型では DNA 付加体量が高かった (Flammang ら、1992 年)。これらの結果は、アセチルトランスフェラーゼ活性がマウスの DNA 付加体形成の 速度を決定するものではないことを示唆していると解釈された。McQueen ら(2003 年)の研究で は、C57BL/6、B6.A 及び A/J マウス株と、ヒト NAT1 トランス遺伝子を持つトランスジェニック マウス hNAT1:A/J 及び hNAT1:C57 を用いて、マウス NAT2 対立遺伝子と 4-Aminobiphenyl-DNA 付 加体量との間には相関関係がないという同様の結論に達した。しかし、マウスの NAT2 活性の違 いは軽微であり、おそらく 4-Aminobiphenyl の遺伝毒性に影響を与えるには十分ではなかった。最 近の研究では、ヒトでは N-hydroxy-4-aminobiphenyl の 0-アセチル化には NAT2 ではなく NAT1 が 関与していることが示唆されている(Oda、2004 年)。

また、説明が必要なマウスの系統特異的突然変異もある。例えば、B6C3F1 では、4-Aminobiphenyl は、*H-ras* 遺伝子のコドン 61 において主に C→A 突然変異(非コード鎖の G→T トランスバージョンを反映)を誘発するのに対し、CD-1 マウスでは、*H-ras* 遺伝子コドン 61 における主な突然変異は A→T トランスバージョンであった(Manjanatha ら、1996 年)。

腫瘍の発生には細胞増殖も必要であるが、4-Aminobiphenylの発がん過程の初期段階での細胞増 殖を調べた研究は少ない。また、先に述べた発がん性試験(Schieferstein ら、1985年)では、膀胱 がんの発生は雄のみであったが、過形成の発生率は雌雄ともに高いことが報告されている。しか しこのことについてはそれ以上調査されていない(後述)。

要約すると、4-Aminobiphenyl 誘発性膀胱発がんの MOA は、代謝的活性化、DNA 付加体形成、 遺伝子突然変異を含む一連の key events が関与していることが明らかになった。

このことは、構造的に関連のある芳香族アミンを用いた研究によってさらに強化されている。 しかし、関与する特定の酵素の詳細、種間での臓器特異性の違いの根拠や効力の詳細、ヒトにお ける用量反応曲線の形状については、データギャップが残っている。これは、競合する代謝経路 の複雑さを考えれば、想定内である。利用可能なデータは仮説 MOA を支持するのに十分である と考えられるが、これらの不確実性の影響については総合的な定量的評価を考慮する必要がある (表 3)。

## 表 3. 4-Aminobiphenyl 膀胱発がん性に影響を与える調節因子

- 1 エステル化酵素の競合的活性
- 2 酵素の活性化または不活性化に影響を与える遺伝的多型(例: slow acetylator 及び rapid acetylator)
- 3 尿の pH(主に食事の影響を受ける)と他の尿成分
- 4 尿路粘膜細胞増殖(4-アミノビフェニルの高用量投与、または尿路粘膜増殖に影響を与える 他の薬剤との併用投与により誘導される)

# 実験動物とヒトとの間の key evants の根本的、質的な違いに基づいて、MOA のヒト との関連性を合理的に排除することができるか

4-Aminobiphenyl 誘発性膀胱がんの key events それぞれを支持するヒト及びヒトの細胞系におけ る有力なエビデンスがある。N-hydroxylamine への代謝的活性化が実証されており、活性化のため にいくつかの酵素が示されているほか、N-アセチル化など N-ヒドロキシル化の効果を増強または 減少させる可能性のある他の酵素も示唆されている。遺伝的多型はこれらの酵素活性に大きく影 響し、4-Aminobiphenyl ばく露に対する膀胱発がんの感受性に影響する変異を生じさせる。マウス やイヌの DNA から検出されたものと同一の DNA 付加体がヒトの尿路上皮細胞で確認されてお り、同様の変異原性を有することが明らかになった。さらに、広範な疫学的研究から、4-Aminobiphenyl のヒトにおける膀胱発がん性が証明されている。

膀胱がんは、喫煙や職業的ばく露といった 4-Aminobiphenyl の摂取と関連している。4-Aminobiphenyl は、1935年から1955年まで米国で製造され(Melick ら、1955年)、効率のいいゴ ム酸化防止剤として使用されていたが、現在では商業的には生産されていない。市販の 4-Aminobiphenyl に職業的にばく露された労働者の1系列に限定した疫学研究では、膀胱がんの発生 率が高いことが報告されている(Melick ら、1955年、1971年; Melamed ら、1960年; Koss ら、 1965年、1969年)。503人の労働者のうち、細胞診において 59例が陽性、そのうち 35例は組織学 的に膀胱がんが確認された;公表時、7例は細胞診において陽性のまま、7例は他の原因で死亡し、 10例は追跡調査できていない(Koss ら、1969年)。たばこの煙に加えて、炭素及び窒素を含む物 質の燃焼で生じるものへのばく露や不明確な環境中の物質もあるようである(Skipper ら、2003年)。

#### IPCS Framework for Analysing the Relevance of a Cancer Mode of Action for Humans and Case-Studies

喫煙が原因とされているものは、米国とヨーロッパにおける膀胱がんの症例の 40%から 70%を占めている(IARC、1986年; Castelao ら、2001年)。黒タバコ(自然乾燥)は、ブロンドタバコ(熱風乾燥)に比べて 4-Aminobiphenyl をより多く含んでいる(Bryant ら、1988年)。

4-Aminobiphenylの膀胱発がんにおけるマウスやイヌで示された key events は、主にタバコの煙中の 4-Aminobiphenyl にばく露されたヒトを対象に評価されているが、ヒトの尿路上皮細胞を用いた in vitro 評価法も利用されている(表4を参照)。

表 4.4-Aminobiphenyl による尿路膀胱発がんの key events の種間一致性評価

key events	マウス	イヌ	ヒト
1. 反応性親電子物質への代謝的活性化	+	+	+
2. DNA 付加体の形成	+	+	+
3. 変異原性	+	+	+
4. 発がん	+	+	+

吸収された 4-Aminobiphenyl は、CYP1A2 によって肝臓で N-酸化される。CYP1A2 は CYP1A1 との相同性がかなり高いにもかかわらず、異なる基質特異性を有しており、肝臓でのみ見出される (Lang & Pelkonen、1999)。他の酵素は、N-hydroxylamine への代謝的活性化をサポートする。

NAT1 及び NAT2 はそれぞれ、3 種類のアセチル化を触媒する。すなわち、アリルアミンの N-ア セチル化、N-hydroxylamineのO-アセチル化及びアリルヒドロキサム酸のN, O-アセチル化である (Flammang & Kadlubar、1986 年; Mattano ら、1989 年; Fretland ら、1997 年; Hein ら、2000 年)。 N-アセチルトランスフェラーゼによる N-アセチル化は、主に、形成された 4-Aminobiphenyl のア セトアミドがアミンに比べて N-ヒドロキシル化の基質として小さいために、膀胱発がん性に対し て保護効果を有すると考えられている。NAT アイソフォームをコードする 2 つの遺伝子には、 NATIとNAT2 があり、対立遺伝子の変異はヒトにおける膀胱がんの感受性と関連している(Hein ら、2000年)。ほとんどの研究は、NAT2の slow acetylator が膀胱発がんのリスク増加を示唆して いるが、芳香族アミン膀胱発がんに対する NATI 遺伝子型の寄与は明らかではない(Cartwright ら、 1982年; Hein ら、2000年)。喫煙者の間では、slow acetylator の発現に関連する 4-Aminobiphenyl -ヘモグロビン付加体がより多く存在する (Vineis ら、1990年)。また、NAT1 と NAT2 の相互作用 が示唆されている(Cascorbiら、2001年)。ドイツの膀胱がん患者 425 人を対象とした研究で、 Cascorbi ら(2001 年)は、以下のことを明らかにした。(1) NATI\*10 遺伝子型の NAT2\*4 遺伝子 型への部分的な連鎖(2)調査した症例中の rapid NAT2 遺伝子型を有するヒトにおける、NAT1\*10 遺伝子型の発現量の低さ(3)職業ばく露歴とNAT2\* slow /NATI\*4 遺伝子型の組み合わせは、職業 ばく露によるリスクのない対照群に比べて、がん症例は 5.96 倍(2.96-12.0)の頻度であった  $(P < 0.0001)_{\odot}$ 

したがって、特に環境リスク因子にばく露される場合、NAT2\*4 及び NAT1\*10 を有する個体は、 膀胱がんのリスクが有意に低いことが示唆される。

*CYP1A2* (Oscarson ら、n.d.) 及び *NAT2* (Hein ら、2000 年)遺伝子の多型は、ヒト集団における これらの酵素活性の変動と関連しているが、CYP1A2 活性の変動が遺伝的要因によるものである かはまだ明らかにされていない (Sachse ら、2003 年)。さらに、喫煙者に誘導される *CYP1A2* 遺伝 子の発現は、CYP1A2 酵素活性を高める (Sesardic ら、1988; Eaton ら、1995 年)。4-Aminobiphenyl にばく露され、CYP1A2 と高い *slow NAT2* 活性を発現する個体は、CYP1A2 と低い *rapid NAT2* 活 性を発現する個体よりも、*N*-hydroxy-4-aminobiphenyl のレベルが高い。したがって、肝臓と膀胱に おける 4-Aminobiphenyl -ヘモグロビン付加体と 4-Aminobiphenyl-DNA 付加体の高いレベルを有す ることが予測される。

腫瘍抑制遺伝子 RB1 及び TP53 は、膀胱がん、特に低悪性度の乳頭腫瘍よりも高悪性度の尿路 上皮がんに関与しているようである。両遺伝子は細胞周期の調節に関与している。さらに、TP53 は、DNA 損傷、細胞死及び血管新生の役割を果たし(Hickman ら、2002 年)、その遺伝子産物は、 複数の遺伝子の発現を調節する(Vousden & Lu、2002 年)。RB1 の不活性化と筋肉内への浸潤に強 い関連が見出されている(Cairns ら、1991 年; Ishikawa ら、1991 年; Presti ら、1991 年; Primdahl ら、2000年)。45 例の膀胱がんを対象とした研究では、TP53 変異を有する 9 人のうち 7 人がグレ ード3の腫瘍(周囲組織への浸潤を含む)であった(Martoneら、1998年)。RB1の不活性化は、 筋肉内浸潤性膀胱がんの 30~80%で発生し(Cairns ら、1991 年; Logothetis ら、1992 年; Wright ら、1995年; Ioachim ら、2000年)、多くの場合、ヘテロ接合性 13q 欠失と残りの対立遺伝子の突 然変異の結果発生する (Cordon-Cardo & Reuter、1997 年)。少なくとも 30 の腫瘍を調査した研究 では、浸潤性膀胱がんの 40~60%で TP53 突然変異が認められた(Tiguert ら、2001 年; Lu ら、 2002年)。特定変異のホットスポットは確認されなかったが、変異の90%以上はエクソン4-9に発 生していた。TP53のエクソン 5、7 及び 8 を含む DNA 断片における N-hydroxy-4-aminobiphenyl の 結合スペクトルの研究では、非 CpG 部位である 285 コドン及び CpG 部位である 175 及び 248 コ ドンに優先的に結合することが確認されたが、C5シトシンメチル化が起こった後にのみ確認され た(Fengら、2002 年)。著者らは、膀胱がんにおける TP53 の変異スペクトルが、この腫瘍の原因 である 4-Aminobiphenyl の役割を強く示唆していると結論づけた。

4-Aminobiphenylの環境中ばく露の源であるタバコの煙へのばく露は、成人と胎児の両方で、4-Aminobiphenyl-ヘモグロビン付加体量の増加と関連している。喫煙者(*n*=14)と非喫煙者(*n*=38)の女性の研究では、4-Aminobiphenyl-ヘモグロビンレベルは、喫煙者では183±108 pg/g ヘモグロビン、非喫煙者では22±8 pg/g ヘモグロビンであったのに対し、それぞれの胎児のレベルは92±54 pg/g ヘモグロビンと17±13 pg/g ヘモグロビン (Coghlin ら、1991年)であった。この差は、腫瘍組織 DNA の研究において成人でも観察されている (Curigliano ら、1996年)。イタリア、トリノの男性における研究では、ヘモグロビン付加体量(ばく露量の代用として、また DNA 付加体の可能性の指標として使用される)は、4-Aminobiphenyl の供給源であるタバコへのばく露量と関連しており(黒タバコ>膀胱がんのリスクでも同様の傾向がみられた(Bryant ら、1988年)。主にばく露の指標である付加体の存在とがん発生とを結びつける情報には大きなギャップがある。

ヒトでは、4-Aminobiphenyl は膀胱がんとのみ関連しているが、マウスでは肝臓と膀胱の腫瘍が 誘発されている。臓器特異性におけるこれらの種差の具体的な理由は明らかにされていないが、 競合する N-エステル化酵素の活性化の違いによるものと考えられる。硫酸化は芳香族アミンによ る肝発がんと密接に関連しているようだが、N-グルクロン酸化は膀胱発がんと関連しているよう である。アセチル化には様々な効果があるが、ヒトでは主に解毒プロセスであり、アセチル化が 速いか遅いかを決定する*N*-アセチルトランスフェラーゼの型に大きく影響される。ヒトの組織が、 4-Aminobiphenyl とその代謝物の代謝に関与しているかについて研究されてきた。CYP1A2は、ヒ ト肝ミクロソーム分画による 4-aminobiphenyl から N-hydroxy-4-aminobiphenyl への代謝に関与して いる (Butler ら、1989 年 b)。*N*-hydroxy-4-aminobiphenyl は、ヒト肝臓及びそれより程度は低いが、 結腸由来の細胞質性スルホトランスフェラーゼによって、牛胸腺 DNA と共有結合する生成物に 代謝されるが、膵臓や膀胱由来のものによっては代謝されない。膀胱でのスルホトランスフェラ ーゼ活性の欠如を考慮すると、肝スルホトランスフェラーゼは肝外組織での N-hydroxy-4aminobiphenyl の生物学的利用能を低下させ、膀胱の解毒機構として機能する可能性が示唆されて いる (Chou ら、1995 年)。一方、ヒト尿路上皮細胞に存在する N-アセチルトランスフェラーゼ (Frederickson ら、1992; Swaminathan & Reznikoff、1992年)は、N-hydroxy-4-aminobiphenyl 及び そのアセチル化化合物 N-hydroxy-4-acetylaminobiphenyl 及び N-アセトキシ-4-アセチルアミノビフ エニルを DNA 反応性物質に代謝することができる。N-(deoxyguanosin-8-yl)-4-aminobiphenyl と主 要な付加体はコクロマトグラフされ、N-hydroxy-4-aminobiphenyl のサイトゾル媒介結合で得た DNA を用いた <sup>32</sup>P-ポストラベリング法により、4 つの放射性スポットが明らかになった。健康な ヒト尿路上皮細胞を用いた場合には5つの付加体が認められたが、そのうち2つはサイトゾルを 用いた場合に認められた2つの付加体と同じであった。このことから、アセチル化以外の活性化 経路の存在が示唆された。

イヌ組織を用いた実験と同様の実験により、ヒトの尿路上皮細胞ミクロソームがアセチル基転移活性を有していることが示されており、N-hydroxy-4-aminobiphenylのRNAやDNAへの結合は、 4-Acetylaminobiphenyl、N-hydroxy-4-acetylaminobiphenyl、またはアセチル CoA をアセチル基供与体とした場合に起こることが示されている(Hatcher ら、1993 年)。また、N-hydroxy-4-aminobiphenyl、 N-acetoxy-4-acetylaminobiphenyl、N-acetoxy-4-aminobiphenyl と反応させて生成した DNA 付加体の  $^{32}$ P-ポストラベリングは、類似のプロファイルを示し、N-acetoxy-4-aminobiphenyl から生じるアリ ルニトレニウムイオンが共通の反応種であることを発見した。この付加体の構造は、N-(deoxyguanosin-8-yl)-4-aminobiphenyl(dG-C8-aminobiphenyl) や N-(deoxyadenosin-8-yl)-4aminobiphenyl(dA-C8-aminobiphenyl)の 3',5'-ビスホスホ誘導体(Frederickson ら、1992 年; Hatcher & Swaminathanosin、1995 年)及び N-(deoxyguanosin-N(2)-yl)-4-azobiphenyl (Hatcher & Swaminathan、 2002 年)として同定されている。

喫煙者と非喫煙者を比較した結果は、仮説 MOA のヒトへの関連性を支持するものである。T1 膀胱がん 46 例の研究では、4-Aminobiphenyl-DNA 付加体の平均相対染色強度は、非喫煙者(113±71、n=22)よりも現在の喫煙者(275±81、n=24)の方が有意に高かった(Curigliano ら、1996 年)。同様の結果が喉頭組織(Flamini ら、1998 年)及び乳腺組織(Faraglia ら、2003 年)についても報告されている。4-Aminobiphenyl-ヘモグロビン付加体をばく露の指標として使用すると、膀胱がん患者は対照者よりも高いレベルであったのに対し(Del Santo ら、1991 年)、肺がん患者はそうではなかった(Weston ら、1991 年)。この違いの根拠は不明である。

ヒト以外の試験系で得られた遺伝毒性のエビデンスに加えて、4-Aminobiphenylは、ヒト尿路上 皮細胞のミクロソーム調製物によって、*S. typhimurium* YG1024(*O*-アセチルトランスフェラーゼ 活性の高い TA98 の派生株)の変異原性物質に代謝されることがあるが、TA98 株自体では代謝さ れない(Hatcher ら、1993 年)。この研究では、他の種または他のヒト組織は調べられていない。

6-チオグアニン耐性変異体は、4-Aminobiphenyl 自体へのばく露、または N-hydroxy-4aminobiphenyl、N-hydroxy-4-aminobiphenyl、N-acetoxy-4-acetylaminobiphenyl へのばく露によって、 非腫瘍性 SV40 不死化ヒト尿路上皮細胞株で誘導することができる(Bookland ら、1992 年 a)。観 察された活性には、外因性代謝的活性化経路は必要とされなかった。変異体分画の統計的に有意 な増加をもたらすための最小濃度は以下の通りであった。N-acetoxy-4-acetylaminobiphenyl、2 µmol/L; N-hydroxy-4-acetylaminobiphenyl、5µmol/L; N-hydroxy-4-aminobiphenyl、20µmol/L; 及び 4-Aminobiphenyl、100 µmol/L。また、これらの物質のうちの 3 つは処理した細胞をヌードマウス に皮下注射したときの発がんをエンドポイントとした in vitro-in vivo アッセイにおいて、同じヒト 不死化尿路上皮細胞を使用した腫瘍性形質転換についても検討が実施された(Bookland ら、1992 年 b)。形質転換はすべての試験で示されたが、最小濃度は以下の通りであった。N-hydroxy-4acetylaminobiphenyl、0.5 µmol/L; N-hydroxy-4-aminobiphenyl、0.5 µmol/L; 及び 4-Aminobiphenyl、0.5 µmol/L; N-hydroxy-4-aminobiphenyl、0.5 µmol/L; 海防 4-Aminobiphenyl、20 かどのように解釈すべきかは明らかではない。それは、形質転換が突然変異に依存せず、形質転換 次要素のようにするの素のと同じているか、または単にあるの感

要約すると、マウス、イヌ、ヒトにおいて、MOA の key events は定性的には同じである: *N*-hydroxylamine への代謝的活性化とそれに続く反応性親電子物質(おそらくニトレニウムイオン)の形成、グアニン付加体の形成、遺伝子突然変異及びがんの形成である。どの遺伝子が変異し、 どのようにしてがんが誘発されるのかなど、遺伝子変異とがんとの間に介在する事象は明らかに されていない。それにもかかわらず、MOA は明確に示されており、動物モデルでもヒトでも同じ である。

# 実験動物とヒトとの間の動態的または薬力学的要因のいずれかの量的差異に基づいて、MOAのヒトへの関連性を合理的に排除することができるか

以上詳述したように、4-Aminobiphenylの代謝的活性化、DNA 付加体、変異原性は、マウス、イ ヌ、ヒトでは定性的に同じであり、これら3種では膀胱腫瘍を誘発し、マウス、ラット、ウサギ ではその他の腫瘍を誘発する。吸収、分布、排泄に関する詳細は報告されていないが、マウス、 イヌ、ヒトで発生する尿路上皮における DNA 付加体形成量が類似していることから、3種の間で は速度論的な差異は有意ではないことが示唆されている。

#### IPCS Framework for Analysing the Relevance of a Cancer Mode of Action for Humans and Case-Studies

3 種の酵素の過程は類似しているが、量的な違いは明らかである。これらの違いは、種間で見られ る標的臓器の特異性の違いの一部を説明し、DNA 付加体の生成における定量的な違いを示唆して いる可能性がある。それにもかかわらず、これらの違いは、どの種でも、あるいは異なる標的臓 器でも、全体的な MOA を否定するものではなく、代謝的活性化と不活性化のための競合する経 路の複雑さと一致している。

おそらく、異なる付加体の修復能や種間、組織間における量的な違いが存在するだろう。しか し、3種すべてで比較的多くの付加体が検出されたことから、かなり多くの安定的な付加体が産 生されていることがわかる。

マウス、イヌ、ヒトに共通する標的組織である膀胱の尿路上皮は、形態学的に類似している(Pauli ら、1983年)。尿路上皮は、腔内表面の尿に対するバリア機能の大部分を担う特徴的な非対称性単 位膜を有している。尿路上皮は、尿路上皮特異的タンパク質であるウロプラキンから構成されて おり、その配列は種間で高度に保存されている(Wuら、1994年)。さらに、尿路上皮は、3種す べての種において代謝的に活性化している。

また、尿 pH や排尿頻度など、尿路上皮 DNA 付加体の最終的な産生量に影響を与える因子も同 定されている(Cohen ら、1995年; Sarkar ら、2002年)。pH の範囲は種によって異なるが、マウ ス、イヌ及びヒトの尿 pH は、容易に酸性及びアルカリ性、また中性に変動する。繰り返しになる が、量的な違いは生じるものの、これらはヒトにおける MOA の存在を排除するものではない。

DNA 反応性以外の MOA を示唆するエビデンスはない。しかし、4-Aminobiphenyl の膀胱発がん に対する見かけの影響に関しては、種間で量的な差が存在する。4-Aminobiphenylの代謝物はDNA と同様にタンパク質(ヘモグロビンなど)とも相互作用し、4-Aminobiphenylの代謝物は細胞毒性 を有することが明らかになっている (Schieferstein ら、1985 年; Reznikoff ら、1986 年; Kadlubar ら、1991年)。4-Aminobiphenylの高用量投与によるマウス膀胱の細胞毒性と再生性増殖には、尿 路上皮細胞タンパク質との相互作用が関与している可能性がある。DNAの反応性と、相反する変 異原性と細胞増殖の相互作用は、DNA 付加体の用量反応が直線的であるにもかかわらず、腫瘍の 用量反応曲線がシグモイド型であることを説明している(Cohen & Ellwein、1990年)。尿路上皮細 胞毒性を生じる可能性があるマウスの尿中に見られる高濃度の4-Aminobiphenvlは、一般的に受動 喫煙者では達成されていない。しかし、他の(未知の)物質は、喫煙者(Auerbach & Garfinkel、 1989年)で尿路上皮の過形成を生成するように見える。この細胞増殖の増加は、標的となる DNA 複製細胞の数を大幅に増やし、正常にゆっくりと複製する少数の尿路上皮と比較して、膀胱に対 する 4-Aminobiphenyl の影響を大幅に増強する。このように、マウスと比較してヒトの方が 4-Aminobiphenyl の明らかに大きな効力は考えにくい。しかし、マウスでは 4-Aminobiphenyl 単一の 物質による DNA 反応性と細胞増殖の相乗効果がタバコの煙の複雑な混合物中の様々な物質によ って引き起こることが示されている。

4-Aminobiphenyl への職業的ばく露は、たばこの煙よりも 4-Aminobiphenyl の用量が多いと考えられる。なぜなら、膀胱がんの発生率が喫煙者に比べて職業的にばく露される集団の方がかなり高かったためである。しかし、これらの職業ばく露が発生した時点では代謝物濃度や尿路上皮細胞内の DNA 付加体レベルを定量的に測定することができず、また、個人の喫煙歴を評価することはなかった(Koss ら、1965 年、1969 年)。

要約すると、種間での量的な違いは存在するが、マウスやイヌと同じ MOA がヒトにも当ては まることを排除するものではない。

#### |結論:信頼性、解析及び帰結の記述

推定される MOA の初期段階は、代謝的活性化、DNA 付加体形成及び突然変異の key events が、 マウス、イヌ及びヒトにおいて定性的に同じであることを示す。これは利用可能なエビデンスに よって十分に支持されている。4-Aminobiphenyl がヒトの膀胱発がん物質であるという強力かつ十 分なエビデンスがある。しかし、突然変異とがんの発生との間に介在するステップについてのエ ビデンスは不足している。付加体量と TP53 突然変異との関連について説明したが、これらの特定 の遺伝的変化は腫瘍の進行から遅れて現れ、しばしば内因性の原因 (例えば、メチル化された CpG 部位での脱プリン) であるため、説得力のあるものではない。膀胱がんにおける TP53 突然変異に ついては、症例対照研究で研究されている (Schroeder ら、2003 年)。さらに、ヒトの尿路上皮腫 瘍のほとんどは低悪性度の乳頭病変であり、一般に TP53 変異を有していない。

N-hydroxy-4-acetylaminobiphenylの変異スペクトルは、Big Blue mouseの胚性線維芽細胞におい て研究されている(Bessaratinia ら、2002年)。これらの細胞を24時間処理すると、cII 遺伝子の突 然変異頻度がバックグラウンドと比較して最大 12.8 倍の用量依存的な増加をもたらした。一塩基 置換は、処理細胞では突然変異の 86%、対照細胞では突然変異の 74%を占めていた。これらの変 異のうち、63%と 36%はそれぞれ cll 遺伝子に沿ったグアニン残基で発生した。処置細胞では cll 遺伝子の変異の 47%が G→T のトランスバージョンであったのに対し、対照細胞では最も一般的 な変異は挿入であり、これは変異の19%を占めていた。誘導された付加体のマッピングにより、 5 つの DNA 付加体部位が確立された。そのうちの 4 つは N-hydroxy-4-acetylaminobiphenyl による 主な変異部位であり、特に G→T トランスバージョンを生じていた。しかしながら、ヒト膀胱が んの TP53 遺伝子では、G→A トランジションが優勢(53%) であり、その5つの変異ホットスポ ット(コドン175、248、273、280、285)のすべてで優勢で、そのうちの3つはメチル化 CpGホ ットスポット(175、248、273)にあった。cll 遺伝子では、誘導される突然変異ホットスポット も、メチル化 CpG ジヌクレオチドに偏っていない。この研究から、*cII* 遺伝子における *N*-hydroxy-4-acetylaminobiphenyl によって誘導される突然変異パターンと、ヒト膀胱がんにおける TP53 遺伝 子で観察される突然変異パターンとの間には大きなギャップがあると結論づけられる。しかし、 4-Aminobiphenyl によって誘導される突然変異スペクトルにおけるメチル化状態や転写活性の役 割はまだ明らかにされていない。また、TP53遺伝子の変異スペクトルは、腫瘍発生過程の選択を 反映したものであることにも留意しなければならない。

#### IPCS Framework for Analysing the Relevance of a Cancer Mode of Action for Humans and Case-Studies

以上の解析から、4-Aminobiphenyl 発がん MOA は動物モデルで知られており、その MOA は定 性的にも定量的にもヒトに関連していることが明らかになった。この評価に基づく結論は、疫学 的なエビデンスがなくても、4-Aminobiphenyl はヒトに対して発がんの危険性があるということで ある。

完全なリスク評価を行うためには、用量反応及びヒトへのばく露に関する追加情報が必要であ る。上記の情報に基づいて、職業的(過去の)ばく露と喫煙ばく露など予想されるばく露による 発がんリスクを予測している。非喫煙者の環境ばく露における潜在的リスクについては、さらな る解析が必要である。MOA 解析は、そのような評価のための基礎と基盤を提供する。4-Aminobiphenyl に関する疫学的エビデンスは、MOA の HRF によって推定される結論を支持してい る。

## 4-Aminobiphenyl とヒト関連性フレームワーク

4-Aminobiphenyl は、提唱されている IPCS HRF を用いて MOA 解析に基づいて評価した。その 結果、DNA 反応性 MOA の key events である代謝的活性化、DNA 付加体形成、変異原性、発がん は、ヒトにおいてもマウスやイヌなどの動物モデルと同様であり、4-Aminobiphenyl はヒトに対し て発がんの危険性を示すことが明らかになった。この MOA 解析の情報は、ヒトに対する完全な がんリスク評価を構築するための実質的な基礎を提供するものである。この化学物質については、 HRF 解析から導き出された結論を検証するための実質的な疫学的エビデンスも存在する。

この MOA では、どのような遺伝子が突然変異し、その遺伝子変化がどのようにして発がんに つながるのかという追加の key events は、4-Aminobiphenyl では知られていない。しかし、ここで 提示されたフレームワーク解析に基づいて MOA のエビデンスの信頼性を考えると、このことは 結論を損なうものではない。

ある化学物質が DNA 反応性 MOA によって発がんすると結論づけるには、どのようなデータが 必要なのか?我々が提案するのは、少なくとも DNA 付加体が、標的組織で生成され、その化学物 質に変異原性(代謝的活性化の有無にかかわらず)があることを実証することである。変異原性 は、ここでは遺伝毒性という広い意味よりも、より具体的で限定的な意味で用いられている。in vivo ばく露後の標的組織における DNA 付加体及び変異原性が証明されれば、推定された MOA の 信頼性が向上する。特定の代謝経路と誘導される特定の DNA 付加体を同定することにより、動物 モデルをヒトに外挿するための優れた根拠が得られる。

この事例は、MOA 解析における代替化合物に関するデータの潜在的な有用性を示している。しかし、関連化合物に関するデータの妥当性は、in vivo であれ in vitro であれ、十分に正当化される必要がある。また、DNA 反応性や変異原性については、これまでに十分に開発されてきた構造活性相関に関するエビデンスの重み付け解析も、フレームワーク解析に貢献すべきである。

# 謝辞

この論文は、米国環境保護庁(USEPA)のガイダンスに基づいてレビューされているが、必ずしもUSEPAの方針を反映したものではない。Andrew Kligerman 博士と Doug Wolf 博士の慎重なレビューに感謝する。

# ホルムアルデヒド及びグルタルアルデヒドの鼻腔内細胞毒性: 発がん MOA のヒトへの関連性を解析するための IPCS フレームワークを用いた事例研究<sup>1</sup>

#### Douglas McGregor, Hermann Bolt, Vincent Cogliano, & Hans-Bernhard Richter-Reichhelm

ホルムアルデヒド及びグルタルアルデヒドは、吸入によりラット及びマウスの鼻腔上皮に毒性を 示す。また、一定濃度以上のホルムアルデヒドはラットとマウスの鼻腔腫瘍を用量依存的に増加さ せるが、グルタルアルデヒドにそのような作用はない。発がん MOA 解析のための 2006 年国際化 学物質安全性計画(International Programme on Chemical Safety: IPCS)のヒトフレームワークを用い て、ホルムアルデヒドの MOA を策定し、非発がん性のグルタルアルデヒドの特性との関連性につ いて検討した。これらの化合物は、病理組織学的検査及び遺伝毒性試験において同様の反応パター ンを示した (ホルムアルデヒドの方が広範囲に研究されているものの)。 MOA は、 持続的な細胞毒 性と再生細胞増殖の誘発に基づいており、長期ばく露によりホルムアルデヒドが鼻腔内腫瘍を誘 発する濃度で生じるというものである。key eventsの用量依存性と時間的関係に関するデータは、 この MOA と一致している。少なくとも in vitro 評価で遺伝毒性が明らかな化合物については、遺 伝毒性 MOA を除外することはできない。しかし、提示されている MOA の基本となる非遺伝毒性 は、鼻の腫瘍性病変を説明することができ、リスク評価において遺伝毒性よりも有益な情報を提供 するかもしれない。グルタルアルデヒドを吸入しても発がん性を示さない理由はまだ完全には解 明されていないが、固有の毒性が重要な要因である可能性がある。グルタルアルデヒドの二つのア ルデヒド官能基は、ホルムアルデヒドに比べて、(特に分化制御に関与するタンパク質の場合)運 動性の低下や、(核酸の)修復機能の低下へとつながる損傷を引き起こす可能性が高い。グルタル アルデヒドに関連した発がん性に関する研究はほとんどない。一方、ホルムアルデヒドがヒトの発 がん物質であるというエビデンスは、副鼻腔がんでは少ないが、鼻咽頭がんについては多い。ホル ムアルデヒドの吸入ばく露がはるかに少ない副鼻腔の腫瘍を鼻腔腫瘍と区別せず分類しているこ とが一因となり、見かけの不一致を生み出していると考えられる。提示されているげっ歯類におけ るホルムアルデヒドの MOA はヒトへの関連性評価については、key events は妥当ではあるが、ヒ トのデータが限られているため限定的である。げっ歯類におけるホルムアルデヒドの MOA のヒト への関連性は、動態的または薬力学的な理由から除外できないことは明らかである。

# 序文

ホルムアルデヒド、グルタルアルデヒドはそれぞれ脂肪族のモノアルデヒド、ジアルデヒドで あり、アルデヒドに典型的な反応を経てアセタール、シアノヒドリン、オキシム、ヒドラゾン、 重亜硫酸塩錯体を形成する。これらは反応性の高い化学物質であり、DNA やタンパク質と共有結 合で架橋した錯体を生成する。これらの代謝には、アルデヒド脱水素酵素によって酸化されると いう共通点がある。いくつかの研究では、ホルムアルデヒドの吸入ばく露はラットに鼻腔腫瘍を 引き起こすことが示されているが、グルタルアルデヒドをラットに2年間吸入ばく露させた試験 では鼻腔腫瘍は観察されなかった。

<sup>&</sup>lt;sup>1</sup> WHO が著作権を有するこの論文は、Critical Reviews in Toxicology, Volume 36, pages 821-835 に 2006 年に掲載されたもの である。この論文は、WHO の出版物のために編集されたものであり、コリジェンダが含まれている。

#### ホルムアルデヒド

ホルムアルデヒドの発がん性試験は、マウス、ラット、シリアンハムスターを対象とした吸入 試験、ラットを対象とした経口投与(飲料水)試験、マウスを対象とした皮膚貼付試験、ラット を対象とした皮下投与試験が行われている。ラットではホルムアルデヒドが発がん物質であると いう決定的なエビデンスは吸入試験の結果から得られている。

ホルムアルデヒドへの長期吸入ばく露は、ラットの前方及び後方の側鼻道腫瘍の発生率を、非 線形性用量相関的に増加させるというエビデンスがある(Morgan ら、1986; Feron ら、1988年; Woutersen ら、1989年; Monticello ら、1996年; Kamata ら、1997年; CIIT、1999年)。ホルムア ルデヒド濃度が 7.2 mg/m<sup>3</sup>以上になると、腫瘍発生率が急激に増加する。2.4 mg/m<sup>3</sup>以下の濃度で はばく露しても、悪性の鼻腔腫瘍は誘発されなかった。表1は、同じ研究室で実施された2つの ラットの試験データ(Kerns ら、1983年a; Monticello ら、1996年)と、これらの研究のうちの1 つで、公表時には調査されていなかった数匹のラットについての追加情報を組み合わせたもので ある(Schlosser ら、2003年)。ホルムアルデヒド誘発性腫瘍の多くは扁平上皮がんであった。

ホルムアルデヒド濃度	リスクを抱えるラットの数。	実際の腫瘍数り		
$(mg/m^3)$				
0	122	0		
0.84	27	0		
2.4	126	0		
7.2	113	3		
12	34	22		
18	182	157		

表 1. ホルムアルデヒドにばく露されたラットにおける鼻腔扁平上皮がんの複合発生率

注: Schlosser ら (2003) からの引用

<sup>a</sup> リスクを抱えるラットとは、2年まで生存し、その時点で検査を受けたラットと、腫瘍が見つかった2年以内に死亡したラットのことである。

<sup>b</sup>2年以内に腫瘍が認められたラット

対照的に、シリアンハムスターを対象とした吸入試験では、12.3 mg/m<sup>3</sup>の単回投与で発がん性 を示さなかった(Dalbey、1982年)。マウスを用いた2つの吸入試験のうち1つは、17.6 mg/m<sup>3</sup>の 高用量濃度で雌には変化がなく、2年の時点でと殺した雄17匹のうち2匹には扁平上皮がんが認 められた(Kerns ら、1983年 a、1983年 b)。もう1つの試験は評価が不十分であった(Horton ら、 1963年)。

ラットを対象とした他のばく露経路を用いた試験では、4 つの飲水投与試験のうち 2 つの試験 (Takahashi ら、1986 年; Tobe ら、1989 年)では有意な結果は得られなかった。もう 1 つの試験 (Til ら、1989 年)では前胃乳頭腫、さらにもう一つの試験(Soffritti ら、1989 年)では白血病及 び消化管腫瘍を認めた。しかし、最後に挙げた試験の解釈は疑問視されている(Feron ら、1990)。 マウスの皮膚貼付試験及び皮下投与試験は評価に適さなかった。げっ歯類を対象とした研究では、 ラットを対象とした 5 つの吸入ばく露試験以外に、鼻腔内腫瘍の有意な増加が認められた研究は なかった。

### グルタルアルデヒド

グルタルアルデヒドの発がん性については、マウス及びラットでは吸入試験、ラットでは経口 投与(飲水投与)試験が行われている。吸入試験では、B6C3F1マウスに400µg/m<sup>3</sup>の単濃度で78 週間ばく露させた場合(Zissu ら、1998年)、または1000µg/m<sup>3</sup>までの複数濃度で2年間ばく露さ せた場合(NTP、1999年)、またはF344 ラットに3000µg/m<sup>3</sup>までの濃度で2年間ばく露させた場 合(NTP、1999年)のいずれにおいても発がん性は認められなかった。雌雄のF344 ラットを最大 4000 mg/m<sup>3</sup>のグルタルアルデヒド濃度に2年間ばく露した飲水試験では、すべてのばく露濃度で 雌の脾臓に大顆粒リンパ球性白血病の発生率増加が認められた(Ballantyne、1995; Van Miller ら、 1995年)。

### 1. 動物における作用機序(MOA)を立証するのにエビデンスの重み付けは十分か

#### A. 推定される MOA

一定濃度以上のホルムアルデヒドを長時間ばく露させると、持続的な細胞毒性と細胞増殖が誘発される。この増殖細胞塊内における遺伝的変化の結果、腫瘍が発生する。このような遺伝的変化は、ホルムアルデヒドによって明らかに誘導される細胞毒性、化生、過形成の二次的なものであると推測されている。ホルムアルデヒドは in vitro では遺伝毒性物質であり、DNA-タンパク質架橋(DPX)を形成する。DPX はホルムアルデヒドばく露の指標として確立されているが、それらが腫瘍発生に必要な突然変異前病変(DNA 複製エラーを起こし、突然変異をもたらす)であるかは明らかではない。ラットで DPX が豊富であることを除けば、ホルムアルデヒドが生体内で哺乳類の細胞に変異原性を示すというエビデンスはほとんどない。

この MOA は、主に3 つの key events (持続的な細胞増殖、DPX、腫瘍) すべてについて一貫した非線形の用量反応関係が観察されたこと及び鼻腔全体でこれらの影響の発生率が一致していることに基づいて推測される。

## **B** Key events

#### ホルムアルデヒド

ホルムアルデヒドばく露後の障害が侵入口に限定されることは明らかに重要であり、その過程 では代謝が重要な役割を果たしている。ホルムアルデヒド誘発性鼻腔腫瘍における侵入口の重要 性は、ホルムアルデヒド溶液を経口ばく露させたラットにおいて、主要な非腫瘍性の影響が前胃 及び腺胃の組織学的変化の進展であったことから裏付けられる(Til ら、1989 年; Tobe ら、1989 年)。

ホルムアルデヒドは、細胞内の N-、O-及び S-脱メチル化反応の内因性代謝産物であり(Hardman ら, 2001 年)、ばく露を受けていない哺乳類の正常な血中濃度は約 2.0~2.6 µg/g である(Heck ら、1982 年、1985 年; Casanova ら、1988 年)。外因性ホルムアルデヒドは吸収されると急速に解毒される。ホルムアルデヒドを静脈内投与されたラットにおける血漿中の半減期は約 1 分で(Rietbrock、1965 年)、還元されたグルタチオンと容易かつ自然に結合する。そして、アルコール脱水素酵素 3

(ADH3,グルタチオン依存性ホルムアルデヒド脱水素酵素としても知られている)の基質である S-ヒドロキシメチルグルタチオンを形成し、S-ホルミルグルタチオンを産生する(Uotila & Koivusalo、1974年; Koivusaloら、1989年)。 これは S-ホルミルグルタチオンヒドロラーゼ(Uotila & Koivusalo、1997年)によってさらにギ酸に代謝され、グルタチオンを減少させる。ADH3 とヒドロキシ-メチルグルタチオンの初期結合のための K<sub>M</sub> 値は約 0.004 mmol/L であり、遊離ホルムアルデヒドの濃度はさらに低い可能性が高い(Uotila & Koivusalo、1997年; Hedberg ら、1998年)。また、ホルムアルデヒドがシステイン及びシステイニルグリシンのようなチオール類と結合することは、毒性学的に重要であるかもしれない(Holmquist & Vallee、1991年)。この効率的な解毒代謝メカニズムに加えて、絨毛粘膜はガスや蒸気から下層の上皮を保護する。したがって、標的組織において細胞毒性が発生する遊離ホルムアルデヒドを高濃度で得るためには、これらの保護機構を克服することが必要であり、比較的高濃度のホルムアルデヒド蒸気を標的部位に到達させる必要がある。発がん性にとって明確で意義のある機序的な事象は、ラットにおけるホルムアルデヒドの解毒機構が飽和している用量で発現することである(Casanova & Heck、1987年)。

ホルムアルデヒド吸入ばく露後に測定された鼻のがん形成と関連している主な非腫瘍性及び前 腫瘍性徴候には、細胞毒性、DPX 形成、鼻腔上皮細胞の再生性増殖、扁平上皮化生及び炎症が含 まれる。これらは部位特異的で高度に非線形な反応過程であり、鼻腔がんの発生率と一致してい る。

相対的な細胞増殖の亢進の程度は、鼻腔内の特定領域内の標的細胞集団の大きさに依存し、ば く露期間または累積ばく露の総量と常に相関するわけではない(Swenberg ら、1983 年、1986 年; Monticello ら、1991 年、1996 年; Monticello & Morgan、1994 年)。これらの因子は、ラット、サル 及びヒト上皮細胞を対象とした多くの研究で明らかにされ、測定されている。3、6、12 及び 18 ヶ 月の途中計画殺を伴う 24 ヶ月の発がん性試験では、7.2、12 及び 18 mg/m<sup>3</sup>の濃度でばく露された ラットはすべての時点で細胞増殖活性が実証された(Monticello ら、1991、1996 年)。

免疫組織化学的手法を用いて、同一腫瘍の病理組織切片中の細胞増殖マーカーである p53 タン パク質(増殖細胞核抗原、または PCNA)及び腫瘍成長因子(TGF)を評価した。正常な鼻粘膜は 陰性であったが、扁平上皮がんでは p53 陽性となり、特に前腫瘍性病変である角化亢進性プラー ク内において角化した細胞での p53 陽性が観察された。PCNA の免疫染色の分布と p53 の免疫染 色の分布との間に相関関係が認められた(Wolf ら、1995 年)。

ラットにおける DPX の形成は、濃度の非線形関数であり(Casanova & Heck、1987年; Casanova ら、1989年、1994年; Heck & Casanova、1995年)、腫瘍の部位特異性と一致している(Casanova ら、1994年)。架橋はラットの嗅粘膜または骨髄では検出されなかった(Casanova-Schmitz ら、1984 年; Casanova & Heck、1987年)。DPX はホルムアルデヒド吸入ばく露後のアカゲザルで認められ ており、その濃度が最も高い部位は中鼻甲介で、次いで前側壁中隔及び鼻咽頭であった(Casanova ら、1991年)。

ラット、マウス、シリアンハムスター及びアカゲザルにホルムアルデヒドを 13 週間(マウス) または 26 週間ばく露した研究において、ラット及びアカゲザルでは鼻尖部の扁平上皮化生が 3.7 mg/m<sup>3</sup>で発現したが、シリアハムスター及びマウスでは 4.9 mg/m<sup>3</sup>でも発現しなかった(Rusch ら、 1983 年; Maronpot ら、1986 年)。細胞の複製は、ラット鼻腔上皮のうち腫瘍感受性がより高い領 域の特徴でもある(Casanova ら、1994 年)。

# グルタルアルデヒド

400 μg/m<sup>3</sup>の濃度でグルタルアルデヒドを 78 週間吸入ばく露させた結果、雌マウスの鼻前庭に 非腫瘍性の病変が生じた。その病変は、背側壁を覆う扁平上皮の過形成及びアトリオタービネート(atrioturbinate)の側方面の過形成である(Zissu ら、1998 年)。

グルタルアルデヒドの米国国家毒性プログラム (NTP)の研究では、雌雄ラットにおいて以下の ような鼻の変化が認められた。

- 鼻腔の最も吻側にある扁平上皮、外鼻腔の後ろにある扁平上皮では、過形成と炎症の発生率が 増加していた。過形成は、細胞層数の増加による上皮の不均一な肥厚と、より重篤な症例では、 様々な程度のケラチンの蓄積を特徴とする変化であった。
- 2. 呼吸上皮では、過形成、軽微な杯細胞過形成(主に鼻中隔及び腹側中隔に沿って)、炎症及び扁 平上皮化生が認められ、重度の症例では上皮表面にケラチンが蓄積していた。
- 3. 背側中膜の嗅覚上皮では、硝子変性がわずかに認められた。

扁平上皮及び呼吸上皮で観察されたグルタルアルデヒド関連の炎症は、好中球、リンパ球及び 形質細胞の多巣性から広範な浸潤にわたる様々な程度の変化があった。時折、固有層内に数個の マクロファージが存在し、重度の場合には上皮にも存在していた。この研究では雌雄のマウスに おいて、病変の質はラットと類似していたが、雌の方が雄よりも重症度は高かった。

グルタルアルデヒドは、TK6ヒトリンパ芽細胞株において DPX を誘発した(St. Clair ら、1991年)。in vivo では、グルタルアルデヒドは、吸入(Gross ら、1994年)及び鼻腔内投与(St. Clair ら、1990年)によってばく露されたラット及びマウスの鼻腔内細胞において細胞増殖(S期)を誘導した。同じ著者による並行して実施された鼻腔内投与試験において、ホルムアルデヒドでは、20 倍高いモル濃度で同様の細胞増殖を誘発した。

## C. 用量反応関係

### ホルムアルデヒド

ホルムアルデヒドをばく露したラットから得られたデータによると、key events の用量反応パタ ーンは非線形であり、2.4 mg/m<sup>3</sup>では反応を認めず、7.2 mg/m<sup>3</sup>では最小の反応を認め、12 及び 18 mg/m<sup>3</sup>では急激に反応が増加している。 ホルムアルデヒドにばく露されたラットでは、2.4 mg/m<sup>3</sup>以下の濃度に亜慢性または慢性的にば く露した後の鼻粘膜で、細胞の再生及び DNA 合成の増加は認められなかった (Rusch ら、1983 年; Zwart ら、1988 年; Monticello ら、1991 年; Casanova ら、1994 年)。Wistar ラットでは細胞の再生 速度の部位特異的な軽度の増加が 3.7 mg/m<sup>3</sup> (6 時間/日、5 日/週、13 週間) で認められた (Zwart ら、1988 年)。同様の期間ばく露した Fischer 344 ラットでは DNA 合成速度の増加が 7.2 mg/m<sup>3</sup>で 認められた (Casanova ら、1994 年)。しかしながら、これらの濃度では、6 週間後 (Monticello ら、 1991 年)または 13 週間後 (Zwart ら、1988 年) の細胞再生率がばく露 1~4 日後よりも低いため、 ラットの鼻腔上皮では適応反応が起こると思われる。単位長ラベリング指数 (ULLI) 法を用いて、 0、0.84、2.4、7.2、12、または 18 mg/m<sup>3</sup>のホルムアルデヒド濃度に 6 時間/日、5 日/週、3、6、12、 18、または 24 ヶ月間ばく露した雄の Fischer 344 ラットにおける増殖を測定した。ULLI の有意な 上昇は 12 及び 18 mg/m<sup>3</sup>群でのみ認められ、前側側鼻道及び内側上顎鼻甲介での上昇が大きかっ た。前背側中隔における ULLI の上昇は、ばく露後しばらくしてから発現した。この遅発性の ULLI 上昇は、鼻腔腫瘍の影響を受けやすい部分における、病変の成長と空隙の歪みに関連する局所的 なホルムアルデヒド濃度の変化でおこる気流変化による二次的なものと考えられた (Monticello ら、 1996 年)。

ホルムアルデヒド誘発性 DPX 形成、上皮細胞増殖及びその後の鼻腔腫瘍の非線形関係を表2に示す。Casanova ら(1994 年)が提示した高腫瘍領域と低腫瘍領域の指定は最適なものではなく、 真に腫瘍発生率の高い領域の DPX 反応は、中間的な腫瘍発生率(後方側鼻道)領域の DPX 反応 によって希釈されている可能性がある。

他の研究では、1.2 mg/m<sup>3</sup>(1日22時間、7日/週、26週間)にばく露した Fischer 344 ラットで は、検出可能な鼻腔病変は認められなかったが、3.6 mg/m<sup>3</sup>において組織学的変化は鼻甲介の扁平 上皮化生のみであった(Rusch ら、1983年)。同様に 2.4 mg/m<sup>3</sup>(6時間/日、5日/週、24ヶ月間) にばく露した Fischer 344 ラットの鼻甲介においても、軽度な扁平上皮化生の発生が示された (Kerns ら、1983年b)。これらのラットでは上皮異形成及び鼻炎も観察された。扁平上皮化生の 発生は、報告されている生体内反応の中で最も低濃度のホルムアルデヒドで発生する組織学的所 見だと思われる。

ラットにおいて正確に計算された解剖学的流体力学モデルを用いて、ホルムアルデヒドによっ て誘発される扁平上皮化生の分布が、扁平上皮の後方にある高流量領域に関係しているかどうか を検証した。50%以上が扁平上皮に置き換わっている場合、扁平上皮化生が生じているとみなさ れた。2.4 mg/m<sup>3</sup>以下でばく露されたラットの鼻には扁平上皮化生は認められなかった。7.2 mg/m<sup>3</sup> 以上のばく露では側鼻道に、12 または 18 mg/m<sup>3</sup>のばく露では気道の側壁及び内側壁に扁平上皮化 生がみられた(Kimbell ら、1997 年)。

4.8 mg/m<sup>3</sup>以上の吸入ばく露では、ラットで鼻組織内のホルムアルデヒドのグルタチオン介在性の解毒が飽和状態に達するというエビデンスがある。ホルムアルデヒド代謝の飽和は、この濃度以上のばく露における DPX、細胞増殖及び腫瘍発生率の用量反応関係の非線形性に寄与する可能性がある(Casanova & Heck、1987年)。

表 2. ホルムアルデヒドばく露の影響の比較:細胞増殖、DNA-タンパク質架橋及び 腫瘍発生率

a 指定された濃度のホルムアルデヒドに 6 時間/日、週 5 日/日、3 ヶ月間ばく露した雄の F344 ラットの鼻腔上皮の 3 箇所で測定した細胞増殖 (Monticello ら、1996 年)。

b 指定された濃度のホルムアルデヒドに6時間/日、5日/週、約12週間ばく露した雄のF344 ラットの鼻腔(呼吸器粘膜)の2つの領域で測定した DNA-タンパク質架橋形成の程度。腫瘍低発生領域は、鼻腔及び側鼻道の内側壁、後側壁、嗅覚領域を除く後背側鼻道及び鼻中隔からなる(Casanova ら、1994年)。データは引用文献中のグラフに基づいている。

c 指定された濃度のホルムアルデヒドに1日6時間、1日5日/週、24ヶ月間ばく露した雄性F344 ラットにおける鼻腔全体または鼻腔内の鼻腔腫瘍の発生率、または前側鼻道、後側鼻道、または前中隔の発生率(Monticello ら、1996年)。

# グルタルアルデヒド

グルタルアルデヒドにばく露したラット及びマウスを用いた一連の反復投与試験が NICNAS (1994 年)にまとめられている。その中で、ラットの鼻腔に病変を生じる最も低い濃度は 1000 µg/m<sup>3</sup>(6時間/日、5日/週、13週間)であった(NTP、1993 年)。最も重篤な病変は鼻腔前部に発 生し、呼吸上皮と嗅上皮の両方を障害した。過形成及び扁平上皮化生は、鼻腔の側壁及び鼻尖部 に最もよく認められた。病変は 4000 µg/m<sup>3</sup>にばく露されたラットで最も広範囲に認められたが、 1000 及び 2000 µg/m<sup>3</sup>群でも認められ、500 µg/m<sup>3</sup>群の雄 1 匹でも認められた。ラットを用いた別 の研究では、最大 776 µg/m<sup>3</sup>の濃度で 14 週間投与しても鼻の病変は観察されなかった (Bushy Run、 1983 年)。

マウスはグルタルアルデヒド吸入による感受性が高いようであり、13週間の試験で雌マウスで は最低濃度の250µg/m<sup>3</sup>で、雄マウスでは1000µg/m<sup>3</sup>でも鼻腔の炎症が観察された。このような感 受性の違いは、マウスのほうが気道が狭いためゴミなどで閉塞しやすいためと考えられる(NTP、 1993年)。呼吸器の病理組織学的病変は4000µg/m<sup>3</sup>群のマウスで最も重篤であり、喉頭上皮の扁 平上皮の軽度から中程度の扁平上皮化生、鼻腔前部の膿瘍性炎症がみられた。 鼻尖部の扁平上皮化生は軽度であった。壊死と炎症は低濃度で、主に鼻腔前部で認められた。

グルタルアルデヒドを用いた NTP(1993 年)の13週間の試験では、鼻前庭の扁平上皮と、それよりも軽度ではあるが、背側鼻道のアトリオタービネートの呼吸器上皮において、ばく露に関連した ULLI の有意な増加が認められた。ばく露に関連した細胞増殖活性は、一般的にマウスよりもラットの方が高かった。個々のマウスを調べたところ、鼻前庭の扁平上皮では、粘膜に好中球浸潤が認められたマウスでのみ細胞増殖率の増加が認められた。ただし、細胞増殖の程度と浸潤の重症度は相関していなかった。これらの観察は、特に雌マウスでは13週目に最も明らかになった。ラットでは、前庭の扁平上皮の増殖増加に加えて、背側のアトリオタービネートの呼吸器上皮でも同様に顕著な増殖増加がみられたが、マウスではこの領域での反応は弱かった。

#### D. 時間的関連性

#### ホルムアルデヒド

ラットの呼吸器上皮内の細胞増殖に対するホルムアルデヒドばく露の影響について、短期、中 期、長期の研究では、ばく露期間にかかわらず、2.4 mg/m<sup>3</sup>以上の濃度にばく露した後、鼻腔上皮 細胞の増殖が持続的に増加することが示されている。ホルムアルデヒドにばく露したラットでは、 3日間という短い期間から細胞増殖が観察された。すでに述べた ULLI 研究では、一般的に細胞増 殖の増加率は時間の経過とともに減少したが、この影響は、特定の鼻腔部位では対照群の約 2~ 10倍の増加を示し、最長で 18 ヶ月間の観察期間を含めて試験終了まで持続していた(Monticello ら、1996年)。

ほとんどのホルムアルデヒド吸入による DPX 形成の研究は短期間(すなわち、ばく露期間が1 日まで)であるため、DPX の時間的関連性に関するデータは乏しい。ホルムアルデヒド誘発性 DPX は、ラットとアカゲザルの鼻腔上皮における研究で一貫して示された(Casanova ら、1991 年)。 しかし、ホルムアルデヒドに約 12 週間ばく露したラットの急性及び累積 DPX 収量を調べる研究

(Casanova ら、1994 年)において、7.2 mg/m<sup>3</sup>以上の濃度では、事前にばく露されたラットの側鼻 道(腫瘍発生率の高い部位)の急性 DPX 収量は、対照群の約半分であったが、内側及び後側の鼻 道(腫瘍発生率の低い部位)では差が見られなかった。事前にばく露されたラットでは、DPX の 有意な蓄積は認められなかった。

ホルムアルデヒド誘発細胞毒性後の再生性細胞増殖は、DNA 複製数を増加させる。その結果、 DPX が誘発する DNA 複製エラーを増加させ、突然変異を引き起こす。この仮説は、高濃度にお けるラットの鼻での DNA 複製の阻害(Heck & Casanova、1995 年)及び前腫瘍病変における p53 発現の増加(Wolf ら、1995 年)によって支持される。

18 mg/m<sup>3</sup>に最大 2 年間ばく露して誘発されたラットの扁平上皮がんの 11 例中 5 例では、p53 相補的 DNA (cDNA) 配列の GC 塩基対に点突然変異が認められた (Recio ら、1992 年)。

# グルタルアルデヒド

ラット及びマウスの13週間のグルタルアルデヒド吸入試験(NTP、1993年)における細胞増殖 の研究では、マウスで得られた結果とは対照的に、ラットの鼻前庭における細胞増殖の増加(ULLI) は、早い時期(数日以内)に発生し、試験期間中は上昇したままであるか、またはわずかに減少 した。マウスの鼻前庭における ULLIの増加は時間の経過とともに増加する傾向があった。マウ スを用いた吸入試験(Zissuら、1994年)では、1.2 mg/m<sup>3</sup>に4日間ばく露した後、鼻中隔の呼吸 上皮及び鼻及び顎甲介に最初の病変が観察された。4.0 mg/m<sup>3</sup>ばく露終了2週間後にも重篤な病理 組織学的変化が認められた。気管及び肺ではばく露に関連した組織学的異常は認められなかった。

# E. 腫瘍発生と key events との関連性の強さ、一貫性及び特異性

## ホルムアルデヒド

ホルムアルデヒド誘発性腫瘍に関する広範な研究がある。入手可能なデータを見る限り、ラットやサル、ラットやヒトの様々な動物種や、ラットやヒトの様々な細胞の in vitro で明らかになっ ている。。同程度のばく露量では、DPX の濃度はラットよりもアカゲザルの方が約一桁低いことが 明らかになった。ホルムアルデヒドへの組織ばく露後のヒト上皮細胞増殖の亢進が、ヒトの気管 支上皮細胞を移植したラット気管を胸腺欠損マウスに異種移植したモデル系で報告された。

key events と局所的な腫瘍発生率及び腫瘍発生部位との間には相関関係がある。腫瘍が観察され ている鼻腔領域では、細胞増殖、化生及び DPX の増加が認められた。DPX、細胞毒性、細胞増殖、 化生、腫瘍についての非線形用量反応関係は一貫しており、ある試験では 2.4 mg/m<sup>3</sup> で化生の有意 な増加が認められ、4.8 mg/m<sup>3</sup> 以上の濃度では全てのエンドポイントが観察された。これはまた、 粘膜クリアランスが抑制され、グルタチオンを介した代謝が飽和する濃度、すなわち 4.8 mg/m<sup>3</sup> と 密接な相関関係を示している。Morgan ら(1986年)による雄ラットの鼻粘膜に対する吸入ホルム アルデヒドの影響を検討した研究では、2.4 mg/m<sup>3</sup>、7.2 mg/m<sup>3</sup>、18 mg/m<sup>3</sup>の濃度で1日、9日及び 14 日間ばく露後、18 時間の回復期間を設けた群が含まれていた。粘膜クリアランスの阻害は、ば く露時間が長くなるにつれて徐々に範囲が広がったが、ばく露停止 18 時間後の回復はほとんど、 あるいは全く認められなかった。 ある濃度のホルムアルデヒドにばく露後発生する鼻腔腫瘍において、マウスはラットよりも感 受性が低いようである。しかしながら、マウスでは有害化学物質の吸入に反応して換気量/分が減 少することがよく知られている(Brown ら、1986年; CIIT、1999年)。

### グルタルアルデヒド

ホルムアルデヒドと比較して、グルタルアルデヒドによって誘発された病変は、扁平上皮を含む鼻の前方に位置していた。また、それらの病変は異なる特徴を有しており、ホルムアルデヒドを 13 週間投与した動物にみられる細胞異型及び異形成を伴う局所的な角化亢進及び過形成は認められなかった(Monticello、1990年; Morgan & Monticello、1990年)。

## F. 生物学的妥当性及び整合性

#### ホルムアルデヒド

長期間にわたる再生性細胞増殖が化学物質による発がんの原因であるという仮説を支持するエ ビデンスが蓄積され続けている (PCS、2002 年)。吸入ばく露された動物におけるホルムアルデヒ ド誘発性鼻腔腫瘍に対する MOA は、生物学的に妥当性があり、利用可能なデータと一致してい る。ラットを対象とした短期・中期毒性試験や他種の研究では、鼻腔内の持続的な細胞増殖活性 が観察されている。鼻腔内の病理組織学的影響(上皮細胞の異形成と化生)は、亜慢性及び慢性 の動物実験で一貫していた。しかし、ラットの鼻腔腫瘍誘導における DPX、突然変異及び細胞増 殖のそれぞれの役割は完全には解明されていないことに留意すべきである。

### グルタルアルデヒド

吸入したグルタルアルデヒドの影響は、ホルムアルデヒドほど研究されていない。吸入試験で は、グルタルアルデヒドはラットとマウスの鼻腔腫瘍を誘発しなかった。しかし、ホルムアルデ ヒドの鼻発がん性において key events とみなされる細胞毒性と細胞増殖が、グルタルアルデヒド にばく露されたラットとマウスでも実証されている。このことは、これらの過程がホルムアルデ ヒドにとって重要であることの妥当性を低下させるように見えるかもしれない。

### G. 考えられる代替 MOA

#### ホルムアルデヒド

変異原性がホルムアルデヒド誘発性腫瘍の発生に関与している可能性がある。利用可能なデー タを評価すると、ホルムアルデヒドは in vitro では遺伝毒性はあるが、標準的な in vivo アッセイ では概して遺伝毒性はないことが示されている。しかし、DPX を産生することを示す研究は数多 くある。

ホルムアルデヒドは in vitro での遺伝毒性について広く研究されており、細菌や哺乳類細胞を用 いた試験(Ames 試験、遺伝子突然変異)で陽性結果が得られ、DNAの一本鎖切断や DPX の産生 を認めた(IARC、2005 年レビュー)。生体内では、ホルムアルデヒドはショウジョウバエで再現 性のある突然変異を誘発したが、げっ歯類の骨髄細胞試験では、その遺伝毒性について有力なエ ビデンスはない。しかし、ホルムアルデヒドのばく露が、ヒトの鼻や頬の細胞や末梢血リンパ球 における染色体異常や小核発現頻度の増加と関連しているというわずかなエビデンスはある (IARC、2005 年; 付録参照)。 DPX がホルムアルデヒドの突然変異誘発性及び発がん性にどの程度寄与しているかは不明であ る(Recio、1997年; Merk & Speit、1998年; Speit ら、2000年; Liteplo & Meek、2003年)。DPX の存在は主にばく露の指標として考えられてきたが、これらの病変の特徴は前変異原性であり、 それゆえに直接的な遺伝毒性メカニズムのエビデンスであるという見方もある。しかし、DPX は 形成された細胞にダメージを与える可能性があり、高頻度で発生すると細胞死が起こる可能性が 高い。また、本研究では細胞への影響はそれほど深刻ではないものの、タンパク質-タンパク質架 橋(PPX)が起こる可能性があることも示唆されている。もし主要なタンパク質が PPX の形成に 関与していれば、分化の制御を含む細胞の制御機構に影響を及ぼす可能性がある。化生領域が出 現しているため、このような変化は、ホルムアルデヒドにばく露されたラットの鼻腔上皮で生じ ている。遺伝毒性の MOA を示す有力なエビデンスがない限り、腫瘍は単に化生の一種と見なす ことができる。

Gaylor ら(2004 年)は、J 型濃度曲線を特定するように設計された統計手法を用いて、ラット におけるホルムアルデヒド誘発性細胞増殖の濃度-反応関係を解析し、異なるデータの解釈を提示 した。解析の際、がん発生率に関する定量的なデータが不十分であったため、細胞増殖のデータ を使用した。彼らの解析は、鼻腔腫瘍の発生に対する閾値を有する用量反応性が、低用量におけ る軽度な遺伝毒性の結果であり、これにより細胞毒性を有する高用量において J 字型の細胞増殖 曲線を呈するという仮説を支持するものである(Lutz、1998 年)。低用量では、漸増する DNA 損 傷は細胞増殖の減少によって打ち消される可能性があるため、明らかな閾値があるにもかかわら ず、データは遺伝毒性メカニズムと一致している。

ホルムアルデヒドにばく露されたラットにおいて、*p53* 遺伝子の進化的に保存された領域 II-V の cDNA 配列の GC 塩基対における点突然変異が、原発性鼻腔扁平上皮がん 11 例のうち 5 例で認 められた (Recio ら、1992 年)。この結果は、発がん過程におけるホルムアルデヒドにより誘発さ れた遺伝毒性過程を示すものと解釈される。しかし、出現した腫瘍における特定の突然変異の存 在は、それらが腫瘍の初期段階に存在していたエビデンスでも、それらが化学物質によって直接 誘導されたことを示すものではない。直接的な突然変異原性を示す可能性はあるが、これらの突 然変異は、化学物質によって誘発されたクロマチンタンパク質の機能的変化により間接的に生じ た可能性もある。これらの観察された突然変異が腫瘍の発生段階のどの段階で生じたかは推測の 域を出ない。これらの突然変異は一般的な事象であることは明らかであるが、すべて同じタイプ の腫瘍が発生するわけではないので、本質的な事象ではないこともまた明らかである。これらの 突然変異の発生は、遺伝毒性のメカニズムが排除されていないことを示しているが、必ずしも支 持するものでもない。

また、遺伝子発現の特異的な変化も生体内で観察されている。その結果、ホルムアルデヒドへのばく露は、異物代謝、細胞周期制御、DNA 合成と修復、がん遺伝子、アポトーシスを含むいくつかの機能に関与する遺伝子の発現レベルに変化をもたらすことが示された(Hester ら、2003 年)これらの変化がホルムアルデヒドにどの程度特異的であるか、あるいは発がん性においてどのような役割を果たしているのかは、現時点では明らかになっていない。

# グルタルアルデヒド

グルタルアルデヒドは、ホルムアルデヒドに比べて in vitro 及び in vivo での遺伝毒性に関する 試験があまり行われていない。グルタルアルデヒドは、in vitro 試験では軽微かつ不規則な陽性所 見を示し、in vivo 試験の大部分では活性がない。最近、グルタルアルデヒドの遺伝毒性に関する レビューが発表された(Zeiger ら、2005 年)。

グルタルアルデヒドは細菌では DNA 修復系を誘導し、サルモネラ菌や大腸菌では弱い変異原 性を示した。不定期 DNA 合成(UDS)、DPX、二本鎖切断はヒト細胞株で認められたが、ラット 初代細胞では認められなかった。哺乳類細胞を用いた染色体異常及び姉妹染色体交換(SCE)試験 では、軽微かつ一貫性のない反応がみられ、培養シリアンハムスター胚(SHE)細胞においてグル タルアルデヒドは形質転換を誘導しなかった。

生体内では、ラット及びマウスの鼻腔内投与後、グルタルアルデヒドは鼻腔内細胞にS期のDNA 合成を誘導した。グルタルアルデヒドはラット肝臓ではDNA損傷を生じず、ラット精巣DNAや 精子細胞では架橋を生じなかった。ラット及びマウスの骨髄細胞を用いた染色体異常試験では、 概ね陰性であった。グルタルアルデヒドは、マウスの骨髄細胞に小核や優性致死性突然変異を誘 発しなかった。このように、グルタルアルデヒドは遺伝毒性を有する可能性があり、データベー スはホルムアルデヒドほど豊富ではないが、接触部位における遺伝毒性の発生が予想される。し たがって、遺伝毒性がホルムアルデヒドの主要な発がんMOAであるとすれば、なぜグルタルア ルデヒドが効果を発揮しないのかを説明する必要がある。

## H. 不確実性、矛盾、データギャップ

#### ホルムアルデヒド

ホルムアルデヒドを用いたがんのバイオアッセイのほとんどは、細胞毒性の指標としての増殖 反応や DPX などの中間エンドポイントに関するデータが限られている。そのため、中間病変と腫 瘍の発生率を直接比較することには制限がある。加えて DPX と突然変異誘発との直接的な関係に 関する情報及び DPX が突然変異につながる確率に関する情報が望まれる。一方で、腫瘍の発生に 必要な突然変異の生成にはどの再生性細胞増殖が関与しているかを決定する必要がある。

ホルムアルデヒドばく露ヒト細胞における hprt 遺伝子突然変異スペクトルの研究により、突然 変異の 50%は欠失であり、50%は A:T 塩基対での点突然変異によるものであることが明らかに なった (Crosby ら、1988 年; Liber ら、1989 年)。ホルムアルデヒド誘発性扁平上皮がんにおいて、 ホルムアルデヒド突然変異スペクトルの一部として欠失が認められたことで、p53 遺伝子で観察 されるホモ塩基対変異の性質を説明できるかもしれない。しかし、変異している塩基対に関して は矛盾がある。ヒト及び哺乳類細胞株では hprt 遺伝子の A:T であり、ホルムアルデヒド誘発性 扁平上皮がんでは p53 の G:C であることが明らかになっている (Recio、1997 年)。in vitro では ホルムアルデヒドによってこのような突然変異が誘導されるが、このタイプの突然変異はホルム アルデヒドの発がん性の根本ではない可能性がある。

### グルタルアルデヒド

グルタルアルデヒドは二官能性アルキル化剤であるためか、ホルムアルデヒドよりも明らかに 細胞毒性が強い。経鼻投与試験では、水溶液を鼻粘膜に単回投与した場合、モル比でグルタルア ルデヒドはホルムアルデヒドの10~20倍の毒性があることが実証されている(St. Clair ら、1990 年)。グルタルアルデヒドの13週間吸入試験(NTP、1993年)の結果とホルムアルデヒドの同様 の吸入試験(Heck ら、1990年; Monticello ら、1990年; Monticello ら、1991年)との比較は、こ の経路でもグルタルアルデヒドはホルムアルデヒドより約20倍の毒性があることを示している。 肺障害及び壊死は、かなり高い濃度のグルタルアルデヒドで発生する。細胞毒性は、グルタルア ルデヒドを吸入した場合には外鼻に近いところで発現するため、主に影響を受ける組織はホルム アルデヒドを吸入した場合と同じではない。唯一の違いが毒性の強さであるならば、グルタルア ルデヒドは、低用量でもホルムアルデヒドと同様の影響をもたらすと予想されるため、毒性作用 部位における違いは特に重要かもしれない。

### I. 推定される MOA の評価

### ホルムアルデヒド

重要なエビデンスの観点より、ホルムアルデヒド誘発性鼻腔腫瘍の仮説 MOA は一貫して、key events すべてにおける用量反応関係の一致、データベースの生物学的妥当性と整合性など、いく つかの基準を満たしている。鼻腔内腫瘍誘発におけるホルムアルデヒドの推定される MOA は多 くの実験データと一致しているため、この MOA は信頼性が高いと考えられる。

### グルタルアルデヒド

細胞毒性、細胞増殖及び DPX 形成の key events (in vitro) は、グルタルアルデヒドへのばく露 で実証されている。しかし、グルタルアルデヒドはラットやマウスでは鼻腔内腫瘍を発生させな い。したがって、推定されているホルムアルデヒドの MOA を維持するためには、この矛盾を説 明する必要がある。この矛盾の理由は特定されていないが、仮説を提示することは可能である。 グルタルアルデヒドの二つのアルデヒド官能基は、細胞環境内で高分子のさらなる反応を阻害す る重要な因子である。これらの高分子は、生存に関与するタンパク質であり、それらの不動化は、 おそらく分化状態の変化よりも細胞死につながる。このグルタルアルデヒドの高分子を不動化さ せる特性が、ホルムアルデヒドよりも高分解能顕微鏡(例えば電子顕微鏡)用の優れた固定剤に なる理由である。そのことはほぼ確実にジアルデヒドの非常に高い毒性につながっている。また、 ホルムアルデヒドのアルデヒド官能基は細胞障害を引き起こすが、細胞の分化に関与するタンパ ク質は、腫瘍の初期変化となりうる分化方向の変化を伴うものの、その役割を維持することがで きるかもしれない。一方、これらのアルデヒドが核酸と反応する場合(グルタルアルデヒドがこ のように反応するというエビデンスは実質的なものではない)、ホルムアルデヒドが DNA と相互 作用した後にアルキル化されたヌクレオチドの修復が起こるのに対し、グルタルアルデヒドの場 合は、困難、あるいは不可能かもしれない。このように、発がん性におけるホルムアルデヒドの 作用様式が推定されている通りなのか、それとも遺伝毒性が主な原因なのかにかかわらず、グル タルアルデヒドばく露に対する反応の違いを説明することができる。

# 2. 実験動物とヒトとの間の key evants の根本的、質的な違いに基づいて、MOA のヒトとの 関連性を合理的に排除することができるか

### A. ホルムアルデヒド

7.2 mg/m<sup>3</sup>のホルムアルデヒドに 1~6 週間ばく露したアカゲザルにおいて、ホルムアルデヒド に誘発された病変は、対照群の最大 18 倍を示す細胞増殖率の増加を伴っており、6 週間のばく露 後も有意に高い値が続いた。組織学的な病変と細胞増殖の増加は鼻腔で最も広範囲に見られ、下 気道では最小限であったが、上顎洞ではホルムアルデヒドばく露に対する反応のエビデンスは認 められなかった。病変の程度及び細胞増殖のデータに基づいて、7.2 mg/m<sup>3</sup>の用量でのホルムアル デヒドの急性及び亜急性影響に対する感受性はラットよりもアカゲザルの方が高いと考えられた (Monticello ら、1989 年)。アカゲザルの上顎洞における反応がないことは、疫学研究において(あ るいは、腫瘍部位の報告において)特別な注意を払うに値する所見である。副鼻腔がんのほとん どの疫学研究では、鼻に発生した腫瘍と副鼻腔に発生した腫瘍を区別していない。そのため、副 鼻腔に発生するがんに対応するリスクがなければ、鼻腔がんのリスクは希釈される傾向にあり、 統計的に検出されない可能性がある。

多くの疫学研究では、ホルムアルデヒドばく露と気道がんとの関連が調査されている。最も有 力なエビデンスは、鼻咽頭がんで観察されている。工場労働者を対象とした最大規模のコホート 研究(Hauptmann 6, 2004 年)では、鼻咽頭がんによる死亡者数の増加が観察されており、最大 ばく露量と累積ばく露量についてばく露-反応関係を示している。死体防腐処理業者を対象とした 米国最大のコホート研究では、上咽頭がんによる死亡者の増加が死亡率分析で観察されている (Hayes 6、1990 年)。ホルムアルデヒドを製造または使用している企業の労働者を対象としたデ ンマークの研究では、鼻咽頭がんの症例数の増加が観察された(Hansen & Olsen、1995 年)。他の コホート研究では、予想よりも鼻咽頭がんの症例数は少なかったと報告されている(Walrath & Fraumeni、1983 年; Coggon 6、2003 年; Pinkerton 6、2004 年)。鼻咽頭がんに関する7件の症例 対照研究のうち、5件ではホルムアルデヒドばく露によるリスク増加が認められた。

いくつかの症例対照研究では、ホルムアルデヒドへのばく露と副鼻腔がんとの関連が調査されている。12 件のプール解析では、木粉または革粉にばく露されたことがない男女における腺がんのリスク増加が示され、累積ばく露の指標に対し、ばく露用量反応性を示す傾向が示された(Luceら、2002 年)。他の1 件の症例対照研究(Olsen & Asnaes、1986 年)と発生率研究(Hansen & Olsen、1995 年)では、副鼻腔がん、特に扁平上皮がんのリスクの増加が示された。しかしながら、工場労働者を対象とした3 件の最も有力なコホート研究では、副鼻腔がんの増加は認められなかった(Coggon ら、2003 年; Hauptmann ら、2004 年; Pinkerton ら、2004 年)。

この一連のエビデンスを評価するにあたり、国際がん研究機関(IARC)は、ホルムアルデヒドがヒトで鼻咽頭がんを引き起こすという十分な疫学的エビデンスがあるが、ホルムアルデヒドがヒトで副鼻腔がんを引き起こすという疫学的エビデンスは限られている。

また、白血病とホルムアルデヒドの職業ばく露との間に因果関係があるという十分なエビデンスはない、と結論づけた(Cogliano ら、2005)。

ホルムアルデヒドにばく露されたヒトの鼻の細胞における DPX について記述している論文は ない。ホルムアルデヒドにばく露された労働者の末梢リンパ球における DPX の評価では、全体的 なばく露との関連性が示された(Shaham ら、2003 年)。単一の DPX 試験では、14 の病院の各病 理部門で働く 399 人が参加し、ホルムアルデヒドばく露のカテゴリーは低レベル(平均 0.5 mg/m<sup>3</sup>、 範囲 0.05~0.8 mg/m<sup>3</sup>)及び高レベル(平均 2.7 mg/m<sup>3</sup>、範囲 0.86~6.7 mg/m<sup>3</sup>)であった。調整後の 平均 DPX は被曝群で有意に高かった。この研究で用いられた物理的分離法の感度及び再現性には 疑問があるようである(Heck & Casanova、2004 年)。

いくつかの研究では、ホルムアルデヒドに職業ばく露された労働者の鼻腔上皮内の組織学的変 化を調査しているが、結果はまちまちであり、いくつかの研究では木粉への共ばく露があったた め、鼻腔上皮細胞の再生性増殖がどの程度起こるのかは未解明である(Berke、1987年; Edling ら、 1988年; Holmström ら、1989年; Boysen ら、1990年; Ballarin ら、1992年)。

鼻腔前部の粘膜クリアランスは、ホルムアルデヒドの 0.30 mg/m<sup>3</sup> でのばく露後に減少した (Andersen & Mølhave、1983 年)。

ホルムアルデヒドに関する動物とヒトの key events の一致を表3にまとめた。

key events	動物におけるエビデンス	ヒトにおけるエビデンス
細胞毒性	in vivo で陽性(標的細胞)	妥当性あり
細胞増殖	in vivo で陽性(標的細胞)	妥当性あり (エビデンスはあるが、共 ばく露によって交絡されている)
遺伝毒性	DPX(in vivo 標的細胞)	DPX (非標的細胞、リンパ球など)
突然変異	in vitro では陽性、in vivo では説得 力がない	陽性(?細胞)
鼻腔腫瘍	陽性(主に前外側鼻腔)	陽性(鼻咽頭) ?(副鼻腔)

### 表3. ホルムアルデヒドの用語索引表

### B. グルタルアルデヒド

グルタルアルデヒドへのばく露とヒトのがんに関する疫学的研究はほとんどない。グルタルア ルデヒド製造に携わる男性労働者 186 名のがん死亡者の増加は認められなかった。グルタルアル デヒドに初めてばく露されてからの平均期間は 20.6 年、ばく露期間は 3~7 年であった。モニタ リングばく露期間中、大気中のグルタルアルデヒド濃度は 0.04~1.4 mg/m<sup>3</sup> の範囲であった

(NICNAS、1994年)。グルタルアルデヒドの潜在的な影響について、遺体整復師、病理医及び米 国解剖学会のメンバーを対象とした研究では、すべての研究ががんリスクの増加を示している。 しかしこのグループはホルムアルデヒドにもばく露されていた(Walrath & Fraumeni、1983年、遺 伝毒性変異;ホルムアルデヒドに関するコンセンサスワークショップ、1984年; Stroup ら、1986 年)。 ヒトの鼻組織におけるグルタルアルデヒドばく露と DPX 形成、細胞毒性及び細胞増殖を検討した研究はない。

グルタルアルデヒドに関する動物とヒトの key events の一致を表4にまとめた。

key events	動物におけるエビデンス	ヒトにおけるエビデンス
細胞毒性	陽性	妥当性あり
細胞増殖	in vivo で陽性	妥当性あり
遺伝毒性	DPX (in vitro)	不明
突然変異	in vitro で陽性	不明
鼻腔腫瘍	陰性(どの部位にもエビデンスが ない)	不明

# 3. 実験動物ととトとの間の動態的または薬力学的要因のいずれかの量的差異に基づいて、MOAのとトへの関連性を合理的に排除することができるか

### A. ホルムアルデヒド

推定される MOA に関する実験動物とヒトとの間の定量的差異は、標的組織におけるホルムア ルデヒドの濃度がもたらす作用にある。細胞毒性を引き起こすのはホルムアルデヒドそのもので あり、その代謝物ではない。吸入された外因性のホルムアルデヒドは、広く分布する多数の細胞 酵素、特にホルムアルデヒド脱水素酵素によって急速に代謝されギ酸塩になる。この効率的な代 謝解毒メカニズムに加えて、粘膜絨毛機構が、その下の上皮をガスや蒸気から保護する。したが って、標的組織において細胞毒性が発生するのに十分な遊離ホルムアルデヒドの濃度を達成する ためには、これらの保護機構を克服することが必要であり、比較的高濃度のホルムアルデヒド蒸 気を標的部位に到達させる必要がある。明らかに有意な発がん性をもたらす薬力学的事象は、ラ ットのホルムアルデヒド解毒機構が飽和した用量で発生する (Casanova & Heck、1987年)。

呼吸器系におけるホルムアルデヒド誘発性毒性の定量的な種差を考慮する際には、投与量を考 慮することが重要である。吸入されたホルムアルデヒドは、生体高分子との高い反応性のため、 最初に接触する上気道の領域に多く沈着し、容易に吸収される(Heck ら、1983 年; Swenberg ら、 1983 年)。鼻の生体機構、換気量、呼吸パターン(鼻または鼻腔)の間の複雑な関係が、種によっ て上気道のどこでホルムアルデヒドの吸収が起こるかを決定する。鼻呼吸であるげっ歯類では、 沈着と吸収は主に鼻腔内で起こる。対照的に霊長類は口鼻呼吸であり、吸収と沈着は主に口腔粘 膜と鼻腔で起こる可能性が高いが、気管と気管支でも起こる可能性がある(Monticello ら、1991 年)。 この仮説は、サルの上気道内のより遠位まで病理組織学的変化、上皮細胞の増殖及び DPX 形成 が観察されることによって支持されている。

ヒトにおけるホルムアルデヒドの鼻腔発がんリスクを予測するために開発された2段階のクロ ーン増殖モデルでは、用量評価における種差が考慮されている(Conolly ら、2004年)このモデル には、ラットとヒトの正常成長曲線、細胞周期の時間及び気道の異なる領域におけるリスクのあ る細胞に関するデータも組み込まれている。

マウスは反復ばく露により呼吸速度と一回換気量の両方を低下させることができるため、マウスはラットよりもホルムアルデヒドの沈着が少なく、その結果、鼻腔上皮の組織損傷と細胞の再 生率が低下する(Chang ら、1981年、1983年)。これらの特徴は、マウスの鼻で腫瘍発生がないこ とを説明するのに役立つかもしれない。

動物とヒトとの間には、気道の用量評価の違いによる定量的な違いがあると思われるが、推定 される MOA がヒトでは発生しないことを示すような根本的な違いはないようである。

### B. グルタルアルデヒド

実験動物におけるグルタルアルデヒドの動態は、ホルムアルデヒドに比べてあまり知られていない。吸入試験は実施されていないようである。半減期は、静脈内投与(ラット10時間、ウサギ 15~30時間)と経皮投与(ラット40~110時間、ウサギ20~100時間)の両方で長くなっているが、これはグルタルアルデヒドがタンパク質に結合し、代謝物の排泄が遅いためと考えられる。 代謝物は同定されていないが、おそらくグルタルアルデヒドの代謝は、アルデヒド脱水素酵素による対応するカルボン酸への初期酸化を伴うと推定されている。酸化によって産生されたグルタ ル酸は、コエンザイムA(CoA)と反応してグルタリル CoAを産生する。そして、グルタリル CoA デヒドロゲナーゼによってグルタコニル CoA に酸化され、最終的にはアセテートを介して二酸化 炭素に分解される(Beauchamp ら、1992年; NTP、1993年; NICNAS、1994年; Ballantyne、1995 年)。

グルタルアルデヒドは、主にアミノ基間の架橋剤としてタンパク質と容易に反応する。この反応は迅速で pH に依存しており (pH>9 で反応速度が増加)、Schiff 塩基を生成する。さらに反応すると、多くの複雑な反応生成物が得られるが、架橋反応のメカニズムはまだ完全には解明されていない。

グルタルアルデヒドと DNA との相互作用についてはほとんど情報がないが、グルタルアルデ ヒドが DNA と反応するのは 60℃以上の場合のみであることが報告されており(Hopwood、1975 年)、生理的条件下では反応しないことを示唆するデータもある(Sewell ら、1984年; Douglas & Rogers、1998年; Vock ら、1999年)。

91

### 4. 信頼性、解析及び帰結の記述

### A. ホルムアルデヒド

持続的な細胞毒性と細胞増殖は、いくつかの動物種における腫瘍誘発に対して提唱されている MOA にとっての key events である。ラットにおけるホルムアルデヒド誘発性鼻腔腫瘍の MOA を 支持するデータは多数存在する。細胞毒性、DPX 形成、鼻腔上皮細胞の再生性増殖、扁平上皮化 生、炎症はラットの研究で観察されており、部位特異的で非線形の濃度反応過程であり、鼻腔腫 瘍の発生率と一致している。

エビデンスの重み付けに基づいて、動物 MOA は少なくとも定性的にはヒトに関連している可 能性が高い。ホルムアルデヒド蒸気にばく露されたサルでは、上気道上皮内の細胞増殖及び DPX 形成の増加が観察されている。また、ホルムアルデヒドへの組織ばく露後のヒト上皮細胞の増殖 は、ヒト気管支上皮細胞を移植したラット気管を胸腺欠損マウスに異種移植したモデル系でも観 察されている。主にホルムアルデヒドにばく露されたヒトの鼻の病理学的病変に関する数少ない エビデンスは、定性的に類似している実験動物の上気道の病変と一致している。さらに、いくつ かの疫学研究では、ホルムアルデヒドばく露に伴う鼻腔がんのリスク増加が示唆されている。

したがって、MOA はヒトに関連していると考えられ、ヒトのリスク評価のために、動物の鼻腔 腫瘍やその他の裏付けとなるデータを活用すべきである。このプロセスには、ホルムアルデヒド が非線形で用量依存的に腫瘍を誘発することを示唆するデータを考慮することが含まれる。また、 定量法の違いにより推定される MOA については種間の反応に量的な差異があるかもしれない。

### B. グルタルアルデヒド

グルタルアルデヒドの疫学研究は非常に限られており、鼻腔腫瘍との関連性は示されていない。 動物実験では、ラットとマウスの吸入試験において、グルタルアルデヒドは細胞毒性、細胞増殖、 DPX 産生を引き起こすことが示されているが、鼻腔腫瘍は引き起こさないことが示されている。 グルタルアルデヒドの方がホルムアルデヒドよりも明らかに毒性が強いという事実は、発がん性 の違いの説明にはならない。グルタルアルデヒドはホルムアルデヒドよりも低用量での細胞死が 多いため、発がん性があるとすれば、ホルムアルデヒドよりも低い用量でそのことが証明されな ければならない。

ホルムアルデヒドで推定される MOA、すなわち持続的な細胞毒性と細胞増殖は、グルタルアル デヒドに関連しているように思われるが、腫瘍形成では実証されていない。これらのアルデヒド に対する病理学的反応の違いは、ホルムアルデヒドがモノアルデヒドであるのに対し、グルタル アルデヒドはジアルデヒドであるためであることが暫定的に示唆されている。この違いが、グル タルアルデヒドの架橋生成物が生物学的機能を保持する可能性も修復する可能性もないように、 架橋の形態が異なるという結果になっているのかもしれない。この事例研究は、動物の腫瘍デー タが不十分な場合に HRF を適用することの難しさを浮き彫りにしている。

# 非発がん MOA のヒトへの関連性を解析するための IPCS フレームワーク

ヒトに対するがん MOA の妥当性を解析するための IPCS フレームワーク(第1部参照)の完成 後、2006 年にジュネーブで専門家会議が開催され、化学物質リスク評価に IPCS フレームワーク を一般的に適用できるか否か(すなわち、がん以外のフレームワークを開発すること)という問 題が議論された。この専門家会議の参加者は、フレームワークはすべてのエンドポイントに適用 可能であるべきであると結論付け、会期外に出版物の草案を作成した。この草案は、ハーモナイ ゼーションプロジェクト運営委員会のメンバーによって査読され、その後、受領した査読コメン トを考慮して著者によって修正された。

# 非発がん MOA のヒトへの関連性を解析するための

# IPCS フレームワーク<sup>1</sup>

# Alan R. Boobis, John E. Doe, Barbara Heinrich-Hirsch, M.E. (Bette) Meek, Sharon Munn, Mathuros Ruchirawat, Josef Schlatter, Jennifer Seed, & Carolyn Vickers

体系化されたフレームワークは、化学物質のリスク評価の透明性と調和のとれたアプローチを促進する上で非常に有用である。これが成功している分野の一つに、発がん化学物質の MOA の実験動物とヒトの間の関連性の解析がある。最近、国際化学物質安全性計画(International Programme on Chemical Safety: IPCS)はヒトとの関連性に対処するために、動物における MOA フレームワークの更新版を発表した(がんヒト関連フレームワーク、または HRF)。この作業は現在、発がん以外の影響にまで拡大されており、最終的には、発がんと非発がんの両方のエンドポイントに対するフレームワークの適用を調和させることを目的としている。発がん HRF と同様に、最初のステップは、実験的観察に基づくエビデンスの重み付けが、仮説 MOA を確立するのに十分であるか否かを判断することである。これは、毒性影響に因果関係のある一連の key events からなり、Bradford Hill 基準に基づくアプローチを用いて同定される。実験動物とヒトの間でこれらの事象を、先ずは定性的に、それから定量的に比較する。解析により、結果の信頼性、解析及び帰結とともに、明確な結論が記述される。このフレームワークは、データの透明性のある評価、主要なデータギャップの特定、用量反応関係などの化合物のリスク評価に価値のある情報の特定、ライフステージの考慮などに基づく潜在的に感受性の高いサブグループを認識するための手段を提供している。

本論文に記載されているフレームワークは、非発がんヒト関連性フレームワーク(HRF)であ り、国際化学物質安全性計画(IPCS)(WHO/ILO/UNEP)の化学物質へのばく露によるリスク評価 のアプローチの調和プロジェクトによって作成されたものである。この世界的な「調和プロジェ クト」は、リスク評価手法の一貫性の向上と国際的なガイダンス文書の構築を通じて、化学物質 のリスク評価に対する世界的適用を目的としている。このプロジェクトは、環境と開発に関する 国際連合会議(1992年、国際連合)、化学物質の安全性に関する政府間フォーラム(1994年)、持 続可能な開発に関する世界首脳会議(2002年、UNEP)、国際的化学物質管理に関する戦略的アプ ローチ(2006年、WHO)などで合意された化学物質のリスク評価手法の調和に関する公約を達成 できるようにするものである。このプロジェクトには、化学物質の評価が行われる様々な分野の 専門家が参加しているため、作成された文書は、工業用化学物質、殺生物剤、殺虫剤、動物用化 学物質、医薬品、化粧品、天然毒物、食品添加物ならびに、食品中、水中、大気中及び消費者製品 中の環境汚染物質の評価に適用することができる。

調和プロジェクトの主な成果として、化学発がんに対する MOA 評価のための IPCS フレームワ

<sup>&</sup>lt;sup>1</sup>本論文は、WHO が著作権を有するもので、2008年に Critical Reviews in Toxicology, Volume 38, pages 87-96に掲載された。本 論文はWHO の出版物のために編集された。

ーク(Sonich-Mullin ら、2001 年)と、それに続くがん MOA のヒトへの関連性を解析するための IPCS フレームワーク(IPCS cancer HRF)(Boobis ら,2006 年;本文書の第1部も参照)がある。 MOA 解析は、因果関係の Bradford Hill 基準 (Hill、1965 年)に基づくエビデンスの重み付け (weight of evidence) アプローチを利用している。これは、腫瘍の原因に沿った一連の key events の特定を 必要とするエビデンスの重み付けアプローチを適用することで、動物実験で観察された発がん作 用に対する MOA を確立できるか判断することを目的としている。実験動物で MOA が確立され た場合、がん HRF は、MOA のヒトへの関連性を検討するために透明性のあるデータ評価を可能 にする解析ツールを提供できる。

これを受けて、IPCS は、必要に応じて修正を加えながら、他のエンドポイントとそれに関連す る MOA にもがんのフレームワークを適用できるか否かを検討することにした。国際生命科学研 究機構(ILSI)のリスクサイエンス研究所(RSI)は、がん以外のリスク評価に適用するために、 同様のフレームワークを開発した。また、IPCSは2006年3月にジュネーブで国際会議を開催し た。そこで、ILSIのフレームワークが一般的に化学物質のリスク評価に適用できるかという問題 を探るために、ILSIの出版物(Seed ら、2005年)と、ILSIのがんHRF(Boobis ら、2006年;本 文書の第1部も参照)を評価、検討した。要約すると、このIPCS会議では、フレームワークが発 がんと非発がんの両方のエンドポイントに適用されるべきであり、これを実践に移すための更な る作業を推奨している。そしてこれには、本稿にも記載しているが、フレームワークのより一般 的適用のための根拠の文書化及びフレームワークの利用と利用を促進するための手順が含まれて いる。

IPCS 会議では、化学物質リスク評価において非発がん HRF は下記のような複数の有用性を持つことが認識された。

- 実験動物における MOA の確立とヒトとの関連性について、国際的に調和のとれたアプローチ を提供する。
- MOA の基準が作成され、後続のケースを考慮することができるようになる。すなわち、ある 化合物に確立された MOA を適合できるかを示すことができるようになる。
- MOA のヒトとの関連性に関する重要な情報が明らかになり、MOA を共有する他の化学物質の 評価に情報を提供できるようになる。
- 一般的に、このフレームワークを適用することで、重要データの不足や必要な研究が明らかに なり、定性的・定量的な評価に役立てることができるようになる。

### 非発がんとト関連性フレームワークの必要性

非発がん HRF は、動物 MOA のヒトとの関連性を評価するための体系化されたアプローチを提供する手段であり、エビデンスの重み付けの文脈の中で、動物において推定される MOA のヒト への関連性を評価する。その後、推定される MOA のヒトへの外挿性を明確に検討することが含 まれており、多くの場合、種間の解剖学的、生理学的及び生化学的な差異などの一般的情報の検 討に基づいている。このようにして、フレームワークは、透明性のある解析方法で、化学物質に 特異的な情報と一般的な情報の両方を最大限に利用することを奨励している。

フレームワークを用いてヒトへの関連性を決定する際の透明性を確保するために極めて重要な のは、key events の様々な種におけるエビデンスの性質を明確にし、検討することである。すなわ ち、推定される MOA における、測定可能で毒性学的反応の誘発に重要であると想定される key events に関するエビデンスの性質を明らかにし、考慮することである。実験動物とヒトの差異を 明確に考慮した上での key events の一致性の評価は、ヒトとの関連性に関するエビデンスの重み 付けを考慮する上での透明性を保つための基礎となる。

主にハザード評価において、非発がん HRF は、その後のヒトに関連すると考えられる MOA の 用量反応解析に関わる適切な key events の明確な定義とデータの検討を通じて、リスク評価の透 明性を高めることにも貢献している。実験動物における MOA がヒトと定性的に関連があると判 断された場合には、ヒトとの関連性が否定されるか否かを判断するために、実験動物とヒトの双 方からの動態学的及び薬力学的情報を考慮に入れた、より定量的な評価が必要である。

これらのデータは、その後の関連があると考えられる MOA の用量反応解析に極めて重要であ る(IPCS、2005年)。例えば、化学物質特異的調整係数(CSAFs)の定義づけにおいて、デフォル トの不確実係数を置き換えるための基礎として、利用可能な情報の妥当性を考慮する場合である。 この情報は、標的組織における反応代謝物の形成速度の種差を考慮して、毒物動態の種間差に対 するデフォルトのサブファクターを CSAF で置き換えるための適切な根拠となり得る(IPCS、2005 年)。

また、この非発がんHRFの使用はすべてのエンドポイントのリスク評価適用の調和を促進する。 例えば、発がん影響と非発がん影響に関するこれまでの異なるアプローチの架け橋となる。ここ でいう調和とは、関連情報を最大限に活用するために生物学的関連性を探ることが重要であり、 すべてのエンドポイントのリスク評価における一貫したアプローチを意味する。例えば多くの場 合、臓器毒性は同一部位に腫瘍を誘発すると推定される MOA において key events となる。非発が ん HRF は、その後の用量反応解析における種間差及び個体間のばらつきの定量化に関連する、重 要な前がん病変の key events を特定するための段階を設定する。他にも、推定される MOA が複数 の臓器に毒性効果をもたらす可能性があれば同じ非発がん HRF 解析で検討されることになる。

さらに、透明性のあるフレームワークで検討することで、それ自体は毒性学的影響に必須では ない(すなわち key events ではない)が、key events を修飾し、種や個体間の差異に寄与する因子 を特定できる可能性がある。そのような要因には、代謝経路の遺伝的差異、競合する代謝経路、 及び同時進行する病理学的要因により誘発される細胞増殖が含まれる。

このような解析は、特定の用量範囲でのみ、作動する可能性のある推定される MOA の構成要

素に関する指標も提供するかもしれない。MOA に必須な事象を引き起こすのに、対象の化合物の 高用量ばく露が必要とされる場合、ヒトのリスクとの関連性はばく露量に依存する問題となる。 このように、リスク評価におけるばく露評価は、包括的な評価を行う上で非常に重要である。

重要なことは、非発がん HRF を適用することで、リスクが高い集団(例えば遺伝的素因を持つ 人)を特定し、様々なライフステージにおける相対リスクに関連する情報を提供できるようにな るということである。これは多くの場合、化学物質固有の情報に基づくのではなく、MOA の知識 に基づき特定の年齢層でのリスクが増加しているか減少しているかを推論することに基づいてい る。このためには、ヒト及び動物モデルにおける発達及び老化過程を比較し、事象を明確に検討 する必要がある。これらの検討事項は、後続のリスク評価過程において用量反応解析など、どこ に重点を置くべきか決定する上で重要となる。

推定される MOAs のエビデンスの重み付けと透明性のあるヒトとの関連性を示すこと(利用可 能なデータベースの長所と短所を明確に検討し、種間の質的・量的な類似性と相違点及び関連す る不確実性を強調することを必要とする)は、利用可能なデータの矛盾を特定し、重要なデータ ギャップと研究の必要性を明らかにすることにもなる。これは、各ステップにおいて、解析の基 礎となるデータの質と量、フレームワーク内での解析の一貫性、データベースの一貫性(つまり 研究が互いに矛盾していないこと)、そして一致解析の質的・量的な信頼性を明確に評価する必要 があることに由来している。

すべてのデータが利用可能になる前であっても、推定される MOA 及びヒトとの関連性の解析 に、非発がん HRF を繰り返して適用することは、追加情報の獲得とともに研究戦略を策定・改良 するための基礎として有益である。すなわち、フレームワークは動物における推定される MOA の ヒトへの関連性解析を支援するデータの性質について、リスク評価者と研究者が共に理解を深め ること、データ取得に向け次の一手を決める手助けとなるに違いない。また、研究戦略を立案す る際に MOA を繰り返し検討することで、重要な分野に資源を集中させ、より階層的で集中的な アプローチを行うことができ、効率性を高めることが期待される。

知識の進歩に伴い、MOA は化学物質に特化したものから、関連する主要な生物学的プロセスに 基づいて、ある化合物から別の化合物へとヒトとの関連性をより一般化させることになるだろう。 MOA を構成する key events が発生していることを厳密に立証することが常に必要であるものの、 MOA を確立する際に化学物質固有のデータを必要とすることは少なくなるだろう。

非発がん HRF を適用した推定 MOA の透明性は、解析と推論を裏付ける明確で一貫性のある文 書化を奨励している。そして、それを満たすことで結果の信頼性を高める重要なデータギャップ を特定し、データの矛盾や不確実性を明らかにし、到達した結論に対する信頼性を向上させる。 このような透明性は、リスク評価者と研究者との議論を促進させるだけでなく、異なる規制機関 間の意見合意にも貢献すると期待される。 また非発がん HRF は、専門家の関与やピアレビューのために改善されたプロセスや内容の基礎 を提供し、推定される MOA 及びそのヒトへの関連性についての助言や承認を得るための基礎と して、解析の明確性や透明性の最低限の基準を明らかにする。これらの基準に従うことで、他者 が key events や他の MOA の除外、対象 MOA のヒトへの関連性の結論の根拠を、明確に認識でき るようになる。

### 非発がん HRF はどのような場合に適用されるのか

非発がん HRF は MOA を評価するための貴重なツールを提供するが、かなりの労力と実験的作 業を必要とするため、すべての化学物質の評価に用いられるものではない。HRF の主な目的は、 動物でみられるすべての影響がヒトに関連するというデフォルトの仮定を適用するか否かを決定 することであろう。この疑問は、リスク評価の過程で上記の仮定を適用した場合に評価結果がヒ トに有害な影響が発生する可能性が高いことを示す場合に重要性が増す。例えば、検討中の影響 が発生する最低用量とヒトの推定ばく露量との差が小さい場合、特にヒトのばく露量の推定値が 既に精緻化されている場合である。そしてその場合、リスク管理対策が必要かを知ることが重要 になる。このことは、新たな影響を特定したデータ、化学物質の用量反応関係に関する追加デー タ、または使用パターンの変更やばく露推定値の変更など、既に使用されている化学物質のリス ク評価を変更するような新たなデータが出てきた場合に最も懸念されることである。

非発がん HRF の使用は、動物での影響が神経毒性や催奇形性など、ヒトで発生した場合に重大 な影響を及ぼす可能性がある場合にも有用である。これらの影響は非常に厳格なリスク評価プロ セスの対象となるため、比較的頻繁にリスク管理措置の必要性が示唆される。

がん以外にHRFの使用を検討すべきもう一つの状況は、影響の種類または影響が発生する用量 レベルのいずれかに種差がある場合である。このような場合には、どの種がヒトへの外挿におい て最も適切なものであるかを理解することが重要である。この指針は、同一種の性別又は系統間 の違いにも適用される。

これらの状況は、さらなる検討が必要であることを示しており、非発がん HRF はこれを行う方 法を提供している。このフレームワークは、影響を検討するプロセスのどの段階でも適用でき、 科学者の道しるべとなるよう、影響を調査する過程で反復的に適用されるべきである。最初に影 響が観察され、懸念が生じたとき、フレームワークは、調査者が対処すべき問いを示すことによ って作業プログラムを構成できるようにする。研究の進展とともに、HRF はデータが作成された ときには、データを評価する研究者を導き、また他のデータが必要かどうか、どのようなデータ が必要かを決定する際の指標となる。

大量のデータがある状況では、フレームワークにより、評価者はその重要性と量に応じてエビ デンスの重み付けが可能となる。 非発がん HRF は、既にフレームワークを用いて確立されている MOA によって、化学物質が影響を 起こすことが観察された場合や、化学物質が既に確立された MOA を持つ化学物質と構造的類似があ る場合にも有用である。MOA を確立するために非発がん HRF を早期に使用することで、MOA を新し い化学物質に適用させるために調査する必要がある重要なステップを特定することができる。これは、 新しい研究や試験を設計する際の前向きな方法としても、データを遡及的に評価する方法でも、価値 あるものになるだろう。

### 非発がん HRF の検討

非発がん HRF は、推定される MOA とヒトとの関連性を評価するための全体的なエビデンスの重み 付けのための手段を体系化する解析ツールである。このフレームワークは、状況に応じて異なるため、 情報が十分であるか否かに対する絶対的な答えを提供するようには設計されていない。これは基準の チェックリストではなく、あくまでもデータの評価と提示の手段である。フレームワーク適用による 成果は、化合物のリスク評価を継続するための基礎となる。

非発がん HRF は、臓器、組織、細胞の構造と機能の変化(生理学的影響や神経行動学的影響を含む) を含む幅広い毒性学的エンドポイントに適用されることが想定されている。このフレームワークを用 いて対処できる毒性の種類には、以下のものが含まれるが、これらに限定されるものではない。

- 臓器毒性:例)ベンゼンによる血液毒性(再生不良性貧血)、パラコートによる肺毒性、クロロ キンによる眼毒性など
- 生殖毒性:例)フタル酸による男性不妊、ダイオキシンによる女性の受胎能力障害など
- 発達毒性:例)メチル水銀による発達神経毒性、レチノイドによる催奇形性など
- 神経毒性:例)鉛による末梢神経障害、アクリルアミドによる軸索障害、1-メチル-4-フェニル -1,2,3,6-テトラヒドロピリジン(MPTP)によるパーキンソン病など
- 免疫毒性:例)オルガノチンによる免疫抑制、イソニアジドによる全身性エリテマトーデス(SLE) 様症候群、汚染された L-トリプトファンによる好酸球増多症症候群(EMS)など

### MOA の紹介

非発がん HRF 解析に着手する前に、実験動物における化学物質へのばく露による毒性学的反応のエ ビデンスの重みを慎重に評価する必要がある。非発がん HRF の特徴は一度に1つの MOA のみを解析 する点である。したがって、例えば、化学物質の投与に関連した異なる毒性学的影響は、たとえ同じ動 物で観察されたとしても、各影響の MOA を識別するために別のフレームワーク解析を必要とする。代 謝的活性化と解毒における種や組織の違いと同様に、一部の毒性物質では毒性発現部位の一致性が低 い場合がある。動物とヒトのデータを比較する際には、この点に留意する必要がある。

### 推定されるMOA (事例における仮説)

ここで、被験物質の毒性学的影響の原因となっていると推定される MOA における一連の事象

の概要を簡単に説明している。この記述は次のセクションにつながり、MOAの中で「重要」と考えられる事象(すなわち、必要かつ測定可能な事象)を特定するものである。

#### Key events

MOAにおける「key events」を簡潔に説明する。key events とは、推定される MOA で仮定され た毒性学的反応の誘発に重要な事象であり、測定可能な事象である。ある事象を key events とし て支持するためには、その事象を特徴づける、一貫した測定実験データが必要である。関連する 可能性のある情報の種類には、例えば、類似の細胞における毒性学的反応と関連する key events、 理論上関連する作用部位、特定の生化学的事象、酵素の発現または活性の変化、受容体とリガン ドの相互作用、補因子レベルへの影響、組織学における特異的変化、細胞増殖の変化(増加また は減少)、ホルモンのホメオスタシスまたは他のシグナル伝達経路(細胞内または細胞外)、セカ ンドメッセンジャー、またはイオン流束、高分子の分解性の増加、さらには膜透過性または膜統 合性の変化などがある。

### 用量反応関係の一致

それぞれの key events と毒性学的反応の量的反応関係を特徴づけ、Bradford Hill 基準(Hill、1965 年)を参考にして相互関係を検討すべきである。理想としては、key events の大きさ(または頻度) の増加の用量依存性と、その後に発生する他の key events の重症度(例えば、病変の進行)の増 加、最終的な毒性学的反応に関連づけられるべきである。key events と毒性学的反応の変化の大き さを比較することは、用量反応の一致を検討するのに役立つことが多い。

用量反応曲線の異なる部分において生物学的反応に根本的な違いがあるか否かを考慮することが重要である(Slikker ら、2004 年)。もしあれば、用量反応曲線の異なる部分に関連する key events を定義し、フレームワーク解析に用いる必要がある。

### 時間的関連性

各 key events と毒性反応の時間的関係を特徴付ける必要がある。key events は毒性が明らかにな る前に観察可能であり、時間的に互いに一貫している必要がある。これは、データが推定される MOA を支持しているか否かを判断する上で不可欠なステップである。毒性反応と同時に(試験終 了時など) key events を観察しても、時間的関連性についての結論は出ないが、次のセクションで 説明する解析に貢献することができる。

### kev events と毒性学的反応との関連の強さ、一貫性及び特異性

key events、前駆病変及び毒性学的反応を結びつけるエビデンスの重みに注目すべきである(エ ビデンスの重みの意味についての考察は Weed [2005 年]を参照)。key events を遮断または減少さ せた場合に毒性が発現しない、または減少したことを示す中止/回復試験は関連性の試験として特 に有用である。

様々な実験計画は未知のバイアスや交絡を減らすことができるため、実際デザインの異なる多

くの研究で一貫した結果が得られることは、MOA の支持を高める。一貫性(Consistency)は、異なる研究において仮定された MOA の key events の再現性であるが、整合性(coherence)とは異なるものであり、仮定された MOA と観察との関係をより広く扱うものである(次のポイントを参照)。ここで価値があると思われる観察には、類似の細胞における毒性学的反応や関連する key events、論理的に関連する作用部位、中止/回復試験の結果などが含まれる。

### 生物学的妥当性及び整合性

MOA が、ターゲットとなる順序/場所の生物学一般についての知見と一致しているかどうか (生物学的妥当性)、また物質の全体的な生物学的影響について具体的に知られていることとの関 連性(整合性)を考慮すべきである。推定される MOA とそれに関連する key events が生物学的に 妥当であるためには、現在の生物学的知見と一致している必要がある。しかし、生物学的妥当性 をエビデンスの重みを評価する基準として用いる場合には、我々の知識との間にギャップが生じ る可能性を考慮することが重要である。推定される MOA と化学物質固有の観察結果との関係を より広く、例えば、毒性学的反応の MOA と他のエンドポイントの MOA との関連性などは、整合 性(前項で述べた)とは区別する必要がある。一貫性を評価する際には、構造類似体に関する情 報に価値があるかもしれない(すなわち、構造活性解析)。また、推定される MOA を共有する他 の化合物から得た性差、種差、系統の違いや key events との関係などに関する情報も有用であろ う。さらに、このセクションでは、推定される MOA を支持するために、その物質に関するデータ ベースが内部的に一貫しているかどうかを検討すべきである。

### その他のMOA

論理的に存在する代替 MOA を検討すべきである。代替 MOA が支持される場合、それらは 別の非発がん HRF 解析を必要とする。これらは、検討中の MOA の一部として扱われるため、 単一の MOA の追加的な構成要素とは区別されるべきである。

### 不確実性、矛盾及びデータギャップ

不確実性は完全かつ明示的に記載すべきである。不確実性には、毒性反応の生物学的性質に関 連するものと、評価対象の化合物のデータベースに関するものが含まれるべきである。矛盾する ものはすべて記載し、データギャップを特定すべきである。また特定されたデータギャップが、 推定される MOA を支持する上で重要であるか否かも明記すべきである。

### 推定されるMOA の評価

推定される MOA に対する高、中、低など信頼度を示す解析結果の明確な記述があるべきであ る。新規 MOA が推定されている場合は、これを明確に示すべきである。しかし、MOA が以前に 説明されたものと同じである場合は、key events がこの MOA に適合する程度を明示的に記載する 必要がある。主要な相違点はすべて記載し、MOA の適用が与える影響を議論すべきである。

### ライフステージの考察

化学物質ばく露に対する生物の反応は、その一生を通じて変化する可能性があるため、すべて の毒性エンドポイントの MOA 解析において、ライフステージを考慮することが重要である。器 官の感受性は臨界期、主要な代謝酵素の発生時期、あるいは母体と胎児の相互作用に依存するか もしれないため、特に発生期のばく露で生じる影響において重要である(Zoetis & Walls、2003 年 を参照)。さらに、発生過程の障害はその下流に影響をもたらす可能性がある。

老化を考慮することも、いくつかの理由から重要である。第一に、発育期のばく露では、かな り後にならないと毒性が検出されないことがある。さらに、器官系ごとに種特異的な老化パター ンが存在する可能性がある。例えば、生殖器はげっ歯類とヒトでは病因が異なり、げっ歯類の系 統によっても異なることがある。

### ヒトとの関連性

動物において毒性学的影響の MOA を確立することができれば、次の段階でヒトへの関連性を 評価する必要がある。IPCS の非発がん HRF は、一連の3つの(または4つの)問いに答えるア プローチとして提示されており、毒性学的影響の根底にある MOA のヒトへの外挿性に関する文 書化された論理的な結論を導き出すことができる。このガイダンスを適用すると、4つ(または5 つ)のセクションで構成された説明文が作成され、リスクアセスメントのハザード評価に組み込 むことができる。

1. 動物における MOA を確立するのにエビデンスの重み付けは十分か。この問いは、因果関係の Bradford Hill 基準(Hill、1965年)に基づいた、上記のような MOA 解析を行うことで解決される。可能性のある代替 MOA におけるエビデンスの重みを考慮し、検討中の MOA を支持するエビデンス全体の強さに基づいて結論を出す必要がある。このようなアプローチは、重要なデータギャップを特定する。このデータギャップが埋められることにより、提示された MOA はより信頼性を高めるであろう。推定される MOA が他の化学物質について既に記述されている場合、そのヒトへの外挿性は評価されているだろう。推定される MOA が新規である場合、ヒトへの外挿性は新たに評価する必要がある。

2. 実験動物とヒトとの間のkey events の根本的、質的な違いに基づいて、MOA のヒトとの関連 性を合理的に排除することができるか。この問いでは、ヒトに対する MOA の関連性の質的評価 を行う。動物の MOA で発生する重要な key events をリストアップし、各 key events がヒトで発生 する可能性があるかどうかを直接評価することで、評価が容易になり、プロセスの透明性が高ま る。一致表と呼ばれる表形式での提示は特に有用である。この表に従って証明するため、表の情 報は比較的簡潔でなければならない。1 つの列には、key events のそれぞれについてのヒトへの影 響が評価されている。毒性をもたらさない異なる系統、種、性、または異なる投与経路の結果に 関する列は、比較するのに有用である。それ自体は重要ではないが、key events を修飾し、種差ま たは個体差に寄与する因子が同定される場合がある。例としては、代謝経路における遺伝的差異、 競合する代謝経路及び同時並行的な病態によって誘発される影響などが挙げられる。特定されたそのような要因はすべて、一致表の脚注に記載する必要がある。

代謝経路における遺伝的差異、競合する代謝経路及び同時並行的な病態によって誘発される影響などが挙げられる。特定されたそのような要因はすべて、一致表の脚注に記載する必要がある。 ある化学物質のヒトにおける MOA の key events の一致性の評価は、特定の化学物質の評価という よりは、ヒトにおける MOA の評価である。一般的に、初期の key events の詳細は、より化学物質 に特化したものになる可能性が高い。その後の事象は、MOA により一般的に当てはまる事象とな る。ヒトにおける key events を評価するための情報は、物質そのものに関する in vitro 及び in vivo 研究から得られるが、解剖学、生理学、内分泌学、遺伝的疾患、疫学、その他ヒトにおける key events に関して知られているあらゆる基本的な情報が重要となる。

この問いに答える際には、エビデンスの重みとヒトの情報における信頼度の評価を記述した説 明文を作成する必要がある。有用な情報の具体例としては、以下のようなものがある。

- 必要に応じて、年齢、性別、人種差、化学物質やその他環境因子などの危険因子を含む、対象 となる解剖学的部位や細胞種における発生率の背景値
- 生理的、細胞的、生化学的レベルの制御機構や発生、構造(肉眼、組織)を含む標的部位の性質と機能に関する知識
- 標的器官の制御と応答に関する考察をもたらすヒト及び動物の疾患状態
- 対象となる臓器や影響を含む、短期、中期、または長期ばく露後の、評価対象の化学物質また は構造類似体に対するヒト及び動物の反応

MOA がヒトには関連性がないと明確に結論づけるためには、相当量の情報が必要である。その ような結論がデータによって強く支持されている場合、その MOA のみで毒性を生じる化学物質 はヒトにリスクをもたらさず、このエンドポイントに関する追加のリスク評価は必要ない。

関連性の問題は、すべての集団とライフステージを考慮している。MOA が作動する条件が、主 に感受性の高い集団やライフステージにいる人に発生する可能性がある。例えばすでにウイルス に感染しているか、ホルモンバランスの不均衡を有する人または疾患を持っている人である。感 受性の質的または量的差異を示唆する情報は、リスクの特徴付けに使用するため強調される。

非発がんHRF解析では、ライフステージに関連して考慮すべきいくつかの側面がある。第一に、 解析ではヒトと動物モデルで起こる発生過程と事象を比較検討すべきである (Zoetis & Walls、2003 年参照)。この比較は、ヒトと動物モデルにおいて発生過程がどの程度類似しているかを示すもの である。一般的に、発生過程はそんなに変化しておらず、このような場合には、動物 MOA はヒト MOA にも当てはまるという結論が導き出される。しかし、いくつかの種には特有の発生過程があ り、その場合種特異的な MOA となり、ヒトにもあてはまるとは限らない。 第二に、解析では、ヒトと動物モデルにおける発生過程や事象の相対的な時期や段階の特異性 を考慮する必要がある。重要な発生過程における事象は、発生期の異なる時期に生じる可能性が ある。いくつかの発生過程における事象は、動物では出生前の早い時期に発生し、ヒトでは出生 前の遅い時期に発生する可能性がある。その他発生過程における事象は、ヒトでは出生前に発生 し、動物では出生後に発生することもあれば、その逆もある。胎盤移行と乳汁移行に大きな差が ある場合には、発生時期の違いが線量基準に影響を与える可能性がある。同様に、発生過程に関 連する主要な代謝酵素の発生時期を比較すると、ヒトと動物モデルの間にかなりの差があること が明らかになる可能性がある。このような考察から、ヒトでは動物モデルの MOA は妥当ではな いという結論が導き出されるかもしれない。

実験動物とヒトとの間の薬力学的または動態的要因のいずれかの量的差異に基づいて、MOA 3. のヒトヘの関連性を合理的に排除することができるか。実験動物における MOA がヒトと定性的 に無関係であると判断できない場合(問い2に「No」)、実験動物とヒトから得られるあらゆる動 態学的及び薬力学的情報を考慮して、より定量的な評価が行われる。このようなデータは、必然的 に化学物質と MOA に固有のものであり、可能であれば、毒性を引き起こす薬力学的影響が発現 する用量を含むべきである。動態学的考察には、吸収の速度及び程度、組織分布、代謝及び排泄が 含まれる。胎生の違いは、胎盤移行及び乳汁移行において実質的な種差をもたらす可能性があり、 これは定量的な影響を及ぼす。したがって、これによりヒトと実験動物との間で MOA の量的差 異がもたらされる可能性がある。同様に、主要な代謝酵素の発現時期の違いにより、ヒトと実験 動物の間ではかなりの差が生じる可能性がある。薬力学的な考慮事項には、化学物質と細胞、組 織及び器官との相互作用が含まれる。量的差異に基づいてヒトへの外挿性を否定することができ るのは、ごくまれである。定量的ばく露評価は HRF よりもむしろその後のリスクの判定の一部で あるため、その差はヒトへのばく露がそのようなレベルに達するとは考えられないほどの大きさ でなければならない。ほとんどの場合、後続のリスクの判定で正式なばく露評価を行わなければ、 そのような結論に達することはできない。したがって、問いの答えは「No」であるが、その後の リスク評価では、リスクは無視できる程度であると結論づけられるかもしれない。メラミン誘発 性膀胱発がんは、この点を説明する有用な事例研究を提供している(Meek ら、2003 年)ここで も、実験動物とヒトからのデータを表形式で比較することが評価に役立つ。同様または類似の MOA によって作用する他の化合物の研究から得られた情報も価値がある。実験動物とヒトの間の 反応の違いの基礎的な理解が深まれば、定性的であると考えられていた key events の違いが、定 量的な違いによるものであることが示されるかもしれない。

量的差異に基づいて毒性 MOA がヒトと関連性がないと結論づけることはできないかもしれな いが、評価の中で、これらの差異の程度はリスク評価に顕著な影響を与えるのに十分である。し たがって、この問いへの回答の説明文は包括的であり、可能な限り定量的な情報を把握しておく ことが重要である。

117

問い2と同様に、この質問への回答が「Yes」であれば、この MOA のみで毒性を示す化学物質 へのばく露はヒトにリスクをもたらさず、追加のリスク特性評価は必要ない。

前述の3つの質問は、決定ツリーを構成している(図1参照)。

# 図 1. 実験動物で観察された毒性に対する MOA のヒトへの関連性を判断するための 決定ツリー

### 用量反応評価への影響

リスク評価を進める前に、毒性に対する MOA のヒトへの関連性を除外することはできないが、 更なる問いに対処すべきである。それは以下の点である。これは、4. 種や個体差の不確実性因子 のデフォルト値を変更できるような、key events に量的な違いがあるか。このような情報は、動態 学又は薬力学のいずれかに関するものである。これは CSAF を計算するために使用することがで き、その場合動態学又は薬力学における種又は個体差のデフォルト値の1つ以上が、化学物質固 有の情報に基づく値に置き換えられる (IPCS、2005 年)。調整係数の他の要素は変更しない。この ような情報は、通常のデフォルト値と比較して調整係数の増加または減少をもたらす可能性があ る。

### 発表された事例研究

がん以外のエンドポイントに対する MOAs のヒトへの関連性を評価するためのフレームワーク を決定するにあたり、ILSI/RSI はまた、一連の例示的な事例研究を実施した。これらの事例研究 は以下の通り。

モリネートによる精子形成阻害(Kavlock & Cummings、2005年a)、
エチレングリコールの腎及び発育への影響(Corley ら、2005年)、
ニコチンの発達神経毒性(Slikker ら、2005年)
フタル酸エステルの男性の生殖発達に対する影響(Foster、2005年)、
ビンクロゾリン誘発性奇形(Kavlock & Cummings、2005年b)、
バルプロ酸の発育への影響(Wiltse、2005年)、

ヘモグロビン系酸素運搬(HBOC)関連先天性奇形(Holson ら、2005 年)、
 アンジオテンシン変換酵素(ACE)阻害剤の発生影響(Tabacova、2005 年)、
 ポリハロゲン化芳香族炭化水素の発達聴器毒性(Crofton & Zoeller、2005 年)、
 プロピルチオウラシルが神経発達に及ぼす影響(Zoeller & Crofton、2005 年)などがある。

これらの事例は、様々なエンドポイントを対象としているが、そのほとんどは発生段階の影響 を対象としている。したがって、上記のような他のエンドポイントに関する追加の事例研究が必 要である。このフレームワークの使用経験の積み重ねにより、公開された事例のいくつかは、フ レームワーク適用ための例示的事例を提供できるように、さらに洗練されていく可能性がある。

一般的に、これらの事例は、この非発がん HRF の基礎となっているいくつかの重要な問題を強 調する上で非常に有用である。例としては、一致解析の重要性、ヒトへの関連性を排除できない 場合のフレームワーク適用中に特定された量的情報の価値、フレームワーク解析の結論を報告す る際の透明性のある包括的な構成の必要性、重要なデータギャップの特定(例:モリネートと HBOC の事例研究)、研究ニーズの特定(例:ビンクロゾリンの事例研究)、特定の代謝物の形成を理解 することの重要性、Bradford Hill 基準(Hill、1965 年)を key events に適用して堅牢な MOA を確 立することの重要性などが挙げられる。

### 信頼性、解析及び帰結の記述

非発がん HRF を適用し、3つ(または4つ)の質問に回答した後、解析の基礎となるデータの 質と量、フレームワーク内での解析の一貫性、データベースの一貫性及び一致性解析の性質と程 度に対応した信頼性を示す文書を提供すべきである。必要に応じて代替的な MOAs は、同様に厳 密に評価されるべきである。重要な成果は、解析の信頼性を高めるために実験的に対処できるデ ータギャップを特定することである。

非発がん HRF を行うことにより、実験動物における毒性 MOA がヒトに関連するかどうかを判 断するだけでなく、それ以上に有用な情報が得られる。また、関連する影響のリスクの判定の次 の段階で重要な情報を得ることができる。例えば、得られた情報に基づいて CSAFs を開発するこ とができるかもしれない。フレームワークを適用することで、リスクに影響を与える可能性のあ る調節因子の情報も提供できる。さらに、推定される MOA の要素のうち、特定の用量範囲での み作用するものを特定することができる。MOA で必須の段階が、ある化合物の高用量投与後にの み発生する場合、ヒトのリスクに対する MOA の関連性はばく露量によって決定される。したが って、効果的なばく露評価は、このような毒性によるヒトリスクの評価にとって特に重要である。

解析もまた、リスクが増加する可能性のある集団(例えば、遺伝的素因を持つ人々)の特定に 寄与し、多くの場合様々なライフステージにおける相対的なリスクを考慮するのに有用な情報を 提供している。これは必ずしも化学物質固有の情報に基づくものではなく、むしろ MOA の知識 に基づいて、年齢によってリスクが異なるかどうかについての推論に基づくものである。 非発がん HRF を用いたデータとその解析は、他の人が到達した結論の根拠を判別できるように 明確かつ包括的な方法で報告されるべきである。

提示の具体的な形式は利用可能なデータの種類によって異なるが、可能であれば、フレームワ ークの主要な見出しを含む形式的な報告書を提供すべきである。発表は、到達した結論の透明性 を確保するために、文脈と思考プロセスの詳細を含めるべきである。一致表を含めることが強く 推奨される。これにより、透明性を高め専門家同士の協力が容易になる。

### フレームワークとその成果の利用

IPCS の非発がん HRF は、主に推定される MOA の key events の堅牢な一致解析に基づいている。以下のようないくつかの分野で調和に貢献するための基礎として、リスク評価と研究コミュニティの双方に価値があると考えられている。

- 動物における推定 MOA の妥当性とエビデンスの重み付けの性質及びヒトへの関連性
- エンドポイント間の MOA の統合
- 専門家の参加とレビューを十分に確保するための透明性のある基準

非発がん HRF の強みは、その柔軟性、透明性及びエンドポイント間で適用できることである。 これには、用量反応曲線の性質と形状の決定、個々の key events に対する生物学的閾値と位置の 特定及びそれらの影響が含まれる。さらに、各 key events に関与する動態学的及び薬力学的要因 を考慮することは、特定の集団、例えば、若年期、特定の疾患を有する人々、または特定の多型 を有する人々への関連性の有無に関して有益である。あるいは、フレームワークを適用すること で、そのようなグループ間の差異に関する定量的な情報を提供することもできる。また、ヒトへ の関連性の有無についての解析において、ある種の生物が、用量制限のために潜在的に関連する エンドポイントの評価には不適切である場合もある。

### 次のステップ

非発がん HRF を効果的に適用するためには、その適用及びその利用の解釈において個人を訓練 する必要がある。発がん性 HRF の利用においては経験が得られており、その得られた専門知識は、 非発がん HRF 使用における訓練にも適用できる。訓練は、適切な事例研究がより多く利用可能と なることによって促進されるであろう。これまでに発表された事例は、この目的のための適切な 基盤となる (Seed ら、2005 年)。さらに、より広範囲のエンドポイントに関する事例を調査する必 要がある。非発がん HRF 解析の経験を持つ組織が指針を作り、訓練を支援するために適切な専門 家がその教材を利用できるようにすることは有用であろう。

一般的に受け入れられている MOA のデータベースを、有益な事例研究とともに編集し、持続 させるべきである。このようなデータベースは、MOA の開発において事例は更新され続けられ、 ある化合物の MOA が新規か、あるいは他の化合物について以前に記載されていたものかを判断 する上でも重要なものとなるだろう。

IPCS の発がん性 HRF から生まれた現在の非発がん HRF は、がん以外のエンドポイントに焦点を 当てている。しかし、発がんと非発がんの効果を評価するための哲学や戦略には顕著な類似点が ある。化学物質のリスク評価の調和における次のステップの一つとして、がんを含むすべての毒 性学的エンドポイントに適用可能な統一的な HRF を作成することが強く推奨される。リスク評価 過程へのフレームワーク適用は、さらに精緻化されるべきであり、その際には、例示が価値ある ものとなるであろう。このようなフレームワーク文書には、リスク評価における HRF 解析の使用 に関するガイダンスと同様に、HRF 解析に着手する前の問題の定式化に関するガイダンスが含ま れるべきである。また、フレームワークを適用することで、用量反応関係の理解が深まることが 多いが、これはハザード評価に反映されるべきである。上述のように、用量の変化に関する知識 は、ばく露データを解釈する上で非常に重要である。MOA における key events を特定することで、 種差及び個体差の原因や程度に関する知見を得ることができる。

レームワーク

本プロジェクトは、化学物質へのばく露によるリスク評価のアプローチの調和に関する IPCS プロジェクトの一環として実施された。

本文書は世界保健機関(WHO)、国際労働機関(ILO)、国連環境計画(UNEP)の共同支援のも とに出版され、化学物質の適正な管理に関する国際機関間プログラムのフレームワークの中で作 成された。

The International Programme on Chemical Safety (IPCS), established in 1980, is a joint venture of the United Nations Environment Programme (UNEP), the International Labour Organization (ILO), and the World Health Organization (WHO). The overall objectives of the IPCS are to establish the scientific basis for assessment of the risk to human health and the environment from exposure to chemicals, through international peer review processes, as a prerequisite for the promotion of chemical safety, and to provide technical assistance in strengthening national capacities for the sound management of chemicals.

The Inter-Organization Programme for the Sound Management of Chemicals (IOMC) was established in 1995 by UNEP, ILO, the Food and Agriculture Organization of the United Nations, WHO, the United Nations Industrial Development Organization, the United Nations Institute for Training and Research, and the Organisation for Economic Co-operation and Development (Participating Organizations), following recommendations made by the 1992 UN Conference on Environment and Development to strengthen cooperation and increase coordination in the field of chemical safety. The purpose of the IOMC is to promote coordination of the policies and activities pursued by the Participating Organizations, jointly or separately, to achieve the sound management of chemicals in relation to human health and the environment.

#### FOREWORD

Harmonization Project Documents are a family of publications by the World Health Organization (WHO) under the umbrella of the International Programme on Chemical Safety (IPCS) (WHO/ILO/UNEP). Harmonization Project Documents complement the Environmental Health Criteria (EHC) methodology (yellow cover) series of documents as authoritative documents on methods for the risk assessment of chemicals.

The main impetus for the current coordinated international, regional, and national efforts on the assessment and management of hazardous chemicals arose from the 1992 United Nations Conference on Environment and Development (UNCED). UNCED Agenda 21, Chapter 19, provides the "blueprint" for the environmentally sound management of toxic chemicals. This commitment by governments was reconfirmed at the 2002 World Summit on Sustainable Development and in 2006 in the Strategic Approach to International Chemicals Management (SAICM). The IPCS project on the Harmonization of Approaches to the Assessment of Risk from Exposure to Chemicals (Harmonization Project) is conducted under Agenda 21, Chapter 19, and contributes to the implementation of SAICM. In particular, the project addresses the SAICM objective on Risk Reduction and the SAICM Global Plan of Action activity to "Develop and use new and harmonized methods for risk assessment".

The IPCS Harmonization Project goal is to improve chemical risk assessment globally, through the pursuit of common principles and approaches, and, hence, strengthen national and international management practices that deliver better protection of human health and the environment within the framework of sustainability. The Harmonization Project aims to harmonize global approaches to chemical risk assessment, including by developing international guidance documents on specific issues. The guidance is intended for adoption and use in countries and by international bodies in the performance of chemical risk assessments. The guidance is developed by engaging experts worldwide. The project has been implemented using a stepwise approach, first sharing information and increasing understanding of methods and practices used by various countries, identifying areas where convergence of different approaches would be beneficial, and then developing guidance that enables implementation of harmonized approaches. The project uses a building block approach, focusing at any one time on the aspects of risk assessment that are particularly important for harmonization.

The project enables risk assessments (or components thereof) to be performed using internationally accepted methods, and these assessments can then be shared to avoid duplication and optimize use of valuable resources for risk management. It also promotes sound science as a basis for risk management decisions, promotes transparency in risk assessment, and reduces unnecessary testing of chemicals. Advances in scientific knowledge can be translated into new harmonized methods.

This ongoing project is overseen by a geographically representative Harmonization Project Steering Committee and a number of ad hoc Working Groups that manage the detailed work. Finalization of documents includes a rigorous process of international peer review and public comment. ハーモナイゼーションプロジェクト文書とは、国際化学物質安全性計画(IPCS)(WHO/ILO/UNEP) のもと世界保健機関(WHO)によって出版された出版物群である。ハーモナイゼーションプロジ ェクト文書は、化学物質のリスク評価方法に関する正式な文書として、環境保健クライテリア (EHC)の方法論シリーズ(黄表紙)を補完するものである。

有害化学物質の評価と管理に関する現在の国際的、地域的及び各国内の協調的な取り組みの主 なきっかけは、1992年の国連環境開発会議(UNCED)にあった。UNCEDアジェンダ21の第19 章において、有害化学物質の環境的に健全な管理のための「青写真」が示されている。各国政府 によるこのコミットメントは、2002年の持続可能な開発に関する世界首脳会議で、さらに2006年 の国際的な化学物質管理のための戦略的アプローチ(SAICM)でも再確認された。化学物質への ばく露によるリスク評価のアプローチの調和に関する IPCS プロジェクト(ハーモナイゼーショ ンプロジェクト)は、このアジェンダ21第19章の下で実施されており、SAICMの実施に貢献し ている。特に、本プロジェクトは、SAICMの目標である「リスク低減」と SAICM 世界行動計画 の活動である「リスク評価のための新たな調和された手法の開発と利用」に対応している。

IPCS ハーモナイゼーションプロジェクトの目的は、共通の原則とアプローチを追求することに よって化学物質のリスク評価を世界的に改善し、持続可能性というフレームワークの中でヒトの 健康と環境をより良く保護するための国内及び国際的な管理手法を強化することである。ハーモ ナイゼーションプロジェクトは、特定の問題に関する国際的なガイダンス文書を作成することを 含め、化学物質リスク評価に対する世界各国のアプローチを調和させることを目的としている。 このガイダンスは、化学物質のリスク評価を実施する際に各国や国際機関で採用され、使用する ことを目的としている。このガイダンスは、世界中の専門家の協力を得て作成されている。本プ ロジェクトは、まず各国の手法や慣行について情報を共有し、理解を深め、異なるアプローチの 統一化が有益となる分野を特定した上で、調和のとれたアプローチの実施を可能にするガイダン スを作成するという段階的アプローチを用いて採用している。本プロジェクトでは、アプローチ の調和を図る上で、特に重要なリスク評価の側面に焦点を当てたビルディングブロック法を採用 している。

このプロジェクトにより、国際的に認められた手法を用いてリスク評価(またはその構成要素) を実施することを可能にし、これらの評価を共有することで重複を避け、リスク管理のための貴 重な資源を最適に利用することが可能となる。また、リスク管理の意思決定の基礎となる健全な 科学を促進し、リスク評価の透明性を高め、不必要な化学物質の試験を減らすことができる。ま た、科学的知識の発展が新たな調和のとれた手法の開発へとつながりうる。

この進行中のプロジェクトは、各地域の代表的なハーモナイゼーションプロジェクト運営委員 会と、詳細な作業を管理するいくつかの特別作業部会によって監督されている。最終的には、国 際的なピアレビュー及びパブリックコメントといった厳格なプロセスが含まれている。

### PART 1

第1部

発がん MOA のヒトへの関連性を解析するための IPCS フレームワーク及び事例研究

### IPCS FRAMEWORK FOR ANALYSING THE RELEVANCE OF A CANCER MODE OF ACTION FOR HUMANS AND CASE-STUDIES

#### PREFACE

Following publication of the International Programme on Chemical Safety (IPCS) Conceptual Framework for Evaluating a Mode of Action for Chemical Carcinogenesis (in animals),<sup>1</sup> an IPCS Cancer Working Group convened on 3–5 March 2004 in Arlington, Virginia, USA. The working group agreed that the issue of human relevance of animal tumours should be further explored with the goal of developing a unified IPCS Human Relevance Framework for use of mode of action information in risk assessment for regulatory and other purposes, and it provided initial guidance for this task. The members of this working group, including secretariat support and a representative of the Organisation for Economic Co-operation and Development, were as follows:

Professor Hermann Bolt, Institut für Arbeitsphysiologie, Germany

- Professor Alan R. Boobis, Department of Health Toxicology Unit, Imperial College London, United Kingdom
- Dr John Bucher, National Institute of Environmental Health Sciences, USA
- Dr Vincent Cogliano, Unit of Carcinogen Identification and Evaluation, International Agency for Research on Cancer, France
- Dr Samuel M. Cohen, Pathology and Microbiology, Havlik-Wall Professor of Oncology, University of Nebraska Medical Center, USA
- Dr William Farland, Office of Research and Development, Environmental Protection Agency, USA
- Dr Jun Kanno, Division of Cellular & Molecular Toxicology, National Institute of Health Sciences, Japan
- Dr Lois D. Lehman-McKeeman, Bristol-Myers Squibb, USA
- Ms Bette Meek, Environmental Health Centre, Health Canada, Canada
- Ms Laurence Musset, Environment, Health and Safety Division, Organisation for Economic Co-operation and Development, France
- Dr Jerry Rice, Consultant, USA
- Ms Cindy Sonich-Mullin, International Programme on Chemical Safety, World Health Organization, USA
- Ms Carolyn Vickers, International Programme on Chemical Safety, World Health Organization, Switzerland
- Ms Deborah Willcocks, Existing Chemicals, National Industrial Chemicals Notification and Assessment Scheme (NICNAS), Australia

Extending the Mode of Action Framework to include consideration of human relevance, taking into account guidance from the Arlington meeting, was the subject of an IPCS international workshop convened in Bradford, United Kingdom, from 21 to 23 April 2005. This workshop prepared draft text for an IPCS Human Relevance Framework, including updating the 2001 Mode of Action Framework. The workshop participants, including

#### 序文

国際化学物質安全性計画(IPCS)の(動物における)<sup>1</sup>「化学物質の発がん作用機序の評価に関 する概念的フレームワーク」の公表を受けて、2004年3月3日から5日に米国バージニア州アー リントンで IPCS がんワーキンググループが開催された。このワーキンググループは、規制やその 他の目的でリスク評価において作用機序に関する情報を利用するための統一された IPCS ヒト関 連性フレームワークを開発することを目標に、動物における腫瘍のヒトへの関連性の問題をさら に検討する必要性があることに合意し、この作業のための初期のガイダンスを提供した。このワ ーキンググループのメンバーは、事務局サポートと経済協力開発機構(OECD)の代表者を含めて 以下の通りである。

Hermann Bolt 教授(ドイツ・生理学研究所) Alan R. Boobis 教授(インペリアル・カレッジ・ロンドン、健康毒性学部門、英国) John Bucher 博士(国立環境衛生科学研究所、米国) Vincent Cogliano 博士(国際がん研究機関発がん物質同定・評価ユニット、フランス) Samuel M. Cohen 博士(病理学・微生物学、ハヴリック・ウォール腫瘍学教授、ネブラス カメディカルセンター大学、米国) William Farland 博士 (環境保護庁研究開発局、米国) Jun Kanno 博士(独立行政法人国立医薬品食品衛生研究所 細胞分子毒性学研究部門、目 太) Lois D. Lehman-McKeeman 博士 (ブリストル・マイヤーズ スクイブ、米国) Bette Meek 氏(カナダ保健省環境衛生センター、カナダ) Laurence Musset 氏(経済協力開発機構環境安全衛生部門、フランス) Jerry Rice 博士 (コンサルタント、米国) Cindy Sonich-Mullin 氏(世界保健機関国際化学物質安全性計画、米国) Carolyn Vickers 氏(世界保健機関国際化学物質安全性計画、スイス) Deborah Willcocks 氏(国家工業化学品届出・評価スキーム(NICNAS)、既存化学品担当、 オーストラリア)

2005 年 4 月 21 日から 23 日に英国のブラッドフォードで開催された IPCS 国際ワークショップ においてアーリントン会議のガイダンスを考慮し、MOA フレームワークに人間への関連性を考慮 した内容に拡張することが検討された。このワークショップでは、2001 年の MOA フレームワー クの更新を含む IPCS ヒト関連性フレームワークの草案が作成された。

<sup>&</sup>lt;sup>1</sup> Sonich-Mullin C, Fielder R, Wiltse J, Baetcke K, Dempsey J, Fenner-Crisp P, Grant D, Hartley M, Knaap A, Kroese D, Mangelsdorf I, Meek E, Rice J, Younes M (2001) IPCS conceptual framework for evaluating a mode of action for chemical carcinogenesis. *Regulatory Toxicology and Pharmacology*, **34**:146–152.

<sup>&</sup>lt;sup>1</sup> Sonich-Mullin C, Fielder R, Wiltse J, Baetcke K, Dempsey J, Fenner-Crisp P, Grant D, Hartley M, Knaap A, Kroese D, Mangelsdorf I, Meek E, Rice J, Younes M (2001) IPCS conceptual framework for evaluating a mode of action for chemical carcinogenesis. *Regulatory Toxicology and Pharmacology*, 34:146–152.

secretariat support and representatives of the European Food Safety Authority and European Chemicals Bureau, were as follows:

- Dr Peter Abbott, Scientific Risk Assessment and Evaluation Branch, Food Standards Australia New Zealand, Australia
- Dr Antero Aitio, International Programme on Chemical Safety, World Health Organization, Switzerland
- Dr Diana Anderson, Department of Biomedical Sciences, University of Bradford, United Kingdom
- Professor Sir Colin Berry, United Kingdom
- Professor Hermann Bolt, Institut für Arbeitsphysiologie, Germany
- Professor Alan R. Boobis, Department of Health Toxicology Unit, Imperial College London, United Kingdom
- Dr Susy Brescia, Health and Safety Executive, United Kingdom
- Dr John Bucher, National Institute of Environmental Health Sciences, USA
- Dr Vincent Cogliano, Unit of Carcinogen Identification and Evaluation, International Agency for Research on Cancer, France
- Dr Samuel M. Cohen, Pathology and Microbiology, Havlik-Wall Professor of Oncology, University of Nebraska Medical Center, USA
- Dr Vicki Dellarco, Office of Pesticide Programs, Environmental Protection Agency, USA
- Ms Christine Dove, School of Life Sciences, University of Bradford, United Kingdom
- Dr Jun Kanno, Division of Cellular and Molecular Toxicology, National Institute of Health Sciences, Japan
- Dr Janet Kielhorn, Department of Chemical Risk Assessment, Fraunhofer Institute for Toxicology and Experimental Medicine, Germany
- Mrs Sandra Kunz, International Programme on Chemical Safety, World Health Organization, Switzerland
- Dr Christian Laurent, Scientific Expert Services, European Food Safety Authority, Italy
- Dr Douglas McGregor, Toxicity Evaluation Consultants, United Kingdom
- Ms Bette Meek, Environmental Health Centre, Health Canada, Canada
- Ms Sharon Munn, Toxicology and Chemical Substances, European Chemicals Bureau, Italy
- Dr R. Julian Preston, National Health and Environmental Effects Research Laboratory, Environmental Carcinogenesis Division, Environmental Protection Agency, USA
- Dr Jerry Rice, Consultant, USA
- Dr Hans-Bernhard Richter-Reichhelm, Federal Institute for Risk Assessment (BfR), Germany
- Ms Carolyn Vickers, International Programme on Chemical Safety, World Health Organization, Switzerland

#### Harmonization Project Document No. 4

The draft was published on the Internet for public comment and sent to a number of WHO Collaborating Centres and IPCS Participating Institutions for peer review. An expert meeting that convened in London in December 2005 considered the comments received and finalized the framework. The expert meeting participants were as follows:

- Professor Alan R. Boobis, Department of Health Toxicology Unit, Imperial College London, United Kingdom (*Rapporteur*)
- Dr Samuel M. Cohen, Pathology and Microbiology, Havlik-Wall Professor of Oncology, University of Nebraska Medical Center, USA
- Dr Vicki Dellarco, Office of Pesticide Programs, Environmental Protection Agency, USA
- Dr William Farland, Office of Research and Development, Environmental Protection Agency, USA (*Chair*)
- Dr Douglas McGregor, Toxicity Evaluation Consultants, United Kingdom
- Ms Carolyn Vickers, International Programme on Chemical Safety, World Health Organization, Switzerland
- Ms Deborah Willcocks, Existing Chemicals, National Industrial Chemicals Notification and Assessment Scheme (NICNAS), Australia

#### Harmonization Project Document No. 4

草案はパブリックコメントのためにインターネット上で公開され、ピアレビューのために多く の WHO 協力機関と IPCS 参加機関に送付された。2005 年 12 月にロンドンで開催された専門家会 議では、寄せられたコメントを検討し、最終的にフレームワークが決定された。専門家会議の参 加者は以下の通りである。

Alan R. Boobis 教授(インペリアル・カレッジ・ロンドン、英国)(報告者)
Samuel M. Cohen 博士(病理学・微生物学、ハヴリック・ウォール腫瘍学教授、ネブラ スカメディカルセンター大学、米国)
Vicki Dellarco 博士(環境保護庁、農薬プログラム部、米国)
William Farland 氏(環境保護庁、研究開発局、米国)(座長)
Douglas McGregor 博士(毒性評価コンサルタント、英国)
Carolyn Vickers 氏(世界保健機関、国際化学物質安全性計画、スイス)
Deborah Willcocks 氏(国家工業化学品届出・評価スキーム(NICNAS)、既存化学品担当、 オーストラリア)

### IPCS FRAMEWORK FOR ANALYSING THE RELEVANCE OF A CANCER MODE OF ACTION FOR HUMANS<sup>1</sup>

Alan R. Boobis, Samuel M. Cohen, Vicki Dellarco, Douglas McGregor, M.E. (Bette) Meek, Carolyn Vickers, Deborah Willcocks, & William Farland

The use of structured frameworks can be invaluable in promoting harmonization in the assessment of chemical risk. The International Programme on Chemical Safety (IPCS) has therefore updated and extended its Mode of Action (MOA) Framework for cancer to address the issue of human relevance of a carcinogenic response observed in an experimental study. The first stage is to determine whether it is possible to establish an MOA. This comprises a series of key events along the causal pathway to cancer, identified using a weight-of-evidence approach based on the Bradford Hill criteria. The key events are then compared first qualitatively and then quantitatively between the experimental animals and humans. Finally, a clear statement of confidence, analysis, and implications is produced. The IPCS Human Relevance Framework for cancer provides an analytical tool to enable the transparent evaluation of the data, identification of key data gaps, and structured presentation of information that would be of value in the further risk assessment of the compound, even if relevancy cannot be excluded. This might include data on the shape of the dose-response curve, identification of any thresholds, and recognition of potentially susceptible subgroups, for example, the basis of genetic or life stage differences.

Fundamental to the evolution of cancer risk assessment over the last three decades has been our increasing understanding of the biology of cancer and the identification of key events in carcinogenesis. Through the mid-1980s, national and international assessments of human cancer hazard and risk depended primarily on lifetime assays in rodents of potentially carcinogenic agents. For few agents was there sufficient human evidence on which to base retrospective cancer assessments, and fewer still would be expected to be detected prospectively, given modern controls on general exposures in the workplace and in the environment generally. Inherent in rodent-based assessments was the assumption that the observation of tumours in laboratory animals could be meaningfully extrapolated to identify potential human carcinogens and, by the use of mathematical models, to provide upper-bound estimates of risk at human doses of regulatory significance. During the same period, the potential significance of mutagenesis in carcinogenesis was becoming accepted by the scientific community. Subsequently, it has become increasingly apparent that an appreciable number of chemicals cause cancer in laboratory animals by processes that do not involve direct interaction with DNA. These developments in our understanding of the biological basis of carcinogenesis in both laboratory animals and humans have benefited risk assessment processes by providing more data on the pharmacokinetics and pharmacodynamics of suspect carcinogenic agents. Consideration of the biological processes involved in the carcinogenesis of specific compounds has led to the concept of mode of action (MOA).

#### 発がん MOA のヒトへの関連性を解析するための

IPCS フレームワーク

Alan R. Boobis, Samuel M. Cohen, Vicki Dellarco, Douglas McGregor, M.E. (Bette) Meek, Carolyn Vickers, Deborah Willcocks, & William Farland

体系化されたフレームワークの利用は、化学物質のリスク評価における調和を促進する上で非常 に重要である。したがって、国際化学物質安全性計画(International Programme on Chemical Safety: IPCS)は、実験的研究で観察された発がん性反応のヒトへの関連性の問題に対処するために、発が ん Mode of Actioin (MOA)フレームワークを更新し、拡張した。第一段階は、MOA を確立する ことが可能かどうかを判断することである。MOA は、Bradford Hill 基準に基づいたエビデンスの 重み付けアプローチを用いて特定された発がんの原因経路に沿った一連の key events で構成され ている。次に、実験動物とヒトの間で key events を定性的に、次に定量的に比較する。最後に、信 頼性、解析的検討及び意義についての明確な報告書が作成される。IPCS 発がん性ヒト関連性フレ ームワークは、データの透明性のある評価、重要なデータギャップの特定及び関連性が排除できな い場合であっても、化合物のさらなるリスク評価において価値のある情報の体系的な提示を可能 にする解析ツールを提供するものである。この価値ある情報には、用量反応曲線の形状に関するデ ータ、閾値の特定及び遺伝的またはライフステージの違いなどに基づいた潜在的に感受性の高い 集団を認知することが含まれる。

過去30年間のがんリスク評価の発展の基礎となったのは、がんの生物学的理解の深まりと発が んにおける key events の特定である。1980 年代半ばまでは、ヒトにおけるがんのハザードとリス クに関する国内及び国際的な評価は、主に発がん性のある物質のげっ歯類を用いた生涯試験に依 存していた。後ろ向きがん研究の基礎となるに十分なヒトにおけるエビデンスが存在する薬剤は ほとんどなく、職場や環境における一般的なばく露に対する現代の規制を考えれば、将来的に発 がん性が検出される薬剤はさらに少ないと予想される。げっ歯類を用いた評価において、実験動 物で観察された腫瘍は、潜在的にヒトに対して発がん性を有する物質を特定するために意味のあ る外挿が可能であり、数学的モデルを用いて規制上重要となるヒトにおけるリスクの上限推定値 を提供することができるという前提があった。同時期に、発がんにおいて変異原性が重要な意義 を有する可能性があるということが科学界に受け入れられつつあった。その後、かなりの数の化 学物質が、DNA との直接的な相互作用を伴わないプロセスによって実験動物にがんを引き起こす ことが次第に明らかになってきた。実験動物とヒトの両方における発がんの生物学的基盤に関す る我々の理解を深めることは、発がん性が疑われる薬剤の薬物動態及び薬理作用に関するより多 くのデータを提供することにより、リスク評価の過程を有益なものとした。特定の化合物の発が んに関与する生物学的プロセスを考察することは、Mode of action(以下、MOA)の概念につなが っている。

<sup>&</sup>lt;sup>1</sup> This article, to which WHO owns copyright, was originally published in 2006 in *Critical Reviews in Toxicology*, Volume 36, pages 781–792. It has been edited for this WHO publication and includes corrigenda.

<sup>&</sup>lt;sup>1</sup> この論文は、WHO が著作権を有するものであり、元々は 2006 年に Critical Reviews in Toxicology, Volume 36, pages 781-792 に掲載されたものです。この論文は WHO の出版物のために編集されたもので、正誤表が含まれています。

A postulated MOA for carcinogenesis is a biologically plausible sequence of key events leading to an observed effect supported by robust experimental observations and mechanistic data. It describes key cytological and biochemical events—that is, those that are both measurable and necessary to the observed carcinogenicity—in a logical framework. MOA contrasts with mechanism of action, which generally involves a sufficient understanding of the molecular basis for an effect and its detailed description so that causation can be established in molecular terms.

In 2001, as part of its efforts to harmonize risk assessment practices, the International Programme on Chemical Safety (IPCS) (WHO/ILO/UNEP) published a framework for assessment of MOA for carcinogenesis in laboratory animals (animal MOA), based on Bradford Hill criteria for causality. The IPCS Human Relevance Framework (HRF) presented in this document updates this MOA Framework and extends it to consider human relevance. It is an analytical tool to provide a means of evaluating systematically the data available on a specific carcinogenic response to a chemical in a transparent manner. While it is envisaged that the framework will be of value to risk assessors both within and outside of regulatory agencies, it will also be a valuable tool to the research community. Among reasons for using the framework are:

- to provide a generic approach to the analysis of data to contribute to harmonization;
- to encourage transparency of the consideration and use of available data and reasons for the conclusions drawn;
- to provide guidance in the presentation of data;
- to identify critical data deficiencies and needs;
- to inform the quantitative assessment of carcinogenic risk to humans.

These and other topics will be discussed in more detail below.

#### THE ROLE OF IPCS IN DEVELOPING THE FRAMEWORK FOR ANALYSING THE RELEVANCE OF A CANCER MOA FOR HUMANS

IPCS has been leading an effort to harmonize approaches to cancer risk assessment as part of its larger project on the Harmonization of Approaches to the Assessment of Risk from Exposure to Chemicals. The first phase of this work resulted in the publication of the IPCS Conceptual Framework for Evaluating a Mode of Action for Chemical Carcinogenesis in experimental animals (Sonich-Mullin et al., 2001). As described in that publication, a major impediment to harmonization identified in the consideration of weight of evidence was the evaluation of MOA in animals. Sonich-Mullin et al. (2001) provided a framework for evaluating MOA of chemical carcinogenesis in animals and recognized the importance of moving on to the next step in the overall characterization of cancer hazard and risk in humans: the assessment of relevance of the MOA of animal carcinogenesis to humans. Adoption of the MOA Framework concept is proceeding through its incorporation in the revised United States Environmental Protection Agency (USEPA) Guidelines for Carcinogen Risk Assessment (USEPA, 1999, 2005), and the framework is now commonly used by other regulatory agencies and international organizations. In the United Kingdom, the framework is being used for the assessment of pesticides and industrial chemicals. The United Kingdom

#### IPCS Framework for Analysing the Relevance of a Cancer Mode of Action for Humans and Case-Studies

推定される発がん MOA とは、試験で観察された影響につながる生物学的に妥当な key events の 一連の流れであり、堅牢な実験観察とメカニズムデータに裏付けられ、重要な細胞学的及び生化 学的事象、すなわち、観察された発がん性に必要かつ測定可能な事象を論理的なフレームワーク で記述している。MOA は作用機序 (mechanism of action)とは対照的であり、作用騎乗では一般的 に、効果の分子的基盤を十分に理解し、その詳細を記述することで、分子的観点から因果関係を 確立することができる。

2001 年に、リスク評価手法の調和の一環として、国際化学物質安全性計画(International Programme on Chemical Safety: IPCS)(WHO/ILO/UNEP)は、因果関係に関する Bradford Hill 基準に基づいた実験動物の発がん MOA(動物 MOA)評価のためのフレームワークを発表した。本文書書で紹介している IPCS ヒト関連性フレームワーク(HRF)は、この MOA フレームワークを更新し、ヒトとの関連性を考慮するために拡張したものである。これは、化学物質の特定の発がん性について利用可能なデータを透明性のある方法で体系的に評価する手段を提供する解析ツールである。フレームワークは、規制当局の内外のリスク評価者にとって価値のあるものであると同時に、研究者にとっても貴重なツールとなることを想定している。フレームワークを利用する理由には、以下のようなものがある。

- データ解析の一般的なアプローチを提供し、調和の推進に貢献する。
- 利用可能なデータの検討と使用及び導き出された結論の論拠の透明性を促進する。
- データの提示におけるガイダンスを提供する。
- 重要なデータの不足と必要な追加データを特定する。
- ヒトに対する発がん性リスクの定量的評価において情報を提供する。

これら及びその他のトピックについて、以下でより詳細に議論する。

# 発がん MOA のとトへの関連性を解析するためのフレームワークを開発する上での IPCS の役割

IPCS は、化学物質へのばく露によるリスク評価のアプローチの調和に関するより大きなプロジ ェクトの一環として、発がんリスク評価への手法を調和させる取り組みを主導してきた。この作 業の第一段階では、実験動物における化学物質の発がん MOA を評価するための「IPCS の概念的 なフレームワーク」の公表につながった(Sonich-Mullin ら, 2001 年)。この出版物に記載されて いるように、エビデンスの重み付けを検討する際にみられる調和への障害は、主に動物 MOA の 評価であった。Sonich-Mullin ら(2001 年)は、動物における化学物質の発がん MOA を評価する ためのフレームワークを提供し、ヒトにおけるがんのハザードとリスクの総合的な判定の次のス テップ、すなわち、動物における発がん MOA のヒトへの関連性の評価に進むことの重要性を認 識した。MOA フレームワークの概念は、米国環境保護庁(USEPA)発がん物質リスク評価ガイド ライン改訂版(USEPA、1999 年、2005 年)に盛り込まれており、MOA フレームワークは現在、 他の規制当局や国際機関でも一般的に用いられている。英国では、このフレームワークが農薬や 工業用化学物質の評価に利用されている。

Committee on Carcinogenicity (2004) has noted the framework's value with regard to both harmonization between agencies and internal consistency in its latest guidelines. The framework has also been adopted and is being used by agencies in Australia and in Canada, in the evaluation of Existing Chemicals under the Canadian Environmental Protection Act. The European Union has incorporated the framework into its technical guidance documents on evaluating new and existing industrial chemicals and biocides, including carcinogenicity. With regard to international organizations, of particular note is the use of the framework by the Joint FAO/WHO Meeting on Pesticide Residues (JMPR), for example, in its evaluation of pyrethrin extract and its incorporation into the resulting monograph.

The step to extend the MOA Framework to include consideration of human relevance has been undertaken by IPCS in cooperation with international partners. It was the subject of an IPCS international workshop convened in Bradford, United Kingdom, from 21 to 23 April 2005. This workshop prepared draft text for an IPCS HRF, including updating the 2001 MOA Framework. The draft was published on the Internet for public comment and sent to a number of WHO Collaborating Centres and IPCS Participating Institutions for peer review. An expert meeting convened in London in December 2005 considered the comments received and finalized the framework. The framework text and the steps leading to its development are discussed in detail in the following sections.

# THE 2001 IPCS CONCEPTUAL MOA FRAMEWORK FOR EVALUATING ANIMAL CARCINOGENESIS

#### **Purpose of the framework**

The IPCS MOA Framework for evaluating carcinogenesis in animals (Sonich-Mullin et al., 2001) remains a fundamental basis for the IPCS Framework for Analysing the Relevance of a Cancer Mode of Action for Humans. The animal MOA Framework provides a generic approach to the principles commonly used when evaluating a postulated MOA for tumour induction in animals by a chemical carcinogen. Thus, the framework is a tool that provides a structured approach to the assessment of the overall weight of the evidence for the postulated MOA. In this context, a supported MOA would have evidence provided by robust experimental observations and mechanistic data to establish a biologically plausible explanation.

The framework is designed to bring transparency to the analysis of a postulated MOA and thereby promote confidence in the conclusions reached through the use of a defined procedure that encourages clear and consistent documentation supporting the analysis and reasoning and that highlights inconsistencies and uncertainties in the available data. The purpose of the framework is to provide a systematic means of considering the weight of the evidence for an MOA in a given situation; it is not designed to give an absolute answer on sufficiency of the information, as this will vary depending on the circumstance. It is not a checklist of criteria, but rather an analytical approach. However, the process can be greatly aided by the presentation of tabular summaries of comparative data on incidence of key events and tumours.

The animal MOA Framework analysis is an important step in the hazard characterization. It is envisaged that the animal MOA Framework will contribute to risk assessments of chemical

#### Harmonization Project Document No. 4

英国発がん性委員会(2004年)は、機関間の調和と最新のガイドラインにおける内部の整合性の 両方の点でフレームワークの価値を指摘している。このフレームワークは、オーストラリアの機 関でも採用され、カナダではカナダ環境保護法の下での既存化学物質の評価に用いられている。 欧州連合(EU)は、新規及び既存の工業用化学物質及び殺生物剤のの評価について、発がん性を 含む技術ガイダンス文書に本フレームワークを組み込んでいる。国際機関では、FAO/WHO合同 残留農薬専門家会議(JMPR)が、例えばピレスリン抽出物の評価やその結果として得られた研究 論文に、このフレームワークを組み入んでいることが。特筆される。

MOA フレームワークを拡張し、ヒトへの関連性の考慮を含めるためのステップは、IPCS が国際的なパートナーと協力して実施されてきた。これは 2005 年 4 月 21 日から 23 日まで英国ブラッドフォードで開催された IPCS の国際ワークショップの議題であった。このワークショップでは、2001 年の MOA フレームワークの更新を含む IPCS HRF の草案が作成された。この草案はパブリックコメントのためにインターネット上で公開され、また、ピアレビューのために多くの WHO 協力機関と PCS 参加機関に送付された。2005 年 12 月にロンドンで開催された専門家会議では、受け取ったコメントが検討され、フレームワークが最終決定された。フレームワークの内容とその発展へとつながるステップについては、以下のセクションで詳述する。

#### 2001年の動物における発がん性評価のための IPCS 概念的 MOA フレームワーク

#### フレームワークの目的

動物における発がん性評価のための IPCS MOA フレームワーク (Sonich-Mullin ら, 2001 年) は 今もなお発がん MOA のヒトとの関連性を解析するための IPCS フレームワークの基本原理とな っている。動物 MOA フレームワークは、発がん性化学物質による動物の腫瘍誘発に対して、想 定される MOA を評価する際に一般的に適用される原則への汎用的アプローチを提供するもので ある。したがって、このフレームワークは想定される MOA に対する総合的なエビデンスの重み 付けの評価に際して体系的なアプローチを提供するツールである。すなわち、この文脈では支持 された MOA は、生物学的に妥当な説明を確立するためにしっかりとした実験的観察とメカニズ ムデータのエビデンスを持つことになる。

このフレームワークは、推定される MOA の解析に透明性をもたらし、その結果、明確にされ た手法(解析と推論を裏付ける明確で一貫性のある文書化を促し、利用可能なデータの矛盾と不 確実性を明らかにする手法)を用いることにより到達した結論の信頼性が増すように設計されて いる。フレームワークの目的は、特定の状況における MOA のエビデンスの重み付けを検討する 体系的な手段を提供することであり、情報が十分か否かに関して絶対的な回答を与えるようには 設計されていない。なぜなら情報は状況によって異なるためである。このフレームワークは基準 のチェックリストではなく、むしろ解析的なアプローチである。しかし、key events 及び腫瘍の発 生に関する比較データの表形式の要約はこのプロセスの大きな助けとなる。

動物 MOA フレームワーク解析は、ハザードの特性評価の重要なステップである。動物 MOA フレームワークは、すべての分野(医薬品、工業用化学物質、農薬、食品添加物など)にわたる発がん化学物質のリスク評価に貢献することが想定されている。

carcinogens across all sectors (drugs, industrial chemicals, pesticides, food additives, etc.). In the resulting risk assessment documentation, the framework analysis would be appropriately positioned within the hazard characterization section. In the absence of adequate epidemiological data, it may be regarded as an essential component in any discussion of human relevance, dose–response relationships, and risk characterization. It is also envisaged that the framework will be useful to both regulators and researchers in identifying research needs based on clear delineation of data gaps and inconsistencies.

MOA analysis can be used to establish either that a compound has an MOA that has been described previously or that it has a novel MOA. Thus, the output of an MOA analysis may serve to support the evaluation of a specific compound or contribute to the generation of a novel MOA. In the former, chemical-specific data play a vital role in the concordance analysis for human relevance. In the latter, it will be important to identify which events are key to the biological processes that represent the MOA.

Thus, an MOA comprising the same set of key events may apply to many different compounds. The evidence necessary to establish that a specific MOA is responsible for a given carcinogenic response will be substantial the first time such an MOA is proposed. As subsequent compounds are found to share this MOA, the "barrier" to acceptance will be lower, although it will always be necessary to establish rigorously that the key events comprising the MOA occur and that they fulfil the criteria described below. It will also be important to exclude other possible MOAs.

Scientific peer participation is a prerequisite for the development and acceptance of a novel postulated MOA. Peer participation includes both peer involvement in the development of an MOA and peer review by scientists who are independent of the process of development of the MOA. Publication in the scientific literature and presentation and discussion at scientific meetings and workshops constitute peer involvement that contributes to acceptance of an MOA by the scientific community.

While acceptance does not necessarily mean unanimity, most of the scientists reviewing an MOA analysis should agree that the relevant scientific information has been identified and appropriately analysed, that "key events" have been identified and are supported by the information presented, that their relationship to carcinogenesis has been clearly established in the hypothesized MOA, and that alternative MOAs have been considered and rejected.

As knowledge advances, the characterization of an MOA will change. Additional key events may be identified, and others may be refined or even dropped. Nevertheless, significant changes to the key events also need some general acceptance, through peer review, such as described above.

#### **Update of framework guidelines**

In development of the IPCS HRF, the 2001 animal MOA Framework text has been updated, and this revised version is presented here.

#### IPCS Framework for Analysing the Relevance of a Cancer Mode of Action for Humans and Case-Studies

結果として得られるリスク評価文書では、フレームワーク解析はハザードの特性評価のセクショ ン内に適切に配置されるであろう。適切な疫学データがない場合には、ヒトとの関連性、用量反 応関係、リスクの特性を議論する上で、フレームワーク解析は不可欠な要素とみなされるかもし れない。また、このフレームワークは、データギャップや矛盾の明確な定義に基づいて研究の必 要性を特定する上で規制当局と研究者の双方にとって有用であると考えられる。

MOA 解析は、化合物が以前に記述されている MOA を有すること、または新規の MOA を有す ることを確認するために用いることができる。したがって、MOA 解析の結果は、特定の化合物の 評価に役立つこともあれば、新規の MOA の確立に貢献することもある。前者において、化学物 質に特有のデータが、ヒトへの関連性を考慮した一致解析において重要な役割を果たす。後者に おいては、どのような事象が MOA を表す生物学的プロセスの鍵となるのかを特定することが重 要になる。

このように、同様の一連の key events で構成された MOA は、多くの異なる化合物にも適用でき る可能性がある。ある MOA が特定の発がん作用の原因であることを立証するために必要なエビ デンスは、そのような MOA が初めて提示される場合には重要である。後発の化合物がこの MOA を共有することが発見される場合に、受け入れに対する「障壁」は低くなるが、MOA を構成する key events が発生すること、また、以下に説明する基準を満たしていることを厳密に立証する必要 がある。また、他の可能性のある MOA を除外することも重要である。

科学的な専門家の関与は、新規に想定される MOA の確立と承認のための必要条件である。「専 門家の関与」には、MOA の確立への専門家の関与と、MOA の研究プロセスから独立した科学者 によるピアレビューの両方が含まれる。科学雑誌への発表、科学会議やワークショップでの発表 や議論も、科学界が MOA を受け入れるための「専門家の関与」を意味する。

容認は必ずしも科学者全員が合意したことを意味するわけではないが、容認されたということは、MOA をレビューした科学者の大部分が、提示された MOA に関して関連する科学的情報が特定され適切に解析されていること、「key events」が特定され提示された情報によって支持されていること、発がんとの関係が仮説の MOA において明確に説明されていること及びその代替 MOA が検討され、それらが除外されていることに合意したということである。

知識の向上につれて MOA は変化するだろう。追加の key events が特定され、他の事象は見直さ れるか、あるいは取り除かれるかもしれない。しかしながら、key events に関する大きな変更は、 上記のようなピアレビューを通してある程度一般に認められることも必要である。

#### フレームワークガイドラインの更新

IPCS HRF の発展において、2001 年の動物 MOA フレームワークの内容が更新されたので、その 改訂版を以下に提示する。

#### Introduction to framework analysis

This section describes the cancer end-point or end-points that have been observed and identifies which of these are addressed in the analysis. Prior to embarking on a framework analysis, there needs to be careful evaluation of the weight of evidence for a carcinogenic response in experimental animals. The nature of the framework is such that only one MOA is analysed at a time; hence, for example, different tumour types associated with chemical treatment, even if recorded in the same animals, will require separate framework analyses to discern each tumour's MOA. However, in considering the pathogenesis of a single type of tumour, it should be recognized that it is possible that a chemical could induce that tumour type by more than one MOA. Hence, it might be necessary to undertake an analysis of more than one MOA for the same tumour type for a single chemical. Consistent with species- and tissue-specific variation in metabolic activation and detoxication, there is often only poor site concordance for genotoxic carcinogens. This will need to be kept in mind when comparing animal and human data. In contrast, consistent with the observation that most carcinogens acting by a non-genotoxic MOA perturb physiological processes that tend to be site specific, site concordance is reasonably assumed, at least as an initial premise in the HRF.

#### 1. Postulated mode of action (theory of the case)

This section comprises a brief description of the sequence of events on the path to cancer for the postulated MOA of the test substance. This explanation of the sequence of events leads into the next section, which identifies the events considered "key" (i.e. necessary and measurable), given the database available for the analysis.

#### 2. Key events

This section briefly identifies and describes the "key events"—measurable events that are critical to the induction of tumours as hypothesized in the postulated MOA. To support an association, a body of experiments needs to define and measure an event consistently. Pertinent observations include, for example, tumour response and key events in the same cell type, sites of action logically related to event(s), increased cell growth, specific biochemical events, changes in organ weight and/or histology, proliferation, perturbations in hormones or other signalling systems, receptor–ligand interactions, effects on DNA or chromosomes, and impact on cell cycle. For example, key events for tumours hypothesized to be associated with prolonged regenerative proliferation might be cytotoxicity as measured histopathologically and an increase in labelling index. As another example, key events for induction of urinary bladder tumours hypothesized to be due to formation of urinary solids composed primarily of calcium phosphate might include elevated urinary free calcium, phosphate, and pH and formation of urinary solids, followed by irritation and regenerative hyperplasia of the uro-thelium.

#### 3. Concordance of dose-response relationships

This section should characterize the dose–effect/response relationships for each of the key events and for the tumour response and discuss their interrelationships, in the context of the Bradford Hill criteria. Ideally, one should be able to correlate the dose dependency of the increases in incidence of a key event with increases in incidence or severity (e.g. lesion progression) of other key events occurring later in the process, and with the ultimate tumour incidence. Comparative tabular presentation of incidence of key events and tumours is often helpful in examining dose–response. In the case of complex data sets, this is almost essential.

#### 序文

このセクションでは、観察された発がんエンドポイントまたはその他エンドポイントについて 記述し、これらのうちのどれが解析で扱われているかを特定する。フレームワーク解析に着手す る前に、実験動物における発がん性反応のエビデンスの重み付けを慎重に評価する必要がある。 フレームワークの性質上、一度に1つの MOA のみが解析される。したがって、例えば、化学物 質の投与に関連した異なる種類の腫瘍は、かりに同じ動物で記録されていても、各腫瘍の MOA を 識別するために別々のフレームワーク解析が必要となる。しかしながら、あるひとつの腫瘍の病 態を検討する際には、化学物質が複数の MOA によってそのタイプの腫瘍を誘発する可能性があ ることを認識しておくべきである。したがって、ある化学物質におけるひとつの腫瘍について複 数の MOA の解析を行う必要があるかもしれない。遺伝毒性発がん物質の場合、代謝活性化と解 毒における種や組織特異的な違いと同様に、発がん部位が異なることも多い。動物とヒトのデー タを比較する際にはこのことについて留意する必要がある。対照的に、非遺伝毒性 MOA に則っ て作用するほとんどの発がん物質は、特異的な傾向のある生理学的プロセスに影響を及ぼすとい う観察結果から、少なくとも HRF の初期の前提として、部位の一致が合理的に想定されている。

#### 1. 推定される MOA (事例における仮説)

このセクションでは、被験物質において推定される MOA について、腫瘍になるまでの一連の 事象を簡単に説明している。この一連の事象の説明は、次のセクションにつながり、解析に利用 可能なデータベースから、「鍵」と考えられる事象(すなわち、必要かつ測定可能な事象)を特定 する。

#### 2. Key events

このセクションでは、「key events」一推定される MOA において仮定された腫瘍の誘発に極めて 重要な測定可能な事象について簡潔に特定し、説明する。関連せを裏付けるためには、一連の実 験で事象を定義し、それを一貫して測定する必要がある。関連する観察項目には、例えば、同じ 種類の細胞における発がん性と key events、事象に論理的に関連する作用部位、細胞増殖の増加、 特定の生化学的事象、臓器重量や組織学的変化、増殖、ホルモンや他のシグナル伝達系の変動、 受容体-リガンド相互作用、DNA や染色体への影響、細胞周期への影響などが含まれる。例えば、 再生性増殖の延長と関連していると推定される腫瘍の発生における key events は、病理組織学的 検索における細胞毒性の検出と標識指標の上昇であるかもしれない。別の例として、リン酸カル シウムを主成分とする尿固形物の形成が原因であると推定される膀胱腫瘍の誘発の key events に は、尿中の遊離カルシウム、リン酸塩、pH の上昇と尿固形物の形成、それに続く尿路上皮への刺 激及び再生性過形成が含まれる。

#### 3. 用量反応関係の一致性

このセクションでは Bradford Hill 基準の観点から、それぞれの key events と発がんの用量-効果/ 反応関係を特徴づけ、それらの相互関係について議論するべきだろう。理想的には、key events の 発生率の増加の用量依存性と、その後に発生する他の key events の発生率または重症度(病変の 進行など)の増加及び最終的な腫瘍の発生率とを相関させることができるようにすべきである。 Key events と腫瘍の発生率を表形式で比較表示することは、しばしば用量反応性を検討する上で しばしば有用である。複雑なデータセットの場合、これはほぼ必須である。 It is important to consider whether there are fundamental differences in the biological response (i.e. dose transitions) at different parts of the dose–response curve for tumour formation (Slikker et al., 2004). If so, key events relevant to the different parts of the dose–response curve will need to be defined and used in the framework analysis.

#### 4. Temporal association

This section should characterize the temporal relationships for each of the key events and for the tumour response. The temporal sequence of key events leading to the tumour response should be determined. Key events should be apparent before tumour appearance and should be consistent temporally with each other; this is essential in deciding whether the data support the postulated MOA. Observations of key events at the same time as the tumours (e.g. at the end of a bioassay) do not contribute to considerations of temporal association, but can contribute to analysis in the next section. Most often, complete data sets to address the criterion of temporality are not available.

### 5. Strength, consistency, and specificity of association of tumour response with key events

This section should discuss the weight of evidence linking the key events, precursor lesions, and the tumour response. Stop/recovery studies showing absence or reduction of subsequent events or tumour when a key event is blocked or diminished are particularly important tests of the association. Consistent observations in a number of such studies with differing experimental designs increase that support, since different designs may reduce unknown biases or confounding. Consistency, which addresses repeatability of key events in the postulated MOA for cancer in different studies, is distinguished from coherence, however, which addresses the relationship of the postulated MOA with observations in the broader database (see point 6). Pertinent observations include tumour response and key events in the same cell type, sites of action logically related to event(s), and results from multistage studies and from stop/recovery studies.

#### 6. Biological plausibility and coherence

One should consider whether the MOA is consistent with what is known about carcinogenesis in general (biological plausibility) and also in relation to what is known for the substance specifically (coherence). For the postulated MOA and the events that are part of it to be biologically plausible, they need to be consistent with current understanding of the biology of cancer. However, the extent to which biological plausibility can be used as a criterion against which weight of evidence is assessed may be limited due to gaps in our knowledge. Coherence, which addresses the relationship of the postulated MOA with observations in the broader database-for example, association of MOA for tumours with that for other end-points—needs to be distinguished from consistency (addressed in point 5), which addresses repeatability of key events in the postulated MOA for cancer in different studies. For coherence, likeness of the case to that for structural analogues may be informative (i.e. structure-activity analysis). Information from other compounds that share the postulated MOA may be of value, such as sex, species, and strain differences in sensitivity and their relationship to key events. Additionally, this section should consider whether the database on the agent is internally consistent in supporting the purported MOA, including that for relevant non-cancer toxicities. Some MOAs can be anticipated to evoke effects other than cancer, such as reproductive effects of certain hormonal disturbances that are carcinogenic.

腫瘍形成に対する用量反応曲線の異なる部分において、生物学的反応(すなわち線量推移)に基本的な相違があるか否かを検討することが重要である(Slikker ら, 2004 年)。もしそうであれば、 用量反応曲線の異なる部分に関連する key events を明らかにし、フレームワーク解析に用いる必要がある。

#### 4. 時間的関連性

このセクションでは、それぞれの key events と腫瘍反応の時間的関係の特徴について述べなけ ればならない。腫瘍反応に至る key events を時系列的に明らかにすべきである。key events は腫瘍 の発現前に明らかにしなければならず、互いに時間的な整合性が取れていなければならない。す なわち、時間的関連性についてはデータが想定される MOA を支持しているかどうかを判断する 上で不可欠である。腫瘍と同時に key events が観察された場合(例えば、バイオアッセイの終了時 など) は、時間的関連性の検討には役立たないが、次のセクションに述べる解析に役立てること ができる。多くの場合、時間的関連性についての基準を満たす完全なデータセットは入手できな い。

#### 5. 腫瘍反応とkey events との関連性の強さ、一貫性、特異性

このセクションでは、key events、前がん病変及び腫瘍反応を結び付けるエビデンスの重み付け について議論しなければならない。Key events を遮断または低減した場合に、その後の事象または 腫瘍が発生しない、または減少することを示す中止/回復試験は、関連性を検証する上で特に重要 である。デザインが異なることによって未知のバイアスや交絡因子を減少させると考えられるた め、異なる実験デザインの研究において一貫した結果が観察されることは、key events と腫瘍の関 連性をより強く裏付けることになる。しかし、さまざまな研究で推定される MOA の key events の 再現性で示される一貫性 (consistency) は、より広範なデータベースでの結果と推定 MOA の相関 性で示される整合性 (coherence) とは区別される (6 参照)。関連する観察項目には、同じ種類の 細胞における腫瘍反応と key events、事象に論理的に関連する作用部位並びに多段階試験及び中止 /回復試験の結果が含まれる。

#### 6. 生物学的妥当性及び整合性

その MOA が、一般的にがんの発生について一般的に知られていることと一致している(生物 学的に妥当である)かどうか、また、その物質について知られていることと関連している(理論 的な整合性がある)かどうかを検討しなければならない。推定される MOA とその一部である事 象が生物学的に妥当であるとするためには、それらが現在のがんについての生物学的理解と一致 している必要がある。しかしながら、我々の知識には限りがあるために生物学的妥当性について エビデンスの重み付けを評価する際の基準として用いることができる範囲は限られているであろ う。推定される MOA とより広範なデータベースの観測値との関係 一例えば、発がん MOA と他 のエンドポイントの MOA との関連性一を扱う「整合性」は、異なる研究における推定される発 がん MOA における key events の再現性を扱う「一貫性」(ポイント5参照)とは区別される必要 がある。理論的な整合性については、構造的アナログにおける事例との類似性が参考になるかも しれない(すなわち、構造-活性解析)。推定される MOA を共有する他の化合物からの情報、たと えば、感度における性差、種差及び系統差や key events との関係に関するような情報は重要とな るだろう。さらに、このセクションでは、その薬剤に関するデータベースが内部で一貫して関連 している発がん以外の毒性を含めた MOA を支持しているかどうかを検討しなければならない。 MOA の中には、発がんにつながるホルモン障害による生殖への影響のような、発がん以外の影響 を引き起こすことが予想されるものがある。

#### 7. Other modes of action

This section discusses alternative MOAs that logically present themselves in the case. If alternative MOAs are supported, they need their own framework analysis. These should be distinguished from additional components of a single MOA that likely contribute to the observed effect, since these would be addressed in the analysis of the principal MOA.

#### 8. Uncertainties, inconsistencies, and data gaps

Uncertainties should include those related to both the biology of tumour development and those for the database on the compound of interest. Inconsistencies should be flagged and data gaps identified. For the identified data gaps, there should be some indication of whether they are critical as support for the postulated MOA.

#### 9. Assessment of postulated mode of action

This section should include a clear statement of the outcome with an indication of the level of confidence in the postulated MOA—for example, high, moderate, or low. If a novel MOA is being proposed, this should be clearly indicated. However, if the MOA is the same as that proposed for other compounds, the extent to which the key events fit this MOA needs to be stated explicitly. Any major differences should be noted, and their implications for the MOA should be discussed.

#### ADDRESSING THE ISSUE OF HUMAN RELEVANCE

In 2000, an IPCS Harmonization Project Cancer Planning Work Group convened in Carshalton, United Kingdom (IPCS, 2000). (This initial IPCS working group differed in membership from the subsequent IPCS working group convened to work on the human relevance project.) Among the recommendations of that meeting was the suggestion that IPCS and the International Life Sciences Institute (ILSI) move forward together and in parallel on the development of the extension of the IPCS MOA Framework towards addressing human relevance. It was recognized that ILSI could provide much help in technical workshops. In June 2001, the ILSI Risk Science Institute (RSI) with support from the USEPA and Health Canada formed a working group to examine key issues in the use of MOA information to determine the relevance of animal tumours. These efforts have resulted in several published reports that are described below. An IPCS Cancer Working Group, convened on 3–5 March 2004 in Arlington, Virginia, USA, agreed that these reports should form the starting point for further exploration of the issue of human relevance of animal tumours by IPCS with the goal of developing a unified IPCS HRF for use of MOA information in risk assessment for regulatory and other purposes (IPCS, 2004).

To address the issue of the human relevance of the MOAs determined in animals, ILSI/RSI charged its working group with expanding the IPCS MOA Framework to include evaluation of the human relevance of a cancer MOA determined in animals. The details of the process, the case-studies, and the framework were published as a series of papers in the November 2003 issue of *Critical Reviews in Toxicology* (Cohen et al., 2003; Meek et al., 2003). These articles describe the ILSI/RSI HRF and provide guidance for its application. In addition, references to specific examples on which the framework is based are included. Several iterations of case-studies of chemicals with generally well known MOAs were used to

#### 7. その他のMOA

このセクションでは、事例の中で論理的に提示された代替 MOA について議論する。代替 MOA が支持されている場合は、それ自体のフレームワーク解析が必要である。これら代替 MOA は観察された影響に寄与していると考えられる推定される MOA の追加的な構成要素とは区別し、異なる独立した MOA として解析しなければならない。さもなくば、代替 MOA ではなく、元々の解析の対象であった MOA に関する解析になってしまう。

#### 8. 不確実性、矛盾、データギャップ

不確実性には、腫瘍発生の生物学的知見に関連するものと、対象の化合物のデータベースに関 連するものの両方を含まなければならない。矛盾点にはフラグを立て、データギャップについて 特定しなければならない。特定されたデータギャップについては、推定される MOA の裏付けと して重要か否かを示すべきである。

#### 9. 推定される MOA の評価

このセクションには、推定される MOA の信頼度を示す指標と共に(例えば、高、中、低など) 結果に関する明確な記述を含まなければならない。新規の MOA が推定されている場合は、新規 であることを明確に示すべきである。しかし、MOA が他の化合物について提示されているものと 同じである場合には、key events がこの MOA にどの程度合致しているかを明示する必要がある。 大きな違いがあれば、それを明記し、MOA に対するその違いの意味合いについて議論すべきであ る。

#### ヒトへの関連性の問題

2000 年に、英国のカーシャルトンで IPCS ハーモナイゼーションプロジェクトがん計画ワーキ ンググループが招集された (IPCS、2000 年) (この最初の IPCS ワーキンググループは、ヒト関連 性プロジェクトの作業のために招集されたその後の IPCS ワーキンググループとはメンバーが異 なっていた)。この会議において、ヒトへの関連性への対応に向けて IPCS MOA フレームワークの 拡張を IPCS と国際生命科学研究機構 (ILSI) が協力して並行して進めていくことが提案された。 ILSI は技術ワークショップにおいて多くの支援を提供できることが認識された。2001 年 6 月、 ILSI リスクサイエンス研究所 (RSI) は、USEPA とカナダ保健省の支援を受けて、動物における 腫瘍とヒトとの関連性を判断するための MOA 情報の使用における重要な問題を検討するための ワーキンググループを結成した。これらの努力の結果、以下に記載されているいくつかの報告書 が公表された。2004 年 3 月 3 日から 5 日に米国バージニア州アーリントンで開催された IPCS が んワーキンググループは、これらの報告書を出発点として、規制目的やその他の目的で MOA 情 報をリスク評価に使用するための統一的な IPCS HRF を作成することを目標に、動物における腫 瘍のヒトへの関連性の問題を IPCS がさらに調査することに合意した (IPCS、2004 年)。

動物で決定された MOA のヒトへの関連性の問題に対処するために、ILSI/RSI は同ワーキング グループに、動物で決定された発がん MOA のヒトへの関連性の評価を含めるために IPCS MOA フレームワークを拡張することを求めた。このプロセス、事例研究及びフレームワークの詳細は、 Critical Reviews in Toxicology 誌の 2003 年 11 月号に一連の論文として発表された(Cohen ら, 2003 年)。これらの論文では ILSI/RSI HRF を説明し、その適用のための指針を提供している。さらに、 フレームワークが基づいた具体的な例への参照も含まれている。統合フレームワークを開発する ために、一般的によく知られている MOA を有する化学物質を複数回にわたって繰り返し検討し た事例研究が使用された。その意図は、動物での MOA と各 key event についてヒトへの関連性を

develop the integrated framework. The intent was to provide guidance for a disciplined, transparent process evaluating the MOA in animals and each key event with respect to human relevance.

The ILSI/RSI HRF is based on three fundamental questions:

- 1. Is the weight of evidence sufficient to establish the mode of action (MOA) in animals?
- 2. Are key events in the animal MOA plausible in humans?
- 3. Taking into account kinetic and dynamic factors, are key events in the animal MOA plausible in humans?

Questions 2 and 3 involve qualitative and quantitative considerations, respectively, in a concordance analysis of human information in relation to the animal MOA and its key events.

These are followed by an explicit description of confidence in the evaluation, identification of specific data gaps, and the implications for risk assessment. It was emphasized by ILSI/RSI that use of this framework would form part of the hazard characterization step of the overall risk assessment process.

# DEVELOPMENT OF AN IPCS HRF GUIDANCE DOCUMENT BASED ON THE IPCS MOA FRAMEWORK AND THE ILSI/RSI HRF

The 2004 IPCS Cancer Working Group discussed the type of document that would be produced as a result of its task to extend the IPCS MOA Framework to address human relevance. It was recognized that one integrated guidance document that worked as a whole would be needed to facilitate uptake and use by regulatory and other risk assessment bodies. The guidance could be supplemented by publication of the other materials generated through the process (e.g. issue papers and case-studies).

There was general agreement among working group members that the questions identified as the critical components of the ILSI/RSI HRF were important and in general appropriate for addressing the human relevance of an MOA determined in animals. However, several issues were identified that could benefit from additional clarification, development, or expansion.

These refinements of the ILSI/RSI HRF were developed through discussions of the IPCS Cancer Working Group and at a workshop convened for this purpose in Bradford, United Kingdom, on 21–23 April 2005 (IPCS, 2005). The resulting IPCS HRF is presented as an approach to answering a series of three questions, leading to a documented, logical conclusion regarding the human relevance of the MOA underlying animal tumours. The application of the guidance results in a narrative with four sections that may be incorporated into the hazard characterization of a risk assessment. The sections are as follows (see Figure 1):

- 1. Is the weight of evidence sufficient to establish a mode of action (MOA) in animals?
- 2. Can human relevance of the MOA be reasonably excluded on the basis of fundamental, qualitative differences in key events between experimental animals and humans?

#### IPCS Framework for Analysing the Relevance of a Cancer Mode of Action for Humans and Case-Studies

評価する規律ある透明なプロセスの指針を提供することであった。

ILSI/RSI HRF は3つの基本的な問いかけに基づいている:

- 1. 動物における Mode of action (動物 MOA) を確立するのにエビデンスの重み付けは十分か?
- 2. 動物の MOA に含まれる key events はヒトにおいて妥当であるか?
- 3. 動態的、薬力学的要因を考慮した上でも、動物の MOA における key events はヒトにおいて妥 当か?

問2と3に関して、動物の MOA とその key events に関連したヒトでの情報の一致解析において、それぞれ定性的な検討と定量的な検討が必要となる。

これらに続いて、ILSI/RSI HRF は評価の信頼性、特異的なデータギャップの特定、それらのリ スク評価の意味合いを明確に記述している。ILSI/RSI では、このフレームワークの利用が全体的 なリスク評価プロセスのハザードの特性評価ステップの一部を形成することを強調した。

#### IPCS MOA フレームワークと ILSI/RSI HRF に基づく IPCS HRF ガイダンス文書の開発

2004 年の IPCS がんワーキンググループでは、ヒトへの関連性に対処するために IPCS MOA フレームワークを拡張する作業の報告書として作成される文書のタイプについて議論された。規制 当局や他のリスク評価機関による採用と利用を促進するためには、全体を一つに統合されたガイ ダンス文書が必要であると認識された。ガイダンスは、発行論文や事例研究といったプロセスを 経て作成された他の公表資料を追加することができる。

ワーキンググループのメンバー間では、ILSI/RSI HRF の重要な構成要素として特定された問い かけは重要であり、動物で決定された MOA のヒトへの関連性に対処するのに適切であるという 点で概ね合意されていた。しかし、フレームワークの補足説明、進展、または拡大が有効と思わ れるいくつかの課題が明らかとなった。

ILSI/RSI HRF のこれらの改良は IPCS がんワーキンググループの議論と、2005 年4月21日から 23 日に英国ブラッドフォードで開催されたワークショップでの議論を経て進められた(IPCS、 2005 年)。結果として得られた IPCS HRF は、動物の腫瘍における MOA のヒトへの関連性に関す る文書化された論理的な結論へとつながる一連の3つの問いかけに答えるためのアプローチとし て提示されている。このガイダンスを適用すると、リスク評価のハザードの特性評価に組み入れ ることができる4つのセクションからなるストーリーができあがる。これらのセクションは以下 の通りである(図1を参照)。

- 1. 動物における Mode of action (動物 MOA) を立証するためにエビデンスの重み付けは十分か?
- 2. 実験動物とヒトとの間の key events の根本的、質的な違いに基づいて、MOA のヒトへの関連性 を合理的に排除できるか?
- 3. 実験動物とヒトとの間の動態的または薬力学的要因のいずれかの量的な違いに基づいて、MOA のヒトへの関連性を合理的に排除できるか?

17

4. 結論:信頼性、解析的検討及び帰結の記述。

- 3. Can human relevance of the MOA be reasonably excluded on the basis of quantitative differences in either kinetic or dynamic factors between experimental animals and humans?
- 4. Conclusion: Statement of confidence, analysis, and implications.

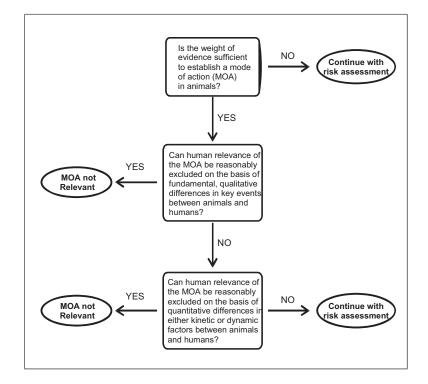

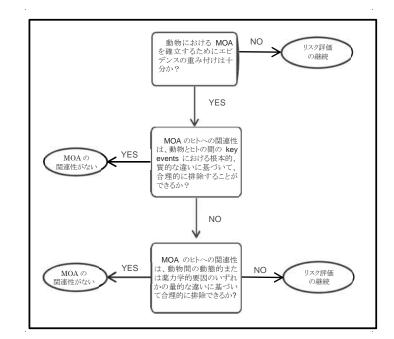

Figure 1. IPCS general scheme illustrating the main steps in evaluating the human relevance of an animal MOA for tumour formation. The questions have been designed to enable an unequivocal answer *yes* or *no*, but recognizing the need for judgement regarding sufficiency of weight of evidence. Answers leading to the left side of the diagram indicate that the weight of evidence is such that the MOA is not considered relevant to humans. Answers leading to the right side of the diagram indicate either that the weight of evidence is such that the MOA is not considered relevant to humans. Answers leading to the right side of the diagram indicate either that the weight of evidence is such that the MOA is likely to be relevant to humans or that it is not possible to reach a conclusion regarding likely relevance to humans, owing to uncertainties in the available information. In these cases, the assessment would proceed to risk characterization. It should be noted that only at this stage would human exposure be included in the evaluation.

In applying this framework for a given chemical, tumours of each animal target organ observed are evaluated independently, with the assumption that different MOAs are possible in different organs, although based on this analysis, MOAs in different tissues may be similar. Similarly, an evaluation of the likelihood of congruence between target organ(s) in different species and in humans needs to be made, based on the MOA analysis.

#### 図 1. IPCS の一般的なスキーム:腫瘍形成に対する動物 MOA のヒトへの関連性を評価す る際の主なステップを示す

質問は、Yes か No かを明確に答えられるように設計されているが、エビデンスの重み付けが十分 であるかどうかを判断する必要がある。図の左側に示された回答は、エビデンスに十分な重みがあ り MOA がヒトに関連するとは考えられないことを示している。図の右側の回答は、MOA がヒト に関連する可能性が高いと考えられるという十分に重みのあるエビデンスの存在を示しているか、 利用可能な情報に不確実性があるため、ヒトへの関連性の可能性についての結論を出すことができ ないことを示している。このような場合、評価はリスクの判定に進むことになる。この段階でのみ、 ヒトへのばく露評価が含まれることに留意すべきである。

このフレームワークをある化学物質に適用する場合、観察された各動物の標的臓器の腫瘍は、 異なる臓器では異なる MOA が存在しうるという仮定の下、独立して評価される。しかし、この 解析手法に基づいたとしても、異なる組織での MOA が類似している可能性はある。同様に、異 なる種とヒトにおいて、標的臓器における MOA が一致する可能性についての評価も MOA 解析 に基づいて行う必要がある。

# Is the weight of evidence sufficient to establish a mode of action (MOA) in animals?

Answering this first question in the IPCS HRF requires application of the (updated) IPCS MOA Framework described previously in this document. The steps in the MOA Framework, which are based on the Bradford Hill criteria for causality, are:

- 1. postulated MOA;
- 2. key events; associated critical parameters;
- 3. dose-response relationships;
- 4. temporal association;
- 5. strength, consistency, and specificity of association of key events and tumour response;
- 6. biological plausibility and coherence;
- 7. possible alternative MOAs;
- 8. uncertainties, inconsistencies, and data gaps;
- 9. conclusion about the MOA.

This process incorporates an evaluation of the weight of evidence for possible alternative MOAs at a given site and an evaluation of the overall strength of evidence supporting the MOA under consideration. Ultimately, a decision concerning the weight of evidence supporting the MOA and the level of confidence in that decision must be made. The process also identifies critically important data gaps that, when filled, would increase confidence in the proposed MOA. It is also necessary to establish whether the postulated MOA has already been described for other chemicals, in which case human relevance will already have been evaluated, or whether the proposed MOA is novel, in which case human relevance needs to be assessed de novo.

For a given chemical, the primary sources of information for evaluating an MOA are likely to be data generated for that specific chemical in the animal model in which tumours were produced. Obviously, data from other sources can and should also be used, as appropriate, along with data on chemicals with similar chemical structures, the same or similar MOAs, or both. If the MOA for a chemical is novel, considerably more data will be required to support the conclusion that it is related to the carcinogenic process of the tumours induced by that chemical than for subsequent examples of chemicals acting by the same MOA. The ILSI/RSI working group and the IPCS Bradford workshop did not address the issue of how many data are sufficient to support a specific MOA for a given chemical per se, except by way of example within the case-studies and recognition that acceptance of a novel MOA requires scientific consensus (described above). Consideration at this stage of the MOA analysis of potential variations between animals and humans also facilitates addressing subsequent steps in the framework.

# Can human relevance of the MOA be reasonably excluded on the basis of fundamental, qualitative differences in key events between experimental animals and humans?

The wording of this question was changed from that in the ILSI/RSI HRF, following discussion at the IPCS workshop on the implications of a *yes* or a *no* answer to the original question. In answering the original question, only an unequivocal *no* would be sufficient to

19

#### IPCS Framework for Analysing the Relevance of a Cancer Mode of Action for Humans and Case-Studies

# 動物における Mode of action (動物 MOA)を確立するのにエビデンスの重み付けは十分 か

IPCS HRF のこの最初の問いかけに答えるためには、上述の(更新された) IPCS MOA フレーム ワークを適用する必要がある。因果関係を説明するための Bradford Hill 基準に基づいた MOA フ レームワークのステップは、次のとおりである:

- 1. 推定される MOA
- 2. Key events; 関連する重要なパラメータ
- 3. 用量反応関係
- 4. 時間的関連性
- 5. Key events と腫瘍反応との関連の強さ、一貫性、特異性
- 6. 生物学的妥当性と整合性
- 7. 可能性のある代替 MOA
- 8. 不確実なこと、矛盾すること及びデータギャップ
- 9. MOA に関する結論

このプロセスには、状況に応じた考え得る代替 MOA のエビデンスの重み付けの評価と、検討 中の MOA を支持するエビデンスの全体的な強度の評価が組み込まれている。最終的には、MOA を支持するエビデンスの重み付けと、それに対する信頼度について決定しなければならない。ま た、このプロセスは、ギャップを満たすことで推定される MOA の信頼性を高めるであろう決定 的に重要なデータギャップを特定する。また、推定される MOA が他の化学物質において既に記 述された MOA であり、ヒトへの関連性について既に評価されているかどうか、または、新規の MOA であり、ヒトへの関連性について新たに評価する必要があるかどうかを確認することも必要 である。

ある化学物質について、MOA を評価するための主な情報源は、腫瘍が発生した動物モデルにお けるデータである可能性が高い。当然、類似の化学構造を持つ化学物質に関するデータや、同じ または類似の MOA に関するデータ、もしくはその両方のデータといった他の情報源からのデー タも必要に応じて利用することができるし、利用すべきである。ある化学物質の MOA が新規で ある場合、その化学物質が誘発された腫瘍の発がんプロセスに関連しているという結論を裏付け るためには、同じ MOA で作用する後続の化学物質よりもかなり多くのデータが必要である。 ILSI/RSI ワーキンググループと IPCS ブラッドフォードワークショップでは、対象の化学物質の MOA を支持するのに十分なデータの数はどのくらいかという問題に関して、事例研究の中で例を 示し、新しい MOA を受け入れるには科学的コンセンサスが必要であるとの認識(上述)を示し てはいるが、それら以外についての方針等は何ら表明していない。この段階における動物とヒト との間の潜在的な違いについての MOA 解析の検討は、フレームワークにおける次のステップの 対応を容易にする。

# 実験動物ととトとの間の key events の根本的、質的な違いに基づいて、MOA のとトとの関連性を合理的に排除することができるか

この質問の文言は、IPCS ワークショップにおける質問に対する回答の意味合いについての議論 を受けて、ILSI/RSI HRF に記載されていた文言から変更された。元の質問への回答では、動物 MOA がヒトへの関連性を持たないという結論を出すには、はっきりとした「No」しか許容されていな かった。また、「plausible」という単語が他の言語に翻訳する際に問題になる可能性があることも

permit the conclusion that the animal MOA was not relevant to humans. Also, it was recognized that translation of the word "plausible" into other languages could be problematic. The question was therefore reworded to enable a *yes/no* answer, but qualified by the descriptor "reasonably", based on recognition that decisions about the adequacy of weight of evidence are not absolute but involve scientific judgement based on transparent analysis of the available data.

This step represents a qualitative assessment of the relevance of the MOA to human cancer potential. Listing the critical specific key events that occur in the animal MOA and directly evaluating whether each of the key events might or might not occur in humans facilitate consideration and transparent presentation of the relevant information. Presentation in tabular form, referred to as a concordance table, can be helpful in delineating the relevant information (for an example, see Meek et al., 2003, case-study 6: kidney and liver tumours associated with chloroform exposure, Table 7: McGregor et al., current document, case-study on formaldehyde, Table 3). The key events (and possibly some of the critical associated processes) are listed with the information regarding these events for the animals in which the tumour was observed. It is intended that the information in these tables be brief, since a narrative explanation is expected to accompany the table. In the right-hand column, the effect on humans for each of the key events is evaluated. An additional column for the results in a different strain, species, sex, or route of administration that does not result in tumours can be useful if information is available for comparison with the model that leads to tumours. In addition, factors may be identified that, while not key themselves, can modulate key events and so contribute to differences between species or individuals. Such factors include genetic differences in pathways of metabolism, competing pathways of metabolism, and cell proliferation induced by concurrent pathology. Any such factors identified should be noted in a footnote to the concordance table.

The evaluation of the concordance of the key events for the MOA for a given chemical in humans is an evaluation of the MOA in humans, rather than an evaluation of the specific chemical. In general, details of the initial key events are likely to be more chemical specific—for example, the enzyme induction response by phenobarbital in rodent liver, or the formation of a cytotoxic metabolite from chloroform by specific cytochrome P-450 enzymes. Later events are more generic to the MOA—for example, pleiotropic stimulation of hepatic proliferation or regenerative hyperplasia. Information that can be utilized to evaluate the key events in humans can come from in vitro and in vivo studies on the substance itself, but also can involve basic information regarding anatomy, physiology, endocrinology, genetic disorders, epidemiology, and any other information that is known regarding the key events in humans. Information concerning an evaluation of the key event in humans exposed directly to the specific chemical is frequently unavailable.

As knowledge concerning the development of cancer evolves, it may become possible to combine some MOAs on the basis of the basic biology of the processes involved, thus relying less on chemical-specific information to reach a conclusion on the human relevance of a given MOA.

認識された。そのため、質問は Yes/No の回答を可能にするように書き換えられたが、エビデンス の重み付けの妥当性に関する決定は絶対的なものではなく、利用可能なデータの透明性のある解 析に基づいた科学的判断が必要であるという認識に基づき、「合理的に」という語句が付け加えら れた。

このステップでは、ヒトにおける発がんの可能性と MOA の関連性を定性的に評価することで ある。動物 MOA で発生する重要な特定の key events をリストアップし、それぞれの key events が ヒトで発生するか否かを直接評価することで、関連する情報の検討と透明性のある提示が容易に なる。一致表 (concordance table) と呼ばれる表形式での提示は、関連情報を明確にするのに役立 つ (例として、事例研究 6:クロロホルムばく露に伴う腎臓及び肝臓の腫瘍、Meek ら、2003 年、表 7;本書、ホルムアルデヒドに関する事例研究、McGregor ら、表 3 を参照)。腫瘍が観察された動 物におけるこれらの事象に関する情報とともに、key events (及び重要と思われるいくつかの関連 プロセス) がリストアップされる。これらの表の情報は簡潔にすることが意図されており、表に は説明文が添付されることが予想される。右側の列では、各 key events についてヒトへの影響を 評価している。追加の列として、腫瘍が発生しない別の系統、種、性、または投与経路での結果 についての情報は、腫瘍が発生するモデルとの比較情報が得られる場合に有用である。さらに、 それ自体は key events ではないが、key events を変化させ、種差または個体差に寄与する因子が同 定されることがある。そのような因子には、代謝経路の遺伝的差異、競合する代謝経路及び同時 進行する病態によって誘導される細胞増殖が含まれる。特定されたそのような要因はすべて、一 致表の脚注に記載されるべきである。

ヒトにおけるある化合物の MOA の key events の一致性の評価は、その特定の化学物質の評価と いうよりは、ヒトにおける MOA の評価である。一般的に、初期の key events の詳細は化学物質に 特異的である可能性が高い。例えば、げっ歯類の肝臓におけるフェノバルビタールによる酵素誘 導反応や、特定のチトクローム P-450 酵素によるクロロホルムからの細胞毒性代謝物の生成など である。その後の事象は MOA においてより一般的なものであり、例えば、多面的な肝増殖刺激 や再生性過形成などである。ヒトにおける key events の評価に利用できる情報は、化学物質の in vitro 及び in vivo 試験に由来するもののほか、解剖学、生理学、内分泌学、遺伝学、疫学、その他 ヒトの key events に関する既知の情報などの基本的な情報が含まれる。特定の化学物質に直接ば く露されたヒトにおける key events の評価に関する情報は、入手できないことが多い。

がんの発生・進行に関する知見が蓄積されるにつれて、関与するプロセスの基本的な生物学的 知見に基づいていくつかの MOA を組み合わせることが可能になるかもしれない。それにより、 MOA のヒトへの関連性について結論付ける際に、その化学物質の特異的な情報への依存度が低く なるかもしれない。

In evaluating the concordance of the information in humans to that in animals, a narrative describing the weight of evidence and an evaluation of the level of confidence for the human information need to be provided. Some specific types of information that are useful include the following:

- 1. cancer incidences at the anatomical site and cell type of interest, including age, sex, ethnic differences, and risk factors, including chemicals and other environmental agents;
- 2. knowledge of the nature and function of the target site, including development, structure (gross and microscopic), and control mechanisms at the physiological, cellular, and biochemical levels;
- 3. human and animal disease states that provide insight concerning target organ regulation and responsiveness;
- 4. human and animal responses to the chemical under review or analogues following short-, intermediate-, or long-term exposure, including target organs and effects.

Obviously, a substantial amount of information is required to conclude that the given MOA is not relevant to humans. If such a conclusion is strongly supported by the data, then chemicals producing animal tumours only by that MOA would not pose a cancer hazard to humans, and no additional risk characterization for this end-point is required. Since there is no cancer hazard, there is no cancer risk for the tumour under consideration.

The question of relevance considers all groups and life stages. It is possible that the conditions under which an MOA operates occur primarily in a susceptible subpopulation or life stage—for example, in those with a pre-existing viral infection, hormonal imbalance, or disease state. Special attention is paid to whether tumours could arise from early-life exposure, considering various kinetic and dynamic aspects of development during these life stages. Any information suggesting quantitative differences in susceptibility is identified for use in risk characterization.

#### Can human relevance of the MOA be reasonably excluded on the basis of quantitative differences in either kinetic or dynamic factors between experimental animals and humans?

The wording of this question was changed from that in the ILSI/RSI HRF, following discussion at the IPCS workshop on the implications of a *yes* or a *no* answer to the original question. In answering the original question, only an unequivocal *no* would be sufficient to permit the conclusion that the animal MOA was not relevant to humans. The question was therefore reworded to enable a *yes/no* answer, but qualified by the descriptor "reasonably", based on recognition that decisions about the adequacy of weight of evidence are not absolute but involve judgement based on transparent analysis of the available data.

For purposes of human relevance analysis, if the experimental animal MOA is judged to be qualitatively relevant to humans, a more quantitative assessment is required that takes into account any kinetic and dynamic information that is available from both the experimental animals and humans. Such data will of necessity be both chemical and MOA specific and will include the biologically effective doses required to produce the relevant dynamic responses from which neoplasia can arise. Kinetic considerations include the nature and time course of

#### IPCS Framework for Analysing the Relevance of a Cancer Mode of Action for Humans and Case-Studies

ヒトの情報と動物の情報との一致性を評価する際には、エビデンスの重み付けを説明し、ヒト の情報の信頼度の評価をする必要がある。有用な情報の具体的な種類としては、以下のようなも のがある。

- 1. 対象の解剖学的部位及び細胞の種類におけるがんの発生率:年齢、性別、人種及び化学物質や その他の環境因子などのリスク因子を含む。
- 標的部位の性質と機能に関する知見:生理的、細胞的、生化学的レベルでの発生、構造(肉眼 的、顕微鏡的)、制御機構を含む。
- 3. ヒト及び動物の疾患状態:標的臓器の調節及び応答性に関する洞察を提供する。
- 4. 短期、中期、または長期ばく露後の、対象となる化学物質または類似物質に対するヒト及び動物の反応:標的臓器及び影響を含む。

当然、対象の MOA がヒトに関連していないと結論づけるには、相当量の情報が必要である。 そのような結論がデータによって強く支持されているならば、その MOA によってのみ動物の腫 瘍を誘発される化学物質は、ヒトに対するがんに関するハザードを有さず、このエンドポイント に対するリスク判定を追加で行う必要はない。がんに関するハザードがないため、検討中の腫瘍 に対する発がんリスクはない。

関連性の質問は、すべての集団とライフステージを考慮している。MOA が作用する状況は、例 えばすでにウイルスに感染しているヒト、ホルモンバランスの不均衡のあるヒト、または病を患 っているヒトなど、主に感受性の高い集団またはライフステージで起こる可能性がある。ライフ ステージの早期における発達に関する様々な動態的及び薬力学的側面を考慮して、腫瘍がライフ ステージの早期におけるばく露から発生するかどうかに特別な注意が払われている。感受性の量 的な違いを示唆するいかなる情報も、リスク判定に用いるために特定される。

#### 実験動物ととトとの間の動態的または薬力学的要因のいずれかの量的差異に基づいて、 MOA のとトへの関連性を合理的に排除することができるか

この質問の文言は、IPCS ワークショップにおける質問に対する回答の意味合いについての議論 を受けて、ILSI/RSI HRF に記載されていた文言から変更された。元の質問への回答では、動物 MOA がヒトへの関連性を持たないという結論を出すには、はっきりとした「No」しか許容されていな かった。そのため、質問は Yes/No の回答を可能にするように書き換えられたが、エビデンスの重 み付けの妥当性に関する決定は絶対的なものではなく、利用可能なデータの透明性のある解析に 基づいた科学的判断が必要であるという認識に基づき、「合理的に」という語句が付け加えられた。

ヒトへの関連性解析の目的では、実験動物の MOA がヒトに定性的に関連性があると判断され る場合には、実験動物とヒトの両方から得られるあらゆる動態的及び薬力学的情報を考慮して、 より定量的な評価が必要である。このようなデータは、必然的に化学物質及び MOA に特有のも のであり、腫瘍形成を起こしうる薬力学的反応を引き起こすために必要な生物学的影響を及ぼす 用量を含むものである。動態的考察には、化学物質の取り込み、分布、代謝及び排泄の性質及び 経時的変化が含まれ、一方、薬力学的考察には、化学物質と細胞、組織及び器官との相互作用の 結果が含まれる。

chemical uptake, distribution, metabolism, and excretion, while dynamic considerations include the consequences of the interaction of the chemical with cells, tissues, and organs. On occasion, the biologically effective dose that would be required to create these conditions would not be possible in humans. It may also be that quantitative differences in a biological process involved in a key event-for example, the clearance of a hormone-are so great that the animal MOA is not relevant to humans. However, the IPCS workshop recognized that only infrequently is it likely that it will be possible to dismiss human relevance on the basis of quantitative differences. As with the qualitative assessment, a tabular comparison of quantitative data from the experimental animals and humans can facilitate the evaluation (for example, see Meek et al., 2003, case-study 5, thyroid tumours associated with exposure to phenobarbital, Table 6; Dellarco et al., current document, case-study on thiazopyr, Table 4). Useful comparisons can also be made with key events identified from studies of other compounds believed to induce effects by a similar MOA. For example, in the case of thiazopyr, information on the effects of phenobarbital in humans was particularly informative in evaluating the relevance of the MOA. As molecular and kinetic approaches continue to evolve, understanding of the similarities and differences of responses in animals and humans will be improved. It may become apparent that qualitative differences in a key event between an animal model and humans will be identified as being due to a specific quantitative difference, thus changing the answer to the second question (described above) to no.

As with question 2, if the conclusion to this question is *yes*, then chemicals producing animal tumours only by that MOA would not pose a cancer hazard to humans, and no additional risk characterization for this end-point is required.

#### Statement of confidence, analysis, and implications

Following the overall assessment of each of the three questions, a statement of confidence is necessary that addresses the quality and quantity of data underlying the analysis, consistency of the analysis within the framework, consistency of the database, and the nature and extent of the concordance analysis. An evaluation of alternative MOAs, using comparable analyses and rigour, is also essential. A critically important outcome of adequate consideration of the weight of the evidence for an overall MOA and the qualitative and quantitative concordance is the identification of specific data gaps that can be addressed experimentally in future investigations to increase confidence.

Infrequently, there may be conclusive epidemiological data on the cancer risk from a chemical that shares the MOA of the compound under consideration—that is, the compound does or does not cause cancer in humans. Obviously, such data would lend considerable weight to the conclusion of the human relevance evaluation. However, there may be occasions when, despite it being possible to establish an MOA in animals, there is insufficient information on the key events in humans to reach a clear conclusion on human relevance. In such circumstances, it might be possible to bridge this data gap by using epidemiological data. For example, the database on key events in humans for compounds that act like phenobarbital via activation of the constitutively active receptor (CAR) to induce hepatic tumours is incomplete. However, there are robust epidemiological data showing that exposure to phenobarbital for prolonged periods at relatively high doses does not cause cancer in humans. One possibility, therefore, is to "read across" from these findings with phenobarbital to any other 時折、これらの条件を作り出すために必要とされる生物学的に影響を及ぼす用量が、ヒトにおい て不可能であることがある。また、ホルモンのクリアランスなど key events に関与する生物学的 プロセスにおける定量的な違いが大きすぎるため、動物の MOA がヒトには関連しないというこ ともあり得る。しかし、量的な差異に基づいて MOA のヒトへの関連性を否定することが可能に なるのは、ごくまれであると IPCS ワークショップでは認識されている。定性評価と同様に、実験 動物とヒトの定量データを表形式で比較することで、評価を容易にすることができる(例えば、 事例研究 5、フェノバルビタールばく露に伴う甲状腺腫瘍、Meek ら、2003 年、表 6;チアゾビル に関する事例研究、Dellarco ら、本書、表 4 参照)。同様の MOA によって効果を誘導すると考え られている他の化合物の研究から同定された key events との比較も有用である。例えば、チアゾ ピルの場合、ヒトにおけるフェノバルビタールの効果に関する情報は、MOA の関連性を評価する 上で特に有用であった。分子学的及び動態学的アプローチが進化し続けるにつれ、動物及びヒト における反応の類似性及び相違点の理解が向上するであろう。動物モデルとヒトとの間の key events における定性的な違いが、特定の定量的な違いによるものであることが明らかになるかも しれない。その場合、第2の問いかけ(上述)への回答を「No」に変更する。

問2と同様に、この問いかけへの結論が「Yes」であれば、そのMOAによってのみ動物に腫瘍 を誘発させる化学物質はヒトにがんに関するハザードをもたらさず、このエンドポイントにおけ る追加のリスク判定は必要ない。

#### 信頼性、解析及び帰結の記述

3 つの問いかけのそれぞれの総合評価に続いて、解析の基礎となるデータの質と量、フレームワ ーク内での解析の一貫性、データベースの一貫性、一致解析の性質と程度についての信頼性につ いての記述が必要である。また、同等の解析法や厳密な評価を用いた代替的な MOAs の評価も不 可欠である。全体的な MOA と質的・量的一致のエビデンスの重み付けを十分に考慮し、その結 果として、MOA の信頼性を高めることができる将来の研究で実験的に特異的なデータギャップを 特定することが極めて重要である。

まれに、検討中の化合物と共通する MOA を有する化学物質の発がんリスクに関する決定的な 疫学的データ、すなわち、その化合物がヒトに発がん性を有するか否かのデータが存在すること がある。当然、そのようなデータは、ヒトへの関連性評価の結論にかなりの重みを与えるであろ う。しかし、動物では MOA を確立することが可能であるにもかかわらず、ヒトでの key events に 関する情報が不十分であり、ヒトへの関連性について明確な結論を出すことができない場合があ る。そのような場合には、疫学データを利用することで、このデータギャップを埋めることがで きるかもしれない。例えば、構成的活性化受容体 (CAR) の活性化を介してフェノバルビタール と同様の作用をして肝腫瘍を誘発する化合物のヒトでの key events に関するデータベースは不完 全である。しかし、比較的高用量のフェノバルビタールに長期間ばく露しても、ヒトでは発がん しないことを示す確固たる疫学的データがある。したがって、1 つの可能性としては、これらのフ ェノバルビタールに関する知見から、げっ歯類に肝腫瘍を誘導する動物 MOA を共有する他の化 合物について「類推」し、そのような化合物によって引き起こされる腫瘍は、ヒトにおける化合 物のリスク評価には関係ないと結論づけることである (Holsapple ら、2006 年)。

compound that shares its MOA in animals in inducing rodent liver tumours and to conclude that the tumours caused by such a compound are not relevant to the risk assessment of the compound in humans (Holsapple et al., 2006). Such a conclusion would be critically dependent on the reliability of the epidemiological data and the similarity between the MOA for the chemical under test to that of the compound for which there are epidemiological data available.

In applying the framework to case-studies, it is apparent that much current research does not address key questions that would facilitate an analysis of an animal MOA or its relevance to humans. Often this has been because of lack of transparent delineation of key data gaps based on consideration of the data in analytical frameworks such as that presented here. Thus, use of the HRF can be very informative to researchers from the outset in the design of their studies.

The output of formal human relevance analysis provides information that is useful for more than just determining whether or not an end-point in animals is relevant to humans. Rather, consideration of the relevant information in a transparent, analytical framework provides much additional information that is critically important in subsequent steps in the risk characterization for relevant effects. Based on a human relevance analysis for a proposed MOA for relevant effects, it may be possible to predict, for example, site concordance or not of observed tumours in animals to humans. Application of the HRF also often provides information on relevant modulating factors that are likely to affect risk, such as hepatitis B and aflatoxin  $B_1$  (see Cohen et al., current document, case-study on 4-aminobiphenyl). Analysis often also provides an indication of those components of a proposed MOA that may operate only over a certain dose range. If a high experimental dose of a given compound is needed to result in an obligatory step in an MOA, then the relevance to human risk becomes a matter of exposure. Thus, the exposure assessment step of the subsequent risk characterization is critical to the proper evaluation of human cancer potential. In addition, information identified during the framework analysis can prove invaluable in hazard quantification based on the key events for the MOA.

Importantly, the human relevance analysis also contributes to identification of any special subpopulations (e.g. those with genetic predisposition) who are at increased risk and often provides information relevant to consideration of relative risk at various life stages. In some cases, this may be based not on chemical-specific information but rather on inference, based on knowledge of the MOA, as to whether or not specific age groups may be at increased or decreased risk.

The data and their analysis using the framework should be reported in a transparent manner, enabling others to determine the basis of the conclusions reached with respect to the key events, the exclusion of other MOAs, and the analysis of human relevance. As the specific form of presentation will vary with the type of data available, it is not helpful to be prescriptive on how the information should be reported. However, presentation should include sufficient details on the context and thought processes to ensure transparency of the conclusions reached. The use of appropriate tables can be helpful in presenting certain data, such as comparative analysis of key events in experimental animals and humans.

#### IPCS Framework for Analysing the Relevance of a Cancer Mode of Action for Humans and Case-Studies

このような結論は、疫学的データの信頼性及び試験対象の化学物質の MOA と疫学的データが利用可能な化合物の MOA との類似性に極めて依存している。

このフレームワークを事例研究に適用すると、現在の研究の多くは、動物 MOA の解析及びヒトとの関連性の解析を容易にするような重要な問いに対処していないことは明らかである。多くの場合、このことは、ここで紹介したような解析フレームワークでのデータの検討に基づいて、主要なデータギャップを透明性をもって記述していないことが原因である。このように、HRFを用いることは試験設計の初期段階から研究者にとって非常に有益である。

統一された形式のヒト関連性解析の結果は、動物のエンドポイントがヒトに関連するかどうか を判断するだけでなく、それ以上に有用な情報を提供してくれる。むしろ、透明性のある解析的 フレームワークの中で関連情報を検討することで、関連する影響のリスク判定における次の段階 で多くの極めて重要な追加情報が提供される。推定される関連影響に関する MOA のヒト関連性 解析に基づくことで、例えば、動物で観察された腫瘍がヒトにおいて発生部位が一致するかどう かを予測することが可能である。また、HRF を適用することで、B型肝炎やアフラトキシン B<sub>1</sub>な どのように、リスクに影響を与える可能性のある関連する調節因子に関する情報が得られること が多い(4 Aminobiphenyl に関する事例研究、Cohen ら、本書を参照)。解析はまた、推定される MOA の構成要素のうち、一定の用量以上でのみ作用する可能性のあるものについての指標を提供 することが多い。MOA に必須なステップを引き起こすために対象の化合物の実験的高用量のばく 露が必要とされる場合、ヒトのリスクとの関連性はばく露の問題となる。このように、その後の リスク判定におけるばく露評価ステップは、ヒトでの発がん性を適切に評価するために重要であ る。さらに、フレームワーク解析で特定された情報は、MOA の key events に基づくハザードの定 量化において非常に貴重なものとなりうる。

重要なことだが、ヒト関連性解析は、リスクが増大している特別な集団(遺伝的素因を持つ集 団など)を特定することにも寄与し、しばしば、様々なライフステージにおける相対リスクの検 討に関連する情報を提供してくれる。場合によっては、これは化学物質固有の情報に基づくので はなく、特定の年齢層のリスクが増加しているか減少しているかについて、MOAの知識に基づい ている場合もある。

フレームワークを用いたデータ及びその解析は、透明性のある方法で報告され、他の者が key events、他の MOA の除外及びヒトとの関連性の解析に関して到達した結論の根拠を判断できるよ うにすべきである。具体的な提示形式は利用可能なデータの種類によって異なるため、情報がど のように報告されるべきかを規定することに意味はない。しかし、到達した結論の透明性を確保 するために、文脈や考察のプロセスに関して十分な詳細情報が含まれていなければならない。実 験動物とヒトにおける key events の比較解析など、特定のデータを提示する際には、適切な表を 使用することが有用である。

#### **Dissemination of the framework**

To assist in the dissemination and application of the IPCS HRF, a database of generally accepted MOAs and informative cases should be constructed and maintained. This would comprise a series of MOAs and their associated key events, for reference by those developing framework analyses for compounds that may act by similar MOAs. The case-studies would comprise worked examples that have been analysed using the framework, to provide an indication of the relevant level of detail of the analyses and nature of the weight of evidence required to support acceptance of a proposed MOA in causing the carcinogenic response. Such cases would be particularly valuable early in the development of a new MOA.

#### Application of the IPCS HRF to DNA-reactive carcinogens

Because of similarities in the carcinogenic process between rodents and humans and the comparable initial interactions with DNA by DNA-reactive carcinogens, it would be expected that, in general, DNA-reactive carcinogens would be assessed as progressing to the step of "ves, the key events in the animal MOA could occur in humans" in the ILSI/RSI HRF, as was the case for ethylene oxide (Meek et al., 2003), and "no" to the equivalent step in the IPCS HRF that asks the question, "Can human relevance of the MOA be reasonably excluded on the basis of fundamental, qualitative differences in key events between experimental animals and humans?", as was the case for 4-aminobiphenyl (Cohen et al., current document). In a recent paper, Preston & Williams (2005) presented a set of key events for tumour development that provided a guide for the use of the ILSI/RSI HRF with DNA-reactive carcinogens. This guide supported the view that for most DNA-reactive chemicals, the animal MOA would be predicted to be relevant to humans. However, it was also argued that there could be exceptions and that the ILSI/RSI HRF would be a valuable tool for identifying these. Use of the ILSI/RSI HRF and the IPCS HRF can also assist in quantifying differences in key events between rodents and humans that may be of value in extrapolating risk to humans. Not all rodent DNA-reactive carcinogens have been established to be human carcinogens, as judged by the International Agency for Research on Cancer (IARC) review process. For some of these exceptions, this human-rodent difference in tumour response is attributable to lower exposure of humans to the agent or to the relative insensitivity of epidemiological studies to detect tumour responses at low exposure levels. However, there are other reasons for such differences that are based on biological considerations. For example, if a DNA-reactive carcinogen induces tumours *only* in a species-specific organ, it is possible that the animal MOA based on key events might not be relevant to humans, although available data on MOA would need to be considered to permit such a conclusion. Similarly, the generally more proficient DNA repair processes that occur in humans compared with rodents (Cortopassi & Wang, 1996; Hanawalt, 2001) or a unique pathway of bioactivation in rodents could result in there being ves answers to the steps in the IPCS HRF that address the queries "Can human relevance of the MOA be reasonably excluded on the basis of fundamental, qualitative differences in key events between experimental animals and humans?" and/or "Can human relevance of the MOA be reasonably excluded on the basis of quantitative differences in either kinetic or dynamic factors between experimental animals and humans?" Alternatively, the IPCS HRF could provide quantitative information on these processes for use later in the risk characterization step.

#### フレームワークの普及

IPCS HRF の普及と適用を支援するために、一般的に受け入れられている MOA と有益な事例の データベースを構築し、維持する必要がある。これは、類似の MOAs で作用する可能性のある化 合物のフレームワーク解析を進めている人が参照できるよう一連の MOAs とそれに関連した key events で構成されている。事例研究は、実際の事例で構成されており、それらは発がん性反応を引 き起こす推定 MOA の受入れを支持するために必要な解析の詳細の関連度とエビデンスの重み付 けの性質を示すために、フレームワークを用いて解析されている。そのような事例研究は、新し い MOA を開発する初期段階では特に貴重であろう。

#### DNA 反応性発がん物質への IPCS HRF の適用

げっ歯類とヒトの発がんプロセスに類似性があり、DNA 反応性発がん物質による DNA との初 期相互作用が類似しているため、一般的に DNA 反応性発がん物質は、エチレンオキサイドの場合 (Meek ら、2003 年)のように ILSI/RSI HRF の「動物の MOA の key events はヒトで起こりうる」 という質問に対し「Yes」のステップに進むと評価され、IPCS HRF における上記質問に相当する 「実験動物とヒトとの間の key evants の根本的、質的な違いに基づいて、MOA のヒトとの関連性 を合理的に排除することができるか」の質問に対し 4-Aminobiphenyl の場合 (Cohen ら、本書) 「No」のステップへと進むと評価されると予想される。最近の論文では、Preston & Williams (2005 年)は、DNA 反応性発がん物質に対する ILSI/RSI HRF の使用の指針となる腫瘍発生の key events のセットを提示した。この指針は、ほとんどの DNA 反応性化学物質について、動物 MOA はヒト に関連すると予測されるという見解を支持した。しかし、例外がある可能性があり、ILSI/RSI HRF はこれらを特定するための貴重なツールになるとも指摘された。ILSI/RSI HRF と IPCS HRF を使 用することは、ヒトへのリスクを外挿する際に価値があるであろうげっ歯類とヒトの間の kev events の違いを定量化するのにも役立つ。国際がん研究機関(IARC)のレビュープロセスで判断 されたように、すべてのげっ歯類における DNA 反応性発がん物質がヒトの発がん物質であると 確立されているわけではない。これらの例外のいくつかについては、発がん性におけるこのヒト-げっ歯類間の違いは、ヒトがその化合物へのばく露量が少ないこと、または低ばく露レベルでの 発がん性を検出する疫学研究の相対的な感度の低さに起因している。しかしながら、このような 違いの理由は他にも生物学的考察に基づくものがある。例えば、DNA 反応性発がん物質が種特異 的な器官でのみ腫瘍を誘発する場合、MOA に関する利用可能なデータを考慮する必要があるが、 この key events に基づく動物 MOA はヒトには関連がない可能性もある。同様に、ヒトではげっ歯 類と比較して一般的に DNA 修復プロセスが発達している (Cortopassi & Wang, 1996 年; Hanawalt, 2001年)、あるいはげっ歯類に特有の生体内活性化の経路があることから、IPCS HRF における「実 験動物とヒトの間の key events の根本的、質的な違いに基づいて、MOA のヒトとの関連性は合理 的に排除できるか」及び/または「実験動物とヒトの間の動態的または薬力学的な要因のいずれ かの量的な違いに基づいて、MOAのヒトとの関連性は合理的に排除できるか」という問いに対し 「Yes」のステップへと進む可能性がある。あるいは、IPCS HRF はこれらのプロセスに関するそ の後のリスク判定の段階で利用可能な定量的な情報を提供しうる。

The need in applying the IPCS HRF for DNA-reactive carcinogens is to develop a set of key events that would clearly describe the cancer process and use these as the guide for establishing the human relevance of a rodent tumour MOA for any particular DNA-reactive carcinogen under consideration.

#### The IPCS HRF and risk assessment

Among the strengths of the framework are its flexibility, general applicability to carcinogens acting by any MOA, and the ability to explore the impact of each key event on the carcinogenic response. This includes determination of the nature of the dose–response curve, the identification and location of thresholds for individual key events, and their consequences for the overall tumour response curve. In addition, by considering the kinetic and dynamic factors involved in each key event, it may be possible to reach conclusions regarding the relevance or not of the carcinogenic response to specific subpopulations—for example, in early life, in those with particular diseases, or in those with specific polymorphisms. Alternatively, application of the framework can provide quantitative information on the differences between such groups. Application of the framework can also more generally inform the risk characterization of the chemical, even when it is concluded that the carcinogenic response per se is not relevant to humans.

As stated at the outset, MOA analysis and its human relevance counterpart are aspects of the hazard identification and characterization phases of risk assessment (National Research Council, 1983; Meek et al., 2003). Consistent with this paradigm, the human relevance case-studies referred to in the present report contribute to, but do not complete, a risk assessment for the chemicals under study. This is because a complete risk characterization requires not only evaluation of doses in the range of observations from experimental or occupational hygiene studies but also extrapolation to human exposure levels of interest in daily and lifetime activities.

Hazard characterization—and related MOA analysis—deals with the potential for harm in general terms, while the complete risk assessment puts this potential hazard into context with respect to exposure for decision-makers. Risk characterization seeks to describe the relationship between these effects and the doses to which humans are exposed in order to understand and estimate the nature and likelihood of effects in humans who are generally exposed at lower dose levels.

Understanding dose–response can have a profound effect on hazard characterization and therefore is an important component of the MOA analysis, particularly when non-linear processes or dose transitions are inherent in the relevant biology. Similarly, quantifying hazard in the context of dose informs the process of risk assessment by suggesting extrapolation models that are consistent with our understanding of the biology.

Estimating these generally lower human exposure levels is the task of the exposure analysis component of the risk assessment process. This usually involves extensive analysis of data collected from environmental media and plant and animal tissues, as well as those derived from pharmacokinetic models. This process also depends on analyses of human activity patterns and life stage and lifestyle factors that may bring about exposure. Ideally, based on

DNA 反応性発がん物質に IPCS HRF を適用する際に必要なことは、発がん過程を明確に説明する一連の key events を開発し、検討中の DNA 反応性発がん物質に対するげっ歯類における発がん MOA のヒトへの関連性を確立するための指針としてこれらを使用することである。

#### **IPCS HRF** 及びリスク評価

このフレームワークの強みは、柔軟性、あらゆる MOA によって作用する発がん物質への広範 な適用性及び発がん性反応における各 key event の影響を探索する能力といった点である。これに は、用量反応曲線の性質の決定、個々の key event の閾値の存在の特定やその値の特定及びそれら の腫瘍の反応曲線全体への影響の特定が含まれる。さらに、各 key event に関与する動態的及び薬 力学的な因子を考慮することで、特定の集団、例えば、幼若な人々、特定の疾患を持つ人々、ま たは特定の遺伝子多型を持つ人々に対する発がん性反応の関連性の有無に関する結論に到達する ことが可能になるかもしれない。あるいは、フレームワークを適用することで、そのようなグル ープ間の違いに関する定量的な情報を得ることができる。フレームワークの適用はまた、発がん 性反応自体がヒトには関連性がないと結論づけられた場合でも、化学物質のリスク評価に概ね有 益なものになりうる。

冒頭で述べたように、MOA 解析とヒトへの関連性の解析は、リスク評価におけるハザードの特定と特性評価の段階の一側面である(National Research Council、1983年; Meek ら、2003年)。このフレームワークに沿って、本文書で言及しているヒトへの関連性に関する事例研究は、完全なものではないが、研究対象の化学物質のリスク評価に貢献する。これは、完全なリスク評価を行うためには、実験的研究や職業衛生研究で設定された範囲の用量を評価するだけでなく、日常生活や生涯の活動における対象化学物質のヒトへのばく露レベルへの外挿を必要とするからである。

ハザードの特性評価及び関連する MOA 解析は、一般的な用語で危害の可能性を扱うのに対し、 完全なリスク評価は、意思決定者に対してこの潜在的なハザードをばく露に関する文脈で説明す るものである。リスク評価は、一般的に低用量レベルで被ばくしているヒトにおける影響の性質 と発生する可能性を理解し、推定するために、これらの影響とヒトへのばく露量との関係を記述 しようとするものである。

用量反応関係を理解することは、ハザードの特性評価に大きな影響を及ぼす可能性があるため、 MOA 解析の重要な要素であり、生物学的に非線形的なプロセスや種間における閾値の差が内在し ている場合には特に重要な要素である。同様に、用量に関連したハザードを定量化することは、 生物学的理解と整合性のある外部モデルを提示することで、リスク評価のプロセスに役立つ。

これらの一般的に低いヒトばく露レベルを推定することは、リスク評価におけるばく露解析の 課題である。これには通常、環境媒体、動植物組織、薬物動態モデルから得られたデータの広範 な解析が含まれる。このプロセスはまた、ヒトの活動パターン、ライフステージや生活様式とい ったばく露をもたらす可能性のある要因の解析にも依存する。

this information, a range of exposure scenarios is developed for different groups (men, women, children, infants, special groups, based, for example, on ethnicity or occupation) for use in identifying populations of concern. While hazard characterization, which is largely included in the framework analysis, involves quantification (dose–response analysis), estimating external exposures and contextualizing the hazard with respect to these estimates comprise subsequent steps in the risk assessment process. For example, in the case of melamine (Meek et al., 2003, case-study 7), it was concluded that the animal MOA was potentially relevant to humans. However, recognition that bladder carcinoma formation occurred only at very high doses carried forward to the subsequent stages of the risk assessment, exposure assessment, and risk characterization. The full risk assessment established that human exposures would not achieve levels necessary to produce bladder carcinomas, by a substantial margin.

#### CONCLUSIONS

This IPCS HRF has been developed based on experience gained from the original 2001 IPCS MOA Framework and consideration of the 2003 ILSI/RSI human cancer relevance framework. Many aspects of these frameworks have been adopted, but a number of changes have been made to improve clarity and to introduce some elements not previously considered (e.g. sensitive subpopulations). The utility and role of the framework as an analytical tool within hazard characterization and within the overall risk assessment/characterization paradigm—that is, informing human relevance and dose–response extrapolation—have been emphasized. A number of general points and conclusions follow from the development of this framework:

- 1. Prior to embarking on a framework analysis, there needs to be careful evaluation of the weight of evidence for a carcinogenic response in experimental animals.
- 2. Peer involvement and independent review are essential prerequisites for the general acceptance and scientific defensibility of a new MOA.
- 3. The framework is applicable to all MOAs for carcinogens, including DNA reactivity.
- 4. Although human relevance is likely to be assumed for most DNA-reactive carcinogens, the human relevance analysis is a valuable approach to enhance understanding, improve characterization of the hazard and risk, and identify exceptions.
- 5. When dealing with a chemical that may operate through a novel MOA, the analysis is focused on the chemical and entails a detailed evaluation via the HRF. However, when a specific chemical produces a tumour response consistent with an already established and peer-reviewed MOA through which other chemicals have been shown to operate, the analysis is then focused on the established MOA and a determination of whether the chemical produces its carcinogenic effect via the same key events established for the pathway.
- 6. When evaluating the human relevance of a tumour response found in experimental animals, the concordance analysis of key events is for the MOA and is not necessarily a chemical-specific evaluation. Chemical-specific and generic information relevant to the carcinogenic process can be valuable in the analysis. As knowledge advances, MOAs will become less chemical specific and will be based even more on the key biological

理想は、この情報に基づいて懸念される集団を特定するために、異なる集団(男性、女性、子供、 乳幼児、民族性や職業などに基づく特別な集団)を対象としたそれぞれのばく露量の範囲に関す るシナリオが作成されることである。その大部分がフレームワーク解析に含まれているハザード の特性評価には定量化(用量反応解析)が含まれているが、外部ばく露量の推定及びこれらの推 定ばく露量におけるハザードの説明は、リスク評価に含まれるその次のステップにおいて行われ る。例えば、メラミンの場合(事例研究 7、Meek ら、2003 年)では、動物の MOA はヒトとの関 連性が高いと結論づけられた。しかし、膀胱がんの形成は非常に高用量でしか起こらないという 認識により、リスク評価、ばく露評価、リスク判定の次の段階へと解析が進められた。リスク評 価全体として、メラミンのヒトへのばく露は膀胱がんの発生に必要なレベルを大きく下回るとい う評価が下された。

#### 結論

この IPCS HRF は、2001 年の IPCS MOA フレームワークから得られた経験と 2003 年の ILSI/RSI ヒト発がん性関連フレームワークの検討に基づいて作成された。これらのフレームワークにおけ る概念の多くが採用されているが、明確性を向上させ、これまで考慮されていなかった要素(例 えば、感受性の高い集団)を導入するために、多くの変更が加えられている。ハザードの特性評 価及び全体的なリスク評価/判定のフレームワークにおける解析ツールとしてのフレームワークの 有用性と役割、すなわちヒトへの関連性と用量反応性の外挿に役立つことが強調されている。こ のフレームワークの開発から得られた、多くの要点と結論は以下のとおりである。

- 1. フレームワーク解析に着手する前に、実験動物における発がん性反応のエビデンスの重み付け を慎重に評価する必要がある。
- 専門家の関与及び第三者によるレビューは、新しい MOA が一般に受け入れられるため、また、 科学的な正当性を得るための必須条件である。
- 3. フレームワークは、DNA 反応性を含むすべての発がん MOA に適用できる。
- 4. ほとんどの DNA 反応性発がん物質についてはヒトへの関連性が想定されると思われるが、ヒト関連性解析は、理解を深め、ハザードとリスクの特性評価/判定を改善し、例外を特定するための重要なアプローチである。
- 5. 新規の MOA を介して作用する可能性のある化学物質を扱う場合、解析はその化学物質に焦点を当て、HRF を介して詳細な評価を行うことが必要となる。しかし、ある化学物質が他の化学物質において既に確立され、専門家のピアレビューを経た MOA と一致した腫瘍反応をもたらす場合、解析は確立されている MOA と、その化学物質がその MOA の一連の流れにおいて確立されている key events を介して発がん作用を生み出すか否かに焦点を当てて行われる。
- 6. 実験動物で発見された腫瘍反応のヒトへの関連性を評価する場合、key eventsの一致解析は MOA に対するものであり、必ずしも化学物質に焦点を当てた評価ではない。発がんプロセス に関連する化学物質特有の情報や化学物質一般の情報は、解析において貴重なものとなり得る。 知識の進歩に伴い、MOA は化学物質特有のものではなくなり、関連する重要な生物学的プロ セスにより一層依拠することとなり、それにより、ある化合物におけるヒトとの関連性を別の 化合物へと一般化することが可能になるであろう。

processes involved, allowing greater generalization of human relevance from one compound to another.

- 7. The biological understanding and significance of the key events can inform the approach to dose–response extrapolation for cancer risk, and thus understanding of the MOA can have a profound effect on the hazard and risk characterization, particularly when nonlinear processes or dose transitions are inherent in the relevant biology.
- 8. It is recommended that a database of generally accepted MOAs and informative casestudies be established and maintained. It should provide examples that add to the existing case-studies developed by ILSI/RSI and IPCS and that are instructive in the application of the framework analysis. This database is particularly important as experience continues to evolve in the development of MOAs of carcinogens.
- 9. It is important to consider potentially susceptible subgroups and different life stages in the analysis.

In conclusion, the IPCS HRF provides a rigorous and transparent approach for judging whether data support a postulated mode of carcinogenic action for a chemical and for evaluating its relevance for humans. The scientific community is encouraged to use this approach as a means to increase the use of mechanistic information in cancer risk assessment and is encouraged to provide feedback, which may lead to additional refinements in the future. The framework is of value to both the risk assessment and research communities in furthering our understanding of carcinogenic processes, in identifying critical data gaps, and in informing the design of studies related to MOAs. When a carcinogenic response is considered potentially relevant to humans, information obtained on the key events during the analysis can prove invaluable in subsequent hazard quantification of the compound. It should be possible to extend the framework to non-cancer end-points, and further work on this is recommended. Thus, application of the IPCS HRF would be an invaluable tool for harmonization across end-points.

#### ACKNOWLEDGEMENTS

IPCS and the authors of this paper acknowledge the numerous experts involved in the scientific meetings and workshops leading to the development of this IPCS Human Relevance Framework for Analysing the Relevance of a Cancer Mode of Action for Humans. These were expert meetings and workshops convened and conducted in accordance with procedures of the IPCS/WHO. The outcomes, including this paper, contain the collective views of an international group of experts and do not necessarily represent the decisions or the stated policy of WHO. The work was funded by donations to IPCS from a number of Member States of the World Health Assembly.

#### IPCS Framework for Analysing the Relevance of a Cancer Mode of Action for Humans and Case-Studies

- 7. Key eventsの生物学的理解と生体における重要性は、発がんリスクの用量反応性の外挿性に関する解解析に情報を提供することができる。そのため MOA の理解はハザードとリスクの判定に大きな影響を与えうる。特に非線形性のプロセスや種間の閾値の差が、関連する生物学的性質に内在する場合に顕著である。
- 8. 一般的に受け入れられている MOA と有益な事例研究のデータベースを構築し、維持することが推奨される。このデータベースは、ILSI/RSI 及び IPCS によって行われた既存の事例研究に加え、フレームワーク解析の適用において有益な事例を提供するものでなければならない。このデータベースは、発がん物質の MOA の研究において知見が蓄積し続ける中で特に重要である。
- 解析において、潜在的に感受性の高い集団やさまざまなライフステージを考慮することが重要である。

結論として、IPCS HRF は、推定される化学物質の発がん MOA をデータが裏付けるかどうかを 判断し、ヒトへの関連性を評価するための厳格で透明性のあるアプローチを提供している。科学 界において発がんリスク評価における作用機序に関する情報の利用を増やす手段として、このア プローチを利用し、フィードバックを行うことが奨励されており、このことが将来的な更なる改 良につながるだろう。このフレームワークは、発がんプロセスの理解を深め、重要なデータギャ ップを特定し、MOA に関連した研究の設計に有益な情報をもたらすという点で、リスク評価と研 究の両方のコミュニティにとって価値がある。発がん反応がヒトに関連する可能性があると考え られる場合、解析中に key events について得られた情報は、その後の化合物のハザードの定量化 において極めて貴重なものとなりうる。このフレームワークは発がん以外のエンドポイントにま で拡張できるようにするべきであり、このことに関する更なる研究が推奨される。したがって、 IPCS HRF の適用は、エンドポイント間の調和のための貴重なツールとなるであろう。

#### 謝辞

IPCS と本論文の著者らは、この発がん MOA のヒトとの関連性を解析するための IPCS フレー ムワークの開発につながった科学的な会議やワークショップに関与した多くの専門家に謝意を表 します。これらは IPCS/WHO の手順に従って招集され、実施された専門家会議及びワークショッ プです。本文書を含む成果物は、国際的な特別作業部会の意見を集約したものであり、必ずしも WHO の決定や表明された方針を代表するものではありません。本事業は、世界保健総会の多くの 加盟国からの IPCS への寄付金により資金提供された。

## THIAZOPYR AND THYROID DISRUPTION: CASE-STUDY WITHIN THE CONTEXT OF THE IPCS FRAMEWORK FOR ANALYSING THE RELEVANCE OF A CANCER MODE OF ACTION FOR HUMANS<sup>1</sup>

Vicki L. Dellarco, Douglas McGregor, Sir Colin Berry, Samuel M. Cohen, & Alan R. Boobis

Thiazopyr increases the incidence of male rat thyroid follicular cell tumours; however, it is not carcinogenic in mice. Thiazopyr is not genotoxic. Thiazopyr exerts its carcinogenic effect on the rat thyroid gland secondary to enhanced metabolism of thyroxine leading to hormone imbalance. The relevance of these rat tumours to human health was assessed by using the 2006 International Programme on Chemical Safety Human Relevance Framework. The postulated rodent tumour mode of action (MOA) was tested against the Bradford Hill criteria and was found to satisfy the conditions of dose and temporal concordance, biological plausibility, coherence, strength, consistency, and specificity that fits with a well established MOA for thyroid follicular cell tumours. Although the postulated MOA could theoretically operate in humans, marked quantitative differences in the inherent susceptibility for neoplasia to thyroid hormone imbalance in rats allows for the conclusion that thiazopyr does not pose a carcinogenic hazard to humans.

A number of chemical substances have been shown to induce thyroid follicular cell tumours in rats through a mode of action (MOA) that involves perturbation of thyroid hormone homeostasis via reduction of circulating thyroid hormones (Hurley et al., 1998; Capen et al., 1999; IARC, 2001). Homeostatic responses to low thyroid hormone concentrations result in a compensatory increase in the release of thyroid stimulating hormone (TSH) from the pituitary gland, which in turn stimulates the thyroid gland to increase thyroid hormone synthesis and release. Persistent elevation of TSH levels leads to thyroid follicular cell hypertrophy and hyperplasia, which, if maintained (as a result of continuous exposure to the compound), can eventually lead to neoplasia. This neoplastic MOA in rats is well accepted by the scientific community, and both the International Agency for Research on Cancer (Capen et al., 1999; IARC, 2001) and the United States Environmental Protection Agency (USEPA, 1998) have established specific guidance or policies for evaluating the human relevance of rodent thyroid follicular cell tumours.

Thiazopyr, a herbicide that induces rat thyroid follicular cell tumours by its effect on thyroid homeostasis, was the case-study used to illustrate the original 2001 International Programme on Chemical Safety (IPCS) framework for mode of carcinogenic action analysis (Sonich-Mullin et al., 2001). Thiazopyr's MOA is revisited as a case-study here to illustrate the additional guidance provided in the 2006 IPCS Human Relevance Framework (HRF) for evaluation of a neoplastic MOA for humans. This updated case-study highlights how accumulating experience with a particular MOA can make subsequent analyses less difficult. Because this case-study is based on an established MOA in which the key events have been well defined, this analysis will focus on whether thiazopyr produces the biological effects

チアゾピルと甲状腺障害:

発がん MOA のヒトへの関連性を解析するための

## IPCS フレームワークを用いた事例研究2

#### Vicki L. Dellarco, Douglas McGregor, Sir Colin Berry, Samuel M. Cohen, & Alan R. Boobis

チアゾビルは雄ラットの甲状腺濾胞細胞腫瘍の発生率を増加させるが、マウスに対して発がん性 はないとされている。チアゾビルに遺伝毒性はない。チアゾビルは、チロキシンの代謝亢進により ホルモンバランスが崩れることにより二次的にラット甲状腺に発がん作用を及ぼす。これらのラ ットにおける腫瘍とヒトの健康への関連性は、2006年の国際化学物質安全性計画ヒト関連性フレ ームワーク(IPCS HRF)を用いて評価された。推定されたげっ歯類における発がん MOA を Bradford Hill 基準に照らして検証したところ、用量と時間の一致、生物学的妥当性、整合性、強度、一貫性、 特異性の条件を満たしており、甲状腺濾胞細胞腫瘍について確立されている MOA に適合している ことがわかった。推定された MOA はヒトでも理論的には作用する可能性はあるが、甲状腺ホルモ ンの不均衡に対するラットの発がん性の感受性がヒトとは量的に顕著に異なることから、チアゾ ビルはヒトに対する発がんに関するハザードを有さないという結論が導き出された。

多くの化学物質が、循環甲状腺ホルモンの減少を介した甲状腺ホルモンのホメオスタシスのか く乱を伴う作用機序(MOA)を介してラットの甲状腺濾胞細胞腫瘍を誘発することが示されてい る(Hurleyら、1998年; Capenら、1999年; IARC、2001年)。甲状腺ホルモンの低下に対しホメ オスタシスを保とうとする反応は、下垂体からの甲状腺刺激ホルモン(TSH)の放出の代償的な増 加をもたらし、その結果、甲状腺を刺激して甲状腺ホルモンの合成及び放出を増加させる。TSH レベルの持続的な上昇は、甲状腺濾胞細胞の肥大及び過形成へとつながり、(化合物への持続的な ばく露の結果)高いTSHレベルが維持された場合、最終的には腫瘍形成へとつながる。ラットに おけるこの腫瘍形成 MOA は、科学界では十分に受け入れられており、国際がん研究機関(Capen ら、1999年; IARC、2001年)及び米国環境保護庁(USEPA、1998年)は、げっ歯類における甲 状腺濾胞細胞腫瘍のヒトへの関連性を評価するための独自のガイダンスまたは方針を確立してい る。

除草剤であるチアゾビルは、甲状腺ホルモンのホメオスタシスへ影響することによりラット甲 状腺濾胞細胞腫瘍を誘発するが、これは発がん MOA 解析のための 2001 年の国際化学物質安全性 計画(International Programme on Chemical Safety: IPCS)のオリジナルフレームワークを示すため に用いられた事例である(Sonich-Mullin ら、2001 年)。ここではチアゾビルの MOA を、事例研究 としてここで再検討し、2006 年の IPCS ヒト関連性フレームワーク(HRF)で提供されたヒトの 腫瘍形成 MOA 評価のための追加ガイダンスを説明した。この更新された事例研究では、ある特 定の MOA での経験の蓄積が、その後の解析の難易度をどの程度下げられるのかについて強調し ている。この事例研究は、key events が十分に定義されている確立された MOA に基づいているた め、この解析では、チアゾビルがこの経路で期待されている生物学的効果をもたらすか否かに焦

expected of this pathway. This case-study also emphasizes the importance of understanding the basic physiological processes underlying a toxicity pathway in animals and humans. For some compounds, chemical-specific data might be critical in evaluating the key events in humans. For others, the underlying biology is sufficient to allow interpretation of the human relevance of the carcinogenic MOA, both qualitatively and quantitatively. Thiazopyr is an example of the latter. Another MOA case-study of thyroid hormone disruption and the human relevance of rat thyroid follicular cell tumours is available for phenobarbital (Lehman-McKeeman & Hill, in Meek et al., 2003).

The present MOA analysis begins with a brief summary of the available information on the carcinogenicity of thiazopyr, followed by a discussion of the experimental biochemical and histopathological data considered for this thyroid disruption MOA. It is not intended to be a comprehensive assessment of the chemical per se.

## CARCINOGENICITY DATA

Human epidemiological data on the carcinogenicity of thiazopyr are not available. Thiazopyr produces effects on liver and thyroid in various laboratory species, including mice, rats, and dogs. Thiazopyr was found to induce thyroid tumours in male rats only and appears to do so by increasing the hepatic metabolism and excretion of thyroid hormones.

Chronic dietary administration of thiazopyr to mice and rats resulted primarily in thyroid follicular cell tumours in male rats but not in female rats (Naylor & McDonald, 1992; Naylor & Raju, 1992). There were no significant increases in the incidences of any tumours in either sex in the chronic study of mice treated with thiazopyr at up to 800 mg/kg in the diet (128.4 mg/kg body weight [bw] per day in males and 215.9 mg/kg bw per day in females) (Naylor & Raju, 1992). In the rat carcinogenicity study, thiazopyr (technical, 94.8% pure) was administered to male and female Sprague-Dawley (SD) rats (60 per sex per group) at dietary concentrations of 0, 1, 10, 100, 1000, or 3000 mg/kg, providing dose levels of 0, 0.04, 0.4, 4.4, 44.2, or 136.4 mg/kg bw per day for males and 0, 0.06, 0.6, 5.6, 56.3, or 177.1 mg/kg bw per day for females (Naylor & McDonald, 1992). The incidences of thyroid follicular cell adenomas and carcinomas were increased in male rats of the 1000 mg/kg (44.2 mg/kg bw per day) and 3000 mg/kg to male rats is primarily accounted for by benign tumours.

# POSTULATED MOA FOR THE INDUCTION OF THYROID FOLLICULAR CELL TUMOURS IN RATS

The postulated MOA for thiazopyr-induced thyroid follicular cell tumours involves the perturbation of homeostasis of the pituitary-thyroid axis by an extrathyroidal mechanism. Specifically, thiazopyr induces hepatic thyroxine (T4)-uridine diphosphate (UDP) glucurono-syltransferase (UGT) activity, leading to enhanced metabolism of T4 by conjugation and increased biliary excretion of the conjugated hormone. The result of this enhanced liver metabolism is a decrease in serum T4 (and sometimes triiodothyronine, or T3) half-life. The pituitary gland responds to a decrease in circulating serum levels of T4 by enhancing the output and serum level of TSH. Prolonged elevation of circulating TSH levels stimulates the

点を当てている。この事例研究はまた、動物及びヒトにおける毒性発現の経路の基礎となる生理 学的プロセスを理解することの重要性を強調している。いくつかの化合物では、化学物質特有の データがヒトでの key events を評価する上で重要な場合があるかもしれないが、その他の化合物 については、基礎となる生物学的知見があれば、発がん MOA のヒトへの関連性を定性的にも定 量的にも解釈できる場合がある。チアゾピルは後者の例である。甲状腺ホルモンのかく乱とラッ ト甲状腺濾胞細胞腫瘍のヒトへの関連性に関する他の MOA 事例研究としてフェノバルビタール についての事例研究がある(Lehman-McKeeman & Hill, in Meek ら、2003 年)。

本 MOA 解析は、チアゾピルの発がん性に関する利用可能な情報の簡単な要約から始まり、続いて、この甲状腺ホルモンかく乱 MOA で考察された生化学的及び病理組織学的な実験データの 議論が行われる。本解析は化学物質そのものの包括的な評価を意図したものではない。

## 発がん性データ

チアゾビルの発がん性に関するヒトの疫学的データは得られていない。チアゾビルは、マウス、 ラット及びイヌを含む様々な実験動物種において、肝臓及び甲状腺に影響を及ぼす。チアゾビル は雄ラットにおいてのみ甲状腺腫瘍を誘発することが確認されており、甲状腺ホルモンの肝代謝 及び排泄を増加させることによってこれを引き起こすようである。

チアゾビルはマウス及びラットへの慢性的な混餌投与により、主に雄ラットに甲状腺濾胞細胞 腫瘍を誘発したが、雌ラットでは誘発しなかった(Naylor & McDonald、1992 年; Naylor & Raju、 1992 年)。チアゾビルを最大 800 mg/kg まで混餌投与したマウスの慢性試験(雄では 1 日あたり 128.4 mg/kg 体重[bw]、雌では 1 日あたり 215.9 mg/kg bw)では、いずれの性においても腫瘍の発 生率に有意な増加は認められなかった(Naylor & Raju、1992 年)。ラット発がん性試験では、チア ゾビル(原体、純度 94.8%)を雄及び雌の Sprague-Dawley ラット(SD ラット)(各群雌雄 60 匹ず つ)に 0、1、10、100、1000 または 3000 mg/kg の濃度で混餌投与し、雄では 1 日あたり 0、0.04、 0.4、4.4、44.2、136.4 mg/kg bw、雌では 1 日あたり 0、0.06、0.6、5.6、56.3 または 177.1 mg/kg bw の用量を与えた(Naylor & McDonald、1992)。甲状腺濾胞細胞腺腫及びがんの発生率は、1000 mg/kg (1 日あたり 44.2 mg/kg bw)及び 3000 mg/kg(1 日あたり 136.4 mg/kg bw)投与群の雄ラットで増 加した(表 1)。なお、雄ラットにおける腫瘍発生率の増加は主に良性腫瘍によるものであったこ とに留意すべきである。

## ラットにおける甲状腺濾胞細胞腫瘍の誘発において推定される MOA

チアゾビル誘発性甲状腺濾胞細胞腫瘍において推定される MOA は、甲状腺外における機序に よる下垂体-甲状腺軸のホメオスタシスの乱れを含むものであった。具体的な流れを以下に述べる。 チアゾビルは肝臓におけるチロキシン(T4)-ウリジン二リン酸(UDP)グルクロン酸転移酵素(UGT) 活性を誘導し、抱合による T4 の代謝を促進し、ホルモンの抱合体の胆汁排泄を増加させる。この 肝臓代謝の促進の結果として、血清 T4 及び時にはトリヨードサイロニン(T3)の半減期が減少す る。下垂体は、TSH の放出及び血清レベルを高めることにより、T4 の循環血清レベルの低下に対 応する。循環 TSH レベルの長期的な上昇は、甲状腺を刺激して甲状腺ホルモンの貯蔵を枯渇させ、 ホルモン産生を誘導し続ける。 thyroid gland to deplete its stores of thyroid hormone and continues to induce hormone production. Thus, the thyroid follicular cells enlarge (hypertrophy) and are induced to proliferate at an increased rate and to increase in number (hyperplasia). With chronic exposure, thyroid hyperplasia eventually progresses to neoplasia.

## Table 1. Thyroid follicular cell tumour incidence in Sprague-Dawley male rats (2-year chronic study).

### **KEY EVENTS IN EXPERIMENTAL ANIMALS**

The sequence of key events in thiazopyr's mode of carcinogenic action includes:

- induction of hepatic UGT activity;
- increase in hepatic metabolism and biliary excretion of T4;
- decrease in serum T4 half-life and concentration;
- increase in circulating TSH concentration;
- cellular thyroid hypertrophy and follicular cell hyperplasia.

An evaluation follows to determine whether thiazopyr works via disruption of thyroid– pituitary status by increasing hepatic clearance of circulating thyroid hormone. Thus, based on the key events listed above, biological indicators of thiazopyr's MOA should include changes in liver metabolism, alterations in hormone levels, increases in thyroid growth, and lesion progression in the thyroid. These effects have been observed and measured in male rats in short-term and subchronic studies, and at interim and terminal sacrifices in a chronic study (Hotz et al., 1997). The dose–response and temporal analyses of the key events and tumour response are presented below.

#### **DOSE-RESPONSE RELATIONSHIP AND CONCORDANCE**

A summary of the no-observed-adverse-effect levels (NOAELs) and lowest-observedadverse-effect levels (LOAELs) for the key effects in thiazopyr's MOA are provided in Table 2. In the 56-day study by Hotz et al. (1997), male SD rats (20 per dose) were fed diets containing thiazopyr at 0, 10, 30, 100, 300, 1000, or 3000 mg/kg (doses not measured, but その結果、甲状腺濾胞細胞は大きくなり(肥大)、高い増殖率で細胞数を増やす(過形成)ように 誘導される。慢性的なチアゾビルのばく露により、甲状腺過形成は最終的には腫瘍へと進行する。

## 表 1. Sprague-Dawley 雄ラットにおける甲状腺濾胞細胞腫瘍の発生率(2年間の慢性試験)

#### 実験動物における key events

チアゾピルの発がん MOA における一連の key events には、以下のものが含まれる。

- T4の肝臓での代謝及び胆汁排泄の増加
- 血清 T4 の半減期及び濃度の低下
- 循環 TSH 濃度の上昇
- 甲状腺濾胞細胞肥大及び濾胞細胞過形成

次に、チアゾビルが、循環甲状腺ホルモンの肝クリアランスを増加させて甲状腺-下垂体軸を乱 すことによって作用するかどうかを評価する。上記の key events に基づき、チアゾビルの MOA の 生物学的指標は、肝臓代謝の変化、ホルモンレベルの変化、甲状腺の成長の増加及び甲状腺の病 変の進行が挙げられることになる。これらの影響は、短期及び亜慢性試験さらに慢性試験におけ る中間及び計画殺において、雄ラットで観察され、測定されている(Hotz ら、1997 年)。Key events 及び腫瘍反応の用量反応性を以下に示す。

## 用量反応関係及び一致性

チアゾビルの MOA における主要な影響について、無毒性量(NOAEL)及び最小毒性量(LOAEL) の概要を表2に示す。Hotz ら (1997)による56日間の試験では、雄SD ラット(各群20匹)に、 チアゾビルを0、10、30、100、300、1000、または3000 mg/kgの濃度で(測定されていないが、 チアゾビルの摂取量は1日あたり0、0.5、1.5、5、50及び150 mg/kg bwと推定される)を56 日間混餌投与し、肝臓(重量、肝T4-UGT活性、T4胆汁排泄)、甲状腺(重量、肥大/過形成)及 びホルモン(T4、T3、リバースT3(rT3)及びTSHの血清レベル)に対する影響を評価した。こ の試験では、チアゾビルの主要作用部位である肝臓への影響が、下垂体-甲状腺のホメオスタシス のかく乱の最も敏感な指標であると考えられる。50 mg/kg bw/day 投与群及び150 mg/kg bw/day 投

estimated to be 0, 0.5, 1.5, 5, 15, 50, and 150 mg/kg bw per day) for 56 days and evaluated for the effects on liver (weights, T4-hepatic UGT activity, T4 biliary elimination), thyroid (weights, hypertrophy/hyperplasia), and hormones (serum levels of T4, T3, reverse T3, or rT3, and TSH). In this study, the effects on liver, thiazopyr's primary site of action, appear to be the most sensitive indicator of pituitary-thyroid homeostasis perturbation. Statistically significant increases in hepatic T4-UGT activity in the 50 and 150 mg/kg bw per day groups (approximately 3- and 6-fold increases in activity over controls when adjusted for liver weight, respectively) were found at the end of the 56-day treatment period. Consistent with the increase in T4-UGT activity, clearance of T4 from the blood and elimination in bile (40% increase in excretion of <sup>125</sup>I-labelled T4) were increased after 150 mg/kg bw per day of thiazopyr (only dose evaluated). Statistically significant increases in liver weight were found at 15, 50, and 150 mg/kg bw per day of thiazopyr in the 56-day study in male rats by Hotz et al. (1997). In the 2-year rat study (Naylor & McDonald, 1992), absolute liver weights were increased by 122% at 44.2 mg/kg bw per day and by 178% at 136.4 mg/kg bw per day relative to controls. There were also statistically significant increases in the incidence of liver hypertrophy at 44.2 and 136.4 mg/kg bw per day (47/61 and 52/60 versus 0/60 in controls, respectively) in the 2-year rat study.

## Table 2. Summary of effects on liver, hormones, and thyroid from a 56-day study (Hotz et al., 1997) and the 2-year chronic study (Naylor & McDonald, 1992) in male rats.

Effect	NOAEL/LOAEL
Liver	
Induction of UGT	15/50 mg/kg bw per day (56-day study)
Increase in T4 biliary elimination	<150/150 mg/kg bw per day (only dose tested in 56-day study)
Increase in liver weight	5/15 mg/kg bw per day (56-day study)
	44.2/136.4 mg/kg bw per day (2-year study)
Hepatocellular hypertrophy	4.4/44.2 mg/kg bw per day (2-year study)
Hormones	
Decrease in serum T4	50/150 mg/kg bw per day (56-day study)
Increase in serum TSH	50/150 mg/kg bw per day (56-day study
Thyroid	
Increase in thyroid weight	15/50 mg/kg bw per day (56-day study)
	44.2/136.4 mg/kg bw per day (2-year study)
Increase in thyroid hyperplasia	44.2/136.4 mg/kg bw per day (2-year study)
Increase in thyroid tumours	4.4/44.2 mg/kg bw per day (2-year study)

Consistent with the enhanced hepatic clearance of T4 described above, when Hotz et al. (1997) treated male SD rats with doses of thiazopyr, statistically significant ( $P \le 0.05$ ) decreases in serum T4 levels (by 30%) and increases in TSH (by 60%) were found after 56 days of treatment at the highest dose tested (Table 3). T3 serum levels were non-significantly lower at 1.5 mg/kg bw per day and statistically significantly higher at 150 mg/kg bw per day after 56 days of treatment. In general, hepatic microsomal enzyme inducers appear to affect T3 less than T4; thus, T4 and TSH tend to be more reliable indicators of altered pituitary–

#### IPCS Framework for Analysing the Relevance of a Cancer Mode of Action for Humans and Case-Studies

与群では、肝 T4-UGT 活性が 56 日間の投与期間終了時に統計学的に有意に増加した(肝重量で標準化したところ、対照群と比較してそれぞれ約3倍と6倍に活性が増加した)。T4-UGT 活性の増加と一致して、血中からのT4のクリアランス及び胆汁中への排泄(125I標識T4の排泄量)は、 チアゾピルを150 mg/kg bw/day 投与後に40%増加した(150 mg/kg bw/day が評価された唯一の投 与量)。Hotz ら(1997年)による雄ラットを対象とした 56 日間の試験では、チアゾピルを1日あ たり15、50 及び150 mg/kg bw 投与した場合に、肝重量の統計学的に有意な増加が認められた。 ラット2年間の試験(Naylor & McDonald、1992年)では、絶対肝重量は対照群と比較して、44.2 mg/kg bw/day 投与群で122%、136.4 mg/kg bw/day 投与群で178%増加した。また、このラットの2 年間試験では、44.2 及び136.4 mg/kg bw/day 投与群で肝肥大の発生率が統計的に有意に増加した (対照群の0/60に対してそれぞれ 47/61 及び 52/60)。

## 表 2. 雄ラットを対象とした 56 日間の試験(Hotz ら、1997)及び 2 年間の慢性試験(Naylor & McDonald、1992)から得られた肝臓、ホルモン及び甲状腺に対する影響の概要

-	······································	
	影響	NOAEL/LOAEL
	肝臓	
	UGT の誘導	15/50 mg/kg bw/day (56 日間試験)
	T4 の胆汁排泄量の増加	<150/150 mg/kg bw/day (56 日間試験において 150 mg/kg bw/day のみ
	身	厚施された)
	肝臓重量の増加	5/15 mg/kg bw/day (56 日間試験)

	甲状腺腫瘍の増加	4.4/44.2 mg/kg bw/day (2 年間試驗)

Hotz ら (1997) が雄 SD ラットにチアゾビルを投与したとき、上述した T4 の肝クリアランスの 亢進と同様に、最高用量の投与 56 日後に血清 T4 濃度の統計学的に有意な (P $\leq$ 0.05) 減少 (30%減 少) と TSH の増加 (60%増加) が認められた (表 3)。T3 の血清レベルは、1.5 mg/kg bw/day では 56 日投与後に統計学的に有意ではないものの低下し、150 mg/kg bw/day では有意に上昇した。一 般に、肝ミクロソーム酵素誘導剤による影響は T4 よりも T3 に影響を与えにくいようである。し たがって、T4 及び TSH は、下垂体-甲状腺のホメオスタシスの変化の指標としてはより信頼性の 高い傾向がある (Liu ら、1995 年、Hurley ら、1998 年、Hood ら、1999 年)。

thyroid homeostasis (Liu et al., 1995; Hurley et al., 1998; Hood et al., 1999). In the case of thiazopyr, there appears to be a poor correlation between the doses causing the T4 and TSH effects and those causing an increased incidence of thyroid follicular cell tumours. The lowest dose of thiazopyr producing a statistically significant (P < 0.05) increase in thyroid follicular cell tumours in male SD rats was 44.2 mg/kg bw per day in the 2-year study, whereas the NOAEL for effects on T4 and TSH was 50 mg/kg bw per day in the 56-day study (Table 2). Generally, effects on liver enzymes/weight and pituitary-thyroid hormone concentrations would be anticipated to occur at doses at least as low as those that produce thyroid weight changes and increases in thyroid tumour incidence, given that this thyroid disruption MOA is a threshold phenomenon. This apparent discrepancy is probably not real, because neither of the doses quoted is accurate. In the 2-year study, the milligrams per kilogram body weight doses were averaged estimates for the entire study, whereas the relevant doses for comparison with the 56-day mechanistic study are those for rats of 12–20 weeks of age. These doses would have been at least 2-fold higher than those that were readily available (so the real LOAEL for neoplasia would have been about 90 mg/kg bw per day). They would also have been more relevant for neoplasia, because the critical period for hormonal perturbations (e.g. prolonged elevation of TSH) to initiate pathological changes would be early, not late, in the 2-year study. The doses calculated for the 56-day study are also likely to be inaccurate, because food intake information was not available in the publication; the doses are estimates based on assumed intakes. Having acknowledged this uncertainty, it is observed that thyroid weights were increased significantly at 50 mg/kg bw per day and liver weights were increased at 15 mg/kg bw per day, which is consistent with the liver being the initial target in thiazopyr's MOA.

#### Table 3. Fifty-six-day study in male rats: Hormonal effects (Hotz et al., 1997).

	Dose (mg/kg bw per day) <sup>a</sup>						
	0	0.5	1.5	5	15	50	150
T4 (µg/dl)	4.1 ± 0.2	4.3 ± 0.3	3.9 ± 0.2	4.1 ± 0.2	4.0 ± 0.2	4.0 ± 0.2	2.9 ± 0.1 <sup>a</sup>
T3 (ng/dl)	84 ± 3	82 ± 4	68 ± 2	84 ± 3	82 ± 3	91 ± 4	$110 \pm 6^{a}$
TSH (ng/ml)	2.7 ± 0.2	$3.5 \pm 0.4$	2.7 ± 0.1	3.1 ± 0.4	2.9 ± 0.3	3.1 ± 0.2	$4.3 \pm 0.4^{a}$

Note: The mg/kg bw per day doses were estimated. Values are mean  $\pm$  standard error of the mean; 19 or 20 animals per group.

<sup>a</sup> Significantly different from control with Dunnett's test after analysis of variance (ANOVA) ( $P \le 0.05$ ).

As stated above, prolonged TSH stimulation leads to both hypertrophy and hyperplasia of the thyroid. In the 2-year rat study, there was a poor dose correlation between thyroid hyperplasia alone and tumour incidence. While tumour incidence was increased at 44.2 mg/kg bw per day, a statistically significant increase in the incidence of hyperplasia (8/58 versus 1/60 in controls) was found only at 136.4 mg/kg bw per day. Furthermore, in the 56-day rat study, where thyroid histology was reported as follicular cell hypertrophy and hyperplasia combined, there was a significant increase in the incidence of this diagnosis at 150 mg/kg bw per day but not at lower doses (Hotz et al., 1997). There was, however, a good dose correlation between increases in thyroid weights in the 56-day study and tumour incidence in the 2-year study. Statistically significant increases in thyroid weights of 46% were found at 150 mg/kg bw per day and 25% at 50 mg/kg bw per day (Hotz et al., 1997).

チアゾピルの場合、T4 及び TSH に影響を及ぼす用量と、甲状腺濾胞細胞腫瘍の発生率の増加を 引き起こす用量との間には、相関関係が乏しいようである。雄 SD ラットにおいて甲状腺濾胞細 胞腫瘍の統計学的に有意(P<0.05)な増加をもたらしたチアゾピルの最低用量は、2年間の試験で は 1 日当たり 44.2 mg/kg bw であったが、T4 及び TSH に対する影響の NOAEL は 56 日間の試験 では1日当たり50mg/kg bwであった(表2)。一般的に、肝酵素/肝重量及び下垂体-甲状腺ホル モン濃度への影響は、この甲状腺ホルモンかく乱 MOA が閾値を有する現象であることを考える と、少なくとも甲状腺の重量変化及び甲状腺腫瘍発生率の増加をもたらす用量と同程度の低用量 で起こると予想される。引用された投与量のどちらも正確ではないので、この見かけの不一致は おそらく真ではない。2年間の試験における体重1kg当たりの投与量は、試験期間全体の平均的 な推定値であったのに対し、比較に用いられた56日間のメカニズム試験での投与量は、12~20週 齢のラットにおけるものである。これらの投与量は、容易に算出可能な投与量よりも少なくとも 2 倍高かったと考えられる(したがって、腫瘍に対する実際の LOAEL は 1 日あたり約 90 mg/kg bw であったはずである)。また、ホルモンのかく乱(例えば TSH の長期上昇)が病理学的変化を もたらし始める臨界期は、2 年間の試験において後期ではなく早期であったため、これらの投与 量は腫瘍に対する関連性も高かったと考えられる。56日間の試験で計算された投与量は公表され た論文からは摂餌量の情報が入手できなかったため、摂餌量の推定値に基づいて計算された。そ のためこれについても不正確である可能性が高い。この不確実性を認識した上で、1 日あたり 50 mg/kg bw で甲状腺重量が有意に増加し、1日あたり 15 mg/kg bw で肝臓重量の増加が認められた が、これはチアゾピルの MOA では最初のターゲットが肝臓であることと一致している。

表 3. 雄ラットにおける 56 日間の試験:ホルモン作用(Hotz ら、1997年)

	Dose (mg/kg bw per day) <sup>a</sup>						
	0	0.5	1.5	5	15	50	150
T4 (µg/dL)	$4.1\pm0.2$	$4.3\pm0.3$	$3.9\pm 0.2$	$4.1\pm0.2$	$4.0\pm0.2$	$4.0\pm0.2$	$2.9\pm0.1^a$
T3 (ng/dL)	$84\pm3$	$82\pm4$	$68\pm2$	$84\pm3$	$82\pm3$	$91\pm 4$	$110\pm 6^a$
TSH (ng/mL)	$2.7\pm0.2$	$3.5\pm 0.4$	$2.7\pm0.1$	$3.1\pm 0.4$	$2.9\pm0.3$	$3.1\pm 0.2$	$4.3\pm0.4^a$
注:投与量 mg/kg							は20匹。

<sup>a</sup>分散分析 (ANOVA)後のDunnettの検定で対照群と統計学的に有意に異なる (P≦0.05)。

上述のように、長期のTSH 刺激は甲状腺の肥大と過形成の両方を引き起こす。ラットの2年間の試験では、甲状腺肥大のみと腫瘍発生率との間には用量相関性は見られなかった。腫瘍発生率は44.2 mg/kg bw/day 投与群で増加したが、過形成の発生率の統計学的に有意な増加(対照群 1/60 に対し 8/58)は136.4 mg/kg bw/day 投与群でのみ認められた。さらに、ラットの56日間の試験では、組織学的に甲状腺濾胞細胞肥大と過形成が併発しており、150 mg/kg bw/day 投与群での発生率は統計学的に有意に増加したが、それ以下の用量では増加しなかったと報告されている(Hotz ら、1997 年)。しかし、56日間の試験での甲状腺重量の増加と2年間の試験での腫瘍発生率との間には良好な用量相関性があった。150 mg/kg bw/day 投与群で 46%、50 mg/kg bw/day 投与群で 25%の統計学的に有意な甲状腺重量の増加が認められた(Hotz ら、1997 年)。

#### **TEMPORAL RELATIONSHIP**

If an event (or events) is an essential element of tumorigenesis, it must precede tumour appearance. Multiple exposure time data at 7, 14, 28, 56, and 90 days are available in which male SD rats were offered diets containing thiazopyr at 3000 mg/kg (150 mg/kg bw per day) (Hotz et al., 1997). Liver weights and hepatic T4-UGT activity were increased at all observation times from the earliest time of assessment on day 7. Biliary excretion of conjugated T4 was not measured in this experiment; however, serum T4 was reduced at all observation times. Increases in circulating TSH were observed at all sampling times, although the increase was not significant at 14 days after treatment began. Increases in thyroid weight were also observed at all sampling times. Histologically, there was a time-related increase in hypertrophy/hyperplasia beginning at 14 days. In the 2-year rat study, the first thyroid adenoma was observed at week 69 at a dose of 136.4 mg/kg bw per day. Thus, there is a logical temporal response for the key events in thiazopyr-induced thyroid follicular cell tumour formation in which all key events precede tumour formation.

# STRENGTH, CONSISTENCY, AND SPECIFICITY OF ASSOCIATION OF THE TUMOUR RESPONSE WITH KEY EVENTS

Strength, consistency, and specificity of the association can be established from the studies described above. The quantifiable precursor events, fundamental to the proposed MOA, are relatively consistent with the emergence of thyroid follicular cell tumours. Observation of liver weight increase and induction of hepatic T4-UGT in rats receiving the thiazopyr in the diet would be consistent with perturbation of homeostasis of the pituitary-thyroid axis by an extrathyroidal mechanism. An increase in hepatic T4-UGT activity is a step occurring before the other key biochemical changes and before thyroid follicular cell hypertrophy and hyperplasia. Thiazopyr treatment clearly results in a decrease in circulating T4 and an increase in TSH following enhanced liver metabolism of T4. Furthermore, in subchronic studies, the increases in thyroid weight and the development of hypertrophy/hyperplasia were shown to appear to a statistically significant degree under the same conditions of dose and time as the appearance and reversal of changes in thyroid hormone levels and thyroid hormone metabolism. Stop/recovery studies (Hotz et al., 1997) showed that cessation of thiazopyr dosing was followed by a return of hormone levels to control values, as well as a reduction in liver and thyroid weights and reversal of hyperplasia of thyroid follicular cells. Early dosing withdrawal would be expected to result in a reversal of hypothyroidism and of lesion progression for this non-genotoxic MOA. The only sign that was slow to reverse was the increase in thyroid weight after the longest dosing period.

#### **BIOLOGICAL PLAUSIBILITY AND COHERENCE**

There are considerable data from studies in laboratory rodents demonstrating the relationship between sustained perturbation of the hypothalamic–pituitary–thyroid axis, prolonged stimulation of the thyroid gland by TSH, and the progression of thyroid follicular cells to hypertrophy, hyperplasia, and eventually neoplasia (McClain, 1995; Hard, 1998; Hurley et al., 1998; Capen et al., 1999; IARC, 2001). Increased secretion of TSH may result via several mechanisms, including increased hepatic clearance of T4, as is the case with thiazopyr.

### 時間的関連性

ある事象が腫瘍形成の必須要素である場合、それは腫瘍の発生に先行して発現しなければなら ない。雄 SD ラットに 3000 mg/kg (1日あたり 150 mg/kg bw)のチアゾピルを混餌投与した 7、14、 28、56 及び 90 日後といった複数のタイミングにおけるデータが利用可能である(Hotz ら、1997 年)。肝重量増加及び肝 T4-UGT 活性上昇は、最も早く測定した 7 日目から全ての測定時期におい て認められた。この実験では抱合化 T4 の胆汁排泄は測定されなかったが、血清 T4 はすべての観 察時期において減少した。循環 TSH の増加は、投与開始後 14 日目においては有意ではなかった が、すべてのサンプリング時期で観察された。甲状腺重量の増加もすべてのサンプリング時期で 観察された。組織学的には、14 日目から肥大/過形成の経時的な増加が認められた。2 年間のラッ ト試験では、1 日あたり 136.4 mg/kg bw を投与した 69 週目に最初の甲状腺腺腫が観察された。こ のように、チアゾピル誘発性甲状腺濾胞細胞腫瘍形成においては、すべての key events が腫瘍形 成に先行するという論理的な経時的反応が認められた。

#### 腫瘍反応と key events との関連性の強さ、一貫性及び特異性

この関連性の強さ、一貫性、特異性は、上述の試験から確立できる。推定される MOA の基礎と なる定量可能な前駆事象は、甲状腺濾胞細胞腫瘍の発現と比較的一致している。チアゾピルを混 餌投与されたラットにおいて、肝重量の増加及び肝 T4-UGT の誘導が観察されることから、甲状 腺外の機序による下垂体-甲状腺軸のホメオスタシスのかく乱と一致しているようである。肝 T4-UGT 活性の上昇は、他の重要な生化学的変化や甲状腺濾胞細胞の肥大及び過形成の前に起こる段 階である。チアゾピルの投与は肝臓における T4 の代謝が促進されるため、循環 T4 の減少及び TSH の増加が明らかである。さらに、亜慢性試験では、甲状腺重量の増加及び肥大・過形成の発 生は、甲状腺ホルモン濃度及び甲状腺ホルモン代謝の変化の出現や回復と同じ用量及び時間の条 件下で統計学的に有意な程度で現れることが示された。中止/回復試験(Hotz ら、1997 年)では、 チアゾピルの投与中止後、ホルモン値がコントロール値に戻り、肝臓と甲状腺の重量が減少し、 甲状腺濾胞細胞の過形成が回復することが示された。早期に投与を中止することで、この非遺伝 毒性 MOA における甲状腺ホルモンの低下と病変の進行が回復することが期待された。唯一回復 が遅くなったのは、最も長い投与期間の後の甲状腺重量の増加であった。

#### 生物学的妥当性及び整合性

実験用のげっ歯類を用いた研究から、視床下部-下垂体-甲状腺軸の持続的なかく乱、TSH による甲状腺への長期的な刺激及び甲状腺濾胞細胞の肥大、過形成、最終的な腫瘍への進行との関係を示すデータが数多く存在する(McClain、1995年; Hard、1998年; Hurley ら、1998年; Capen ら、1999年; IARC、2001年)。チアゾピルの場合と同様に、TSH の分泌増加は、T4 の肝クリア ランスの増加を含むいくつかのメカニズムを介して生じる可能性がある。

35

Circulating levels of T4 are monitored by the thyrotropic cells of the pituitary gland that are responsible for the synthesis of TSH. In the pituitary gland, T4 is metabolized by 5'-deiodinase type II to T3, which then binds to specific receptors in the cell nucleus. A decrease in T3 receptor occupancy results in stimulation of TSH synthesis and secretion. Studies in vivo have shown that injection of rats with TSH leads to reductions in thyroid follicular cell nuclear statin, a non-proliferation-specific nuclear antigen, indicating that these cells were leaving the non-dividing state to resume the cell cycle (Bayer et al., 1992). This study showed that low, repeated doses of TSH (0.25 IU per rat twice daily) produced a cumulative response in nuclear statin levels over 10 days, which returned to normal resting levels within 5 days of cessation of TSH injections. Reduction in nuclear statin is also an early event that parallels the earliest known pinocytotic response to TSH. These data are consistent with increased TSH concentrations alone causing thyroid follicular cells of rats to enter a state of preproliferation. Therefore, the suggestion that thiazopyr causes thyroid follicular cell neoplasms in rats by initially inducing hepatic T4-UGT is coherent with the known physiology of the hypothalamus-pituitary-thyroid dynamic control system, at least to the stage of hypertrophy and hyperplasia.

Lastly, the tumour response elicited by thiazopyr is typical of a rodent thyroid carcinogen, in that thyroid follicular cell tumours are found in male rats but not in female rats or mice. Rats tend to be more sensitive to thyroid carcinogenesis than mice, and male rats are frequently found to be more sensitive than female rats with respect to the proportion of chemicals that induce thyroid tumours (Hurley et al., 1998). In keeping with this, TSH levels are typically higher in male rats than in females (Hill et al., 1989). In addition, male rats are sometimes more prone to hepatic enzyme induction than females of the same strain, but this depends on the enzyme in question, the dose of the inducing compound, and the age of the animals (Sundseth & Waxman, 1992; Agrawal & Shapiro, 1996; Oropeza-Hernandez et al., 2003).

### **OTHER MODES OF ACTION**

Mutagenesis is always one possible MOA to consider, but no genetic toxicity has been demonstrated for thiazopyr in the following tests:

- mutation in four strains of *Salmonella typhimurium* (Bakke, 1989a);
- mutation at the *hgpt* locus of Chinese hamster ovary cells (Li & Myers, 1989);
- micronucleus induction in bone marrow cells of mice treated in vivo (Flowers, 1990);
- unscheduled DNA synthesis induction in hepatocytes of rats treated in vivo (Bakke, 1989b).

Therefore, the available evidence indicates that mutagenesis is not an alternative MOA for thiazopyr.

Additional effects on the hypothalamic–pituitary–thyroid axis and disruption of other pathways of thyroid hormone metabolism are other possibilities for altering thyroid homeostasis. These variations would not differ in any fundamental way from the one that has been proposed for thiazopyr, in that all would lead to prolonged TSH stimulation with continuous exposure.

#### Harmonization Project Document No. 4

T4 の循環レベルは、TSH の合成を担う下垂体の甲状腺刺激細胞によってモニターされている。 下垂体では、T4 は、5-dried-deio-dinase(ヨウ素ペルオキシダーゼ)II 型によりT3 に代謝され、T3 は細胞核内の特定の受容体に結合する。T3 受容体の占有率が低下すると、TSH 合成と分泌が刺激 される。ラットへのTSH の注射が、非増殖細胞特異的核抗原である甲状腺濾胞細胞核スタチンが 減少し、これらの細胞が非分裂状態を脱して細胞周期を再開していることが生体内での研究で示 されている(Bayer ら、1992 年)。この試験では、低用量のTSH を反復投与(ラット1匹あたり 0.25 IUを1日2回)すると、核内スタチンレベルが10日間にわたって累積反応が生じ、TSHの 注射を中止してから5日以内に正常な安静時のレベルに戻ることが示された。核内スタチンの減 少もまた、TSH に対する最も早い反応として知られているピノサイトーシスと類似した初期の事 象である。これらのデータは、TSH 濃度の増加だけでラットの甲状腺濾胞細胞を増殖前の状態に なることと矛盾しない。したがって、チアゾビルが最初に肝T4-UGTを誘導することでラットの 甲状腺濾胞細胞腫瘍を引き起こすという指摘は、少なくとも肥大と過形成の段階までは視床下部 下垂体-甲状腺の動的な制御システムに関する既知の生理学的知見と一致している。

最後に、チアゾビルにより誘発される腫瘍反応はげっ歯類の甲状腺発がん物質の典型的なもの であり、甲状腺濾胞細胞腫瘍は雄ラットにはみられるが、雌のラットやマウスには認められない。 ラットはマウスよりも甲状腺発がん物質に対し感受性が高い傾向があり、さらに、雄ラットは雌 ラットよりも甲状腺腫瘍を誘発する化学物質の割合が大きいことがよくみられている (Hurley ら、 1998年)。このことと一致して、TSH レベルは通常雄ラットの方が雌よりも高い (Hill ら、1989 年)。さらに、雄ラットは時に同系統の雌よりも肝酵素が誘導されやすいことがあるが、これは酵 素の種類、酵素誘導を起こす化合物の用量や動物の年齢に依存する (Sundseth & Waxman、1992年; Agrawal & Shapiro、1996年; Oropeza-Hernandez ら、2003年)。

#### その他の MOA

変異原性は常に考慮すべき可能性のある MOA の 1 つであるが、以下の試験においてチアゾピルの遺伝毒性は示されていない。

- ネズミチフス菌 (Salmonella typhimurium) の4つの菌株を用いた突然変異試験 (Bakke、1989 年 a)。
- チャイニーズハムスター卵巣細胞を用いたの突然変異試験(hgpt 座位)(Li & Myers、1989 年)。
- マウスの骨髄細胞を用いた In vivo 小核試験(Flowers、1990年)。
- ラットの肝細胞を用いた In vivo 不定期 DNA 合成試験(Backke、1989 年 b)。

したがって、利用可能なエビデンスは、突然変異誘発がチアゾピルの代替 MOA ではないこと を示している。

その他の視床下部-下垂体-甲状腺軸への影響及び甲状腺ホルモン代謝における他の経路のかく 乱は、甲状腺のホメオスタシスを変化させる可能性がある。しかし、これらの変化は、チアゾピ ルについて推定されているものと根本的には変わらず、すべて継続的なばく露による TSH 刺激の 長期化につながっているであろう。

#### UNCERTAINTIES, INCONSISTENCIES, AND DATA GAPS

There appears to be a lack of dose concordance for thyroid tumours and hormone changes, but this is likely to be due to inaccuracies in the milligrams per kilogram body weight doses compared—which either were estimated (versus calculated on the basis of food consumption and body weight data) and cover an early period in the life of rats or were averages for the whole duration of the experiment—as well as experimental variability.

## **ASSESSMENT OF POSTULATED MODE OF ACTION**

The data presented are judged, with a moderately high degree of confidence, to be adequate to explain the development of thyroid follicular cell tumours in male rats following chronic dietary exposure to thiazopyr. Thiazopyr clearly increased liver weights (i.e. the initial target organ) at doses lower than those causing tumours and enhanced thyroid growth (i.e. increased thyroid weights) at the lowest tumorigenic dose.

### Human applicability of the proposed MOA

The IPCS HRF, which was developed from the Risk Science Institute/International Life Sciences Institute "Human Relevance Framework" (Meek et al., 2003) and modified based on discussions by the IPCS Cancer Working Group (Boobis et al., current document), presents a four-part approach to addressing a series of three questions and leading to a documented, logical conclusion regarding the human relevance of the MOA underlying animal tumours.

*1. Is the weight of evidence sufficient to establish a mode of action (MOA) in animals?* As described in detail above, there is clear evidence that thiazopyr alters thyroid homeostasis by UGT induction, by reducing serum T4 levels and consequently elevating serum TSH.

2. Can human relevance of the MOA be reasonably excluded on the basis of fundamental, qualitative differences in key events between experimental animals and humans? The current understanding of the regulation of thyroid hormone homeostasis in humans and of the role of increased TSH levels (as a result of altered thyroid homeostasis) as a risk factor for thyroid cancer was considered in order to assess the human relevance of the key events in thiazopyr's animal mode of carcinogenic action. Although there are substantial quantitative dynamic differences (discussed below), the fundamental mechanisms involved in the function and regulation of the hypothalamic-pituitary-thyroid axis in rats are qualitatively similar to those in humans (Bianco et al., 2002). Therefore, an agent that decreases T4 levels in rats could likewise reduce T4 in humans; this, in turn, could potentially lead to an increase in TSH levels. There are data showing that rodents and humans respond in a similar fashion to perturbations of pituitary-thyroid function. For example, it is well known that iodine deficiency, which readily leads to decreased thyroid hormone levels, stimulates thyroid cell proliferation in humans, leading to goitre. If left untreated, iodine deficiency may lead to tumour formation, albeit rarely (Thomas & Williams, 1999). Although there is no evidence of increased susceptibility to thyroid cancer, a number of pharmaceuticals (e.g. propylthiouracil, lithium, amiodarone, iopanoic acid) that disrupt thyroid homeostasis by acting directly on the thyroid gland (e.g. by inhibiting hormone synthesis or release or by blocking the conversion

## 不確実性、矛盾、データギャップ

甲状腺腫瘍とホルモンの変化には用量の一致がみられないが、これは比較に用いられた体重 1 kg 当たりのミリグラム投与量(摂餌量と体重値から算出された)が不正確であること、比較した 投与量が一方は若齢期のラットにおける平均値であり、もう一方が試験全体の平均値であったこ と、また、試験間のばらつきなどに起因している可能性がある。

## 推定される MOA の評価

提示されたデータは、中程度に高い信頼度で、チアゾビルの混餌投与による慢性ばく露後の雄 ラットにおける甲状腺濾胞細胞腫瘍の発生を説明するのに十分であると判断される。チアゾビル は、腫瘍を引き起こす用量よりも低い用量で明らかに肝臓重量を増加させ(すなわち、肝臓が最 初の標的臓器である)、腫瘍を誘発させる中で最も低い用量で甲状腺の成長(すなわち、甲状腺重 量の増加)を促進させた。

## 推定される MOA のヒトへの適用可能性

IPCS HRF はリスクサイエンス研究所/国際生命科学研究機構の「ヒト関連性フレームワーク」 (Meek ら、2003 年)をもとに開発され、「IPCS がんワーキンググループ」の議論をもとに修正さ れたものであり(Boobis ら,本書)、一連の3つの問いかけに対処し、動物の腫瘍における MOA のヒトへの関連性に関する文書化された論理的な結論を導くための4つの部分からなるアプロー チを提示している。

1. 動物 MOA を確立するのにエビデンスの重み付けは十分か?上で詳述したように、チアゾピルは UGT 誘導により血清 T4 レベルを低下させ、その結果として血清 TSH を上昇させることで、 甲状腺ホルモンのホメオスタシスを変化させるという明確なエビデンスがある。

2. 実験動物とヒトとの間のkey events の根本的、質的な違いに基づいて、MOA のヒトとの関連 *性を合理的に排除することができるか*?ヒトにおける甲状腺ホルモンのホメオスタシスの調節に 関する現在の理解と、(甲状腺ホルモンのホメオスタシスの変化の結果としての) TSH レベルの上 昇が甲状腺がんのリスク因子として果たす役割について、チアゾピルの動物における発がん MOA の key events のヒトへの関連性を評価するために検討がなされた。ラットにおける視床下部-下垂 体-甲状腺軸の機能と調節に関与する基本的なメカニズムは、量的な薬力学的差異(後述)はある が、定性的にはヒトのそれと類似している(Biancoら、2002 年)。したがって、ラットで T4 レ ベルを低下させる薬剤は、ヒトでも同様にT4を低下させる可能性があり、その結果、TSH レベル の上昇につながる可能性がある。げっ歯類とヒトは、下垂体-甲状腺機能のかく乱に対して同様の 反応を示すデータがある。例えば、甲状腺ホルモンのレベルを容易に低下させるヨウ素欠乏症は、 ヒトでは甲状腺細胞の増殖を刺激して甲状腺腫を引き起こすことが知られている。ヨウ素欠乏症 を放置すると、まれではあるが腫瘍形成につながることがある(Thomas & Williams、1999年)。甲 状腺がんになりやすいというエビデンスはないが、甲状腺に直接作用して(例えば、ホルモン合 成や放出を阻害する、T4からT3への変換を阻害する)甲状腺ホルモンのホメオスタシスを乱す 多くの医薬品(プロピルチオウラシル、リチウム、アミオダロン、イオパノ酸など)は、ヒトでは 甲状腺ホルモンの低下及び TSH の上昇につながることが知られている(Ron ら、1987年)。

of T4 to T3) are known to lead to hypothyroidism and increases in TSH in humans (Ron et al., 1987).

In contrast to rats, no increases in TSH levels have been found in humans following exposure to agents that induce hepatic microsomal enzymes and reduce circulating T4 levels (discussed in Lehman-McKeeman & Hill, in Meek et al., 2003). For example, the pharmaceutical compounds phenytoin, rifampin, and carbamazepine induce hepatic microsomal enzymes, including UGT, and reduce circulating T4 levels, but TSH levels are unchanged (Curran & DeGroot, 1991); agents that produce thyroid tumours in rats by increasing glucuronidation and biliary excretion of T4 at high experimental doses (e.g. omeprazole, lansoprazole, and pantoprazole) produce no changes in thyroid hormones at clinical doses in humans (Masubuchi et al., 1997). Thus, there appears to be a substantial difference in the dose–response relationship for altered homeostasis of the pituitary–thyroid axis in rats compared with humans. As discussed below, this observation is due to quantitative dynamic differences between rats and humans in the basic physiological processes underlying pituitary–thyroid function.

3. Can human relevance of the MOA be reasonably excluded on the basis of quantitative differences in either kinetic or dynamic factors between experimental animals and humans? Thiazopyr does not target the thyroid directly. Rather, its primary effect is on hepatic metabolizing enzymes, and the increase in metabolic activity indirectly increases the systemic clearance of T4, leading to the hypothyroid state and the compensatory increase in TSH found in rats. Although there are no chemical-specific data on the potential for thiazopyr to disrupt thyroid hormone homeostasis in humans, a number of other microsomal enzyme inducers have been extensively studied, such as phenobarbital (Lehman-McKeeman & Hill, in Meek et al., 2003). As discussed above, agents that produce hypothyroidism by altering hepatic clearance of T4 do not appear to result in elevated TSH levels in humans. Presumably, TSH is not increased because a critical reduction of T4 is not reached.

There are several important physiological and biochemical differences between rats and humans related to thyroid function. Rats have a smaller reserve capacity of thyroid hormones when compared with humans. The rat has a much shorter thyroid hormone half-life than humans. The half-life of T4 is about 12 h in rats compared with 5–9 days in humans (Dohler et al., 1979). The shorter half-life in rats is likely related to the absence of a high affinity binding globulin for T4 that is present in humans (Hill et al., 1989). In rats, the increased clearance contributes to the need for a higher rate of production of T4 (per unit of body weight) to maintain normal levels of T4. In contrast, in humans, the binding of thyroid hormone to this globulin accounts for a slower metabolic degradation and clearance, which in turn result in the thyroid gland being less active than in rats. The constitutive TSH levels are approximately 25 times higher in rats than in humans, reflecting the higher activity of the pituitary–thyroid axis in rats (Dohler et al., 1979; McClain, 1992). Therefore, humans are quantitatively less sensitive than rats to agents that reduce T4 and lead to elevated TSH. There is no increased risk of thyroid tumour development if TSH is not elevated.

Another difference of rats compared with humans is the histological appearance of the thyroid. This histological difference is related to the higher rate of production of T4 to

ラットとは対照的に、ヒトでは、肝ミクロソーム酵素が誘導され、循環 T4 レベルを低下させる 薬剤にばく露されても TSH レベルの上昇は認められていない(Lehman-McKeeman & Hill, in Meek ら、2003 年)。例えば、医薬品のフェニトイン、リファンピン、カルバマゼピンは、UGT を含む 肝ミクロソーム酵素を誘導し、血中の T4 レベルを低下させるが、TSH レベルは変化しない(Curran & DeGroot、1991 年)。同様に、実験的に高用量で T4 のグルクロン酸抱合及び胆汁排泄を増加さ せることによりラットに甲状腺腫瘍を発生させる薬剤(例えば、オメプラゾール、ランソプラゾ ール、パントプラゾール)は、ヒトにおいて臨床用量では甲状腺ホルモンに変化をもたらさない (Masu-buchi ら、1997 年)。このように、ラットにおける下垂体-甲状腺軸のホメオスタシスの変 化の用量反応関係には、ヒトと比較してかなりの違いがあるように思われる。後述するように、 この現象は、ラットとヒトでは下垂体-甲状腺機能の基礎となる生理学的プロセスの量的な薬力学 的差異に起因している。

3. 実験動物とヒトとの間の薬力学的または動態的要因のいずれかの量的差異に基づいて、MOA のヒトへの関連性を合理的に排除することができるか?チアゾビルは甲状腺を直接標的とするも のではない。むしろ、その主な作用は肝代謝酵素に対するものであり、代謝活性の亢進は間接的 に T4 の全身クリアランスを増加させ、ラットでみられるような甲状腺機能低下状態と TSH の代 償性の増加をもたらす。チアゾビルがヒトにおける甲状腺ホルモンの恒常性を乱す可能性につい ては、チアゾビル特有のデータはないが、フェノバルビタール(Lehman-McKeeman & Hill, in Meek ら、2003 年)のような他の多くのミクロソーム酵素誘導剤で広く研究されている。上述したよう に、T4 の肝クリアランスを変化させることで甲状腺機能減退症下を引き起こす薬剤は、ヒトでは TSH レベルの上昇をもたらさないようである。おそらく、T4 の減少が閾値まで達していないので、 TSH は上昇しないのではないかと考えられる。

甲状腺機能に関連して、ラットとヒトの間にはいくつかの重要な生理学的及び生化学的相違が ある。ラットはヒトに比べて甲状腺ホルモンの予備容量が小さい。ラットはヒトに比べて甲状腺 ホルモンの半減期が非常に短く、T4の半減期は、ヒトの5~9日に対し、ラットでは約12時間で ある(Dohler ら、1979年)。ラットの半減期が短いのは、ヒトに存在するT4の高親和性結合グロ ブリンが存在しないことに関係していると考えられる(Hill ら、1989年)。ラットでは、クリアラ ンスの増加によって正常なT4レベルを維持するために、より高い体重あたりのT4産生率を必要 とする。対照的に、ヒトではこのグロブリンへ甲状腺ホルモンが結合することによって、ラット と比較して代謝的分解及びクリアランスが遅く、その結果、甲状腺はラットよりも活性が低い。 恒常的なTSHレベルは、ラットではヒトよりも約25倍高く、ラットでは下垂体-甲状腺軸の活性 が高いことを反映している(Dohler ら、1979年; McClain、1992年)。したがって、ヒトは、T4を 減少させTSHの上昇をもたらす薬剤に対して、ラットよりも定量的に感受性が低い。TSH が上昇 していなければ、甲状腺腫瘍発生のリスクが高まることはない。

ヒトとの比較においてラットのもう一つの違いは、甲状腺の組織像にある。この組織学的な相 違は、ラットでは安定した一定の血清 T4 濃度を維持するための T4 のより高い産生速度と関連し ており、これによりラットの甲状腺は、人間を含む霊長類のそれよりも"機能的に活性化"した状 態となっている(McClain、1995 年)。

maintain a consistent serum concentration, thus making the rat thyroid more "functionally active" than that of primates, including humans (McClain, 1995). More of the follicular epithelium in the rat is stimulated to synthesize thyroglobulin, and therefore more of the follicular cells are tall cuboidal and appear to be active in synthesis. In contrast, more of the follicular cells in humans tend to be short cuboidal or almost squamous in appearance, suggesting they are quiescent. Because rat follicular cells are already generally active, under stimulation from TSH, they will respond with hyperplasia more readily than human follicular cells. Because of the greater storage capability of the human thyroid and the greater numbers of cells in a quiescent state, human thyroid follicular cells will be roused from their quiescent state to synthesize and secrete additional thyroid hormone without the need for a hyperplastic response to re-establish homeostasis. Therefore, the primary response in the human thyroid gland would be thyroglobulin reabsorption and cellular hypertrophy rather than hyperplasia. In short, there is much greater buffering capacity in the biochemistry of the human than the rat thyroid.

Even though certain agents can cause a reduction in thyroid hormone levels in humans, there is no clear evidence that these agents increase susceptibility to thyroid cancer (Ron et al., 1987). For example, epidemiological studies with phenobarbital do not show any increased risk of thyroid cancer (Olsen et al., 1993). Studies of individuals with conditions that would lead to elevated TSH (patients with Graves disease or goitre) indicate that the occurrence of thyroid cancer is rare in these circumstances (e.g. Mazzaferri, 2000; Gabriele et al., 2003). A study of environmental and heritable causes of cancer among 9.6 million individuals, using the nationwide Swedish Family-Cancer Database, found that the environment did not appear to play a principal causative role in thyroid cancer (Lichtenstein & Hemminki, 2002). The only known human thyroid carcinogen is radiation, a mutagenic exposure.

As summarized in Table 4, there is sufficient evidence in the general literature on the biochemical and physiological differences in thyroid function to indicate differences in tumour susceptibility between rats and humans. In contrast to humans, rats are very susceptible to thyroid neoplasia secondary to hypothyroidism. In particular, modest changes in thyroid hormone homeostasis will promote tumour formation in rats. Thus, thyroid tumours induced by thiazopyr involving increased hepatic clearance of hormone and altered homeostasis of the pituitary–thyroid axis in rodents are considered not relevant to humans, based on quantitative dynamic differences.

4. Conclusion: statement of confidence, analysis, and implications. There is sufficient experimental evidence to establish a thyroid disruption MOA for thiazopyr-induced thyroid follicular cell tumours in rats. Although thiazopyr may potentially result in hypothyroidism in humans, there is sufficient quantitative evidence on the basic physiological processes in the general literature to conclude that thyroid tumours induced by a process involving increased hepatic clearance of thyroid hormone and altered homeostasis of the pituitary–thyroid axis in rodents is not likely to lead to an increase in susceptibility to tumour development in humans. Although there are no human data on thiazopyr, clinical data on other hepatic microsomal enzyme inducers were critical to this human relevance analysis. The general literature provided sufficient evidence to show that unlike in the rat, decreased T4 levels typically show no evidence of compensatory increases in TSH levels in humans. There is also cellular and

#### IPCS Framework for Analysing the Relevance of a Cancer Mode of Action for Humans and Case-Studies

ラットの濾胞上皮の多くは、刺激を受けてサイログロブリンを合成するため、濾胞細胞の多くは 背の高い立方体状をしており、活発にホルモン合成しているように見える。対照的に、ヒトの濾 胞細胞の多くは、短い立方体状またはほぼ扁平な外観を呈し、静止状態のように見える傾向があ る。ラットの濾胞細胞はすでに全体的に活性化しているので、TSHによる刺激を受けると、ヒト の濾胞細胞よりも容易に反応し過形成を生じる。ヒトの甲状腺は貯蔵能力が高く、休止状態にあ る細胞の数が多い。そのため、ヒトの甲状腺濾胞細胞は恒常性を回復するための過形成反応を必 要とせずに、休止状態から覚醒して追加の甲状腺ホルモンを合成・分泌する。したがって、ヒト 甲状腺における主要な反応は、過形成ではなくサイログロブリンの再吸収と細胞の肥大であろう。 要するに、ラット甲状腺よりもヒト甲状腺の方が、生化学的な面においてははるかに大きな緩衝 能力を持っているということである。

ある薬剤がヒトにおいて甲状腺ホルモンレベルの低下を引き起こす可能性があるとしても、こ れらの薬剤が甲状腺がんの感受性を高めるという明確なエビデンスはない (Ron ら、1987 年)。例 えば、フェノバルビタールを用いた疫学研究では、甲状腺がんのリスクの増加は示されていない (Olsen ら、1993 年)。TSH が上昇するような状態にある人々 (バセドウ病または甲状腺腫の患者) を対象とする研究は、このような状況においても甲状腺がんの発生はまれであることを示してい る (例えば、Mazzaferri、2000 年;Gabriele ら、2003 年)。全国規模のスウェーデンの家族がんデ ータベースを用いた 960 万人のがんの環境的及び遺伝的原因を調査した結果、環境が甲状腺がん の主な原因となる役割を果たしているようには見えないことが明らかにされた (Lichtenstein & Hemminki、2002 年)。唯一知られているヒト甲状腺の発がん物質は放射線であり、すなわち変異 原性物質のばく露である。

表4に要約されているように、甲状腺機能の生化学的及び生理学的差異に関する一般的な文献 には、ラットとヒトの間で腫瘍に対する感受性に違いがあることを示す十分なエビデンスがある。 ヒトとは対照的に、ラットは甲状腺ホルモンの低下症に続発する甲状腺腫瘍に対して非常に感受 性が高い。特に、甲状腺ホルモンの恒常性にわずかでも変化があるとラットでは腫瘍形成が促進 される。したがって、げっ歯類におけるホルモンの肝クリアランスの増加と下垂体-甲状腺軸のホ メオスタシスの変化を伴うチアゾピルによって誘発される甲状腺腫瘍は、量的な動態の違いから ヒトへの関連性はないと考えられる。

4. 結論:信頼性、解析及び帰結の記述。ラットにおけるチアゾビル誘発性甲状腺濾胞細胞腫瘍に関 して、甲状腺ホルモンかく乱 MOA を確立するのに十分な実験的エビデンスが存在する。チアゾビル はヒトにおいて甲状腺機能減退症を引き起こす可能性があるが、一般的な文献には、げっ歯類におけ る甲状腺ホルモンの肝クリアランスの増加と下垂体-甲状腺軸のホメオスタシスの変化を伴うプロセ スによって誘発される甲状腺腫瘍は、ヒトの腫瘍発生に対する感受性の増加にはつながらないと結論 づけるのに十分な基本的な生理学的プロセスに関する定量的エビデンスがある。チアゾビルに関する ヒトでのデータはないが、他の肝ミクロソーム酵素誘導剤に関する臨床データは、チアゾビルのヒト への関連性の解析には不可欠であった。一般的な文献からは、ラットとは異なりヒトでは T4 レベルの 低下が代償的に TSH レベルを上昇させることを示すエビデンスはないことを示すのに十分なエビデ ンスが得られた。また、ラットの下垂体-甲状腺軸がこのようなホルモンのかく乱に対してヒトよりも はるかに感受性が高いという細胞学的及び生化学的エビデンスもある。

biochemical evidence that the rat pituitary–thyroid axis is much more sensitive than that in humans to such perturbations. This sensitivity is likely the result of the rapid turnover of T4 in rats coupled with the higher demand for TSH to maintain thyroid activity.

#### Table 4. A comparison of key events in rats and humans.

Key event	Evidence in rats	Evidence in humans
Increased hepatic clearance of T4	In short-term and chronic rat studies, the liver is found to be the most sensitive target, and evidence of increased T4 hepatic clearance is provided by studies on T4-hepatic UGT activity, T4 half-life, T4 biliary elimination, liver weights, and hypertrophy.	No data available for thiazopyr, but microsomal enzyme induction is plausible.
Decreased serum T4	Direct experimental evidence.	No data available for thiazopyr, but plausible given that other microsomal enzyme inducers have been shown to reduce T4 in humans.
Increased TSH levels	Direct experimental evidence.	No data available for thiazopyr, but other microsomal enzyme inducers have not been shown to increase TSH levels even when T4 is decreased.
Increased TSH increases thyroid cell proliferation and tumour formation	Direct experimental evidence.	Induction of thyroid follicular cell tumours secondary to hypothyroidism is remote in humans, given the quantitative differ- ences in thyroid function/homeostasis. Occurrence of thyroid cancer is rare even in severely hypothyroid individuals.

#### **IMPLICATIONS OF THE IPCS HRF**

The thiazopyr example is an illustration of an induced tumour response consistent with an MOA that has been previously defined and established. Thus, addressing the first question in the framework analysis, "Is the weight of evidence sufficient to establish a mode of action (MOA) in animals?", became a determination of whether the data set on the chemical conforms to the same key events defined for the pathway of interest. This example further demonstrates how data on the basic understanding of the biological processes involved in the MOA provide an important means to compare the rodent and human key events. Thus, this generic human information was essential to evaluating the qualitative and quantitative differences between experimental animals and humans in addressing the plausibility of the cancer MOA for humans (i.e. questions 2 and 3 in the HRF).

#### Harmonization Project Document No. 4

この感受性の高さは、甲状腺の活動を維持するための TSH の需要が高いことと相まって、ラット における T4 の急速なターンオーバーが早いことに起因すると思われる。

#### 表 4. ラットとヒトにおける key events の比較

## IPCS HRF の結果

チアゾピルの例は、過去に明確にされ、確立された MOA と一致する誘発された腫瘍反応につ いて示したものである。したがって、フレームワーク解析の最初の質問である「動物 MOA を確 立するのにエビデンスの重み付けは十分か」に対応することは、その化学物質に関するデータセ ットが対象となる経路に対して定義にされた同じ key events に適合しているか否かを判断する必 要があった。この例は、MOA に関与する生物学的プロセスの基本的な理解に関するデータが、ど のようにげっ歯類とヒトの key events を比較するための重要な手段となるかを示している。この ように、実験動物とヒトの間の質的及び量的な差異を評価し、ヒトに対する発がん MOA の妥当 性(すなわち、HRF の問 2 と 3)評価するためには、このヒトに関する一般的な情報は、不可欠 であった。

## 4-AMINOBIPHENYL AND DNA REACTIVITY: CASE-STUDY WITHIN THE CONTEXT OF THE IPCS FRAMEWORK FOR ANALYSING THE RELEVANCE OF A CANCER MODE OF ACTION FOR HUMANS<sup>1</sup>

Samuel M. Cohen, Alan R. Boobis, M.E. (Bette) Meek, R. Julian Preston, & Douglas B. McGregor

The International Programme on Chemical Safety (IPCS) Human Relevance Framework (HRF) was evaluated for a DNA-reactive (genotoxic) carcinogen, 4-aminobiphenyl, based on a wealth of data in animals and humans. The mode of action (MOA) involves metabolic activation by *N*-hydroxylation, followed by *N*-esterification leading to the formation of a reactive electrophile, which binds covalently to DNA, principally to deoxyguanosine, leading to an increased rate of DNA mutations and ultimately to the development of cancer. In humans and dogs, the urinary bladder urothelium is the target organ, whereas in mice, it is the bladder and liver; in other species, other tissues can be involved. Differences in organ specificity are thought to be due to differences in metabolic activation versus inactivation. Based on qualitative and quantitative considerations, the MOA is possible in humans. Other biological processes, such as toxicity and regenerative proliferation, can significantly influence the dose–response of 4-aminobiphenyl-induced tumours. Based on the IPCS HRF, 4-aminobiphenyl would be predicted to be a carcinogen in humans, and this is corroborated by extensive epidemiological evidence. The IPCS HRF is useful in evaluating DNA-reactive carcinogens.

4-Aminobiphenyl is carcinogenic when administered to several species by a variety of routes (IARC, 1972, 1986, 1987). It was selected as a chemical for a case-study for the International Programme on Chemical Safety (IPCS) Human Relevance Framework (HRF) as a representative DNA-reactive carcinogen because of its established mode of action (MOA) in animal models, based on substantial data available evaluating its metabolic activation, DNA reactivity, genotoxicity, and carcinogenicity. It is also similar to numerous known animal and human carcinogens belonging to the chemical class of aromatic amines (structure–activity relationships), and there are extensive epidemiological, metabolic, and biochemical data in humans. This case-study illustrates the nature of data that are helpful in delineating MOAs for DNA-reactive carcinogens. Distinction between modulating factors and key events in an MOA analysis is also presented.

Based on the strong animal evidence and extensive epidemiological data, the International Agency for Research on Cancer (IARC) has classified 4-aminobiphenyl as a known human carcinogen (IARC, 1972, 1987). Although initially identified as a human urinary bladder carcinogen in individuals exposed to high levels occupationally, it has subsequently been demonstrated as a major component of cigarette smoke, leading to an increased risk of urinary bladder cancer in cigarette smokers (Del Santo et al., 1991; Curigliano et al., 1996). Additional research has shown that it is a ubiquitous environmental chemical occurring naturally when organic material containing nitrogen undergoes combustion.

4-AminobiphenylとDNAの反応性: 発がん MOA のヒトへの関連性を解析するための IPCS フレームワークを用いた事例研究1

## Samuel M. Cohen, Alan R. Boobis, M.E. (Bette) Meek, R. Julian Preston, & Douglas B. McGregor

DNA 反応性(遺伝毒性)発がん物質である 4-Aminobiphenyl を例に、動物とヒトにおける豊富なデ ータに基づいて国際化学物質安全性計画(International Programme on Chemical Safety: IPCS)のヒト 関連性フレームワーク(Human Relevance Framework: HRF)を評価した。この Mode of action (MOA) は、N-水酸化による代謝的活性化、N-エステル化による反応性親電子物質の生成を経て、この親電 子物質が DNA(主にデオキシグアノシン)と共有結合し、DNAの突然変異を促進させ、最終的に はがんの発生につながると考えられている。ヒトとイヌでは、膀胱が標的臓器であるのに対し、マ ウスでは膀胱と肝臓が標的臓器であり、他の種では他の組織が関与することもある。臓器特異性の 違いは、代謝的活性化と不活性化の違いによるものと考えられている。定性的及び定量的な考察か ら、ヒトの MOA が可能である。毒性や再生性増殖などの他の生物学的プロセスは、4-Aminobiphenyl 誘発性腫瘍の用量反応に大きく影響する可能性がある。IPCS HRF によれば、4-Aminobiphenyl はヒ トにおいて発がん物質であると予測され、これは広範な疫学的エビデンスによって裏付けられて いる。IPCS HRF は DNA 反応性発がん物質の評価に有用である。

4-Aminobiphenyl は、様々な経路で複数の種において発がん性が確認されている(IARC、1972 年、1986年、1987年)。4-Aminobiphenyl は、代謝的活性化、DNA 反応性、遺伝毒性、発がん性を 評価した多くのデータに基づき、動物モデルにおける MOA が確立されていることから、代表的 な DNA 反応性発がん物質として、国際化学物質安全性計画(International Programme on Chemical Safety: IPCS)のヒト関連性フレームワーク(Human Relevance Framework: HRF)の事例研究対象 化学物質に選定された。また、芳香族アミンに属する既知の動物及びヒト発がん物質と類似して おり(構造活性相関)、ヒトにおける疫学的、代謝学的、生化学的データが豊富に存在している。 この事例研究は、DNA 反応性発がん物質の MOA を明確にするのに役立つデータの性質を示して いる。MOA 解析における調節因子と key eventsの区別についても示されている。

動物における有力なエビデンスと広範な疫学的データに基づいて、国際がん研究機関(IARC) は 4-Aminobiphenyl を既知のヒト発がん物質として分類した(IARC、1972 年、1987 年)。4-Aminobiphenyl は最初、職業的に高レベルにばく露されたヒトの膀胱発がん物質として同定された。 その後、タバコの煙の主成分として実証され、喫煙者の膀胱がんのリスク増加につながるといわ れている(Del Santo ら、1991 年; Curigliano ら、1996 年)。追加研究では、窒素を含む有機物が燃 焼する際に自然に発生し、至る所に存在する環境化学物質であることが示されている。

#### **CARCINOGENICITY OF 4-AMINOBIPHENYL IN ANIMALS**

Experimental studies indicate that 4-aminobiphenyl is carcinogenic in mice, rats, rabbits, and dogs, although significant target tissue differences and susceptibility have been observed (IARC, 1972). By most routes of exposure, 4-aminobiphenyl is primarily a carcinogen of the liver and, to a lesser extent, the urinary bladder in mice, whereas in dogs (and humans), the urinary bladder appears to be the target organ. Many of the studies were conducted a number of years ago, and published accounts include only limited details. In addition, potential precursor lesions at interim periods were rarely documented, and none of the studies included protocols, such as stop/recovery, which might be informative in the context of MOA. Nonetheless, results indicate clear species and individual differences in response (e.g. Block et al., 1978), characteristic of MOAs entailing competing metabolic activation and deactivation processes (Table 1).

#### Table 1. Carcinogenicity studies of 4-aminobiphenyl in various species.

Species	Route/dose	Incidence	Comment	Reference
Mice	Gavage; 1 mg/week for 38 weeks	Bladder carcinomas in 2/12 mice surviving to 90 weeks		Clayson et al. (1965)
Mice	Gavage; 0 or 1.5 mg/week for 52 weeks	Bladder carcinomas in 1/21 exposed males vs 0/19 in controls; increased incidence of hepatomas in males and females		Clayson et al. (1967)
Mice	Subcutaneous injection of 200 µg for up to 52 weeks	Hepatomas in 19/20 males and 6/23 females after 48–52 weeks		Gorrod et al. (1968)
Mice (BALB/ cStCrlfC3Hf/ Nctr)	0–220 mg/l in drinking-water (males), 0–300 mg/l (females), for up to 96 weeks	Significant increases in urinary bladder carcino- mas (males only), hepatocellular carcino- mas (females only), and angiosarcomas (males and females)	Hyperplasia of the bladder in most mice of both sexes receiving 75 mg/l (females) and 55 mg/l (males) or greater, but none in controls	Schieferstein et al. (1985)
Mice (newborn B6C3F1)	Different regi- mens; injected prior to weaning	Liver tumours		Dooley et al. (1988, 1992); Von Tungeln et al. (1996); Parsons et al (2005)
Rats	Subcutaneous injection in arachis oil of total dose of 3.6–5.8 g/kg bw	Mammary and intestinal tumours		Walpole et al. (1952)

## 動物における 4-Aminobiphenyl の発がん性

実験的研究では、標的組織と感受性には有意な差が認められているものの、4-Aminobiphenylは マウス、ラット、ウサギ、イヌにおいて発がん性があることが示されている(IARC、1972年)。4-Aminobiphenylは、ほとんどのばく露経路において、マウスでは主に肝臓と、低頻度で膀胱に対し て発がん性が認められるが、イヌ(及びヒト)では膀胱が標的臓器であると考えられる。これら の研究の多くが数年前に行われたものであり、詳細な情報は限られたものしか公表されていない。 さらに、試験途中における潜在的な前駆病変はほとんど記録されておらず、どの研究にも MOA で 参考となる中止/回復などの研究計画書は含まれていなかった。それにもかかわらず、研究結果に は競合する代謝的活性化及び不活性化プロセスが競合する MOA に特徴的な反応における影響の 種及び個体差(例えば、ブロックら、1978年)が示されている(表1)。

## 表 1. 各種種における 4-Aminobiphenyl の発がん性試験

動物種	投与経路/用量	発生率	コメント	参考文献
マウス	経口投与;1 mg/週を38 週間投与	90 週まで生存した 2/12 匹に膀胱がん		Clayson et al. (1965)

#### Table 1 (Contd)

Species	Route/dose	Incidence	Comment	Reference
Rabbits	Oral administra- tion of unspecified dose	Bladder papillomas in 1 animal and carcinomas in 3 animals	Earliest carcinoma observed 4 years after start of treat- ment	Bonser (1962)
Dogs (2)	Gelatin capsules 6 times weekly for life for a total dose of 30 or 34 g	Carcinoma of the bladders appeared in 33 months		Walpole et al. (1954)
Dogs	Gelatin capsules 0.3 g 3 times weekly (total dose: 94.5–144 g per dog)	Bladder carcinomas after 21–34 months		Deichmann et al. (1958)
Dogs (6)	1.0 mg/kg bw 5 times weekly for 34 or 37 months (total dose 5.5–7.0 g per dog)	3 bladder papillomas and 3 bladder carcinomas (transitional cell type)		Deichmann et al. (1965)
Dogs	Single dose	Ineffective in inducing bladder tumours over a 5-year period		Deichmann & MacDonald (1968)
Dogs (24 beagles)	Oral administra- tion 5 days/week for 3 years	Negative or minimal disease in 4 dogs, with no neoplasia in 2; neoplasia developed slowly in 11 dogs, while a rapidly progressive pattern was observed in the remaining 9 dogs		Block et al. (1978)

bw, body weight

Following its oral administration by gavage (1 mg per mouse per week for 38 weeks), 2/12 mice surviving to 90 weeks developed bladder carcinoma (Clayson et al., 1965). In a separate but similar experiment, dosing mice with 1.5 mg of 4-aminobiphenyl for 52 weeks resulted in bladder carcinoma in 1/21 male mice as compared with 0/19 in controls. In this experiment, the frequency of hepatomas in both male and female mice was significantly higher than that in the controls (Clayson et al., 1967). Three subcutaneous injections of mice with 200 µg of 4-aminobiphenyl produced hepatomas in 19/20 males and 6/23 females after 48-52 weeks (Gorrod et al., 1968). Oral administration of 4-aminobiphenyl in drinking-water at concentrations of up to 220 and 300 mg/l to male and female BALB/cStCrlfC3Hf/Nctr mice, respectively, for up to 96 weeks induced dose-related, significant increases in angiosarcomas (males and females), urinary bladder carcinomas (males only), and hepatocellular carcinomas (females only). Hyperplasia of the bladder was observed in most of the mice of both sexes in groups of about 118 receiving concentrations of 75 mg/l (females) and 55 mg/l (males) or greater, whereas none was reported in the control groups of similar size (Schieferstein et al., 1985). In a number of experiments, newborn B6C3F1 mice were primarily susceptible to

動物種	投与経路/用量	発生率	コメント	参考文献
ウサギ	不定量の経口投与	1匹に膀胱乳頭腫、3匹 に膀胱がん	投与開始から4年後に 観察された最も早いが ん	Bonser (1962)
イヌ(2)	ゼラチンカプセルを週6 回終身投与、合計30ま たは34g	膀胱がんが 33 ヶ月で出 現		Walpole et al. (1954)
イヌ	ゼラチンカプセル 0.3 g を週 3 回(総投与量: イヌ 1 匹あたり 94.5~ 144 g)	21~34ヶ月後に膀胱が ん		Deichman et al. (1958)
イヌ(6)	1.0 mg/kg bw を週 5 回、 34 ヵ月または 37 ヵ月間 (イヌ 1 頭あたりの総 投与量 5.5~7.0 g)。	膀胱乳頭腫 3 匹、膀胱 がん(移行上皮型)3 匹		Deichman et al. (1965)
イヌ	単回投与	5年間にわたり膀胱腫 瘍は誘発されなかった		Deichman & MacDonal (1968)
イヌ (24、ビ ーグル)	経口投与週5回、3年間	4 匹のイヌでは陰性ま たは軽症(2 匹で腫瘍 なし) 11 匹では腫瘍はゆっく りと進行したが、残り の9 匹では急速に進行		Block et al (1978)

経口投与(マウス1週あたり1mg、38週間)の後、90週まで生存した 2/12 のマウスに膀胱が んが発生した(Clayson 5、1965年)。別の実験では、マウスに 1.5 mg の 4-Aminobiphenyl を 52 週 間投与したところ、対照群では 0/19 匹であったのに対し、1/21 匹の雄マウスで膀胱がんが発生し た。この実験では、雄マウスと雌マウスの両方で肝臓がんの頻度が対照群よりも有意に高かった (Clayson 5、1967年)。4-Aminobiphenyl 200 µg をマウスに 3 回皮下注射したところ、48~52 週 後に 19/20 匹の雄及び 6/23 匹の雌で肝臓がんが生じた(Gorrod 5、1968年)。4-Aminobiphenyl を、 BALB/cStCrlfC3Hf/Netr マウスの雄と雌に、それぞれ 220 mg/L と 300 mg/L までの濃度で飲水投与 すると、投与量に相関して、血管肉腫(雄と雌)膀胱がん(雄のみ)、肝細胞がん(雌のみ)の有 意な増加が認められた。膀胱の過形成は、75 mg/L(雌)及び 55 mg/L(雄)以上の濃度の投与を 受けた約 118 匹の群では、両性のマウスのほとんどで観察されたが、対照群では報告されていな い (Schieferstein 5、1985年)。多くの実験において、新生児 B6C3F1 マウスは、4-Aminobiphenyl 投与後に、主に肝発がんに感受性があった(Dooley 5、1988年、1992年; Von Tungeln 5、1996 年; Parsons 6、2005年)。

liver carcinogenesis following 4-aminobiphenyl administration (Dooley et al., 1988, 1992; Von Tungeln et al., 1996; Parsons et al., 2005).

Daily subcutaneous injection of rats with 4-aminobiphenyl in arachis oil to a total dose of 3.6–5.8 g/kg body weight (bw) resulted in significant increases in the incidence of mammary gland and intestinal tumours (Walpole et al., 1952).

Among seven rabbits given commercial 4-aminobiphenyl orally (dose unstated), bladder papillomas were found in one and carcinomas in three animals. The earliest carcinoma was observed 4 years after the start of treatment (Bonser, 1962).

Two dogs fed 4-aminobiphenyl in gelatin capsules 6 times weekly for life (total dose per dog: 30, 34 g) developed carcinoma of the bladder in 33 months (Walpole et al., 1954). This was confirmed by similarly feeding capsules containing 4-aminobiphenyl (0.3 g per dog) 3 times weekly. Bladder carcinomas were observed after 21–34 months (total dose: 94.5–144.0 g per dog) (Deichmann et al., 1958). When the dose of 4-aminobiphenyl was reduced to 1.0 mg/kg bw and given to six dogs 5 times weekly for 34 months or 37 months (total dose: 5.5–7.0 g per dog), three bladder papillomas and three bladder carcinomas (transitional cell type) were observed (Deichmann et al., 1965). A single dose was not effective in inducing bladder tumours over a period of 5 years (Deichmann & MacDonald, 1968). Among 24 beagles that received 4-aminobiphenyl orally 5 days per week for 3 years, three basic patterns of bladder carcinogen responses were seen. Negative or minimal disease was seen in four dogs, of which two remained completely free of neoplasia. Neoplasia developed slowly in 11 dogs, while a rapidly progressive pattern was observed in the remaining 9 dogs (Block et al., 1978).

# IS THE WEIGHT OF EVIDENCE SUFFICIENT TO ESTABLISH A MODE OF ACTION (MOA) IN ANIMALS?

The first question of the IPCS HRF is an evaluation of the animal MOA itself. This is based on the process delineated by the MOA Framework developed by IPCS and published in 2001 (Sonich-Mullin et al., 2001), which evolved from the Bradford Hill criteria for causality in epidemiology studies (Hill, 1965).

## A. Postulated mode of action

4-Aminobiphenyl is metabolized by hepatic enzymes to *N*-hydroxy-4-aminobiphenyl, which can be *N*-esterified (*N*-acetylated, *N*-glucuronidated, or *N*-sulfated) in hepatic and other tissues (Miller et al., 1961; Kadlubar et al., 1977, 1991; Miller & Miller, 1977; Delclos et al., 1987; Chou et al., 1995) (Figure 1). *O*-Esterification and ring hydroxylation are competing enzymatic reactions leading to detoxification. Tissue and species differences in the activity of these reactions dictate, at least in part, variations in susceptibility to the carcinogenic effects of 4-aminobiphenyl and differences in organ specificity in the development of tumours. Ultimately, a reactive electrophilic nitrenium ion is formed in the target tissue following *N*-esterification, and this is capable of forming DNA adducts. The principal DNA adduct is *N*-(deoxyguanosin-8-yl)-4-aminobiphenyl (Talaska et al., 1990; Kadlubar et al., 1991; Flammang et al., 1992; Hatcher & Swaminathan, 1995, 2002). As a consequence of the

#### IPCS Framework for Analysing the Relevance of a Cancer Mode of Action for Humans and Case-Studies

ピーナッツオイル中に 4-Aminobiphenyl を混入して合計 3.6~5.8 g/kg 体重(bw)の用量をラットに毎日皮下注射すると、乳腺及び腸の腫瘍の発生率が有意に増加した(Walpole ら、1952年)。

市販の4-Aminobiphenylを経口投与(用量は記載なし)した7匹のウサギのうち、1匹に膀胱乳 頭腫が、3匹に膀胱がんが認められた。最も早い発がんは投与開始から4年後に観察された(Bonser、 1962年)。

4-Aminobiphenyl をゼラチンカプセルで週6回投与し続けた2匹のイヌ(1匹あたりの総投与量: 30、34g)は、33ヶ月で膀胱がんを発症した(Walpole ら、1954年)。同様に4-Aminobiphenylを含むカプセル(イヌ1匹あたり0.3g)を週3回与えても、21~34ヶ月後に膀胱がんが観察された(総投与量:イヌ1匹あたり94.5~144.0g)(Deichmann ら、1958年)。4-Aminobiphenylを1.0 mg/kg bwに減量し、6匹のイヌに週5回、34ヶ月または37ヶ月間投与したところ(総投与量:1匹当た り5.5~7.0g)、それぞれ3例で膀胱乳頭腫及び膀胱がん(移行上皮型)が観察された(Deichmann ら、1965年)。単回投与では、5年間で膀胱腫瘍は誘発されなかった(Deichmann & MacDonald、 1968年)。4-Aminobiphenylを週5日、3年間経口投与した24匹のビーグル犬では、膀胱発がん物 質の反応の基本的な3つのパターンが認められた。陰性または最小限の病変は4匹にみられ、そ のうちの2匹には腫瘍が発生しなかった。腫瘍は11匹のイヌでゆっくりと進行したが、残りの9 匹では急速に進行するパターンが観察された(Block ら、1978年)。

## 動物 MOA を立証するのにエビデンスの重み付けは十分か

IPCS HRF の最初の問いかけは、動物 MOA そのものの評価である。これは、疫学研究における 因果関係を説明するための Bradford Hill 基準 (Hill、1965 年)から発展し、IPCS が開発した、2001 年発表の MOA フレームワーク (Sonich-Mullin ら、2001 年)に示されている手順に基づいている。

#### A. 推定される MOA

4-Aminobiphenyl は、肝酵素によって N-hydroxy-4-aminobiphenyl に代謝され、肝及び他の組織に おいて N-エステル化 (N-アセチル化、N-グルクロン化、または N-硫酸化) される (Miller ら、1961; Kadlubar ら、1977 年、1991 年; Miller & Miller、1977 年; Delclos ら、1987 年; Chou ら、1995 年) (図 1)。O-エステル化及び環状水酸化は、無毒化につながる競合する酵素反応である。これらの 反応の活性における組織差や種差により、少なくとも部分的には、4-Aminobiphenyl の発がん作用 に対する感受性の違いや、腫瘍の発生における臓器特異性に違いを生じさせる。最終的には、N-エステル化の後、反応性親電子ニトレニウムイオンが標的組織に形成され、これが DNA 付加体を 形成しうる。主な DNA 付加体は、N-(deoxyguanosin-8-yl)-4-aminobiphenyl である (Talaska ら、1990 年; Kadlubar ら、1991 年; Flammmang ら、1992 年; Hatcher & Swaminather、1995 年、2002 年)。

mutations that can result from these reactions at critical sites of critical genes, neoplastic cells eventually develop.

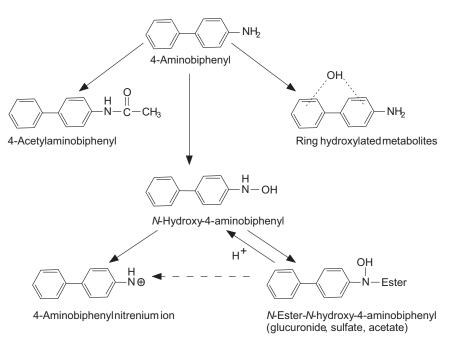

Figure 1. Metabolism of 4-aminobiphenyl

#### **B. Key events**

The major route of hepatic activation of 4-aminobiphenyl begins with its *N*-hydroxylation, catalysed, the balance of evidence indicates, by CYP1A2, at least in rats and humans (Butler et al., 1989b). In mice, there is evidence that CYP1A2 is not the only, or even the primary, form of cytochrome P-450 involved (Kimura et al., 1999). The *N*-hydroxylamine can also be produced by reaction with a variety of oxidases and peroxidases, such as by the prostaglandin synthase component of cyclo-oxygenase (Kadlubar et al., 1982). Whether any of these non-cytochrome P-450 reactions occur in vivo and are of toxicological significance remains unclear. The *N*-hydroxylamine undergoes *N*-acetylation by *N*-acetyltransferase-1 (NAT1) (Flammang & Kadlubar, 1986; Oda, 2004), resulting in an *N*-acetoxy ester that is unstable in acidic conditions, forming an arylnitrenium ion that can react directly with DNA, forming a DNA adduct at the C-8 position of guanine (Hammons et al., 1985; Flammang & Kadlubar, 1986; Hatcher & Swaminathan, 2002). Additionally, the *N*-hydroxylamine generated in liver can serve as a substrate for uridine diphosphate (UDP) glucuronosyltransferase (UGT),

これらの反応が重要な遺伝子の重要な部位で起こることにより突然変異がおこり、その結果、最 終的に腫瘍細胞が発生する。

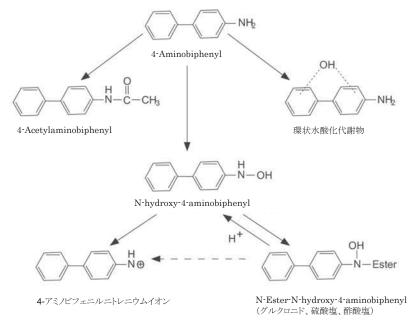

図 1.4-Aminobiphenyl の代謝

#### B. Key events

4-Aminobiphenylの肝活性化の主要経路は、少なくともラットとヒトでは CYP1A2 によって触媒 される 4-Aminobiphenylの N-水酸化から始まる (Butler ら、1989 年 b)。マウスでは、CYP1A2 や チトクローム P-450 が唯一もしくは主要に関与しているわけではないという報告がある (Kimura ら、1999 年)。また、N-hydroxylamine はシクロオキシゲナーゼのプロスタグランジン合成酵素 (Kadlubar ら、1982 年)のような様々なオキシダーゼ及びペルオキシダーゼとの反応によって生 成される。これらの非チトクローム P-450 反応のいずれかが生体内で起こるが、毒性学的に意義 があるかは不明なままである。N-hydroxylamine は、N-アセチルトランスフェラーゼ 1 (NAT1) (Flammang & Kadlubar、1986 年;Oda、2004 年)による N-アセチルトランスフェラーゼ 1 (NAT1) (Flammang & Kadlubar、1986 年;Oda、2004 年)による N-アセチルトシンスフェラーゼ 1 (NAT1) (Flammang & Kadlubar、1986 年;Oda、2004 年)による N-アセチルトシンスフェラーゼ 1 (NAT1) (Flammang & Kadlubar、1986 年;Oda、2004 年)による N-アセチルトシンスフェラーゼ 1 (NAT1) (Flammang & Kadlubar、1986 年;Oda、2004 年)による N-アセチルトランスフェラーゼ 1 (NAT1) (Flammang & Kadlubar、1986 年;Oda、2004 年)による N-アセチルトシンスフェラーゼ 1 (NAT1) (Flammang & Kadlubar、1986 年;Oda、2004 年)による N-アセチルトシンスフェラーゼ 1 (NAT1) (Flammang & Kadlubar、1986 年;Oda、2004 年)による N-アセチル化を受け、酸性条件下では不 安定な N-アセトキシエステルを生じ、DNA と直接反応し得るアリルニトレニウムイオンを形成 し、グアニンの C-8 位に DNA 付加体を形成する (Hammons ら、1985 年;Flammang & Kadlubar、 1986 年;Hatcher & Swaminathan、2002 年)。さらに、肝臓で生成された N-hydroxylamine は、ウリ ジンニリン酸 (UDP) グルクロン酸転移酵素 (UGT)の基質として機能し、N-グルクロニド抱合 体を生じ、これが膀胱に運ばれる (Kadlubar ら、1977 年)。グルクロニドは尿中に排泄されるか、 酸性条件下において、加水分解後に膀胱内の N-hydroxylamine の追加供給源として機能する。N-ア セチルトランスフェラーゼ-2 (NAT2)による 4-Aminobiphenyl の N-アセチル化など、この反応と

yielding an *N*-glucuronide conjugate that is transported to the urinary bladder (Kadlubar et al., 1977). The glucuronide can either be excreted in urine or, under acidic conditions, serve as an additional source of the *N*-hydroxylamine in the urinary bladder, following hydrolysis. There are a number of reactions that can compete with this reaction scheme, including *N*-acetylation of 4-aminobiphenyl by *N*-acetyltransferase-2 (NAT2), but the resulting arylacetamide is a poor substrate for CYP1A2, and it is considered to be primarily a detoxification reaction. As a consequence, *N*-acetylation of the parent amine is considered a deactivating process. Rates of acetylation can thus affect the balance between activation and deactivation. Humans phenotypically are either rapid or slow acetylators (Lower et al., 1979). Mouse strains exist that are analogous to human slow and rapid acetylators. Thus, C57BL/6 is a rapid acetylator strain, while A/J is a slow acetylator (Hein, 1988). Interest in these differences includes a possible explanation for interspecies, interstrain, and interindividual differences in response. As a consequence of the DNA adducts formed, mutations can be produced. The key events are summarized in Table 2.

#### Table 2. Key events in the carcinogenicity of 4-aminobiphenyl in animals.

a) N-Hydroxylation

b) N-Esterification (glucuronide, acetyl, sulfate)

c) Hydrolysis to nitrenium ion

- 2. DNA adduct formation (dG-C8, dA-C8, dG-N2) in pluripotential cell of target organ
- 3. DNA mutation in critical gene(s) leading to cancer
- 4. Cancer

dA, deoxyadenosine; dG, deoxyguanosine

## **C.** Dose-response relationship

In view of the fact that many of the relevant studies were conducted a number of years ago, data on concordance of dose-response for precursor lesions for tumours are restricted to hyperplasia in the mouse urinary bladder. Dogs do not develop bladder tumours after a single dose of 4-aminobiphenyl (Deichmann & MacDonald, 1968), and there do not appear to have been studies of dose-response relationships in this species following multiple exposures. In the only study in which information on the incidence of precursor lesions was reported, male BALB/c mice were treated with drinking-water containing 4-aminobiphenyl at concentrations of 0, 7, 14, 28, 55, 110, or 220 mg/l for up to 96 weeks (Schieferstein et al., 1985). These treatments were associated with bladder carcinoma incidences of 0/116, 1/117, 1/118, 0/118, 6/115, 5/118, and 23/118, respectively. The incidences in the 55 mg/l group and higher were statistically significantly higher than in controls. Female mice were exposed to drinkingwater concentrations of 4-aminobiphenyl of 0, 7, 19, 38, 75, 150, and 300 mg/l. The corresponding incidences of bladder carcinomas were 0/118, 0/118, 0/118, 0/118, 0/118, 5/117, and 1/117. Incidences of hyperplasia were much higher, although severity was not indicated. In males, the incidences of hyperplasia were 0/116, 4/117, 9/118, 71/118, 108/115, 107/118, and 102/118 for doses of 0, 7, 14, 28, 55, 110, and 220 mg/l, respectively, and for females, 0/118, 0/118, 3/119, 53/119, 106/118, 97/117, and 83/117 for doses of 0, 7, 19, 38, 75, 150, and 300 mg/l, respectively. Thus, the dose-response curves for tumours and

#### IPCS Framework for Analysing the Relevance of a Cancer Mode of Action for Humans and Case-Studies

競合する反応が多数存在するが、得られるアリルアセトアミドは、CYP1A2 にとって貧弱な基質 であり、主に解毒反応であると考えられている。その結果、親アミンの N-アセチル化は不活性化 反応と考えられている。アセチル化の速度は、活性化と不活性化のバランスに影響を与える。ヒ トの表現型には、rapid acetylators と slow acetylators が存在する(Lower ら、1979 年)。ヒトのそれ ぞれのアセチレーターに類似したマウスの系統が存在し、C57BL/6 はrapid acetylators 系統であり、 A/J は slow acetylators 系統である(Hein、1988)。これらの違いに対する研究は、種間、系統間、 個体間での反応の違いを説明しうる。形成された DNA 付加体により、突然変異が生じる可能性が ある。key events を表 2 にまとめた。

## C. 用量反応関係

関連する研究の多くが何年も前に実施されたという事実を考慮すると、腫瘍の前駆病変に対す る用量反応の一致に関するデータは、マウスの膀胱過形成に限定されている。イヌでは、4-Aminobiphenylの単回投与後に膀胱腫瘍が発生することはなく(Deichmann & MacDonald、1968 年)、 複数回投与後の用量反応関係の研究は行われていない。前駆病変の発生率に関する情報が報告さ れている唯一の研究では、雄の BALB/c マウスに 0、7、14、28、55、110、220 mg/L の濃度の 4-Aminobiphenylを含む飲料水を介して96週間まで処置したものがある(Schiefersteinら、1985年)。 これらの処置後の膀胱がん発生率は、それぞれ 0/116、1/117、1/118、0/118、6/115、5/118 及び 23/118 であった。55 mg/L 以上の群の発生率は、対照群に比べて統計的に有意に高かった。雌マウスに 4-Aminobiphenyl を濃度 0、7、19、38、75、150 及び 300 mg/Lの飲料水を介してばく露させると、 膀胱がんの発生率は、0/118、0/118、0/119、1/118、0/118、5/117及び1/117であった。重症度は示 されていなかったが、過形成の発生率ははるかに高かった。雄では、0、7、14、28、55、110及び 220 mg/L の投与量で、過形成の発生率は 0/116、4/117、9/118、71/118、108/115、107/118 及び 102/118 であった。雌では、それぞれ0、7、19、38、75、150及び300mg/Lの用量で0/118、0/118、3/119、 53/119、106/118、97/117 及び 83/117 であった。このように、腫瘍及び過形成の用量反応曲線は、 シグモイド型またはホッケースティック型であった。対照的に、尿路上皮細胞のC-8グアニンDNA 付加体の平衡レベルは直線的な用量反応関係を示した(Poirier ら、1995年)。

同研究(Schieferstein ら、1985年)では、雄では肝腫瘍の発生率の増加は認められなかったが、 雌では、それぞれ0、7、19、38、75、150及び300mg/Lの投与量で、肝腫瘍(腺腫及びがんを合 わせたもの)の発生率は0/117、0/120、2/120、4/119、11/119、17/118及び10/117であった。様々 な組織を合わせた血管肉腫の発生率は、雄と雌の高い3用量で増加したが、発生率は雄よりも雌 の方がやや高かった。

Harmonization Project Document No. 4

hyperplasia were sigmoidal or hockey stick-shaped. In contrast, steady-state levels of urothelial C-8 guanine DNA adducts showed a linear dose–response (Poirier et al., 1995).

In this same study (Schieferstein et al., 1985), there was no increase in the incidence of liver tumours in the males, whereas in the females, the incidences of liver tumours (adenomas and carcinomas combined) were 0/117, 0/120, 2/120, 4/119, 11/119, 17/118, and 10/117 at doses of 0, 7, 19, 38, 75, 150, and 300 mg/l, respectively. The incidence of angiosarcomas of various tissues combined was also increased at the three highest doses in males and females, although the incidences were somewhat higher in females than in males.

#### **D.** Temporal relationship

Establishing time sequences for events in a carcinogenic process is partially, but to an important extent, dependent upon the sensitivity of the available methods for their measurement. Thus, tumours must attain a size allowing their histological detection, while the measurement of mutations and DNA adducts requires not only time but sufficient tissue. Consequently, the latter are more usually studied in liver than in urinary bladder, where the paucity of tissue available in the urothelium, particularly in rodents, causes technical difficulties that have no connection with the frequency of the biochemical and biological events. The metabolism and formation of DNA adducts are early events, which can be observed within a few minutes or hours in vitro and within a day following in vivo treatment with 4aminobiphenyl (e.g. Kadlubar et al., 1991; Swaminathan & Reznikoff, 1992; al-Atrash et al., 1995; Hatcher & Swaminathan, 1995; Doerge et al., 1999; Tsuneoka et al., 2003). Many in vivo experiments, however, continue exposure for 3-4 weeks to allow an accumulation of adducts, achieve steady-state levels, and facilitate their detection (e.g. Talaska et al., 1990; Flammang et al., 1992; Poirier & Beland, 1992; Poirier et al., 1995; Underwood et al., 1997). Mutations can also be detected within a short time in vitro, but have generally not been detected in vivo in target tissues until after several weeks or months of exposure (e.g. H-ras in mouse liver: Parsons et al., 2002), although this comparatively long period may not be a true reflection of when mutations first arise. In one study, mutations were detected in a Muta<sup>TM</sup>Mouse urinary bladder assay 14 days after a single dose of 4-aminobiphenyl (Fletcher et al., 1998). Carcinomas and hyperplasia of the urinary bladder are apparently late-occurring lesions in mice and dogs; however, time course changes have not been systematically evaluated. Although mice were killed at intervals beginning at 13 weeks in one 2-year study, and hyperplastic lesions were induced in the urinary bladder, their incidences at different times were not presented (Schieferstein et al., 1985). Tumours in the urinary bladder are commonly not discovered until after about 2 years in mice (Schieferstein et al., 1985) and longer in dogs (Walpole et al., 1954; Deichmann et al., 1958, 1965). However, neoplastic transformation of human urothelial cells (infected with SV40) treated in vitro with 4aminobiphenyl followed by in vitro culture for 6 weeks was demonstrated upon their inoculation into nude mice (Bookland et al., 1992b).

## E. Strength, consistency, and specificity of association of the tumour

## response with key events

Evidence in support of the association of the tumour response with key events comes only in part from studies on bladder; considerable evidence is provided by studies on liver. DNA adduct formation has been demonstrated in both tissues.

#### D. 時間的関連性

発がん過程における事象の順序を確立することは、その測定方法の感度に部分的ではあるが大 いに依存する。したがって、腫瘍は組織学的に検出できる大きさに達していなければならず、一 方で突然変異や DNA 付加体の測定には時間だけでなく十分な量の組織が必要である。その結果、 後者は膀胱よりも肝臓で研究されるのが一般的だが、特にげっ歯類では尿道の組織が少ないため、 生化学的・生物学的事象の頻度とは関係のない技術的な困難が生じている。DNA 付加体の代謝及 び形成は初期の事象であり、4-Aminobiphenyl による in vitro 処理後、数分または数時間以内及び1 日以内に観察される(Kadlubar ら、1991年; Swaminathan & Reznikoff、1992年; al-Atrash ら、1995 年: Hatcher & Swaminathan、1995年: Doerge ら、1999年: Tsuneoka ら、2003年)。しかしながら、 多くの in vivo 実験では、付加体を蓄積させ、平衡レベルに達し、検出を容易にするために、3~4 週間ばく露を継続する(例えば、Talaska ら、1990年; Flammang ら、1992年; Poirier & Beland、 1992 年; Poirier ら、1995 年; Underwood ら、1997 年)。また、突然変異は in vitro では短時間で検 出され得るが、生体内では数週間または数ヶ月のばく露後でないと検出されない(例えば、マウ ス肝臓における H-ras; Parsons ら、2002 年)。この期間は、突然変異が最初に生じた時期を正確に 反映しているとは限らない。ある研究では、4-Aminobiphenyl の単回投与から 14 日後に Muta™Mouse 膀胱アッセイで突然変異が検出された(Fletcher ら、1998年)。膀胱のがんや過形成 は、マウスやイヌでは明らかに遅発性の病変であるが、時間経過の変化は体系的に評価されてい ない。ある2年間の研究では、マウスを13週から一定間隔で安楽殺し、膀胱に渦形成病変を誘導 したが、異なる時期の発生率は示されていない(Schieferstein ら、1985)。膀胱の腫瘍は、一般的 に、マウスでは約2年後(Schieferstein ら、1985年)、イヌではそれより長い時間が経過するまで 発見されない(Walpole ら、1954 年; Deichmann ら、1958 年、1965 年)。しかし、ヒトの(SV40 に感染した)尿道粘膜細胞を 4-Aminobiphenyl で in vitro 処理し、6 週間 in vitro 培養した後、ヌー ドマウスに接種した場合、腫瘍性の形質転換が認められた(Bookland ら、1992 年 b)。

#### E. 腫瘍反応と key events との関連性の強さ、一貫性、特異性

腫瘍反応と key events との関連性を支持するエビデンスは、膀胱に関する研究から得られたものがあるが、肝臓に関する研究からも有力なエビデンスが得られている。DNA 付加体の形成は両 組織で実証されている。

There is an abundance of studies that demonstrate that 4-aminobiphenvl is a mutagen. including positive mutagenicity with certain frameshift mutation and base pair substitutionsensitive strains (TA1538, TA98, and TA100) of Salmonella typhimurium, but only in the presence of rodent liver S9 metabolic activating preparations. The requirement for S9 metabolic activation clearly demonstrates the lack of DNA reactivity and mutagenicity of the parent amine. In addition, 4-aminobiphenyl induces unscheduled DNA synthesis in rat liver cells in vitro (United States Environmental Protection Agency Genetic Activity Profiles). These in vitro studies provide evidence that 4-aminobiphenyl can cause genetic damage following metabolic activation. Bacterial mutation studies have also been conducted comparing metabolic activation systems based on liver homogenates from Aroclor 1254-induced male Sprague-Dawley rats and C57BL/6 mice, using S. typhimurium TA100 tester strains that expressed different levels of N- and O-acetyltransferase (OAT) activity (Dang & McQueen, 1999). TA100 has a single copy of the NAT/OAT gene; YG1029 has multiple copies of the NAT/OAT gene, and TA100/1,8DNP<sub>6</sub> is NAT/OAT-deficient. Effects with mouse and rat S9 were similar (but the effects of Aroclor 1254 treatment were not examined). Using either 4aminobiphenyl or 4-acetylaminobiphenyl as substrates, considerably more mutations were induced in YG1029 than in TA100 or TA100/1.8DNP<sub>6</sub>, in which mutation induction was similar. This supports a role for high acetylation activity in mutation induction by the Nhydroxylamine in these bacteria.

The non-enzymatic step to an arylnitrenium ion in the mechanism of mutagenesis in vivo is supported by the observation that *N*-hydroxy-4-aminobiphenyl mutagenesis in the high OAT-expressing *S. typhimurium* TG1024 strain is dependent on the pH of the medium, with an inverse relationship between mutant numbers and pH over the range 4.0–8.0 (Sarkar et al., 2002).

Administration of 4-aminobiphenyl in the drinking-water of BALB/c mice for 28 days resulted in higher levels of DNA adducts in liver than in urinary bladder of females, while the reverse occurred in males. Thus, in each sex, the DNA adduct level correlated with the susceptibility of the tissue to tumour induction by 4-aminobiphenyl (Poirier et al., 1995). However, the shape of the dose–response curve was linear for DNA adducts in both tissues (although it appears to saturate and is relatively flat in female mice), whereas the tumour dose–response curve was sigmoidal (Poirier et al., 1995).

Adduct levels were also highest in the urinary bladder of female Hsd:ICR(Br) mice that were dosed topically (the more usual exposure route in occupational settings) with 50 nmol 4-aminobiphenyl for 21 weeks. The principal adduct in all tissues examined (bladder, liver, lung, and skin) co-chromatographed with *N*-(deoxyguanosin-8-yl)-4-aminobiphenyl (Underwood et al., 1997).

One study of mutagenesis in male Muta<sup>TM</sup>Mouse transgenic mice (i.e. transgenic CD2F, [BALB/c × DBA/2]) treated orally with 4-aminobiphenyl at 10 mg/kg bw per day for 10 days reported that the mutation frequencies in urinary bladder, liver, and bone marrow were increased by 13.7-, 4.8-, and 2.4-fold, respectively (Fletcher et al., 1998).

#### IPCS Framework for Analysing the Relevance of a Cancer Mode of Action for Humans and Case-Studies

4-Aminobiphenyl が変異原性物質であることを示す研究は豊富にあり、S. typhimurium 菌の特定 のフレームシフト型突然変異及び塩基対置換感受性株(TA1538、TA98及びTA100)に対する陽性 反応が、げっ歯類肝 S9 代謝的活性化製剤の存在下でのみ認められている。S9 による代謝的活性 化が必要であるということは、親アミンの DNA 反応性及び変異原性の欠如を示している。さら に、4-Aminobiphenylは、in vitro でラット肝細胞において不定期 DNA 合成を誘導する(米国環境 保護庁遺伝的活性プロファイル)。これらの in vitro 研究は、4-Aminobiphenyl が代謝的活性化後に 遺伝的損傷を引き起こす可能性があるというエビデンスを示している。また、細菌を用いた突然 変異試験でも代謝的活性化システムの解析が行われている (Dang & McQueen、1999)。Aroclor 1254 誘発雄 Sprague-Dawley ラット及び C57BL/6 マウスの肝臓ホモジネート及び、異なるレベルの N-及び O-アセチルトランスフェラーゼ (OAT) 活性を発現する S. typhimurium TA100 試験菌株が使 用された。TA100 は NAT/OAT 遺伝子のシングルコピーを有し、YG1029 は NAT/OAT 遺伝子のマ ルチコピーを有し、TA100/1.8DNP6 は NAT/OAT 欠損株である。マウス及びラット S9 を用いた効 果は類似していた(ただし、Aroclor 1254 処理の効果は調べなかった)。4-Aminobiphenyl または 4-Acetylaminobiphenyl を基質とした場合、YG1029 では TA100 または TA100/1,8DNP6 よりも多く突 然変異が誘発された。このことは、これらの細菌における N-hydroxylamine による突然変異誘発に は、高いアセチル化活性が関与していることを示唆している。

生体内での突然変異誘発機構におけるアリルニトレニウムイオンへの非酵素的ステップは、高 OAT-発現 S. typhimurium TG1024 株における N-hydroxy-4-aminobiphenyl の突然変異誘発が培地の pH に依存し、4.0~8.0 の範囲で突然変異体数と pH との間に逆相関の関係が観察されたことによ って支持される (Sarkar ら、2002 年)。

BALB/c マウスに 4-Aminobiphenyl を 28 日間飲水投与したところ、雌では膀胱よりも肝臓の方 が DNA 付加体の量が多かったのに対し、雄では逆の結果が得られた。このように、各性におい て、DNA 付加体のレベルは、4-Aminobiphenyl による腫瘍誘導に対する組織の感受性と相関して いた (Poirier ら、1995 年)。しかしながら、用量反応曲線の形状は、両組織の DNA 付加体では直 線的であった (雌マウスでは飽和して比較的平坦)のに対し、腫瘍の用量反応曲線はシグモイド 型であった (Poirier ら、1995 年)。

付加体の量は、50 nmol の 4-Aminobiphenyl を 21 週間にわたって局所投与した Hsd:ICR(Br)マウ スの雌マウスの膀胱で最も高かった (一般的な職業的ばく露経路)。検査した全組織 (膀胱、肝臓、 肺、皮膚)の主な付加体は、N-(deoxyguanosin-8-yl)-4-aminobiphenyl とのコクロマトグラフィーを 用いて検査した (Under-wood ら、1997 年)。

雄の Muta<sup>™</sup>Mouse トランスジェニックマウス(すなわち、トランスジェニック CD2F、 [BALB/c×DBA/2]) に 10 mg/kg bw/日の 4-Aminobiphenyl を 10 日間経口投与した突然変異誘発の研 究では、膀胱、肝臓及び骨髄における突然変異頻度がそれぞれ 13.7 倍、4.8 倍及び 2.4 倍に増加し たことが報告されている(Fletcher ら、1998 年)。

Newborn B6C3F1 (C57BL/6 × C3H) mice responded to treatment with 4-aminobiphenyl by developing a high frequency of liver tumours, many of which carried H-*ras* codon 61 CAA  $\rightarrow$  AAA mutations (Parsons et al., 2005). In vivo, the level of one major DNA adduct [*N*-(deoxyguanosin-8-yl)-4-aminobiphenyl] was present at 5 adducts/10<sup>6</sup> nucleotides in newborn mice treated with 0.3 µmol 4-aminobiphenyl 24 h earlier. After 8 months, the CAA  $\rightarrow$  AAA mutation was detected in 67% of the treated mice and 50% of the vehicle (dimethyl sulfoxide, or DMSO) controls, but the average mutant fraction in treated mice was 45 × 10<sup>-5</sup> compared with only 2 × 10<sup>-5</sup> in controls. After 12 months, liver tumours had developed in 79% of the treated mice and in 8% of the controls. These tumours are not those of the human target organ, but the results of this study support the general MOA proposed for bladder carcinogenesis (i.e. DNA adduct formation, followed by mutation in a key gene and the subsequent emergence of tumours).

Dogs (sex not stated) killed 24 h after a single oral dose of 4-aminobiphenyl (5 mg/kg bw) had 5.4 fmol DNA adducts/ug liver DNA and 4.8 fmol DNA adducts/ug urinary bladder DNA, whereas no DNA adducts were detected in either the liver or bladder of a dog whose bladder had been instilled with 4-aminobiphenyl. In contrast, a dog bladder instilled with the reactive intermediate N-hydroxy-4-aminobiphenyl had 3.9 fmol DNA adducts/µg bladder DNA and no detectable adducts in liver DNA. Quantification was by an immunochemical method (Roberts et al., 1988). Examination of bitches treated with tritium-labelled 4aminobiphenyl (per os, intravenously, or intraurethrally), N-hydroxy-4-aminobiphenyl (intravenously or intraurethrally), or N-hydroxy-4-aminobiphenyl N-glucuronide (intravenously) demonstrated (1) the presence of 4-aminobiphenyl-haemoglobin adducts in blood erythrocytes; (2) that after per os dosing with 4-aminobiphenyl, the major portion of total Nhydroxy-4-aminobiphenyl entering the bladder lumen was free N-hydroxy-4-aminobiphenyl (0.7%), with lower concentrations of the acid-labile *N*-glucuronide (0.3%); (3) that urothelial DNA adducts following intraurethral instillation of N-hydroxy-4-aminobiphenyl were 60 times higher than after intraurethral instillation of 4-aminobiphenyl; and (4) that exposure to N-hydroxy-4-aminobiphenyl and subsequent 4-aminobiphenyl-DNA adduct formation are directly dependent on the frequency of urination and, to a lesser extent, on urinary pH (Kadlubar et al., 1991). The urinary pH of dogs may vary from about 4.5 to 7.5, depending upon the diet (Merck, 1998), time after eating, time of day, and amount of water consumed; these are factors that might influence the carcinogenic response (Cohen, 1995). Studies in vitro with microsomal preparations from dog liver and bladder have shown the presence of transacetylation activities in both organs, so that N-hydroxy-4-aminobiphenyl binding to RNA and DNA occurs in the presence of 4-acetylaminobiphenyl, N-hydroxy-4-acetylaminobiphenyl, or acetyl coenzyme A (CoA) as acetyl donors, although the levels of binding were less with bladder than with hepatic microsomes (Hatcher & Swaminathan, 1992).

Examination of urothelial cells exfoliated into urine of dogs treated with 4-aminobiphenyl showed that DNA adducts were identical to those from DNA modified in vitro with *N*-hydroxy-4-aminobiphenyl and from dog bladder urothelial DNA isolated from 4-aminobiphenyl-dosed dogs at autopsy. A dose-related increase in 4-aminobiphenyl–DNA adduct formation was demonstrated (Talaska et al., 1990).

新生児 B6C3F1(C57BL/6×C3H)マウスは、4-Aminobiphenyl の投与に反応して高頻度の肝腫瘍を 発症し、その多くは *H-ras* 遺伝子のコドン 61 における CAA→AAA 突然変異であった (Parsons 6, 2005 年)。in vivo では、0.3 µmol の 4-Aminobiphenyl を 24 時間前に投与した新生児マウスに おいて、主要な DNA 付加 *N*-(deoxyguanosin-8-yl)-4-aminobiphenyl 量は、5 adducts /10<sup>6</sup> ヌクレオチ ドであった。8 ヶ月後、CAA→AAA 突然変異は、投与マウスの 67%及び対照(ジメチルスルホキ シド、または DMSO)の 50%で検出されたが、投与マウスの平均突然変異率は 45×10<sup>-5</sup> であったの に対し、対照ではわずか 2×10<sup>-5</sup> であった。12 ヵ月後には、投与マウスの 79%、対照マウスの 8% に肝腫瘍が発生していた。これらの腫瘍はヒトの標的臓器の腫瘍ではないが、本研究の結果は、 膀胱がんの発生において提示されている一般的な MOA(すなわち、DNA 付加体の形成、重要な 遺伝子の突然変異、その後の腫瘍の出現)を支持するものである。

4-Aminobiphenyl (5 mg/kg bw) を単回経口投与してから24 時間後に死亡したイヌ (性別は明記 されていない)の DNA 付加体は、肝臓で5.4 fmolDNA adducts/µg、膀胱で4.8 fmolDNA adducts/µg であった。しかし、4-Aminobiphenyl を膀胱に投与したイヌの肝臓と膀胱では DNA 付加体は検出 されなかった。一方、反応性中間体である N-hydroxy-4-aminobiphenyl を膀胱に投与したイヌの膀 胱では、3.9 fmol DNA adducts/µg の DNA 付加体が検出され、肝臓では付加体は検出されなかった。 免疫化学的方法で定量を行った (Roberts ら、1988 年)。トリチウム標識された 4-Aminobiphenyl (経 口、静脈内、または尿道内)、N-hydroxy-4-aminobiphenyl (静脈内、または尿道内)、N-hydroxy-4aminobiphenyl N-glucuronide (静脈内)を投与された雌イヌの試験では以下のことが実証された。 (1)血中赤血球中の 4-aminobiphenyl -ヘモグロビン付加体の存在 (2) 4-aminobiphenyl 投与後、膀 胱内腔に入る N-hydroxy-4-aminobiphenyl の大部分は遊離 N-hydroxy-4-aminobiphenyl を尿道内 に注入した後の DNA 付加体量は、4-Aminobiphenyl を尿道内に注入した後と比較して 60 倍多かっ たこと、(4) N-hydroxy-4-aminobiphenyl へのばく露及びそれに続く 4-Aminobiphenyl-DNA 付加体 の形成は、排尿の頻度及び尿の pH に依存すること (Kadlubar ら、1991 年)。

イヌの尿中 pH は、食事内容(Merck、1998 年)、食後からの時間、時間帯及び消費水量に依存 して、約4.5 から 7.5 まで変化することがあり、これらは発がん性に影響を及ぼす可能性のある因 子である(Cohen、1995)。イヌの肝臓及び膀胱からのミクロソーム調製物を用いた in vitro の研究 では、両臓器においてトランスアセチル化活性が存在することが示されており、そのため、4-Acetylaminobiphenyl、N-hydroxy-4-acetyl-aminobiphenyl、またはアセチルコエンザイム A(CoA)が アセチル供与体として存在する場合には、N-hydroxy-4-aminobiphenylの RNA 及び DNA への結合 が起こるが、結合量は肝臓ミクロソームよりも膀胱ミクロソームの方が少なかった(Hatcher & Swaminathan、1992 年)。

4. Aminobiphenyl を投与したイヌの尿に含まれる尿膜細胞を調べたところ、N-hydroxy-4aminobiphenyl で in vitro で修飾した DNA や、4-aminobiphenyl を投与したイヌの剖検時に単離した イヌの膀胱尿路上皮細胞の DNA と同一の DNA 付加体が検出された。4- aminobiphenyl-DNA 付加 体形成の用量依存的増加が示された(Talaska ら、1990 年)。

#### F. Biological plausibility and coherence

The observations that 4-aminobiphenyl can form adducts with DNA and that it is mutagenic in organs in which tumours develop indicate, in general terms, that the proposed MOA is plausible (Fletcher et al., 1998). In addition, *N*-hydroxy-4-aminobiphenyl is able to cause neoplastic transformation of non-tumorigenic SV40-immortalized human urothelial cells (Bookland et al., 1992b). The findings with 4-aminobiphenyl are also consistent with the vast literature regarding the metabolic activation, DNA adduct formation, mutagenesis, and urinary bladder carcinogenesis in several species (including humans) of several related aromatic amine chemicals (Kadlubar et al., 1977; Miller & Miller, 1977; Delclos et al., 1987). The lack of DNA adduct formation and mutagenicity of the parent amine in various in vitro systems without metabolic activation clearly demonstrates the requirement for metabolic activation. The same DNA adducts are identified in tissues after administration of the amine or following exposure to the *N*-hydroxyl metabolite, with the structure of the adducts having been chemically confirmed. The mutagenic potential of the specific C-8 guanine DNA adduct has also been demonstrated, although the specific biophysical aspects have been better demonstrated for structurally related aromatic amines such as 2-aminofluorene (Kriek, 1992).

#### G. Other modes of action

Alternatives of components of the already described MOA have been suggested. However, they do not detract from the overall described MOA but suggest either alternative specific aspects (such as other activating enzymes) or associative processes that could affect quantitative aspects. 4-Aminobiphenyl is oxidized by hepatic enzymes other than CYP1A2 (Kimura et al., 1999) to the *N*-hydroxylated metabolite that causes liver and urinary bladder toxicity and carcinogenesis, possibly including oxidases and peroxidases (Kadlubar et al., 1982, 1991). Although the specific enzymes involved in metabolic activation may vary, the ultimate sequence of generation of a reactive electrophile, DNA adduct formation, mutagenesis, and carcinogenesis is consistent. Furthermore, it is reasonable to believe that from this point in the MOA, the same sequence occurs as that involving CYP1A2-mediated activation, regardless of the activating enzyme.

In addition to bulky adducts, there is evidence to suggest that *N*-hydroxy-4-aminobiphenyl causes oxidative damage in urothelial DNA, possibly involving endogenous peroxidases (Burger et al., 2001). The relevance of this for the carcinogenic activity of 4-aminobiphenyl is unknown.

*N*-Hydroxy-4-aminobiphenyl and its further activated forms are cytotoxic to urothelial and other cells in vitro (Reznikoff et al., 1986), but the role that this plays in its carcinogenic effects is unclear (see below for discussion of a potentiating role in urothelial carcinogenesis, rather than causative role). It is likely that this process alters the dose–response relationship, but does not alter the fundamental MOA described above.

#### H. Assessment of the postulated mode of action

The early steps in the proposed MOA are well supported by the available evidence, and it has been judged that there is good and sufficient evidence that 4-aminobiphenyl is a urinary bladder carcinogen in dogs and mice, and in other tissues (primarily the liver) in rodents. Thus, it is metabolized to products that can form DNA adducts in the liver and in other target

### F. 生物学的妥当性及び整合性

4-Aminobiphenyl が DNA と付加体を形成し、腫瘍が発生する器官で変異原性を示すという結果 は、一般的に提案されている MOA の妥当性を示している (Fletcher ら、1998 年)。さらに、*N*hydroxy-4-aminobiphenyl は、腫瘍化していない SV40 不死化ヒト尿細管細胞の腫瘍化を引き起こす ことができる (Bookland ら、1992 年 b)。また、4-Aminobiphenyl に関する知見はいくつかの関連 芳香族アミンの代謝的活性化、DNA 付加体形成、突然変異誘発及びいくつかの種 (ヒトを含む) における膀胱発がんに関する膨大な文献と一致している (Kadlubar ら、1977 年; Miller & Miller、 1977 年; Delclos ら、1987 年)。代謝的活性化を伴わない様々な in vitro 系での親アミンの DNA 付 加体形成及び変異原性の欠如は、代謝的活性化の必要性を明確に示している。アミンの投与後、 または *N*-ヒドロキシル代謝物へのばく露後に組織内で同じ DNA 付加体が確認され、付加体の構 造が化学的に確認されている。特定の生物物理学的側面は 2-aminofluorene のような構造的に関連 する芳香族アミンの方がより明らかにされているが、C-8 グアニン DNA 付加体の変異原性につい ても明らかにされている、(Kriek、1992 年)。

#### G. その他の MOA

既に記載されている MOA の構成要素の代替的なものが提案されている。しかし、それらは MOA の全体的な説明を損なうものではなく、限局的側面(他の活性化酵素など)、または定量的側面に 影響を与える可能性のある過程のいずれかを示唆している。4-Aminobiphenyl は、CYP1A2 以外の 肝酵素(Kimura ら、1999年)によって N-水酸化代謝物に酸化され、肝臓及び膀胱の毒性及び発が んを引き起こすが、これには酸化酵素及びペルオキシダーゼが関与している可能性がある (Kadlubar ら、1982年、1991年)。代謝的活性化に関与する酵素は異なるかもしれないが、反応 性親電子物質の生成、DNA 付加体の形成、変異原性、発がんという順序は一貫している。さらに、 MOA のこの時点から、活性化酵素にかかわらず、CYP1A2 を介した活性化と同じ順序で起こると 考えるのが妥当である。

巨大な付加体に加えて、N-hydroxy-4-aminobiphenylは、内因性ペルオキシダーゼが関与している 可能性があり、尿道粘膜DNAに酸化的損傷を引き起こすことを示唆するエビデンスがある(Burger ら、2001年)。このことと 4-Aminobiphenyl の発がん活性との関連性は不明である。

N-hydroxy-4-aminobiphenyl 及びその活性型は、in vitro で尿道粘膜及び他の細胞に対して細胞毒性を示す(Reznikoff ら、1986年)が、これが発がん作用に果たす役割は不明である(原因ではなく、尿道粘膜発がんにおける増強的な役割については以下を参照のこと)。この過程で用量反応関係は変化するが、上述の基本的な MOA は変化しないと考えられる。

#### H. 推定される MOA の評価

推定される MOA の初期段階は、利用可能なエビデンスによって十分に裏付けられており、4-Aminobiphenyl はイヌやマウスでは膀胱発がん物質であり、げっ歯類では他の組織(主に肝臓)で の発がん物質である十分なエビデンスがあると判断されている。このように、肝臓や他の標的臓 器では DNA 付加体を形成しうる生成物に代謝され、突然変異が生じることが実証されている。

organs, and mutations have been demonstrated to arise. Although other organs can also be targets for 4-aminobiphenyl-induced neoplasia, the urinary bladder is the main target in dogs and in some strains of mice. Evidence for the intervening steps between general genotoxicity and the emergence of neoplasia is lacking. There is a notable lack of study of the effects of 4-aminobiphenyl on cell proliferation in the urinary bladder, but information on related aromatic amines and amides is available, particularly the analysis of the interaction between DNA reactivity (and mutagenesis) and cell proliferation induced by 2-acetylaminofluorene in mouse urinary bladder utilizing data from a megamouse, ED-01 study (Cairns, 1979; Gaylor, 1979; Littlefield et al., 1979). The reliance for mutagenicity on cell proliferation can provide an explanation for the sigmoidal shape of the tumour dose–response despite a linear dose–response for DNA adducts (Cohen & Ellwein, 1990). This link has significant implications for assessing potency and dose–response for 4-aminobiphenyl-induced urinary bladder cancer (see discussion below).

#### I. Uncertainties, inconsistencies, and data gaps

Bacterial mutation studies of 4-aminobiphenyl with metabolic activation have shown that most mutations are frameshifts, whereas a single study of sequence analysis of 4-aminobiphenyl-induced mutations in the *lacZ* gene in single-stranded DNA from a bacteriophage M13 cloning vector revealed exclusively base pair substitutions, with over 80% occurring at G sites:  $G \rightarrow T$  transversions predominated, followed by  $G \rightarrow C$  transversions and  $G \rightarrow A$  transitions. The major DNA adduct, *N*-(deoxyguanosin-8-yl)-4-aminobiphenyl, was then inserted within the M13 genome, and the mutational frequency and specificity were measured after in vivo replication. The targeted mutational efficiency was approximately 0.01%, and the primary mutation was  $G \rightarrow C$  transversion. Thus, the observations are consistent with in vivo observations, but the mutagenic activity was weak (Verghis et al., 1997).

Most in vivo investigations have been in mice. Dogs, for understandable reasons, have received less attention, although this is the species that is more sensitive to bladder carcinogenesis. Mouse strain differences in response are evident: B6C3F1 and female BALB/cStCrlfC3Hf/Nctr are more susceptible to liver carcinogenesis, whereas male BALB/cStCrlfC3Hf/Nctr mice develop bladder tumours after exposure to 4-aminobiphenyl (Schieferstein et al., 1985; Dooley et al., 1988, 1992). Nevertheless, mouse strain effects have received relatively little attention in the available studies.

The enzyme considered as fundamental for the metabolism of 4-aminobiphenyl to a product that forms adducts with DNA in liver and bladder is CYP1A2 (Butler et al., 1989a, 1989b). However, comparison of responses in CYP1A2(+/+) wild-type mice with CYP1A2(-/-) knockout mice showed that, contrary to expectations, CYP1A2 expression was not associated with 4-aminobiphenyl-induced oxidative stress or with 4-aminobiphenyl–DNA adduct formation. Furthermore, prior treatment with 2,3,7,8-tetrachlorodibenzo-*p*-dioxin (TCDD), which increased hepatic CYP1A2 protein expression 5-fold along with expression of other phase I and phase II enzymes, either did not change or actually decreased the level of adducts in liver. The specific quantitative effects of such induction will depend on the balance of the enzymes induced. These results suggest either that CYP1A2 is not the major metabolic activator of 4-aminobiphenyl or that other enzymes in mice activate the compound in the absence of CYP1A2 (Tsuneoka et al., 2003). Based on studies with other aromatic amines,

他の臓器も4-Aminobiphenyl 誘発性腫瘍の標的となりうるが、イヌやマウスの一部の系統では勝 胱が主な標的となっている。一般的な遺伝毒性と腫瘍発生との間の段階についてのエビデンスは 十分ではない。4-Aminobiphenyl の膀胱の細胞増殖への影響についての研究は著しく不足している が、関連する芳香族アミンやアミドについての情報は入手可能であり、特にメガマウス ED-01 実 験(Cairns、1979年;Gaylor、1979年;Littlefieldら、1979年)のデータを用いたマウスの膀胱に おける 2-acetylaminofluorene によって誘導される DNA 反応性(及び変異原性)と細胞増殖との間 の相互作用の解析が行われている。変異原性が細胞増殖に依存していることは、DNA 付加体の用 量反応が直線的であるにもかかわらず、腫瘍の用量反応がシグモイド型であることの説明を提供 することができる(Cohen & Ellwein、1990年)。この関連性は、4-Aminobiphenyl 誘発性膀胱がん の発生と用量反応性を評価する上で重要な意味を持つ(以下の議論を参照)。

#### I. 不確実性、矛盾、データギャップ

4-Aminobiphenyl の代謝的活性化を伴う細菌を用いた突然変異試験では、ほとんどの変異がフレームシフトであることが示されているが、バクテリオファージ M13 クローニングベクターから得た一本鎖 DNA 中の lacZ 遺伝子の 4-Aminobiphenyl 誘発突然変異の配列解析を行ったところ、80% 以上が G 部位で生じる塩基対置換が明らかになった。G→T トランスバージョンが優勢で、次に G→C トランスバージョン、G→A トランジションが続いた。次に、主要な DNA 付加体である *N*-(deoxyguanosin-8-yl)-4-aminobiphenyl を M13 ゲノム内に挿入し、生体内複製後に変異頻度と特異性を測定した。目標とする突然変異率は約 0.01%であり、一次突然変異は G→C トランスバージョンであった。このように、in vitro での観察結果は in vivo での観察結果と矛盾しないが、変異原性 は弱いものであった (Verghis 6、1997 年)。

in vivo での研究のほとんどはマウスで行われている。無理からぬ理由ではあるが、イヌは膀胱 発がんに対して感受性が高い種であるにもかかわらず、あまり注目されていない。反応における マウスの系統の違いは明らかである。B6C3F1及び雌のBALB/cStCrlfC3Hf/Netrマウスは、肝臓発 がんに対してより感受性が高く、一方、雄のBALB/cStCrlfC3Hf/Netrマウスは、4-Aminobiphenylへ のばく露後に膀胱腫瘍を発症する(Schieferstein ら、1985年;Dooley ら、1988年、1992年)。そ れにもかかわらず、利用可能な研究では、マウスの系統差による影響はあまり注目されていない。

4-Aminobiphenyl が代謝され、肝臓や膀胱で DNA と付加体を形成する基本的な酵素と考えられ ているのは CYP1A2 である (Butler ら、1989 年 a、1989 年 b)。しかし、CYP1A2(+/+)野生型マウ スと CYP1A2(-/-) ックアウトマウスの影響を比較すると、予想に反して、CYP1A2 の発現は、4-Aminobiphenyl 誘発性酸化ストレスまたは 4-Aminobiphenyl-DNA 付加体形成とは関連していない ことが示された。さらに、他の第 1 相及び第 2 相反応の酵素の発現とともに肝 CYP1A2 タンパク 質の発現を 5 倍に増加させた 2,3,7,8-テトラクロロジベンゾ-*p*-ジオキシン (TCDD) は、肝臓にお ける付加体量を変化させないか、または実際に減少させた。このような誘導の定量的効果は、誘 導された酵素のパランスに依存するであろう。これらの結果は、CYP1A2 が 4-Aminobiphenyl の主 要な代謝的活性化因子ではないか、CYP1A2 の非存在下でもマウスの他の酵素がこの化合物を活 性化させていることを示唆している (Tsuneoka ら, 2003 年) 他の芳香族アミンを用いた研究に基 づくと、活性化酵素は他にも、P-450 酵素、酸化酵素、またはペルオキシダーゼを含むかもしれな い (Lakshmi ら、1990 年; Smith ら、1991 年; Hughes ら、1992 年)。 additional activating enzymes might include other P-450 enzymes, oxidases, or peroxidases (Lakshmi et al., 1990; Smith et al., 1991; Hughes et al., 1992).

Another reaction considered to be important for carcinogenesis induced by 4-aminobiphenyl is acetylation. Acetylation plays several roles in 4-aminobiphenyl carcinogenesis. *O*-Acetylation and *N*,*O*-acetyltransfer of *N*-hydroxy-4-aminobiphenyl are expected to increase risk in humans, whereas *N*-acetylation of 4-aminobiphenyl should reduce risk (Lower et al., 1979). Acetylation can be catalysed by NAT1 or NAT2, with the latter exhibiting a marked polymorphism within the population (Hein et al., 2000; Cascorbi et al., 2001). It is predicted that a slow acetylation phenotype will increase the risk of bladder cancer, since acetylation of the parent amine, 4-aminobiphenyl, is considered to be a detoxification process in humans, whereas a rapid acetylation phenotype should be associated with a decreased risk.

However, studies of acetylator phenotype in mice have produced conflicting results. In one study, male and female homozygous rapid acetylator or homozygous slow acetylator mice that were apparently identical in every other respect were administered 4-aminobiphenyl·HCl (55–300 mg/l) in drinking-water for 28 days. The levels of hepatic DNA adducts increased with dose in both sexes, with the levels being higher in females, but were independent of the mouse acetylator phenotype. In the urinary bladder, DNA adducts increased to a plateau at 100 mg/kg in male mice and were again independent of acetylator phenotype. In female mice, the DNA adduct levels were lower than in males and decreased at the highest dose; the DNA adduct levels were higher in the rapid acetylator phenotype, contrary to expectations (Flammang et al., 1992). These results were interpreted as suggesting that acetyltransferase activities are not rate determining for DNA adduct formation in mice. A similar conclusion that there was no correlation between murine NAT2 alleles and 4-aminobiphenyl-DNA adduct levels was reached by McQueen et al. (2003), using C57BL/6, B6.A, and A/J mouse strains and the transgenic strains hNAT1:A/J and hNAT1:C57, which carry the human NAT1 transgene. However, the differences in murine NAT2 activity were modest and probably not sufficient to affect 4-aminobiphenyl genotoxicity. Recent studies suggest that in humans, NAT1, not NAT2, is responsible for the O-acetylation of N-hydroxy-4-aminobiphenyl (Oda, 2004).

There are also mouse strain-specific mutations that require explanation. Thus, in B6C3F1, 4aminobiphenyl induces predominantly  $C \rightarrow A$  mutations (reflecting  $G \rightarrow T$  transversions in the non-coding strand) in H-*ras* codon 61, whereas in CD-1 mice, the predominant mutation in H-*ras* codon 61 was  $A \rightarrow T$  transversion (Manjanatha et al., 1996).

Cell proliferation is also required for neoplasia, but there have been few studies that have investigated cell proliferation at an early stage of the carcinogenic process of 4-aminobiphenyl. It is also notable that in the carcinogenicity experiment described previously (Schieferstein et al., 1985), although urinary bladder carcinomas developed only in males, a high prevalence of hyperplasia was reported in both males and females. Apparently this observation has not been investigated further (discussed below).

In summary, the evidence is strong for the sequence of key events including metabolic activation, DNA adduct formation, and gene mutation as the MOA for 4-aminobiphenyl-induced 4-Aminobiphenyl によって誘導される発がんにおいて重要であると考えられている別の反応は、 アセチル化である。アセチル化は 4-Aminobiphenyl の発がんにいくつかの役割を果たしている。*N*hydroxy-4-aminobiphenyl の *O*-アセチル化及び *N*,*O*-アセチル化は、ヒトではリスクを増加させると 予想されるが、4-Aminobiphenyl の *N*-アセチル化はリスクを減少させるはずである(Lower ら、 1979 年)。アセチル化は、NAT1 または NAT2 によって触媒され、後者は集団内で顕著な多型が存 在する(Hein ら、2000 年; Cascorbi ら、2001 年)。親アミンである 4-Aminobiphenyl のアセチル化 はヒトでは解毒過程と考えられているため、アセチル化が遅い表現型は膀胱がんのリスクを増加 させると予測されている。それゆえ、アセチル化が速い表現型はリスクの減少と関連しているは ずである。

しかし、マウスの acetylator の表現型の研究では、相反する結果が得られている。ある研究では、 他のすべての点で明らかに同一であると思われるホモ接合性の rapid acetylator マウスまたはホモ 接合性の slow acetylator マウスの雄雌に、4-Aminobiphenyl 塩酸 (55-300 mg/L) を 28 日間飲水投与 した。肝 DNA 付加体のレベルは雌雄ともに投与量の増加とともに増加したが、acetylator の表現 型とは無関係であった。膀胱では、DNA 付加体は雄マウスでは 100 mg/kg でプラトーに到達し、 acetylator の表現型とは無関係であった。雌マウスでは、DNA 付加体量は雄マウスよりも低く、最 高用量で減少したが、予想に反して rapid acetylator 表現型では DNA 付加体量が高かった (Flammang ら、1992 年)。これらの結果は、アセチルトランスフェラーゼ活性がマウスの DNA 付加体形成の 速度を決定するものではないことを示唆していると解釈された。McQueen ら (2003 年)の研究で は、C57BL/6、B6.A 及び A/J マウス株と、ヒト NAT1 トランス遺伝子を持つトランスジェニック マウス hNAT1:A/J 及び hNAT1:C57 を用いて、マウス NAT2 対立遺伝子と 4-Aminobiphenyl-DNA 付 加体量との間には相関関係がないという同様の結論に達した。しかし、マウスの NAT2 活性の違 いは軽微であり、おそらく 4-Aminobiphenyl の遺伝毒性に影響を与えるには十分ではなかった。最 近の研究では、ヒトでは N-hydroxy-4-aminobiphenyl の 0-アセチル化には NAT2 ではなく NAT1 が 関与していることが示唆されている (Oda、2004 年)。

また、説明が必要なマウスの系統特異的突然変異もある。例えば、B6C3F1 では、4-Aminobiphenyl は、H-ras 遺伝子のコドン 61 において主に C→A 突然変異(非コード鎖の G→T トランスバージョンを反映)を誘発するのに対し、CD-1 マウスでは、H-ras 遺伝子コドン 61 における主な突然変異は A→T トランスバージョンであった(Manjanatha ら、1996 年)。

腫瘍の発生には細胞増殖も必要であるが、4-Aminobiphenylの発がん過程の初期段階での細胞増 殖を調べた研究は少ない。また、先に述べた発がん性試験(Schieferstein ら、1985年)では、膀胱 がんの発生は雄のみであったが、過形成の発生率は雌雄ともに高いことが報告されている。しか しこのことについてはそれ以上調査されていない(後述)。

要約すると、4-Aminobiphenyl 誘発性膀胱発がんの MOA は、代謝的活性化、DNA 付加体形成、 遺伝子突然変異を含む一連の key events が関与していることが明らかになった。

urinary bladder carcinogenesis. It is further strengthened by data from studies with structurally related aromatic amines. However, data gaps remain concerning details of the specific enzymes involved, the basis for differing organ specificity between species and details regarding potency, and the shape of the dose–response curve in humans. This is, perhaps, not unexpected in view of the complexity of the relevant competing metabolic pathways. While available data are considered sufficient to support the hypothesized MOA, the impact of these uncertainties needs to be considered quantitatively in the overall assessment (Table 3).

#### Table 3. Modulating factors affecting 4-aminobiphenyl urinary bladder carcinogenesis.

- 1. Competing activities of esterification enzymes
- 2. Genetic polymorphisms affecting enzymatic activation or inactivation (e.g. slow and fast acetylators)
- 3. Urinary pH (mainly affected by diet) and possibly other urinary constituents
- 4. Urothelial cell proliferation (induced by high doses of 4-aminobiphenyl or by co-administration with some other agent affecting urothelial proliferation)

## CAN HUMAN RELEVANCE OF THE MOA BE REASONABLY EXCLUDED ON THE BASIS OF FUNDAMENTAL, QUALITATIVE DIFFERENCES IN KEY EVENTS BETWEEN EXPERIMENTAL ANIMALS AND HUMANS?

There is considerable evidence in humans and human cell systems supporting each of the key events for 4-aminobiphenyl-induced urinary bladder cancer. Metabolic activation to the *N*-hydroxylamine has been demonstrated, with several different enzymes being suggested for activation and several others that might potentiate or reduce the effects of *N*-hydroxylation, such as *N*-acetylation. Genetic polymorphisms significantly affect activities of these enzymes, producing variations in the population that can affect susceptibility to the urinary bladder carcinogenesis response to 4-aminobiphenyl exposures. DNA adducts identical to those detected in DNA from mice and dogs have been identified in human urothelial cells, and consequently they have a similar mutagenic potential. Furthermore, extensive epidemiological evidence demonstrates the urinary bladder carcinogenicity of 4-aminobiphenyl in humans.

Bladder cancer is associated with smoking and occupational exposures to 4-aminobiphenyl. 4-Aminobiphenyl was manufactured in the United States of America from 1935 to 1955 (Melick et al., 1955) and was used as a highly efficient rubber antioxidant, but it is apparently no longer commercially produced. In epidemiological studies, which were confined to one series of workers occupationally exposed to commercial 4-aminobiphenyl, a high incidence of bladder carcinomas was reported (Melick et al., 1955, 1971; Melamed et al., 1960; Koss et al., 1965, 1969). Among 503 workers, 59 cases with positive cytology were identified, among which 35 cases of carcinoma of the urinary bladder were histologically verified; 7 remained cytologically positive at the time of publication, while 7 died from other causes and 10 were lost to follow-up (Koss et al., 1969). In addition to cigarette smoke, there also appear to be other, ill-defined environmental sources of exposure, possibly from other sources of combustion of substances containing carbon and nitrogen (Skipper et al., 2003). Cigarette

#### Harmonization Project Document No. 4

このことは、構造的に関連のある芳香族アミンを用いた研究によってさらに強化されている。 しかし、関与する特定の酵素の詳細、種間での臓器特異性の違いの根拠や効力の詳細、ヒトにお ける用量反応曲線の形状については、データギャップが残っている。これは、競合する代謝経路 の複雑さを考えれば、想定内である。利用可能なデータは仮説 MOA を支持するのに十分である と考えられるが、これらの不確実性の影響については総合的な定量的評価を考慮する必要がある (表 3)。

#### 表 3. 4-Aminobiphenyl 膀胱発がん性に影響を与える調節因子

- 1 エステル化酵素の競合的活性
- 2 酵素の活性化または不活性化に影響を与える遺伝的多型(例: slow acetylator 及び rapid acetylator)
- 3 尿のpH(主に食事の影響を受ける)と他の尿成分
- 4 尿路粘膜細胞増殖(4-アミノビフェニルの高用量投与、または尿路粘膜増殖に影響を与える 他の薬剤との併用投与により誘導される)

## 実験動物とヒトとの間の key evants の根本的、質的な違いに基づいて、MOA のヒト との関連性を合理的に排除することができるか

4-Aminobiphenyl 誘発性膀胱がんの key events それぞれを支持するヒト及びヒトの細胞系におけ る有力なエビデンスがある。N-hydroxylamine への代謝的活性化が実証されており、活性化のため にいくつかの酵素が示されているほか、N-アセチル化などN-ヒドロキシル化の効果を増強または 減少させる可能性のある他の酵素も示唆されている。遺伝的多型はこれらの酵素活性に大きく影 響し、4-Aminobiphenyl ばく露に対する膀胱発がんの感受性に影響する変異を生じさせる。マウス やイヌの DNA から検出されたものと同一の DNA 付加体がヒトの尿路上皮細胞で確認されてお り、同様の変異原性を有することが明らかになった。さらに、広範な疫学的研究から、4-Aminobiphenyl のヒトにおける膀胱発がん性が証明されている。

膀胱がんは、喫煙や職業的ばく露といった 4-Aminobiphenyl の摂取と関連している。4-Aminobiphenyl は、1935 年から 1955 年まで米国で製造され(Melick ら、1955 年)、効率のいいゴ ム酸化防止剤として使用されていたが、現在では商業的には生産されていない。市販の 4-Aminobiphenyl に職業的にばく露された労働者の1系列に限定した疫学研究では、膀胱がんの発生 率が高いことが報告されている(Melick ら、1955 年、1971 年; Melamed ら、1960 年; Koss ら、 1965 年、1969 年)。503 人の労働者のうち、細胞診において 59 例が陽性、そのうち 35 例は組織学 的に膀胱がんが確認された; 公表時、7 例は細胞診において陽性のまま、7 例は他の原因で死亡し、 10 例は追跡調査できていない(Koss ら、1969 年)。たばこの煙に加えて、炭素及び窒素を含む物 質の燃焼で生じるものへのばく露や不明確な環境中の物質もあるようである(Skipper ら、2003 年)。

smoking accounts for between 40% and 70% of the bladder cancer cases in the United States and Europe (IARC, 1986; Castelao et al., 2001). Black (air-cured) tobacco is a greater source of 4-aminobiphenyl than is blonde (flue-cured) tobacco (Bryant et al., 1988).

The key events demonstrated for 4-aminobiphenyl bladder carcinogenesis in mice and dogs have also been specifically evaluated for 4-aminobiphenyl in humans, primarily in individuals exposed to 4-aminobiphenyl in cigarette smoke, but also utilizing in vitro methods with human urothelial cells (see Table 4).

## Table 4. Concordance evaluation of key events of 4-aminobiphenyl-induced urinary bladder carcinogenesis between species.

Key event	Mouse	Dog	Human
Reyevent	wouse	Dog	numan
1. Metabolic activation to reactive electrophile	+	+	+
2. DNA adduct formation	+	+	+
3. Mutagenesis	+	+	+
4. Carcinoma	+	+	+

Absorbed 4-aminobiphenyl is *N*-oxidized in the liver by CYP1A2, which, in spite of its rather high homology with CYP1A1, has an essentially different substrate specificity and is found only in liver (Lang & Pelkonen, 1999). Other enzymes have been suggested to be capable of supporting metabolic activation to the *N*-hydroxylamine.

NAT1 and NAT2 each catalyse three types of acetylation: the N-acetylation of arylamines, the O-acetylation of N-hydroxylamines, and the N,O-acetyltransfer of arylhydroxamic acids (Flammang & Kadlubar, 1986; Mattano et al., 1989; Fretland et al., 1997; Hein et al., 2000). It is believed that N-acetylation by N-acetyltransferases has a protective effect regarding bladder carcinogenicity, primarily because the acetamide of 4-aminobiphenyl formed is significantly less potent as a substrate for N-hydroxylation compared with the amine. Two genes, NAT1 and NAT2, code for the NAT isoforms, and allelic variation has been associated with susceptibility to urinary bladder cancer in humans (Hein et al., 2000). Most studies suggest that NAT2 slow acetylators are at increased risk of developing bladder cancer, whereas the contribution of the NATI genotype to aromatic amine bladder carcinogenesis is less clear (Cartwright et al., 1982; Hein et al., 2000). Among smokers, there is a higher level of 4-aminobiphenyl-haemoglobin adducts associated with the slow acetylator phenotype (Vineis et al., 1990). Interactions of *NAT1* and *NAT2* have been suggested (Cascorbi et al., 2001). In a study of 425 German bladder cancer patients, Cascorbi et al. (2001) found that there is (1) a partial linkage of the NATI\*10 genotype to the NAT2\*4 genotype, (2) a clear underrepresentation of NAT1\*10 genotypes among rapid NAT2 genotypes in the cases studied, and (3) a gene-gene-environment interaction in that NAT2\*slow/NAT1\*4 genotype combinations with a history of occupational exposure were 5.96 (2.96-12.0) times more frequent in cancer cases than in controls without a risk from occupation (P < 0.0001). Hence, the data suggest that individuals with NAT2\*4 and NAT1\*10 are at a significantly lower risk for bladder cancer, particularly when exposed to environmental risk factors.

#### IPCS Framework for Analysing the Relevance of a Cancer Mode of Action for Humans and Case-Studies

喫煙が原因とされているものは、米国とヨーロッパにおける膀胱がんの症例の 40%から 70%を占めている(IARC、1986年; Castelaoら、2001年)。黒タバコ(自然乾燥)は、ブロンドタバコ(熱風乾燥)に比べて 4-Aminobiphenylをより多く含んでいる(Bryant ら、1988年)。

4-Aminobiphenylの膀胱発がんにおけるマウスやイヌで示された key events は、主にタバコの煙中の4-Aminobiphenyl にばく露されたヒトを対象に評価されているが、ヒトの尿路上皮細胞を用いた in vitro 評価法も利用されている(表4を参照)。

表 4.4-Aminobiphenyl による尿路膀胱発がんの key events の種間一致性評価

key events	マウス	イヌ	ድኑ
1. 反応性親電子物質への代謝的活性化	+	+	+
2. DNA 付加体の形成	+	+	+
3. 変異原性	+	+	+
4. 発がん	+	+	+

吸収された 4-Aminobiphenyl は、CYP1A2 によって肝臓で N-酸化される。CYP1A2 は CYP1A1 との相同性がかなり高いにもかかわらず、異なる基質特異性を有しており、肝臓でのみ見出される (Lang & Pelkonen、1999)。他の酵素は、N-hydroxylamine への代謝的活性化をサポートする。

NAT1 及び NAT2 はそれぞれ、3 種類のアセチル化を触媒する。すなわち、アリルアミンの N-ア セチル化、N-hydroxylamineのO-アセチル化及びアリルヒドロキサム酸のN, O-アセチル化である (Flammang & Kadlubar、1986 年; Mattano ら、1989 年; Fretland ら、1997 年; Hein ら、2000 年)。 N-アセチルトランスフェラーゼによる N-アセチル化は、主に、形成された 4-Aminobiphenyl のア セトアミドがアミンに比べて N-ヒドロキシル化の基質として小さいために、膀胱発がん性に対し て保護効果を有すると考えられている。NAT アイソフォームをコードする 2 つの遺伝子には、 NAT1とNAT2があり、対立遺伝子の変異はヒトにおける膀胱がんの感受性と関連している(Hein ら、2000年)。ほとんどの研究は、NAT2の slow acetylator が膀胱発がんのリスク増加を示唆して いるが、芳香族アミン膀胱発がんに対する NATI 遺伝子型の寄与は明らかではない(Cartwright ら、 1982年; Hein ら、2000年)。喫煙者の間では、slow acetylator の発現に関連する 4-Aminobiphenyl-ヘモグロビン付加体がより多く存在する (Vineis ら、1990年)。また、NAT1 と NAT2 の相互作用 が示唆されている(Cascorbiら、2001年)。ドイツの膀胱がん患者 425 人を対象とした研究で、 Cascorbi ら (2001 年) は、以下のことを明らかにした。(1) NAT1\*10 遺伝子型の NAT2\*4 遺伝子 型への部分的な連鎖(2)調査した症例中の rapid NAT2 遺伝子型を有するヒトにおける、NAT1\*10 遺伝子型の発現量の低さ(3)職業ばく露歴とNAT2\* slow/NAT1\*4 遺伝子型の組み合わせは、職業 ばく露によるリスクのない対照群に比べて、がん症例は 5.96 倍(2.96-12.0)の頻度であった (P<0.0001)

Polymorphisms in *CYP1A2* (Oscarson et al., n.d.) and *NAT2* (Hein et al., 2000) genes are associated with variations in the activities of these enzymes in human populations, although the extent to which variation in CYP1A2 activity is due to genetic factors has yet to be determined (Sachse et al., 2003). Moreover, expression of the *CYP1A2* gene is induced in cigarette smokers, leading to even higher CYP1A2 enzyme activities (Sesardic et al., 1988; Eaton et al., 1995). An individual exposed to 4-aminobiphenyl and expressing high levels of CYP1A2 and slow NAT2 activity would be expected to have increased levels of *N*-hydroxy-4-aminobiphenyl and, therefore, higher levels of 4-aminobiphenyl–haemoglobin adducts and 4-aminobiphenyl–DNA adducts in liver and urinary bladder than an individual expressing low levels of CYP1A2 and rapid NAT2 activity.

The tumour suppressor genes *RB1* and *TP53* appear to be involved in bladder cancer, especially high-grade urothelial carcinomas rather than low-grade papillary tumours. Both genes are involved in the regulation of the cell cycle. In addition, TP53 plays a role in response to DNA damage, cell death, and neovascularization (Hickman et al., 2002), and its gene product regulates the expression of multiple genes (Vousden & Lu, 2002). A strong association has been found between *RB1* inactivation and muscle invasion (Cairns et al., 1991; Ishikawa et al., 1991; Presti et al., 1991; Primdahl et al., 2000). In one study of 45 bladder cancers, seven of nine TP53 mutations occurred in grade 3 tumours (i.e. invasion includes perivesicular tissue) (Martone et al., 1998). Inactivation of RB1 occurs in 30-80% of muscle-invasive bladder cancers (Cairns et al., 1991; Logothetis et al., 1992; Wright et al., 1995; Ioachim et al., 2000), most frequently as a consequence of heterozygous 13g deletions in combination with mutation of the remaining allele (Cordon-Cardo & Reuter, 1997). In studies investigating at least 30 tumours, TP53 mutations occurred in 40-60% of invasive bladder cancers (Tiguert et al., 2001; Lu et al., 2002). Although no specific mutational hotspots were identified, more than 90% of the mutations occurred in exons 4–9. In a study of the binding spectrum of N-hydroxy-4-aminobiphenyl in DNA fragments containing exons 5, 7, and 8 of TP53, preferential binding was identified at codon 285, a non-CpG site, and at codons 175 and 248, which are CpG sites, but only after C5 cytosine methylation had occurred (Feng et al., 2002). The authors concluded that the mutational spectrum in TP53 in bladder cancer strongly suggests a role of 4-aminobiphenyl in the etiology of this neoplasm.

Exposure to tobacco smoke, an environmental source of 4-aminobiphenyl, is associated with increased levels of 4-aminobiphenyl–haemoglobin adducts, in both adults and fetuses. In a study of smoking (n = 14) and non-smoking (n = 38) women, 4-aminobiphenyl–haemoglobin levels were  $183 \pm 108$  pg/g haemoglobin in smokers and  $22 \pm 8$  pg/g haemoglobin in non-smokers, whereas the levels in their respective fetuses were  $92 \pm 54$  pg/g haemoglobin adduct levels in adults in studies of tumour tissue DNA (Curigliano et al., 1996). Haemoglobin adduct levels (used as a surrogate for exposure levels and indicator for DNA adduct potential) have been associated with levels of exposure to tobacco as a source of 4-aminobiphenyl (black tobacco > blonde tobacco > non-smokers) in a male study population from Turin, Italy; the risk of bladder cancer followed the same pattern (Bryant et al., 1988). There is a substantial gap in information linking the presence of adducts, primarily an indication of exposure, and the emergence of cancer.

したがって、特に環境リスク因子にばく露される場合、NAT2\*4 及び NAT1\*10 を有する個体は、 膀胱がんのリスクが有意に低いことが示唆される。

CYP1A2 (Oscarson ら、n.d.) 及び NAT2 (Hein ら、2000 年) 遺伝子の多型は、ヒト集団における これらの酵素活性の変動と関連しているが、CYP1A2 活性の変動が遺伝的要因によるものである かはまだ明らかにされていない (Sachse ら、2003 年)。さらに、喫煙者に誘導される CYP1A2 遺伝 子の発現は、CYP1A2 酵素活性を高める (Sesardic ら、1988; Eaton ら、1995 年)。4-Aminobiphenyl にばく露され、CYP1A2 と高い slow NAT2 活性を発現する個体は、CYP1A2 と低い rapid NAT2 活 性を発現する個体よりも、N-hydroxy-4-aminobiphenyl のレベルが高い。したがって、肝臓と膀胱に おける 4-Aminobiphenyl -ヘモグロビン付加体と 4-Aminobiphenyl-DNA 付加体の高いレベルを有す ることが予測される。

腫瘍抑制遺伝子 RBI 及び TP53 は、膀胱がん、特に低悪性度の乳頭腫瘍よりも高悪性度の尿路 上皮がんに関与しているようである。両遺伝子は細胞周期の調節に関与している。さらに、TP53 は、DNA 損傷、細胞死及び血管新生の役割を果たし(Hickman ら、2002 年)、その遺伝子産物は、 複数の遺伝子の発現を調節する(Vousden & Lu、2002 年)。RB1 の不活性化と筋肉内への浸潤に強 い関連が見出されている(Cairns ら、1991年; Ishikawa ら、1991年; Presti ら、1991年; Primdahl ら、2000年)。45 例の膀胱がんを対象とした研究では、TP53 変異を有する9人のうち7人がグレ ード3の腫瘍(周囲組織への浸潤を含む)であった(Martone ら、1998年)。RB1の不活性化は、 筋肉内浸潤性膀胱がんの 30~80%で発生し (Cairns ら、1991 年; Logothetis ら、1992 年; Wright ら、1995年; Ioachim ら、2000年)、多くの場合、ヘテロ接合性 13g 欠失と残りの対立遺伝子の突 然変異の結果発生する(Cordon-Cardo & Reuter、1997年)。少なくとも 30の腫瘍を調査した研究 では、浸潤性膀胱がんの 40~60%で TP53 突然変異が認められた(Tiguert ら、2001 年: Lu ら、 2002年)。特定変異のホットスポットは確認されなかったが、変異の90%以上はエクソン4-9に発 生していた。TP53のエクソン5、7及び8を含む DNA 断片における N-hydroxy-4-aminobiphenylの 結合スペクトルの研究では、非 CpG 部位である 285 コドン及び CpG 部位である 175 及び 248 コ ドンに優先的に結合することが確認されたが、C5シトシンメチル化が起こった後にのみ確認され た(Fengら、2002年)。著者らは、膀胱がんにおける TP53 の変異スペクトルが、この腫瘍の原因 である 4-Aminobiphenyl の役割を強く示唆していると結論づけた。

4-Aminobiphenyl の環境中ばく露の源であるタバコの煙へのばく露は、成人と胎児の両方で、4-Aminobiphenyl-ヘモグロビン付加体量の増加と関連している。喫煙者(n=14)と非喫煙者(n=38)の女性の研究では、4-Aminobiphenyl-ヘモグロビンレベルは、喫煙者では183±108 pg/g ヘモグロビン、非喫煙者では22±8 pg/g ヘモグロビンであったのに対し、それぞれの胎児のレベルは92±54 pg/g ヘモグロビンと 17±13 pg/g ヘモグロビン (Coghlin ら、1991年)であった。この差は、腫瘍組織 DNA の研究において成人でも観察されている(Curigliano ら、1996年)。イタリア、トリノの男性における研究では、ヘモグロビン付加体量(ばく露量の代用として、また DNA 付加体の可能性の指標として使用される)は、4-Aminobiphenyl の供給源であるタバコへのばく露量と関連しており(黒タバコ>膀胱がんのリスクでも同様の傾向がみられた(Bryant ら、1988年)。主にばく露の指標である付加体の存在とがん発生とを結びつける情報には大きなギャップがある。

In humans, 4-aminobiphenvl has been associated only with urinary bladder cancer, whereas in mice, liver and urinary bladder tumours are induced. Although the specific reasons for these species differences in organ specificity are not known, they appear to be due to variations in competing N-esterification enzymatic activations. Sulfation appears to be primarily associated with liver carcinogenesis by aromatic amines, whereas N-glucuronidation appears to be more associated with bladder carcinogenesis. Acetylation has mixed effects, but in humans appears to be principally a detoxification process that can be influenced significantly by N-acetyltransferase polymorphisms that result in fast versus slow acetylation. Human tissues have been studied for their possible involvement in the metabolism of 4aminobiphenyl and its metabolites. CYP1A2 is responsible for the metabolism of 4-aminobiphenyl to N-hydroxy-4-aminobiphenyl by human hepatic microsomal fraction (Butler et al., 1989b). N-Hydroxy-4-aminobiphenyl can be metabolized to a product that binds covalently to calf thymus DNA by cytosolic sulfotransferases from human liver and, to a lesser extent, colon, but not from pancreas or urinary bladder. In view of this lack of sulfotransferase activity in bladder, it has been suggested that hepatic sulformasferase may actually decrease the bioavailability of N-hydroxy-4-aminobiphenyl in extrahepatic tissues and serve as a detoxification mechanism for the urinary bladder (Chou et al., 1995). On the other hand, Nacetyltransferases that are present in human urothelial cells (Frederickson et al., 1992; Swaminathan & Reznikoff, 1992) can metabolize N-hydroxy-4-aminobiphenyl, as well as the acetylated compounds N-hydroxy-4-acetylaminobiphenyl and N-acetoxy-4-acetylaminobiphenyl, to a DNA-reactive material. The major adduct co-chromatographs with N-(deoxyguanosin-8-yl)-4-aminobiphenyl. <sup>32</sup>P-postlabelling analysis of the DNA from cytosolmediated binding of N-hydroxy-4-aminobiphenyl revealed four radioactive spots. Five adducts were found when intact human urothelial cells were used, two of which were the same as two found using cytosol. This suggests the possibility of an activation pathway or pathways in addition to acetylation.

Experiments similar to those performed with dog tissues have shown that human urothelial cell microsomes possess transacetylation activity, so that *N*-hydroxy-4-aminobiphenyl binding to RNA and DNA occurs in the presence of 4-acetylaminobiphenyl, *N*-hydroxy-4-acetylaminobiphenyl, or acetylCoA as acetyl donors (Hatcher et al., 1993). These authors also found that <sup>32</sup>P-postlabelling of DNA adducts formed after reaction with *N*-hydroxy-4-aminobiphenyl, *N*-hydroxy-4-acetylaminobiphenyl, and *N*-acetoxy-4-aminobiphenyl showed similar profiles, suggesting that the arylnitrenium ion, arising from *N*-acetoxy-4-aminobiphenyl, might be the common reactive species. The structures of the adducts have been identified as the 3',5'-bisphospho derivatives of *N*-(deoxyguanosin-8-yl)-4-aminobiphenyl (dG-C8-aminobiphenyl), *N*-(deoxyadenosin-8-yl)-4-aminobiphenyl (dA-C8-aminobiphenyl) (Frederickson et al., 1992; Hatcher & Swaminathan, 1995), and *N*-(deoxyguanosin-*N*(2)-yl)-4-azobiphenyl (Hatcher & Swaminathan, 2002).

The results available comparing tobacco smokers with non-smokers support the relevance to humans of the hypothesized MOA. In a study of 46 T1 bladder cancer cases, mean relative staining intensity for 4-aminobiphenyl–DNA adducts was significantly higher in current smokers ( $275 \pm 81$ , n = 24) than in non-smokers ( $113 \pm 71$ , n = 22) (Curigliano et al., 1996). Similar results have been reported for laryngeal tissue (Flamini et al., 1998) and for mammary tissue (Faraglia et al., 2003). Using 4-aminobiphenyl–haemoglobin adducts as an

#### IPCS Framework for Analysing the Relevance of a Cancer Mode of Action for Humans and Case-Studies

ヒトでは、4-Aminobiphenylは膀胱がんとのみ関連しているが、マウスでは肝臓と膀胱の腫瘍が 誘発されている。臓器特異性におけるこれらの種差の具体的な理由は明らかにされていないが、 競合する N-エステル化酵素の活性化の違いによるものと考えられる。硫酸化は芳香族アミンによ る肝発がんと密接に関連しているようだが、N-グルクロン酸化は膀胱発がんと関連しているよう である。アセチル化には様々な効果があるが、ヒトでは主に解毒プロセスであり、アセチル化が 速いか遅いかを決定する N-アセチルトランスフェラーゼの型に大きく影響される。ヒトの組織が、 4-Aminobiphenyl とその代謝物の代謝に関与しているかについて研究されてきた。CYP1A2 は、ヒ ト肝ミクロソーム分画による 4-aminobiphenyl から N-hydroxy-4-aminobiphenyl への代謝に関与して いる (Butler ら、1989 年 b)。*N*-hydroxy-4-aminobiphenyl は、ヒト肝臓及びそれより程度は低いが、 結腸由来の細胞質性スルホトランスフェラーゼによって、牛胸腺 DNA と共有結合する生成物に 代謝されるが、膵臓や膀胱由来のものによっては代謝されない。膀胱でのスルホトランスフェラ ーゼ活性の欠如を考慮すると、肝スルホトランスフェラーゼは肝外組織での N-hydroxy-4aminobiphenyl の生物学的利用能を低下させ、膀胱の解毒機構として機能する可能性が示唆されて いる (Chou ら、1995 年)。一方、ヒト尿路上皮細胞に存在する N-アセチルトランスフェラーゼ (Frederickson ら、1992: Swaminathan & Reznikoff、1992年)は、N-hydroxy-4-aminobiphenyl 及び そのアセチル化化合物 N-hydroxy-4-acetylaminobiphenyl 及び N-アセトキシ-4-アセチルアミノビフ エニルを DNA 反応性物質に代謝することができる。N-(deoxyguanosin-8-yl)-4-aminobiphenyl と主 要な付加体はコクロマトグラフされ、N-hydroxy-4-aminobiphenyl のサイトゾル媒介結合で得た DNA を用いた <sup>32</sup>P-ポストラベリング法により、4 つの放射性スポットが明らかになった。健康な ヒト尿路上皮細胞を用いた場合には5つの付加体が認められたが、そのうち2つはサイトゾルを 用いた場合に認められた2つの付加体と同じであった。このことから、アセチル化以外の活性化 経路の存在が示唆された。

イヌ組織を用いた実験と同様の実験により、ヒトの尿路上皮細胞ミクロソームがアセチル基転移活性を有していることが示されており、N-hydroxy-4-aminobiphenylのRNAやDNAへの結合は、 4-Acetylaminobiphenyl、N-hydroxy-4-acetylaminobiphenyl、またはアセチル CoA をアセチル基供与体とした場合に起こることが示されている(Hatcher ら、1993年)。また、N-hydroxy-4-aminobiphenyl、 N-acetoxy-4-acetylaminobiphenyl、N-acetoxy-4-aminobiphenyl と反応させて生成した DNA 付加体の <sup>32</sup>P-ポストラベリングは、類似のプロファイルを示し、N-acetoxy-4-aminobiphenyl から生じるアリ ルニトレニウムイオンが共通の反応種であることを発見した。この付加体の構造は、N-(deoxyguanosin-8-yl)-4-aminobiphenyl)の 3',5'-ビスホスホ誘導体(Frederickson ら、1992年; Hatcher & Swaminathanosin、1995年)及び N-(deoxyguanosin-N(2)-yl)-4-azobiphenyl (Hatcher & Swaminathan、 2002年)として同定されている。

喫煙者と非喫煙者を比較した結果は、仮説 MOA のヒトへの関連性を支持するものである。T1 膀胱がん46例の研究では、4-Aminobiphenyl-DNA 付加体の平均相対染色強度は、非喫煙者(113±71、 n=22)よりも現在の喫煙者(275±81、n=24)の方が有意に高かった(Curiglianoら、1996年)。同 様の結果が喉頭組織(Flaminiら、1998年)及び乳腺組織(Faragliaら、2003年)についても報告 されている。4-Aminobiphenyl-ヘモグロビン付加体をばく露の指標として使用すると、膀胱がん患 者は対照者よりも高いレベルであったのに対し(Del Santoら、1991年)、肺がん患者はそうでは なかった(Westonら、1991年)。この違いの根拠は不明である。 indicator of exposure, it was found that bladder carcinoma patients had higher levels than controls (Del Santo et al., 1991), whereas lung cancer patients did not (Weston et al., 1991). The basis for this difference is unknown.

In addition to the evidence of genotoxicity generated with non-human test systems, 4-aminobiphenyl can be metabolized by human urothelial cell microsomal preparations to a mutagen in *S. typhimurium* YG1024 (a derivative of TA98 with elevated *O*-acetyltransferase activity) but not in strain TA98 itself (Hatcher et al., 1993). No other species or other human tissues were examined in this study.

6-Thioguanine-resistant mutants can be induced in a non-tumorigenic, SV40-immortalized human urothelial cell line by exposure to 4-aminobiphenyl itself or exposure to N-hydroxy-4aminobiphenyl, N-hydroxy-4-acetylaminobiphenyl, or N-acetoxy-4-acetylaminobiphenyl (Bookland et al., 1992a). No exogenous metabolic activation system was required for the observed activity. The lowest effective concentrations to produce a statistically significant increase in the mutant fraction were as follows: N-acetoxy-4-acetylaminobiphenyl, 2 µmol/l; N-hydroxy-4-acetylaminobiphenyl, 5 umol/l; N-hydroxy-4-aminobiphenyl, 20 umol/l; and 4aminobiphenyl, 100 µmol/l. Three of these substances were also tested for tumorigenic transformation using the same human immortalized urothelial cells in an in vitro-in vivo assay in which the end-point was carcinoma development when treated cells were injected subcutaneously into nude mice (Bookland et al., 1992b). Transformation was demonstrated after all treatments, the lowest concentrations being as follows: N-hydroxy-4-acetylaminobiphenyl, 0.5 µmol/l; N-hydroxy-4-aminobiphenyl, 0.5 µmol/l; and 4-aminobiphenyl, 20 µmol/l. The lower concentrations required for transformation in comparison with those for mutation are noted, but how this should be interpreted is not clear. It is consistent with the transformation being independent of mutation and with the transformation assay having a higher sensitivity, or it could merely reflect a difference in sensitivity of the methods.

In summary, on a qualitative basis, the key events in the MOA are the same in mice, dogs, and humans: metabolic activation to the *N*-hydroxylamine with subsequent formation of a reactive electrophile (presumably the nitrenium ion), formation of guanine adducts, gene mutation, and the ultimate formation of cancer. The intervening events between gene mutation and cancer, such as which genes are mutated and how cancer is induced, are not known. The MOA, nevertheless, has been clearly demonstrated and is the same in the animal models and in humans.

## CAN HUMAN RELEVANCE OF THE MOA BE REASONABLY EXCLUDED ON THE BASIS OF QUANTITATIVE DIFFERENCES IN EITHER KINETIC OR DYNAMIC FACTORS BETWEEN EXPERIMENTAL ANIMALS AND HUMANS?

As described in detail above, the metabolic activation, DNA adducts, and mutagenicity of 4aminobiphenyl are qualitatively the same in mice, dogs, and humans, leading to the induction of urothelial tumours of the urinary bladder in these three species and other tumours in mice, rats, and rabbits. Although detailed aspects of absorption, distribution, and excretion have not been reported, similarity in the levels of DNA adduct formation in the urothelium occurring in mice, dogs, and humans suggests that kinetic differences are not significant between these ヒト以外の試験系で得られた遺伝毒性のエビデンスに加えて、4-Aminobiphenyl は、ヒト尿路上 皮細胞のミクロソーム調製物によって、5. typhimurium YG1024 (O-アセチルトランスフェラーゼ 活性の高い TA98 の派生株)の変異原性物質に代謝されることがあるが、TA98 株自体では代謝さ れない (Hatcher ら、1993 年)。この研究では、他の種または他のヒト組織は調べられていない。

6- f + f / r = v 耐性変異体は、4-Aminobiphenyl 自体へのばく露、または N-hydroxy-4aminobiphenyl、N-hydroxy-4-aminobiphenyl、N-acetoxy-4-acetylaminobiphenyl へのばく露によって、 非腫瘍性 SV40 不死化ヒト尿路上皮細胞株で誘導することができる(Bookland ら、1992 年 a)。観 察された活性には、外因性代謝的活性化経路は必要とされなかった。変異体分画の統計的に有意 な増加をもたらすための最小濃度は以下の通りであった。N-acetoxy-4-acetylaminobiphenyl、2 µmol/L;N-hydroxy-4-acetylaminobiphenyl、5µmol/L;N-hydroxy-4-aminobiphenyl、20µmol/L;及び 4-Aminobiphenyl、100 µmol/L。また、これらの物質のうちの3つは処理した細胞をヌードマウス に皮下注射したときの発がんをエンドポイントとした in vitro-in vivo アッセイにおいて、同じヒト 不死化尿路上皮細胞を使用した腫瘍性形質転換についても検討が実施された(Bookland ら、1992 年 b)。形質転換はすべての試験で示されたが、最小濃度は以下の通りであった。N-hydroxy-4acetylaminobiphenyl、0.5 µmol/L;N-hydroxy-4-aminobiphenyl、0.5 µmol/L;及び 4-Aminobiphenyl、0.5 µmol/L;N-hydroxy-4-aminobiphenyl、0.5 µmol/L;及び 4-Aminobiphenyl、0.5 µmol/L;N-hydroxy-4-aminobiphenyl、0.5 µmol/L;N-hydroxy-4acetylaminobiphenyl、0.5 µmol/L;N-hydroxy-4-aminobiphenyl、0.5 µmol/L;N-hydroxy-6-aminobiphenyl、0.5 µmol/L;N-hydroxy-6-aminobiphenyl、0.5 µmol/L;N-hydroxy-6-aminobiphenyl、0.5 µmol/L;N-hydroxy-6-aminobiphenyl、0.5 µmol/L;N-hydroxy-6-aminobiphenyl、0.5 µmol/L;N-hydroxy-6-aminobiphenyl、0.5 µmol/L;N-

要約すると、マウス、イヌ、ヒトにおいて、MOA の key events は定性的には同じである: *N*-hydroxylamine への代謝的活性化とそれに続く反応性親電子物質(おそらくニトレニウムイオン)の形成、グアニン付加体の形成、遺伝子突然変異及びがんの形成である。どの遺伝子が変異し、どのようにしてがんが誘発されるのかなど、遺伝子変異とがんとの間に介在する事象は明らかにされていない。それにもかかわらず、MOA は明確に示されており、動物モデルでもヒトでも同じである。

# 実験動物とヒトとの間の動態的または薬力学的要因のいずれかの量的差異に基づいて、MOAのヒトへの関連性を合理的に排除することができるか

以上詳述したように、4-Aminobiphenylの代謝的活性化、DNA 付加体、変異原性は、マウス、イ ヌ、ヒトでは定性的に同じであり、これら3種では膀胱腫瘍を誘発し、マウス、ラット、ウサギ ではその他の腫瘍を誘発する。吸収、分布、排泄に関する詳細は報告されていないが、マウス、 イヌ、ヒトで発生する尿路上皮における DNA 付加体形成量が類似していることから、3種の間で は速度論的な差異は有意ではないことが示唆されている。

three species. Although similar enzymatic processes occur in the three species, quantitative differences are evident. These differences may explain some of the variations seen in target organ specificity among the species and might suggest possible quantitative differences in generation of the DNA adducts. Nevertheless, these differences do not negate the overall MOA for any of the species or the different target organs and are consistent with the complexity of the competing pathways for metabolic activation and deactivation.

Presumably there is a potential for repair of the different adducts, and quantitative differences might exist among species and even among tissues. However, the detection of relatively high numbers of adducts in all three species indicates that significant numbers of stable adducts are produced.

The target tissue common among mice, dogs, and humans, the urinary bladder urothelium, is similar morphologically (Pauli et al., 1983). The urothelium has a characteristic asymmetric unit membrane at the luminal surface that provides a major part of the barrier function to urine. It is composed of urothelium-specific proteins, the uroplakins, the sequence of which is highly conserved among species (Wu et al., 1994). In addition, the urothelium is metabolically active in all three species.

Modulating urinary factors have also been identified that can quantitatively affect the ultimate formation of urothelial DNA adducts, such as pH and frequency of urination (Cohen, 1995; Sarkar et al., 2002). Although the range of pH varies among species, the pH in mice, dogs, and humans readily reaches acidic and alkaline levels as well as neutral. Again, although quantitative differences occur, these do not preclude the existence of this MOA in humans.

There is no evidence implicating another MOA besides DNA reactivity. However, significant quantitative differences exist between species with regard to apparent potency of 4aminobiphenyl with respect to urinary bladder carcinogenesis. It is clear, however, that metabolites of 4-aminobiphenyl interact with proteins (e.g. haemoglobin) as well as with DNA and that metabolites of 4-aminobiphenyl are cytotoxic (Schieferstein et al., 1985; Reznikoff et al., 1986; Kadlubar et al., 1991). Interaction with urothelial cellular proteins might be responsible for the cytotoxicity and regenerative proliferation seen in the mouse bladder at higher doses of 4-aminobiphenyl. The interaction of DNA reactivity and consequent mutagenicity and cell proliferation provide an explanation for the sigmoidal shape of the dose-response curve for tumours despite a linear dose-response for DNA adducts (Cohen & Ellwein, 1990). The high concentrations of 4-aminobiphenyl found in the urine of mice that can produce urothelial cytotoxicity are generally not attained in humans exposed to cigarette smoke. However, other (unknown) substances appear to produce urothelial hyperplasia in cigarette smokers (Auerbach & Garfinkel, 1989). This increased cell proliferation significantly potentiates the effects of 4-aminobiphenyl on the bladder, providing a significantly greater number of DNA-replicating cell targets on which to act in comparison with the small number present in the normal, slowly replicating urothelium. Thus, the apparent greater potency of 4-aminobiphenyl in humans compared with mice is unlikely, but represents the synergy of DNA reactivity and cell proliferation produced by a single substance, 4-aminobiphenyl, in mice, but by different substances in the complex mixture of cigarette smoke.

#### IPCS Framework for Analysing the Relevance of a Cancer Mode of Action for Humans and Case-Studies

3 種の酵素の過程は類似しているが、量的な違いは明らかである。これらの違いは、種間で見られ る標的臓器の特異性の違いの一部を説明し、DNA 付加体の生成における定量的な違いを示唆して いる可能性がある。それにもかかわらず、これらの違いは、どの種でも、あるいは異なる標的臓 器でも、全体的な MOA を否定するものではなく、代謝的活性化と不活性化のための競合する経 路の複雑さと一致している。

おそらく、異なる付加体の修復能や種間、組織間における量的な違いが存在するだろう。しか し、3種すべてで比較的多くの付加体が検出されたことから、かなり多くの安定的な付加体が産 生されていることがわかる。

マウス、イヌ、ヒトに共通する標的組織である膀胱の尿路上皮は、形態学的に類似している(Pauli ら、1983年)。尿路上皮は、腔内表面の尿に対するパリア機能の大部分を担う特徴的な非対称性単 位膜を有している。尿路上皮は、尿路上皮特異的タンパク質であるウロプラキンから構成されて おり、その配列は種間で高度に保存されている(Wu ら、1994年)。さらに、尿路上皮は、3種す べての種において代謝的に活性化している。

また、尿 pH や排尿頻度など、尿路上皮 DNA 付加体の最終的な産生量に影響を与える因子も同 定されている(Cohen ら、1995年; Sarkar ら、2002年)。pH の範囲は種によって異なるが、マウ ス、イヌ及びヒトの尿 pH は、容易に酸性及びアルカリ性、また中性に変動する。繰り返しになる が、量的な違いは生じるものの、これらはヒトにおける MOA の存在を排除するものではない。

DNA 反応性以外の MOA を示唆するエビデンスはない。しかし、4-Aminobiphenyl の膀胱発がん に対する見かけの影響に関しては、種間で量的な差が存在する。4-Aminobiphenylの代謝物はDNA と同様にタンパク質(ヘモグロビンなど)とも相互作用し、4-Aminobiphenylの代謝物は細胞毒性 を有することが明らかになっている (Schieferstein ら、1985 年; Reznikoff ら、1986 年; Kadlubar ら、1991年)。4-Aminobiphenylの高用量投与によるマウス膀胱の細胞毒性と再生性増殖には、尿 路上皮細胞タンパク質との相互作用が関与している可能性がある。DNA の反応性と、相反する変 異原性と細胞増殖の相互作用は、DNA 付加体の用量反応が直線的であるにもかかわらず、腫瘍の 用量反応曲線がシグモイド型であることを説明している(Cohen & Ellwein、1990年)。尿路上皮細 胞毒性を生じる可能性があるマウスの尿中に見られる高濃度の4-Aminobiphenylは、一般的に受動 喫煙者では達成されていない。しかし、他の(未知の)物質は、喫煙者(Auerbach & Garfinkel、 1989年)で尿路上皮の過形成を生成するように見える。この細胞増殖の増加は、標的となる DNA 複製細胞の数を大幅に増やし、正常にゆっくりと複製する少数の尿路上皮と比較して、膀胱に対 する 4-Aminobiphenyl の影響を大幅に増強する。このように、マウスと比較してヒトの方が 4-Aminobiphenyl の明らかに大きな効力は考えにくい。しかし、マウスでは 4-Aminobiphenyl 単一の 物質による DNA 反応性と細胞増殖の相乗効果がタバコの煙の複雑な混合物中の様々な物質によ って引き起こることが示されている。

Occupational exposure to 4-aminobiphenyl presumably resulted in greater doses of 4-aminobiphenyl than did exposure to cigarette smoke, since the incidence of bladder cancer in such populations was considerably higher than in smokers. However, quantitative measurements of metabolite concentrations or DNA adduct levels in urothelial cells could not be determined at the time these occupational exposures occurred, and cigarette smoking history in those individuals was not assessed (Koss et al., 1965, 1969).

In summary, although quantitative differences among species exist, they do not exclude the same MOA in mice and dogs occurring in humans.

# CONCLUSION: STATEMENT OF CONFIDENCE, ANALYSIS, AND IMPLICATIONS

The early steps in the proposed MOA are well supported by the available evidence, indicating that the key events of metabolic activation, DNA adduct formation, and mutation are the same qualitatively in mice, dogs, and humans. There is strong and sufficient evidence that 4-aminobiphenyl is a human urinary bladder carcinogen. Evidence for the intervening steps between mutation and cancer development is lacking. The associations described for adduct levels and *TP53* mutations are not compelling because these particular genetic alterations appear late in tumour progression and are often the result of endogenous causes (e.g. spontaneous depurination at methylated CpG sites). This aspect of *TP53* mutations in bladder cancer has been studied in a case–control study (Schroeder et al., 2003). In addition, most urothelial tumours in humans are low-grade papillary lesions, which generally do not have *TP53* mutations.

The mutational spectrum of N-hydroxy-4-acetylaminobiphenyl has been studied in embryonic fibroblasts of the Big Blue mouse (Besaratinia et al., 2002). Treatment of these cells for 24 h resulted in a dose-dependent increase in mutation frequency of the *cII* transgene of up to 12.8-fold over background. Single-base substitutions comprised 86% of the mutations in the treated cells and 74% of the mutations in the controls. Of these mutations, 63% and 36%. respectively, occurred at guarantee residues along the *cII* gene. Whereas  $G \rightarrow T$  transversions accounted for 47% of the mutations in the treated *cII* gene, the most common mutations in untreated cells were insertions, which accounted for 19% of the mutations. Mapping of the induced adducts established five preferred DNA adduction sites, of which four were major mutation sites for N-hydroxy-4-acetoxyaminobiphenyl, especially  $G \rightarrow T$  transversions. In the TP53 gene in human bladder cancer, however,  $G \rightarrow A$  transitions predominate (53%) and are prevalent at all of its five mutational hotspots (codons 175, 248, 273, 280, and 285), three of which are at methylated CpG hotspots (175, 248, and 273). In cII, neither the preferred adduction sites nor the induced mutational hotspots are biased towards methylated CpG dinucleotides. It is concluded from this study that there is a serious discordance between the mutation pattern induced by N-hydroxy-4-acetoxyaminobiphenyl in the cII gene and the mutational pattern observed in TP53 in human bladder cancer. However, the role of methylation status and transcriptional activity on the mutation spectrum induced by 4aminobiphenvl has vet to be determined. It is also to be noted that the TP53 mutation spectrum is a reflection of a selection process during tumour development.

#### Harmonization Project Document No. 4

4-Aminobiphenyl への職業的ばく露は、たばこの煙よりも 4-Aminobiphenyl の用量が多いと考えら れる。なぜなら、膀胱がんの発生率が喫煙者に比べて職業的にばく露される集団の方がかなり高 かったためである。しかし、これらの職業ばく露が発生した時点では代謝物濃度や尿路上皮細胞 内の DNA 付加体レベルを定量的に測定することができず、また、個人の喫煙歴を評価することは なかった(Koss ら、1965 年、1969 年)。

要約すると、種間での量的な違いは存在するが、マウスやイヌと同じ MOA がヒトにも当ては まることを排除するものではない。

## 結論:信頼性、解析及び帰結の記述

推定される MOA の初期段階は、代謝的活性化、DNA 付加体形成及び突然変異の key events が、 マウス、イヌ及びヒトにおいて定性的に同じであることを示す。これは利用可能なエビデンスに よって十分に支持されている。4-Aminobiphenyl がヒトの膀胱発がん物質であるという強力かつ十 分なエビデンスがある。しかし、突然変異とがんの発生との間に介在するステップについてのエ ビデンスは不足している。付加体量と TP53 突然変異との関連について説明したが、これらの特定 の遺伝的変化は腫瘍の進行から遅れて現れ、しばしば内因性の原因 (例えば、メチル化された CpG 部位での脱プリン) であるため、説得力のあるものではない。膀胱がんにおける TP53 突然変異に ついては、症例対照研究で研究されている (Schroeder ら、2003 年)。さらに、ヒトの尿路上皮腫 瘍のほとんどは低悪性度の乳頭病変であり、一般に TP53 変異を有していない。

N-hydroxy-4-acetylaminobiphenylの変異スペクトルは、Big Blue mouseの胚性線維芽細胞におい て研究されている(Bessaratinia ら、2002年)。これらの細胞を24時間処理すると、cII遺伝子の突 然変異頻度がバックグラウンドと比較して最大12.8倍の用量依存的な増加をもたらした。一塩基 置換は、処理細胞では突然変異の86%、対照細胞では突然変異の74%を占めていた。これらの変 異のうち、63%と36%はそれぞれ cll 遺伝子に沿ったグアニン残基で発生した。処置細胞では cll 遺伝子の変異の 47%が G→T のトランスバージョンであったのに対し、対照細胞では最も一般的 な変異は挿入であり、これは変異の19%を占めていた。誘導された付加体のマッピングにより、 5 つの DNA 付加体部位が確立された。そのうちの 4 つは N-hydroxy-4-acetylaminobiphenyl による 主な変異部位であり、特に G→T トランスバージョンを生じていた。しかしながら、ヒト膀胱が んのTP53遺伝子では、G→Aトランジションが優勢(53%)であり、その5つの変異ホットスポ ット (コドン 175、248、273、280、285)のすべてで優勢で、そのうちの 3 つはメチル化 CpG ホ ットスポット(175、248、273)にあった。cH 遺伝子では、誘導される突然変異ホットスポット も、メチル化 CpG ジヌクレオチドに偏っていない。この研究から、cII 遺伝子における N-hydroxy-4-acetylaminobiphenyl によって誘導される突然変異パターンと、ヒト膀胱がんにおける TP53 遺伝 子で観察される突然変異パターンとの間には大きなギャップがあると結論づけられる。しかし、 4-Aminobiphenyl によって誘導される突然変異スペクトルにおけるメチル化状態や転写活性の役 割はまだ明らかにされていない。また、TP53 遺伝子の変異スペクトルは、腫瘍発生過程の選択を 反映したものであることにも留意しなければならない。

Based on the preceding analysis, it is clear that the MOA for 4-aminobiphenyl carcinogenesis is known in the animal model, and the MOA is relevant to humans both qualitatively and quantitatively. The conclusion based on this evaluation, even without epidemiological evidence, is that 4-aminobiphenyl poses a cancer hazard to humans.

To perform a full risk assessment requires additional information regarding the doseresponse and human exposures. Based on the information described above, it is clear that the data predict a cancer hazard for humans at expected exposures, at least for occupational (historical) and cigarette smoking exposures. Further analysis is required regarding the potential risk at ambient exposures in those who are not cigarette smokers. The MOA analysis provides the basis and foundation for such an assessment. The epidemiological evidence on 4-aminobiphenyl supports the conclusions suggested by the MOA HRF.

### **4-AMINOBIPHENYL AND THE HUMAN RELEVANCE FRAMEWORK**

4-Aminobiphenyl was evaluated using the proposed IPCS HRF based on an MOA analysis. The defined key events for this DNA reactivity MOA—metabolic activation, DNA adduct formation, mutagenicity, and cancer induction—clearly are the same in humans as in the animal (mice, dogs) models, indicating that 4-aminobiphenyl presents a cancer hazard for humans. The information for this MOA analysis provides a substantive foundation on which to build a complete cancer risk assessment for humans. For this chemical, there is also substantial epidemiological evidence to verify the conclusions derived from the HRF analysis.

The additional key events for this MOA—which genes are mutated and how do these genetic alterations lead to cancer—are not known for 4-aminobiphenyl. However, this does not detract from the conclusions, given the strength of evidence for the proposed MOA, based on the framework analysis presented here.

What data are necessary to conclude that a chemical produces cancer by a DNA-reactive MOA? Our suggestion is that at the very least there be a demonstration that DNA adducts are produced, preferably in the target tissue, and that the chemical is mutagenic (either with or without metabolic activation). Mutagenicity is used here in a more specific, restricted sense than the broader term genotoxicity. Demonstration of DNA adducts and mutagenicity in the target tissue after in vivo exposure increases confidence in the proposed MOA. Identification of the specific metabolic pathway and specific DNA adducts induced provides a significantly better basis for extrapolating between the animal model and humans.

This case demonstrates the potential utility of data on surrogate compounds in MOA analysis. However, the relevance of data on related compounds, whether in vivo or in vitro, needs to be adequately justified. Weight-of-evidence analysis of structure–activity relationships, which have been well developed for DNA reactivity and mutagenicity, should also contribute to framework analysis.

#### IPCS Framework for Analysing the Relevance of a Cancer Mode of Action for Humans and Case-Studies

以上の解析から、4-Aminobiphenyl 発がん MOA は動物モデルで知られており、その MOA は定 性的にも定量的にもヒトに関連していることが明らかになった。この評価に基づく結論は、疫学 的なエビデンスがなくても、4-Aminobiphenyl はヒトに対して発がんの危険性があるということで ある。

完全なリスク評価を行うためには、用量反応及びヒトへのばく露に関する追加情報が必要であ る。上記の情報に基づいて、職業的(過去の)ばく露と喫煙ばく露など予想されるばく露による 発がんリスクを予測している。非喫煙者の環境ばく露における潜在的リスクについては、さらな る解析が必要である。MOA 解析は、そのような評価のための基礎と基盤を提供する。4-Aminobiphenyl に関する疫学的エビデンスは、MOA の HRF によって推定される結論を支持してい る。

#### 4-Aminobiphenyl とヒト関連性フレームワーク

4-Aminobiphenyl は、提唱されている IPCS HRF を用いて MOA 解析に基づいて評価した。その 結果、DNA 反応性 MOA の key events である代謝的活性化、DNA 付加体形成、変異原性、発がん は、ヒトにおいてもマウスやイヌなどの動物モデルと同様であり、4-Aminobiphenyl はヒトに対し て発がんの危険性を示すことが明らかになった。この MOA 解析の情報は、ヒトに対する完全な がんリスク評価を構築するための実質的な基礎を提供するものである。この化学物質については、 HRF 解析から導き出された結論を検証するための実質的な疫学的エビデンスも存在する。

この MOA では、どのような遺伝子が突然変異し、その遺伝子変化がどのようにして発がんに つながるのかという追加の key events は、4-Aminobiphenyl では知られていない。しかし、ここで 提示されたフレームワーク解析に基づいて MOA のエビデンスの信頼性を考えると、このことは 結論を損なうものではない。

ある化学物質が DNA 反応性 MOA によって発がんすると結論づけるには、どのようなデータが 必要なのか?我々が提案するのは、少なくとも DNA 付加体が、標的組織で生成され、その化学物 質に変異原性(代謝的活性化の有無にかかわらず)があることを実証することである。変異原性 は、ここでは遺伝毒性という広い意味よりも、より具体的で限定的な意味で用いられている。in vivo ばく露後の標的組織における DNA 付加体及び変異原性が証明されれば、推定された MOA の 信頼性が向上する。特定の代謝経路と誘導される特定の DNA 付加体を同定することにより、動物 モデルをヒトに外挿するための優れた根拠が得られる。

この事例は、MOA 解析における代替化合物に関するデータの潜在的な有用性を示している。しかし、関連化合物に関するデータの妥当性は、in vivo であれ in vitro であれ、十分に正当化される必要がある。また、DNA 反応性や変異原性については、これまでに十分に開発されてきた構造活性相関に関するエビデンスの重み付け解析も、フレームワーク解析に貢献すべきである。

## ACKNOWLEDGEMENTS

This paper has been reviewed in accordance with United States Environmental Protection Agency (USEPA) guidance but does not necessarily reflect USEPA policy. We thank Drs. Andrew Kligerman and Doug Wolf for their careful review of this paper.

# FORMALDEHYDE AND GLUTARALDEHYDE AND NASAL CYTOTOXICITY: CASE-STUDY WITHIN THE CONTEXT OF THE IPCS FRAMEWORK FOR ANALYSING THE RELEVANCE OF A CANCER MODE OF ACTION FOR HUMANS<sup>1</sup>

Douglas McGregor, Hermann Bolt, Vincent Cogliano, & Hans-Bernhard Richter-Reichhelm

Formaldehyde and glutaraldehyde cause toxicity to the nasal epithelium of rats and mice upon inhalation. In addition, formaldehyde above certain concentrations induces dose-related increases in nasal tumours in rats and mice, but glutaraldehyde does not. Using the 2006 International Programme on Chemical Safety (IPCS) human framework for the analysis of cancer mode of action (MOA), an MOA for formaldehyde was formulated and its relevance tested against the properties of the non-carcinogenic glutaraldehyde. These compounds produce similar patterns of response in histopathology and in genotoxicity tests (although formaldehyde has been much more extensively studied). The MOA is based on the induction of sustained cytotoxicity and reparative cell proliferation induced by formaldehyde at concentrations that also induce nasal tumours upon long-term exposure. Data on dose dependency and temporal relationships of key events are consistent with this MOA. While a genotoxic MOA can never be ruled out for a compound that is clearly genotoxic, at least in vitro, the non-genotoxic properties fundamental to the proposed MOA can explain the neoplastic response in the nose and may be more informative than genotoxicity in risk assessment. It is not yet fully explained why glutaraldehyde remains non-carcinogenic upon inhalation, but its greater inherent toxicity may be a key factor. The dual aldehyde functions in glutaraldehyde are likely to produce damage resulting in fewer kinetic possibilities (particularly for proteins involved in differentiation control) and lower potential for repair (nucleic acids) than would be the case for formaldehyde. While there have been few studies of possible glutaraldehyde-associated cancer, the evidence that formaldehyde is a human carcinogen is strong for nasopharyngeal cancers, although less so for sinonasal cancers. This apparent discrepancy could be due in part to the classification of human nasal tumours with tumours of the sinuses, which would receive much less exposure to inhaled formaldehyde. Evaluation of the human relevance of the proposed MOA of formaldehyde in rodents is restricted by human data limitations, although the key events are plausible. It is clear that the human relevance of the formaldehyde MOA in rodents cannot be excluded on either kinetic or dynamic grounds.

# INTRODUCTION

Formaldehyde and glutaraldehyde are aliphatic mono- and dialdehydes, respectively, that undergo reactions typical of aldehydes to form acetals, cyanohydrins, oximes, hydrazones, and bisulfite complexes. They are highly reactive chemicals and produce covalently crosslinked complexes with DNA and proteins. Their metabolism has some commonality in that they are both oxidized by aldehyde dehydrogenases. Several studies have demonstrated that inhalation exposure to formaldehyde causes nasal tumours in rats, whereas no nasal tumours were observed in the only 2-year inhalation study of rats exposed to glutaraldehyde. IPCS Framework for Analysing the Relevance of a Cancer Mode of Action for Humans and Case-Studies

# ホルムアルデヒド及びグルタルアルデヒドの鼻腔内細胞毒性: 発がん MOA のヒトへの関連性を解析するための IPCS フレームワークを用いた事例研究<sup>1</sup>

#### Douglas McGregor, Hermann Bolt, Vincent Cogliano, & Hans-Bernhard Richter-Reichhelm

ホルムアルデヒド及びグルタルアルデヒドは、吸入によりラット及びマウスの鼻腔上皮に毒性を 示す。また、一定濃度以上のホルムアルデヒドはラットとマウスの鼻腔腫瘍を用量依存的に増加さ せるが、グルタルアルデヒドにそのような作用はない。発がん MOA 解析のための 2006 年国際化 学物質安全性計画(International Programme on Chemical Safety: IPCS)のヒトフレームワークを用い て、ホルムアルデヒドの MOA を策定し、非発がん性のグルタルアルデヒドの特性との関連性につ いて検討した。これらの化合物は、病理組織学的検査及び遺伝毒性試験において同様の反応パター ンを示した (ホルムアルデヒドの方が広範囲に研究されているものの)。MOA は、持続的な細胞毒 性と再生細胞増殖の誘発に基づいており、長期ばく露によりホルムアルデヒドが鼻腔内腫瘍を誘 発する濃度で生じるというものである。key events の用量依存性と時間的関係に関するデータは、 この MOA と一致している。少なくとも in vitro 評価で遺伝毒性が明らかな化合物については、遺 伝毒性 MOA を除外することはできない。しかし、提示されている MOA の基本となる非遺伝毒性 は、鼻の腫瘍性病変を説明することができ、リスク評価において遺伝毒性よりも有益な情報を提供 するかもしれない。グルタルアルデヒドを吸入しても発がん性を示さない理由はまだ完全には解 明されていないが、固有の毒性が重要な要因である可能性がある。グルタルアルデヒドの二つのア ルデヒド官能基は、ホルムアルデヒドに比べて、(特に分化制御に関与するタンパク質の場合)運 動性の低下や、(核酸の)修復機能の低下へとつながる損傷を引き起こす可能性が高い。グルタル アルデヒドに関連した発がん性に関する研究はほとんどない。一方、ホルムアルデヒドがヒトの発 がん物質であるというエビデンスは、副鼻腔がんでは少ないが、鼻咽頭がんについては多い。ホル ムアルデヒドの吸入ばく露がはるかに少ない副鼻腔の腫瘍を鼻腔腫瘍と区別せず分類しているこ とが一因となり、見かけの不一致を生み出していると考えられる。提示されているげっ歯類におけ るホルムアルデヒドの MOA はヒトへの関連性評価については、kev events は妥当ではあるが、ヒ トのデータが限られているため限定的である。げっ歯類におけるホルムアルデヒドの MOA のヒト への関連性は、動態的または薬力学的な理由から除外できないことは明らかである。

# 序文

ホルムアルデヒド、グルタルアルデヒドはそれぞれ脂肪族のモノアルデヒド、ジアルデヒドで あり、アルデヒドに典型的な反応を経てアセタール、シアノヒドリン、オキシム、ヒドラゾン、 重亜硫酸塩錯体を形成する。これらは反応性の高い化学物質であり、DNA やタンパク質と共有結 合で架橋した錯体を生成する。これらの代謝には、アルデヒド脱水素酵素によって酸化されると いう共通点がある。いくつかの研究では、ホルムアルデヒドの吸入ばく露はラットに鼻腔腫瘍を 引き起こすことが示されているが、グルタルアルデヒドをラットに2年間吸入ばく露させた試験 では鼻腔腫瘍は観察されなかった。

## Formaldehyde

Formaldehyde has been tested for carcinogenicity by the inhalation route in mice, rats, and Syrian hamsters, by oral administration (drinking-water) in rats, by skin application in mice, and by subcutaneous injection in rats. There is conclusive evidence from the inhalation studies that formaldehyde is a carcinogen in rats.

There is considerable evidence that prolonged inhalation exposure to formaldehyde induces highly non-linear dose-related increases in the incidence of tumours of the anterior and posterior lateral meatus of rats (Morgan et al., 1986; Feron et al., 1988; Woutersen et al., 1989; Monticello et al., 1996; Kamata et al., 1997; CIIT, 1999). There are sharp increases in tumour incidence at formaldehyde concentrations equal to and greater than 7.2 mg/m<sup>3</sup>. Exposure to concentrations of 2.4 mg/m<sup>3</sup> and lower induced no malignant nasal tumours. Table 1 combines the data from two published rat studies (Kerns et al., 1983a; Monticello et al., 1996) conducted at the same laboratory and some additional information from one of these studies on a number of rats that had not been examined at the time of the publications (Schlosser et al., 2003). The majority of formaldehyde-induced neoplasms were squamous cell carcinomas.

# Table 1. Combined incidence of nasal squamous cell carcinomas in rats exposed to formaldehyde.

Formaldehyde concentration		
(mg/m <sup>3</sup> )	Number of rats at risk <sup>a</sup>	Actual number of tumours <sup>b</sup>
0	122	0
0.84	27	0
2.4	126	0
7.2	113	3
12	34	22
18	182	157

Note: Adapted from Schlosser et al. (2003).

<sup>a</sup> Rats at risk are those that survived to 2 years and were examined at that time plus those that died before 2 years in which tumours were found.

<sup>b</sup> Rats in which tumours were found at or before 2 years.

In contrast, inhalation studies in Syrian hamsters showed no carcinogenic effect at a single dose of 12.3 mg/m<sup>3</sup> (Dalbey, 1982), and one of two inhalation studies in mice showed no effect in females and squamous cell carcinomas in 2/17 males killed at 2 years at a high-dose concentration of 17.6 mg/m<sup>3</sup> (Kerns et al., 1983a, 1983b), whereas the other was inadequate for evaluation (Horton et al., 1963).

Studies on rats using other routes of exposure produced no significant results in two of four drinking-water studies (Takahashi et al., 1986; Tobe et al., 1989), forestomach papillomas in one study (Til et al., 1989), and leukaemia and gastrointestinal tract tumours in another (Soffritti et al., 1989), but the interpretation of the last study has been questioned (Feron et al., 1990). Mouse skin application and subcutaneous injection studies were not suitable for evaluation. In no study in rodents was there a significant increase in nasal tumours other than in the five inhalation exposure studies in rats—that is, at the entry portal.

#### Harmonization Project Document No. 4

#### ホルムアルデヒド

ホルムアルデヒドの発がん性試験は、マウス、ラット、シリアンハムスターを対象とした吸入 試験、ラットを対象とした経口投与(飲料水)試験、マウスを対象とした皮膚貼付試験、ラット を対象とした皮下投与試験が行われている。ラットではホルムアルデヒドが発がん物質であると いう決定的なエビデンスは吸入試験の結果から得られている。

ホルムアルデヒドへの長期吸入ばく露は、ラットの前方及び後方の側鼻道腫瘍の発生率を、非 線形性用量相関的に増加させるというエビデンスがある(Morgan ら、1986; Feron ら、1988年; Woutersen ら、1989年; Monticello ら、1996年; Kamata ら、1997年; CIIT、1999年)。ホルムア ルデヒド濃度が 7.2 mg/m<sup>3</sup>以上になると、腫瘍発生率が急激に増加する。2.4 mg/m<sup>3</sup>以下の濃度で はばく露しても、悪性の鼻腔腫瘍は誘発されなかった。表1は、同じ研究室で実施された2つの ラットの試験データ(Kerns ら、1983年a; Monticello ら、1996年)と、これらの研究のうちの1 つで、公表時には調査されていなかった数匹のラットについての追加情報を組み合わせたもので ある(Schlosser ら、2003年)。ホルムアルデヒド誘発性腫瘍の多くは扁平上皮がんであった。

# 表1. ホルムアルデヒドにばく露されたラットにおける鼻腔扁平上皮がんの複合発生率

ホルムアルデヒド濃度	リスクを抱えるラットの数。	実際の腫瘍数り
$(mg/m^3)$		
0	122	0
0.84	27	0
2.4	126	0
7.2	113	3
12	34	22
18	182	157

注:Schlosser ら(2003)からの引用

\* リスクを抱えるラットとは、2年まで生存し、その時点で検査を受けたラットと、腫瘍が見つかった2年以内に死亡したラットのことである。

<sup>b</sup>2年以内に腫瘍が認められたラット

対照的に、シリアンハムスターを対象とした吸入試験では、12.3 mg/m<sup>3</sup>の単回投与で発がん性 を示さなかった(Dalbey、1982年)。マウスを用いた2つの吸入試験のうち1つは、17.6 mg/m<sup>3</sup>の 高用量濃度で雌には変化がなく、2年の時点でと殺した雄17匹のうち2匹には扁平上皮がんが認 められた(Kerns ら、1983年 a、1983年 b)。もう1つの試験は評価が不十分であった(Horton ら、 1963年)。

ラットを対象とした他のばく露経路を用いた試験では、4 つの飲水投与試験のうち 2 つの試験 (Takahashi ら、1986年; Tobe ら、1989年) では有意な結果は得られなかった。もう1 つの試験 (Til ら、1989年) では前胃乳頭腫、さらにもう一つの試験(Soffritti ら、1989年) では白血病及 び消化管腫瘍を認めた。しかし、最後に挙げた試験の解釈は疑問視されている(Feron ら、1990)。 マウスの皮膚貼付試験及び皮下投与試験は評価に適さなかった。げっ歯類を対象とした研究では、 ラットを対象とした 5 つの吸入ばく露試験以外に、鼻腔内腫瘍の有意な増加が認められた研究は なかった。

# Glutaraldehyde

Glutaraldehyde has been tested for carcinogenicity by the inhalation route in mice and rats and by oral administration (drinking-water) in rats. Inhalation studies showed no carcinogenic effect in either B6C3F1 mice exposed to a single concentration of 400  $\mu$ g/m<sup>3</sup> for 78 weeks (Zissu et al., 1998) or multiple concentrations up to 1000  $\mu$ g/m<sup>3</sup> for 2 years (NTP, 1999) or F344 rats exposed to concentrations of up to 3000  $\mu$ g/m<sup>3</sup> for 2 years (NTP, 1999). In a drinking-water study in which male and female F344 rats were exposed to glutaraldehyde concentrations of up to 4000 mg/m<sup>3</sup> for 2 years, increased incidences of large granular cell lymphatic leukaemia were found in the spleen of females at all exposure concentrations (Ballantyne, 1995; Van Miller et al., 1995).

# **1. IS THE WEIGHT OF EVIDENCE SUFFICIENT TO ESTABLISH A MODE OF ACTION (MOA) IN ANIMALS?**

# A. Postulated mode of action

Prolonged exposure to formaldehyde above a critical concentration induces sustained cytotoxicity and cell proliferation. As a result of genetic changes within this proliferating cell population, neoplasia emerges. The genetic changes are postulated to be secondary to the cytotoxicity, metaplasia, and hyperplasia that are clearly induced by formaldehyde. Formal-dehyde is a genotoxic substance in vitro and forms DNA–protein cross-links (DPX). DPX are a well established indicator of formaldehyde exposure, but it is not clear whether they are premutational lesions required to produce neoplasia (by initiating DNA replication errors, resulting in mutation). Apart from the abundance of DPX observations in rats, there is little evidence that formaldehyde is mutagenic to mammalian cells in vivo.

This postulated MOA is mainly based on observations of consistent, non-linear doseresponse relationships for all three key events (sustained cell proliferation, DPX, and tumours) and concordance of incidence of these effects across regions of the nasal passages.

# **B. Key events**

# Formaldehyde

Limitation of damage to the entry portal following exposure to formaldehyde is clearly important, with metabolism playing a significant role in the process. The importance of the entry portal for formaldehyde-induced nasal tumours is supported by the observation that the principal non-neoplastic effect in rats exposed orally to formaldehyde solutions is the development of histological changes within the forestomach and glandular stomach (Til et al., 1989; Tobe et al., 1989).

Formaldehyde is an endogenous metabolic product of *N*-, *O*-, and *S*-demethylation reactions within cells (Hardman et al., 2001), and circulating concentrations of about 2.0–2.6  $\mu$ g/g blood are normal in unexposed mammals (Heck et al., 1982, 1985; Casanova et al., 1988). Exogenous formaldehyde is rapidly detoxified upon absorption. It has a half-life in plasma of about 1 min in rats exposed intravenously (Rietbrock, 1965), and it readily and spontaneously combines with reduced glutathione to form *S*-hydroxymethylglutathione, the substrate for alcohol dehydrogenase 3 (ADH3, also known as glutathione-dependent formaldehyde

## グルタルアルデヒド

グルタルアルデヒドの発がん性については、マウス及びラットでは吸入試験、ラットでは経口 投与(飲水投与)試験が行われている。吸入試験では、B6C3F1マウスに400µg/m<sup>3</sup>の単濃度で78 週間ばく露させた場合(Zissu ら、1998年)、または1000µg/m<sup>3</sup>までの複数濃度で2年間ばく露さ せた場合(NTP、1999年)、またはF344 ラットに3000µg/m<sup>3</sup>までの濃度で2年間ばく露させた場 合(NTP、1999年)のいずれにおいても発がん性は認められなかった。雌雄のF344 ラットを最大 4000 mg/m<sup>3</sup>のグルタルアルデヒド濃度に2年間ばく露した飲水試験では、すべてのばく露濃度で 雌の脾臓に大顆粒リンパ球性白血病の発生率増加が認められた(Ballantyne、1995; Van Miller ら、 1995年)。

# 1. 動物における作用機序(MOA)を立証するのにエビデンスの重み付けは十分か

# A. 推定される MOA

ー定濃度以上のホルムアルデヒドを長時間ばく露させると、持続的な細胞毒性と細胞増殖が誘 発される。この増殖細胞塊内における遺伝的変化の結果、腫瘍が発生する。このような遺伝的変 化は、ホルムアルデヒドによって明らかに誘導される細胞毒性、化生、過形成の二次的なもので あると推測されている。ホルムアルデヒドは in vitro では遺伝毒性物質であり、DNA-タンパク質 架橋 (DPX)を形成する。DPX はホルムアルデヒドばく露の指標として確立されているが、それ らが腫瘍発生に必要な突然変異前病変 (DNA 複製エラーを起こし、突然変異をもたらす)である かは明らかではない。ラットで DPX が豊富であることを除けば、ホルムアルデヒドが生体内で哺 乳類の細胞に変異原性を示すというエビデンスはほとんどない。

この MOA は、主に3 つの key events (持続的な細胞増殖、DPX、腫瘍) すべてについて一貫した非線形の用量反応関係が観察されたこと及び鼻腔全体でこれらの影響の発生率が一致していることに基づいて推測される。

## **B** Key events

## ホルムアルデヒド

ホルムアルデヒドばく露後の障害が侵入口に限定されることは明らかに重要であり、その過程 では代謝が重要な役割を果たしている。ホルムアルデヒド誘発性鼻腔腫瘍における侵入口の重要 性は、ホルムアルデヒド溶液を経口ばく露させたラットにおいて、主要な非腫瘍性の影響が前胃 及び腺胃の組織学的変化の進展であったことから裏付けられる(Til ら、1989 年; Tobe ら、1989 年)。

ホルムアルデヒドは、細胞内の *N*・*O*-及び *S*・脱メチル化反応の内因性代謝産物であり(Hardman 6,2001年)、ばく露を受けていない哺乳類の正常な血中濃度は約2.0~2.6 μg/g である(Heck ら、 1982年、1985年; Casanova ら、1988年)。外因性ホルムアルデヒドは吸収されると急速に解毒さ れる。ホルムアルデヒドを静脈内投与されたラットにおける血漿中の半減期は約1分で(Rietbrock、 1965年)、還元されたグルタチオンと容易かつ自然に結合する。そして、アルコール脱水素酵素 3 (ADH3,グルタチオン依存性ホルムアルデヒド脱水素酵素としても知られている)の基質である *S*-ヒドロキシメチルグルタチオンを形成し、*S*-ホルミルグルタチオンを産生する(Uotila & Koivusalo、1974年; Koivusalo ら、1989年)。 dehydrogenase) (Uotila & Koivusalo, 1974; Koivusalo et al., 1989), to form *S*-formylglutathione, which is further metabolized to formic acid and reduced glutathione by *S*-formylglutathione hydrolase (Uotila & Koivusalo, 1997). The  $K_{\rm M}$  for initial binding of hydroxymethylglutathione with ADH3 is about 0.004 mmol/l, and the concentration of free formaldehyde is likely to be even lower (Uotila & Koivusalo, 1997; Hedberg et al., 1998). It may be toxicologically significant that formaldehyde also combines with thiols such as cysteine and cysteinylglycine (Holmquist & Vallee, 1991). In addition to this efficient metabolic detoxification mechanism, the mucociliary apparatus provides protection of the underlying epithelium from gases and vapours. Thus, in order to attain free formaldehyde concentrations that may be cytotoxic to the target tissue, relatively high concentrations of formaldehyde vapour must be delivered to the target site to overcome these protective mechanisms. Mechanistic events of clear significance for carcinogenicity occur at dose levels where formaldehyde detoxification mechanisms are saturated in rats (Casanova & Heck, 1987).

The predominant non-neoplastic and preneoplastic events that have been measured and associated with nasal cancer formation following inhalation exposure of the nasal epithelium to formaldehyde include cytotoxicity, DPX formation, nasal epithelial cell regenerative proliferation, squamous metaplasia, and inflammation, which are site-specific, highly non-linear response processes in concordance with the incidence of nasal tumours.

The relative magnitude of an increase in cell proliferation is dependent upon the size of the target cell population within specific regions of the nasal cavity and not always directly related to the length of exposure, or total cumulative exposure (Swenberg et al., 1983, 1986; Monticello et al., 1991, 1996; Monticello & Morgan, 1994). These factors have been well defined and measured in a number of studies in rat, monkey, and human epithelial cells. In a 24-month carcinogenicity assay with interim sacrifices at 3, 6, 12, and 18 months, cell proliferation was demonstrated in rats exposed to 7.2, 12, and 18 mg/m<sup>3</sup> at all times (Monticello et al., 1991, 1996).

An immunohistochemical technique was used to assess the presence of p53 protein, a marker of cell proliferation (proliferating cell nuclear antigen, or PCNA), and tumour growth factor (TGF)- $\alpha$  in the histopathological sections of the same tumours. In addition to the p53-positive immunostaining in squamous cell carcinomas, especially in cells with keratinization, p53-positive immunostaining was observed in preneoplastic hyperkeratotic plaques, while normal nasal mucosa did not stain. A correlation was found between the distribution of immunostaining of PCNA and that of p53 (Wolf et al., 1995).

The formation of DPX in rats is a non-linear function of concentration (Casanova & Heck, 1987; Casanova et al., 1989, 1994; Heck & Casanova, 1995) and correlates with the site specificity of tumours (Casanova et al., 1994). Cross-links were not detected in the olfactory mucosa or in the bone marrow of rats (Casanova-Schmitz et al., 1984; Casanova & Heck, 1987). DPX have been found in rhesus monkeys following inhalation exposure to formal-dehyde, with the highest concentrations in the middle turbinates, followed by the anterior lateral wall septum and nasopharynx (Casanova et al., 1991).

#### Harmonization Project Document No. 4

これはS-ホルミルグルタチオンヒドロラーゼ (Uotila & Koivusalo、1997 年) によってさらにギ 酸に代謝され、グルタチオンを減少させる。ADH3 とヒドロキシ-メチルグルタチオンの初期結合 のための K<sub>M</sub> 値は約 0.004 mmol/L であり、遊離ホルムアルデヒドの濃度はさらに低い可能性が高 い (Uotila & Koivusalo、1997 年; Hedberg ら、1998 年)。また、ホルムアルデヒドがシステイン及 びシステイニルグリシンのようなチオール類と結合することは、毒性学的に重要であるかもしれ ない (Holmquist & Vallee、1991 年)。この効率的な解毒代謝メカニズムに加えて、絨毛粘膜はガス や蒸気から下層の上皮を保護する。したがって、標的組織において細胞毒性が発生する遊離ホル ムアルデヒドを高濃度で得るためには、これらの保護機構を克服することが必要であり、比較的 高濃度のホルムアルデヒド蒸気を標的部位に到達させる必要がある。発がん性にとって明確で意 義のある機序的な事象は、ラットにおけるホルムアルデヒドの解毒機構が飽和している用量で発 現することである (Casanova & Heck、1987 年)。

ホルムアルデヒド吸入ばく露後に測定された鼻のがん形成と関連している主な非腫瘍性及び前 腫瘍性徴候には、細胞毒性、DPX形成、鼻腔上皮細胞の再生性増殖、扁平上皮化生及び炎症が含 まれる。これらは部位特異的で高度に非線形な反応過程であり、鼻腔がんの発生率と一致してい る。

相対的な細胞増殖の亢進の程度は、鼻腔内の特定領域内の標的細胞集団の大きさに依存し、ば く露期間または累積ばく露の総量と常に相関するわけではない(Swenberg ら、1983年、1986年; Monticello ら、1991年、1996年; Monticello & Morgan、1994年)。これらの因子は、ラット、サル 及びヒト上皮細胞を対象とした多くの研究で明らかにされ、測定されている。3、6、12及び18ヶ 月の途中計画殺を伴う24ヶ月の発がん性試験では、7.2、12及び18 mg/m<sup>3</sup>の濃度でばく露された ラットはすべての時点で細胞増殖活性が実証された(Monticello ら、1991、1996年)。

免疫組織化学的手法を用いて、同一腫瘍の病理組織切片中の細胞増殖マーカーである p53 タン パク質(増殖細胞核抗原、または PCNA)及び腫瘍成長因子(TGF)を評価した。正常な鼻粘膜は 陰性であったが、扁平上皮がんでは p53 陽性となり、特に前腫瘍性病変である角化亢進性プラー ク内において角化した細胞での p53 陽性が観察された。PCNAの免疫染色の分布と p53 の免疫染 色の分布との間に相関関係が認められた(Wolf ら、1995 年)。

ラットにおける DPX の形成は、濃度の非線形関数であり(Casanova & Heck、1987年; Casanova
 ら、1989年、1994年; Heck & Casanova、1995年)、腫瘍の部位特異性と一致している(Casanova
 ら、1994年)。架橋はラットの嗅粘膜または骨髄では検出されなかった(Casanova-Schmitz ら、1984年; Casanova & Heck、1987年)。DPX はホルムアルデヒド吸入ばく露後のアカゲザルで認められており、その濃度が最も高い部位は中鼻甲介で、次いで前側壁中隔及び鼻咽頭であった(Casanova
 ら、1991年)。

Studies of rats, mice, Syrian hamsters, and rhesus monkeys exposed to formaldehyde for 13 (mice) or 26 weeks found that squamous metaplasia in the nasal turbinates developed in rats and rhesus monkeys at 3.7 mg/m<sup>3</sup>, but not in Syrian hamsters or, at 4.9 mg/m<sup>3</sup>, in mice (Rusch et al., 1983; Maronpot et al., 1986). Cell replication is also a feature of the more tumour-susceptible areas of the nasal epithelium of rats (Casanova et al., 1994).

# Glutaraldehyde

Inhalation exposure to glutaraldehyde at 400  $\mu$ g/m<sup>3</sup> for 78 weeks resulted in non-neoplastic lesions in the nasal vestibule of female mice, consisting of hyperplasia of the squamous epithelium lining the dorsal wall and the lateral aspect of the atrioturbinate (Zissu et al., 1998).

In the United States National Toxicology Program (NTP) studies of glutaraldehyde, the nasal changes observed in male and female rats included the following:

- 1. In the squamous epithelium in the most rostral part of the nasal passage, behind the external nares, there were increased incidences of hyperplasia and inflammation. The hyperplasia was a minimal to marked change characterized by variable thickening of the epithelium due to an increase in the number of cell layers and, in the more severe cases, varying degrees of keratin accumulation.
- 2. In the respiratory epithelium, there was hyperplasia, minimal goblet cell hyperplasia (primarily along the nasal septum and ventral meatus), inflammation, and squamous metaplasia, with accumulation of keratin on the epithelial surface in the more severe cases.
- 3. In the olfactory epithelium of the dorsal meatus, there were slightly increased incidences of hyaline degeneration.

The glutaraldehyde-associated inflammation that was observed in the squamous epithelial and respiratory epithelial regions was a minimal to marked change consisting of multifocal to locally extensive infiltrates of neutrophils, lymphocytes, and plasma cells. Occasionally, there were a few macrophages within the lamina propria and, in severe cases, within the epithelium itself. In male and female mice of this same study, the lesions were qualitatively similar to those found in rats. Females were more severely affected than male mice.

Glutaraldehyde induced DPX in a TK6 human lymphoblast cell line (St. Clair et al., 1991). In vivo, glutaraldehyde induced cell proliferation (S-phase nuclei) in nasal cells in rats and mice exposed by inhalation (Gross et al., 1994) and nasal instillation (St. Clair et al., 1990). In a parallel nasal instillation study by the same authors, formaldehyde induced the same level of cell proliferation at 20-fold higher molar concentrations.

# C. Dose-response relationship

## Formaldehyde

Available data from rats exposed to formaldehyde show a highly non-linear dose–response pattern for the key events, with no observed effects at 2.4 mg/m<sup>3</sup>, a minimal response at 7.2 mg/m<sup>3</sup>, and a sharp increase at 12 and 18 mg/m<sup>3</sup>.

#### IPCS Framework for Analysing the Relevance of a Cancer Mode of Action for Humans and Case-Studies

ラット、マウス、シリアンハムスター及びアカゲザルにホルムアルデヒドを 13 週間 (マウス) または 26 週間ばく露した研究において、ラット及びアカゲザルでは鼻尖部の扁平上皮化生が 3.7 mg/m<sup>3</sup>で発現したが、シリアハムスター及びマウスでは 4.9 mg/m<sup>3</sup>でも発現しなかった (Rusch ら、 1983 年; Maronpot ら、1986 年)。細胞の複製は、ラット鼻腔上皮のうち腫瘍感受性がより高い領 域の特徴でもある (Casanova ら、1994 年)。

## グルタルアルデヒド

400 μg/m<sup>3</sup>の濃度でグルタルアルデヒドを 78 週間吸入ばく露させた結果、雌マウスの鼻前庭に 非腫瘍性の病変が生じた。その病変は、背側壁を覆う扁平上皮の過形成及びアトリオタービネート (atrioturbinate)の側方面の過形成である (Zissu ら、1998 年)。

グルタルアルデヒドの米国国家毒性プログラム (NTP)の研究では、雌雄ラットにおいて以下のような鼻の変化が認められた。

- 鼻腔の最も吻側にある扁平上皮、外鼻腔の後ろにある扁平上皮では、過形成と炎症の発生率が 増加していた。過形成は、細胞層数の増加による上皮の不均一な肥厚と、より重篤な症例では、 様々な程度のケラチンの蓄積を特徴とする変化であった。
- 2. 呼吸上皮では、過形成、軽微な杯細胞過形成(主に鼻中隔及び腹側中隔に沿って)、炎症及び扁 平上皮化生が認められ、重度の症例では上皮表面にケラチンが蓄積していた。
- 3. 背側中膜の嗅覚上皮では、硝子変性がわずかに認められた。

扁平上皮及び呼吸上皮で観察されたグルタルアルデヒド関連の炎症は、好中球、リンパ球及び 形質細胞の多巣性から広範な浸潤にわたる様々な程度の変化があった。時折、固有層内に数個の マクロファージが存在し、重度の場合には上皮にも存在していた。この研究では雌雄のマウスに おいて、病変の質はラットと類似していたが、雌の方が雄よりも重症度は高かった。

グルタルアルデヒドは、TK6 ヒトリンパ芽細胞株において DPX を誘発した(St. Clair ら、1991年)。in vivo では、グルタルアルデヒドは、吸入(Gross ら、1994年)及び鼻腔内投与(St. Clair ら、1990年)によってばく露されたラット及びマウスの鼻腔内細胞において細胞増殖(S期)を誘導した。同じ著者による並行して実施された鼻腔内投与試験において、ホルムアルデヒドでは、20 倍高いモル濃度で同様の細胞増殖を誘発した。

# C. 用量反応関係

# ホルムアルデヒド

ホルムアルデヒドをばく露したラットから得られたデータによると、key eventsの用量反応パタ ーンは非線形であり、2.4 mg/m<sup>3</sup>では反応を認めず、7.2 mg/m<sup>3</sup>では最小の反応を認め、12 及び18 mg/m<sup>3</sup>では急激に反応が増加している。

In rats exposed to formaldehyde, no increases in cell turnover or DNA synthesis were found in the nasal mucosa after subchronic or chronic exposure to concentrations of  $\leq 2.4 \text{ mg/m}^3$ (Rusch et al., 1983; Zwart et al., 1988; Monticello et al., 1991; Casanova et al., 1994). Small, site-specific increases in the rate of cell turnover were noted at 3.7 mg/m<sup>3</sup> (6 h/day, 5 days/week, for 13 weeks) in Wistar rats (Zwart et al., 1988) and in the rate of DNA synthesis at 7.2 mg/m<sup>3</sup> in Fischer 344 rats exposed for a similar period (Casanova et al., 1994). At these concentrations, however, an adaptive response would seem to occur in rat nasal epithelium, since cell turnover rates after 6 weeks (Monticello et al., 1991) or 13 weeks (Zwart et al., 1988) are lower than those after 1–4 days of exposure. The unit length labelling index (ULLI) method was used to establish the proliferation in male Fischer 344 rats exposed to formaldehyde concentrations of 0, 0.84, 2.4, 7.2, 12, or 18 mg/m<sup>3</sup> for 6 h/day, 5 days/week, for 3, 6, 12, 18, or 24 months. Significant increases in ULLI were present only in the 12 and 18 mg/m<sup>3</sup> groups, with the greater increases on the anterior lateral meatus and the medial maxilloturbinate. Elevated ULLI in the anterior dorsal septum developed later in the course of the exposure. This belated elevation of ULLI may have been secondary to changes in airflow patterns and thus local formaldehyde concentrations associated with growth of lesions and distortion of the airspace in those areas of the nose more susceptible to neoplasia (Monticello et al., 1996).

The non-linear relationships for formaldehyde-induced DPX formation, epithelial cell proliferation, and subsequently nasal tumours are demonstrated in Table 2. It is arguable that the designations of high- and low-tumour areas proposed by Casanova et al. (1994) are not the most appropriate, and consequently the truly high tumour incidence region DPX response may have been diluted by that of the intermediate tumour incidence (posterior lateral meatus) region.

Other studies showed that Fischer 344 rats exposed to 1.2 mg/m<sup>3</sup> (22 h/day, 7 days/week, for 26 weeks) developed no detectable nasal lesions, whereas at 3.6 mg/m<sup>3</sup>, the only histological change was squamous metaplasia in the nasal turbinates (Rusch et al., 1983). The development of mild squamous metaplasia was similarly demonstrated in the nasal turbinates of Fischer 344 rats exposed to 2.4 mg/m<sup>3</sup> (6 h/day, 5 days/week, for 24 months) (Kerns et al., 1983b). Epithelial dysplasia and rhinitis were also observed in these rats. The occurrence of squamous metaplasia appears to be the histological feature requiring the lowest formaldehyde concentration of any of the in vivo responses reported.

A rat, anatomically accurate computational fluid dynamics model was used to test whether the distribution of formaldehyde-induced squamous metaplasia was related to the location of high-flux regions posterior to the squamous epithelium. Squamous metaplasia was considered present when  $\geq$ 50% of a subsection was lined by squamous epithelium. No squamous metaplasia was present in sections of nose from rats exposed to 2.4 mg/m<sup>3</sup> or less. Squamous metaplasia was present on the lateral meatus after exposure to 7.2 mg/m<sup>3</sup> or more and on the lateral and medial walls of the airway after exposure to 12 or 18 mg/m<sup>3</sup> (Kimbell et al., 1997).

There is evidence that glutathione-mediated detoxification of formaldehyde within nasal tissues becomes saturated in rats at inhalation exposures above 4.8 mg/m<sup>3</sup>. This saturation of

ホルムアルデヒドにばく露されたラットでは、2.4 mg/m<sup>3</sup>以下の濃度に亜慢性または慢性的にば く露した後の鼻粘膜で、細胞の再生及び DNA 合成の増加は認められなかった (Rusch 6、1983 年; Zwart 6、1988 年; Monticello 6、1991 年; Casanova 6、1994 年)。Wistar ラットでは細胞の再生 速度の部位特異的な軽度の増加が 3.7 mg/m<sup>3</sup> (6 時間/日、5 日/週、13 週間) で認められた (Zwart 6、1988 年)。同様の期間ばく露した Fischer 344 ラットでは DNA 合成速度の増加が 7.2 mg/m<sup>3</sup> で 認められた (Casanova 6、1994 年)。しかしながら、これらの濃度では、6 週間後 (Monticello 6、 1991 年) または 13 週間後 (Zwart 6、1988 年)の細胞再生率がばく露 1~4 日後よりも低いため、 ラットの鼻腔上皮では適応反応が起こると思われる。単位長ラベリング指数 (ULLI) 法を用いて、 0、0.84、2.4、7.2、12、または 18 mg/m<sup>3</sup> のホルムアルデヒド濃度に 6 時間/日、5 日/週、3、6、12、 18、または 24 ヶ月間ばく露した雄の Fischer 344 ラットにおける増殖を測定した。ULLI の有意な 上昇は 12 及び 18 mg/m<sup>3</sup> 群でのみ認められ、前側側鼻道及び内側上顎鼻甲介での上昇が大きかっ た。前背側中隔における ULLI の上昇は、ばく露後しばらくしてから発現した。この遅発性の ULLI 上昇は、鼻腔腫瘍の影響を受けやすい部分における、病変の成長と空隙の歪みに関連する局所的 なホルムアルデヒド濃度の変化でおこる気流変化による二次的なものと考えられた (Monticello 6、 1996 年)。

ホルムアルデヒド誘発性 DPX 形成、上皮細胞増殖及びその後の鼻腔腫瘍の非線形関係を表 2 に 示す。Casanova ら (1994 年) が提示した高腫瘍領域と低腫瘍領域の指定は最適なものではなく、 真に腫瘍発生率の高い領域の DPX 反応は、中間的な腫瘍発生率(後方側鼻道)領域の DPX 反応 によって希釈されている可能性がある。

他の研究では、1.2 mg/m<sup>3</sup> (1日 22 時間、7日/週、26 週間)にばく露した Fischer 344 ラットで は、検出可能な鼻腔病変は認められなかったが、3.6 mg/m<sup>3</sup>において組織学的変化は鼻甲介の扁平 上皮化生のみであった(Rusch ら、1983 年)。同様に 2.4 mg/m<sup>3</sup> (6 時間/日、5日/週、24ヶ月間) にばく露した Fischer 344 ラットの鼻甲介においても、軽度な扁平上皮化生の発生が示された (Kerns ら、1983 年 b)。これらのラットでは上皮異形成及び鼻炎も観察された。扁平上皮化生の 発生は、報告されている生体内反応の中で最も低濃度のホルムアルデヒドで発生する組織学的所 見だと思われる。

ラットにおいて正確に計算された解剖学的流体力学モデルを用いて、ホルムアルデヒドによっ て誘発される扁平上皮化生の分布が、扁平上皮の後方にある高流量領域に関係しているかどうか を検証した。50%以上が扁平上皮に置き換わっている場合、扁平上皮化生が生じているとみなさ れた。2.4 mg/m<sup>3</sup>以下でばく露されたラットの鼻には扁平上皮化生は認められなかった。7.2 mg/m<sup>3</sup> 以上のばく露では側鼻道に、12 または 18 mg/m<sup>3</sup>のばく露では気道の側壁及び内側壁に扁平上皮化 生がみられた (Kimbell ら、1997 年)。

4.8 mg/m<sup>3</sup>以上の吸入ばく露では、ラットで鼻組織内のホルムアルデヒドのグルタチオン介在性の解毒が飽和状態に達するというエビデンスがある。ホルムアルデヒド代謝の飽和は、この濃度以上のばく露における DPX、細胞増殖及び腫瘍発生率の用量反応関係の非線形性に寄与する可能性がある(Casanova & Heck、1987 年)。

formaldehyde metabolism may contribute to the non-linearity of the dose–response relationships for DPX, cell proliferation, and tumour incidence at exposures above this level (Casanova & Heck, 1987).

## Table 2. Comparative effects of formaldehyde exposure upon cell proliferation, DNAprotein cross-linking, and tumour incidence.

<sup>a</sup> Cell proliferation measured in three locations of the nasal epithelium in male F344 rats exposed to the indicated concentrations of formaldehyde, 6 h/day, 5 days/week, for 3 months (Monticello et al., 1996).

<sup>b</sup> Extent of DNA-protein cross-link formation measured in two regions of the nasal cavity (respiratory mucosa) in male F344 rats exposed to the indicated concentrations of formaldehyde, 6 h/day, 5 days/week, for about 12 weeks; the complete lateral meatus was designated the "high-tumour region"; the "low-tumour region" comprised the medial aspects of naso- and maxilloturbinates, posterior lateral wall, posterior dorsal septum excluding olfactory region, and nasopharyngeal meatuses (Casanova et al., 1994). Data were derived from graphical representations in the reference cited.

<sup>c</sup> Incidence of nasal tumours within the entire nasal cavity or the anterior lateral meatus, posterior lateral meatus, or anterior mid-septum in male F344 rats exposed to the indicated concentrations of formaldehyde, 6 h/day, 5 days/week, for 24 months (Monticello et al., 1996).

## Glutaraldehyde

A series of repeated-dose experiments with rats and mice exposed to glutaraldehyde has been summarized by NICNAS (1994). Among these, the lowest concentration producing lesions of the nasal cavity of rats was 1000  $\mu$ g/m<sup>3</sup> (6 h/day, 5 days/week, for 13 weeks) (NTP, 1993). The most severe lesions occurred in the anterior portions of the nasal passages and involved both the respiratory and olfactory epithelium. Hyperplasia and squamous metaplasia were most commonly noted on the lateral wall of the nasal cavity and on the tips of the nasoturbinates. Lesions were most extensive in rats exposed to 4000  $\mu$ g/m<sup>3</sup>. In another study in rats, no nasal lesions were observed at concentrations up to 776  $\mu$ g/m<sup>3</sup> delivered for 14 weeks (Bushy Run, 1983).

Mice appeared to be more sensitive to glutaraldehyde inhalation in a 13-week study, with inflammation of the nasal cavity being observed in female mice even at the lowest concentration of 250  $\mu$ g/m<sup>3</sup> and in male mice at 1000  $\mu$ g/m<sup>3</sup>. The species difference in

a 指定された濃度のホルムアルデヒドに6時間/日、週5日/日、3ヶ月間ばく露した雄のF344 ラットの鼻腔上皮の3箇所で測定した細胞増殖 (Monticello ら、1996年)。

b 指定された濃度のホルムアルデヒドに6時間/日、5日/週、約12週間ばく露した雄のF344 ラットの鼻腔(呼吸器粘膜)の2つの領域で測定した DNA-タンパク質架橋形成の程度。腫瘍低発生領域は、鼻腔及び側鼻道の内側壁、後側壁、嗅覚領域を除く後背側鼻道及び鼻中隔からなる(Casanova ら、1994年)。データは引用文献中のグラフに基づいている。

c 指定された濃度のホルムアルデヒドに1日6時間、1日5日/週、24ヶ月間ばく露した雄性F344 ラットにおけ る鼻腔全体または鼻腔内の鼻腔腫瘍の発生率、または前側鼻道、後側鼻道、または前中隔の発生率 (Monticello ら、1996年)。

# グルタルアルデヒド

グルタルアルデヒドにばく露したラット及びマウスを用いた一連の反復投与試験が NICNAS (1994 年)にまとめられている。その中で、ラットの鼻腔に病変を生じる最も低い濃度は 1000 µg/m<sup>3</sup>(6時間/日、5日/週、13週間)であった(NTP、1993 年)。最も重篤な病変は鼻腔前部に発 生し、呼吸上皮と嗅上皮の両方を障害した。過形成及び扁平上皮化生は、鼻腔の側壁及び鼻尖部 に最もよく認められた。病変は 4000 µg/m<sup>3</sup>にばく露されたラットで最も広範囲に認められたが、 1000 及び 2000 µg/m<sup>3</sup>群でも認められ、500 µg/m<sup>3</sup>群の雄 1 匹でも認められた。ラットを用いた別 の研究では、最大 776 µg/m<sup>3</sup>の濃度で14週間投与しても鼻の病変は観察されなかった(Bushy Run、 1983 年)。

マウスはグルタルアルデヒド吸入による感受性が高いようであり、13週間の試験で雌マウスで は最低濃度の250µg/m<sup>3</sup>で、雄マウスでは1000µg/m<sup>3</sup>でも鼻腔の炎症が観察された。このような感 受性の違いは、マウスのほうが気道が狭いためゴミなどで閉塞しやすいためと考えられる(NTP、 1993年)。呼吸器の病理組織学的病変は4000µg/m<sup>3</sup>群のマウスで最も重篤であり、喉頭上皮の扁 平上皮の軽度から中程度の扁平上皮化生、鼻腔前部の膿瘍性炎症がみられた。 sensitivity is probably due to the smaller airways of mice being more prone to blockage by debris (NTP, 1993). Histopathological lesions in the respiratory tract were most severe in mice in the 4000  $\mu$ g/m<sup>3</sup> group and consisted of minimal to mild squamous metaplasia of the laryngeal epithelium, suppurative inflammation in the anterior parts of the nasal cavity, and minimal squamous metaplasia on the tips of the nasoturbinates. Necrosis and inflammation were noted at lower concentrations, primarily in the anterior portion of the nasal passage.

In the NTP (1993) 13-week studies with glutaraldehyde, there were significant, exposurerelated increases in ULLI in the squamous epithelium of the nasal vestibule and, to a lesser extent, the respiratory epithelium of the atrioturbinate of the dorsal meatus. The exposurerelated increase in cell replication was generally greater in rats than in mice. Upon examining the results in individual mice, it was found that there was an increased rate of cell replication in the squamous epithelium of the nasal vestibule only of those mice in which there was also neutrophilic infiltration of the mucosa; however, the severity of the infiltrate did not correlate with the degree of cell proliferation. These observations were clearest at 13 weeks, particularly in female mice. In rats, in addition to increased replication in the squamous epithelium of the vestibule, there was an equally prominent increase in replication in the respiratory epithelium of the dorsal atrioturbinate, whereas in mice, the response in this area was weak.

## **D.** Temporal association

## Formaldehyde

A number of short-, medium-, and long-term studies of the effect of formaldehyde exposure on cell proliferation within the respiratory epithelium of rats have indicated a sustained increase in proliferation of nasal epithelial cells following exposure to concentrations greater than 2.4 mg/m<sup>3</sup>, irrespective of the exposure period. Cell proliferation was observed in rats exposed to formaldehyde for periods from as short as 3 days. In the ULLI study already described, the magnitude of increased cell proliferation generally decreased over time but remained significantly increased by approximately 2- to 10-fold over controls, for certain nasal locations, up to and including the 18-month observation period when this effect was last examined (Monticello et al., 1996).

Data relating to temporal associations for DPX are limited, as most formaldehyde inhalation studies of DPX formation are of short duration (i.e. exposure duration up to 1 day). Formaldehyde-induced DPX in the nasal epithelium of rats and rhesus monkeys was shown consistently in these studies (Casanova et al., 1991). However, a well conducted study investigating both acute and cumulative DPX yields in rats exposed to formaldehyde for about 12 weeks (Casanova et al., 1994) found that the acute DPX yield in the lateral meatus (a high tumour yield site) of previously exposed rats was about half that in naive rats at concentrations greater than 7.2 mg/m<sup>3</sup>, while there were no differences in the medial and posterior meatuses (low tumour yield sites). No significant accumulation of DPX occurred in previously exposed rats.

Regenerative cell proliferation following formaldehyde-induced cytotoxicity increases the number of DNA replications and thus increases the probability of DPX-initiated DNA

鼻尖部の扁平上皮化生は軽度であった。壊死と炎症は低濃度で、主に鼻腔前部で認められた。

グルタルアルデヒドを用いた NTP (1993 年) の 13 週間の試験では、鼻前庭の扁平上皮と、そ れよりも軽度ではあるが、背側鼻道のアトリオタービネートの呼吸器上皮において、ばく露に関 連した ULLI の有意な増加が認められた。ばく露に関連した細胞増殖活性は、一般的にマウスよ りもラットの方が高かった。個々のマウスを調べたところ、鼻前庭の扁平上皮では、粘膜に好中 球浸潤が認められたマウスでのみ細胞増殖率の増加が認められた。ただし、細胞増殖の程度と浸 潤の重症度は相関していなかった。これらの観察は、特に雌マウスでは 13 週目に最も明らかにな った。ラットでは、前庭の扁平上皮の増殖増加に加えて、背側のアトリオタービネートの呼吸器 上皮でも同様に顕著な増殖増加がみられたが、マウスではこの領域での反応は弱かった。

## D. 時間的関連性

## ホルムアルデヒド

ラットの呼吸器上皮内の細胞増殖に対するホルムアルデヒドばく露の影響について、短期、中 期、長期の研究では、ばく露期間にかかわらず、2.4 mg/m<sup>3</sup>以上の濃度にばく露した後、鼻腔上皮 細胞の増殖が持続的に増加することが示されている。ホルムアルデヒドにばく露したラットでは、 3 日間という短い期間から細胞増殖が観察された。すでに述べた ULLI 研究では、一般的に細胞増 殖の増加率は時間の経過とともに減少したが、この影響は、特定の鼻腔部位では対照群の約 2~ 10 倍の増加を示し、最長で 18 ヶ月間の観察期間を含めて試験終了まで持続していた (Monticello ら、1996 年)。

ほとんどのホルムアルデヒド吸入による DPX 形成の研究は短期間(すなわち、ばく露期間が1 日まで)であるため、DPX の時間的関連性に関するデータは乏しい。ホルムアルデヒド誘発性 DPX は、ラットとアカゲザルの鼻腔上皮における研究で一貫して示された(Casanova ら、1991年)。 しかし、ホルムアルデヒドに約12週間ばく露したラットの急性及び累積 DPX 収量を調べる研究 (Casanova ら、1994年)において、7.2 mg/m<sup>3</sup>以上の濃度では、事前にばく露されたラットの側鼻 道(腫瘍発生率の高い部位)の急性 DPX 収量は、対照群の約半分であったが、内側及び後側の鼻 道(腫瘍発生率の低い部位)では差が見られなかった。事前にばく露されたラットでは、DPX の 有意な蓄積は認められなかった。

ホルムアルデヒド誘発細胞毒性後の再生性細胞増殖は、DNA 複製数を増加させる。その結果、 DPX が誘発する DNA 複製エラーを増加させ、突然変異を引き起こす。この仮説は、高濃度にお けるラットの鼻での DNA 複製の阻害(Heck & Casanova、1995年)及び前腫瘍病変における p53 発現の増加(Wolf ら、1995年)によって支持される。 increased cell replication (ULLI) in the nasal vestibule of rats occurred early (within a few days) and either remained elevated or decreased slightly through the course of the study. Increases in ULLI in the nasal vestibule of mice tended to develop with time. In an inhalation study with mice (Zissu et al., 1994), the earliest lesions were observed in the respiratory epithelium of the septum and the naso- and maxilloturbinates after 4 days of exposure to 1.2 mg/m<sup>3</sup>. Severe histopathological changes were still observed 2 weeks after the end of the exposure to 4.0 mg/m<sup>3</sup>. No exposure-related histological abnormalities were detected in the trachea and lungs.

IPCS Framework for Analysing the Relevance of a Cancer Mode of Action for Humans and Case-Studies

replication errors, resulting in mutations. This hypothesis is supported by the observed

inhibition of DNA replication in the rat nose at elevated concentrations (Heck & Casanova,

1995) and increased p53 expression in preneoplastic lesions (Wolf et al., 1995). In 5 of 11 squamous cell carcinomas from rats exposed to  $18 \text{ mg/m}^3$  for up to 2 years, there were point

mutations at the GC base pairs in the p53 complementary DNA (cDNA) sequence (Recio et

The study of cell replication in the 13-week rat and mouse inhalation studies with

glutaraldehyde (NTP, 1993) showed that, in contrast to the results obtained for mice, the

# E. Strength, consistency, and specificity of association of tumour response with key events

#### Formaldehyde

al., 1992).

Glutaraldehvde

There are extensive studies investigating formaldehyde-induced neoplasia. Available data revealed formaldehyde-induced DPX formation and increased epithelial cell proliferation within the upper respiratory tract in a range of species including rats and monkeys and a variety of rat and human cells in vitro. It was found that at similar levels of exposure, concentrations of DPX were approximately an order of magnitude lower in rhesus monkeys than in rats. Increased human epithelial cell proliferation following in situ exposure to formaldehyde was reported in a model system in which rat tracheae populated with human tracheobronchial epithelial cells were xenotransplanted into athymic mice.

There is good correlation between key events and regional tumour incidence and tumour sites. Cell proliferation, metaplasia, and increased DPX were seen in the regions of the nasal cavity where tumours have been observed. The highly non-linear dose–response relationships for DPX, cytotoxicity, cell proliferation, metaplasia, and tumours are consistent, with significant increases in metaplasia occurring at 2.4 mg/m<sup>3</sup> in one study and all end-points being observed at concentrations of greater than 4.8 mg/m<sup>3</sup>. This is also in good correlation with the concentration at which mucociliary clearance is inhibited and glutathione-mediated metabolism is saturated—that is, 4.8 mg/m<sup>3</sup>. The study by Morgan et al. (1986) examining effects of inhaled formaldehyde on the nasal mucociliary apparatus in male rats also included 18-h recovery groups following days 1, 9, and 14 of exposure to concentrations of 2.4 mg/m<sup>3</sup>, 7.2 mg/m<sup>3</sup>, and 18 mg/m<sup>3</sup>. Inhibition of mucociliary clearance was progressively more extensive with increasing duration of exposure, but showed little or no evidence of recovery 18 h after cessation of exposure.

#### IPCS Framework for Analysing the Relevance of a Cancer Mode of Action for Humans and Case-Studies

18 mg/m<sup>3</sup>に最大 2 年間ばく露して誘発されたラットの扁平上皮がんの 11 例中 5 例では、p53 相補 的 DNA (cDNA) 配列の GC 塩基対に点突然変異が認められた(Recio ら、1992 年)。

#### グルタルアルデヒド

ラット及びマウスの13週間のグルタルアルデヒド吸入試験(NTP、1993年)における細胞増殖 の研究では、マウスで得られた結果とは対照的に、ラットの鼻前庭における細胞増殖の増加(ULLI) は、早い時期(数日以内)に発生し、試験期間中は上昇したままであるか、またはわずかに減少 した。マウスの鼻前庭におけるULLIの増加は時間の経過とともに増加する傾向があった。マウ スを用いた吸入試験(Zissuら、1994年)では、1.2 mg/m<sup>3</sup>に4日間ばく露した後、鼻中隔の呼吸 上皮及び鼻及び顎甲介に最初の病変が観察された。4.0 mg/m<sup>3</sup>ばく露終了2週間後にも重篤な病理 組織学的変化が認められた。気管及び肺ではばく露に関連した組織学的異常は認められなかった。

### E. 腫瘍発生と key events との関連性の強さ、一貫性及び特異性

#### ホルムアルデヒド

ホルムアルデヒド誘発性腫瘍に関する広範な研究がある。入手可能なデータを見る限り、ラッ トやサル、ラットやヒトの様々な動物種や、ラットやヒトの様々な細胞の in vitro で明らかになっ ている。。同程度のばく露量では、DPX の濃度はラットよりもアカゲザルの方が約一桁低いことが 明らかになった。ホルムアルデヒドへの組織ばく露後のヒト上皮細胞増殖の亢進が、ヒトの気管 支上皮細胞を移植したラット気管を胸腺欠損マウスに異種移植したモデル系で報告された。

key events と局所的な腫瘍発生率及び腫瘍発生部位との間には相関関係がある。腫瘍が観察され ている鼻腔領域では、細胞増殖、化生及び DPX の増加が認められた。DPX、細胞毒性、細胞増殖、 化生、腫瘍についての非線形用量反応関係は一貫しており、ある試験では 2.4 mg/m<sup>3</sup> で化生の有意 な増加が認められ、4.8 mg/m<sup>3</sup> 以上の濃度では全てのエンドポイントが観察された。これはまた、 粘膜クリアランスが抑制され、グルタチオンを介した代謝が飽和する濃度、すなわち 4.8 mg/m<sup>3</sup> と 密接な相関関係を示している。Morgan ら (1986 年)による雄ラットの鼻粘膜に対する吸入ホルム アルデヒドの影響を検討した研究では、2.4 mg/m<sup>3</sup>、7.2 mg/m<sup>3</sup>、18 mg/m<sup>3</sup>の濃度で1日、9日及び 14 日間ばく露後、18 時間の回復期間を設けた群が含まれていた。粘膜クリアランスの阻害は、ば く露時間が長くなるにつれて徐々に範囲が広がったが、ばく露停止 18 時間後の回復はほとんど、 あるいは全く認められなかった。

Mice appear to be less susceptible than rats to the development of nasal tumours following exposure to a given concentration of formaldehyde. However, it is well known that mice decrease their minute volume in response to inhalation of noxious chemicals (Brown et al., 1986, in CIIT, 1999).

# Glutaraldehyde

In comparison with formaldehyde, the glutaraldehyde-induced lesions were located in a more anterior part of the nose, involving the squamous epithelium. Also, they were of a different character, with none of the focal hyperkeratosis and hyperplasia with cellular atypia and dysplasia found in animals receiving formaldehyde for 13 weeks (Monticello, 1990; Morgan & Monticello, 1990).

# F. Biological plausibility and coherence

# Formaldehyde

Evidence supporting the hypothesis that prolonged regenerative cell proliferation can be a causal mechanism in chemical carcinogenesis continues to accumulate (IPCS, 2002). This proposed MOA for formaldehyde-induced nasal tumours in animals exposed by inhalation is consistent with biological plausibility and the available data. Sustained increased cell proliferation has been observed in the nasal cavity in extensive short- and medium-term toxicity studies in rats and a few studies in other species. Histopathological effects in the nasal cavity (epithelial cell dysplasia and metaplasia) were consistent in a range of sub-chronic and chronic animal studies. It should be noted, however, that the respective roles of DPX, mutation, and cellular proliferation in the induction of nasal tumours in the rat have not been fully elucidated.

# Glutaraldehyde

Effects of inhaled glutaraldehyde have not been as extensively studied as those of formaldehyde. In inhalation studies, glutaraldehyde did not induce nasal tumours in rats and mice. However, the same key events that are considered key events in the nasal carcinogenicity of formaldehyde—cytotoxicity and cell proliferation—have been demonstrated in rats and mice exposed to glutaraldehyde. This might appear to reduce the plausibility of these processes being important for formaldehyde.

# G. Possible alternative modes of action

# Formaldehyde

There is the possibility that mutagenicity could play a role in the development of formaldehyde-induced tumours. Evaluation of the available data indicates that formaldehyde is genotoxic in vitro, but is generally not genotoxic in standard in vivo assays, although there are many studies demonstrating that it produces DPX.

Formaldehyde has been extensively studied for genotoxicity in vitro, with positive results in studies with bacterial and mammalian cells (Ames test, gene mutation), and produced DNA single-strand breaks and DPX (reviewed in IARC, 2005). In vivo, formaldehyde has reproducibly induced mutations in *Drosophila*, but there is no convincing evidence of its genotoxic activity in rodent bone marrow cell tests. There is limited evidence that formaldehyde expo-

ある濃度のホルムアルデヒドにばく露後発生する鼻腔腫瘍において、マウスはラットよりも感 受性が低いようである。しかしながら、マウスでは有害化学物質の吸入に反応して換気量/分が減 少することがよく知られている(Brown ら、1986年; CIIT、1999年)。

# グルタルアルデヒド

ホルムアルデヒドと比較して、グルタルアルデヒドによって誘発された病変は、扁平上皮を含む鼻の前方に位置していた。また、それらの病変は異なる特徴を有しており、ホルムアルデヒドを 13 週間投与した動物にみられる細胞異型及び異形成を伴う局所的な角化亢進及び過形成は認められなかった(Monticello、1990 年; Morgan & Monticello、1990 年)。

# F. 生物学的妥当性及び整合性

# ホルムアルデヒド

長期間にわたる再生性細胞増殖が化学物質による発がんの原因であるという仮説を支持するエ ビデンスが蓄積され続けている (PCS、2002 年)。吸入ばく露された動物におけるホルムアルデヒ ド誘発性鼻腔腫瘍に対する MOA は、生物学的に妥当性があり、利用可能なデータと一致してい る。ラットを対象とした短期・中期毒性試験や他種の研究では、鼻腔内の持続的な細胞増殖活性 が観察されている。鼻腔内の病理組織学的影響(上皮細胞の異形成と化生)は、亜慢性及び慢性 の動物実験で一貫していた。しかし、ラットの鼻腔腫瘍誘導における DPX、突然変異及び細胞増 殖のそれぞれの役割は完全には解明されていないことに留意すべきである。

# グルタルアルデヒド

吸入したグルタルアルデヒドの影響は、ホルムアルデヒドほど研究されていない。吸入試験で は、グルタルアルデヒドはラットとマウスの鼻腔腫瘍を誘発しなかった。しかし、ホルムアルデ ヒドの鼻発がん性において key events とみなされる細胞毒性と細胞増殖が、グルタルアルデヒド にばく露されたラットとマウスでも実証されている。このことは、これらの過程がホルムアルデ ヒドにとって重要であることの妥当性を低下させるように見えるかもしれない。

# G. 考えられる代替 MOA

# ホルムアルデヒド

変異原性がホルムアルデヒド誘発性腫瘍の発生に関与している可能性がある。利用可能なデー タを評価すると、ホルムアルデヒドは in vitro では遺伝毒性はあるが、標準的な in vivo アッセイ では概して遺伝毒性はないことが示されている。しかし、DPX を産生することを示す研究は数多 くある。

ホルムアルデヒドは in vitro での遺伝毒性について広く研究されており、細菌や哺乳類細胞を用 いた試験(Ames 試験、遺伝子突然変異)で陽性結果が得られ、DNAの一本鎖切断や DPXの産生 を認めた(IARC、2005 年レビュー)。生体内では、ホルムアルデヒドはショウジョウバエで再現 性のある突然変異を誘発したが、げっ歯類の骨髄細胞試験では、その遺伝毒性について有力なエ ビデンスはない。しかし、ホルムアルデヒドのばく露が、ヒトの鼻や頬の細胞や末梢血リンパ球 における染色体異常や小核発現頻度の増加と関連しているというわずかなエビデンスはある (IARC、2005 年;付録参照)。

sure is associated with increased chromosomal aberration and micronucleus frequencies in human nasal and buccal cells and peripheral blood lymphocytes (reviewed in IARC, 2005; see Appendix).

It is unclear to what extent DPX contributes to the mutagenesis and carcinogenicity of formaldehyde (Recio, 1997; Merk & Speit, 1998; Speit et al., 2000; Liteplo & Meek, 2003). The presence of DPX has been considered mainly as an indicator of exposure, although some have also seen these lesions as premutagenic in character and therefore evidence of a direct genotoxic mechanism. DPX are, however, potentially damaging to the afflicted cell, and cell death is a likely outcome should they occur at high frequency. They also indicate that protein–protein cross-linkage (PPX) may occur, with potentially less serious effects for the cell. Should key proteins be involved in the PPX formation, this could have consequences on the regulatory machinery of the cell, including the regulation of differentiation. Such a change clearly occurs in the nasal epithelium of rats exposed to formaldehyde, since areas of metaplasia emerge. Neoplasia could be viewed as simply a different kind of metaplasia, unless there is compelling evidence for a genotoxic mode of action.

A different interpretation of the data has been offered by Gaylor et al. (2004), who analysed the concentration-response relationship for formaldehyde-induced cell proliferation in rats using statistical methods designed to identify J-shaped concentration curves. Cell proliferation data were used because there were insufficient quantal data on cancer incidence to perform the analysis. Their analysis supports the hypothesis that the threshold-type dose-response for nasal tumour incidence is the result of a minor genotoxicity at low dose that is superimposed by a J-shaped dose-response for cell proliferation at high cytotoxic dose levels (Lutz, 1998). At low doses, the effect of incremental DNA damage may be cancelled out by a reduction in cell proliferation; therefore, in spite of the apparent threshold, the data remain consistent with a genotoxic mechanism.

In rats exposed to formaldehyde, point mutations at GC base pairs in the cDNA sequence of the evolutionarily conserved regions II–V of the *p53* gene were found in 5 of 11 primary nasal squamous cell carcinomas (Recio et al., 1992). This observation may be interpreted to indicate genotoxic processes induced by formaldehyde in the carcinogenic process; however, the presence of specific mutations in the emergent tumour is not evidence that they were present in the early stages of neoplasia or that they were directly induced by the chemical. While there is the possibility of a direct mutagenic event occurring, it is also possible that these mutations arose indirectly of exposure as a result of functional changes in chromatin proteins induced by the chemical. At what stage in the life history of the tumour these observed mutations occurred is also open to speculation: they are relatively common events, it is clear, but it is also clear that they are not essential events (since they do not occur in all tumours that are apparently of the same type). The occurrence of these mutations indicates that a genotoxic mechanism has not been excluded, but this evidence does not necessarily support one.

Specific changes in gene expression have also been observed in vivo. The results indicated that exposure to formaldehyde can cause alteration in the expression levels of genes involved in several functional categories, including xenobiotic metabolism, cell cycle regulation, DNA synthesis and repair, oncogenes, and apoptosis (Hester et al., 2003). It is not clear at present

#### IPCS Framework for Analysing the Relevance of a Cancer Mode of Action for Humans and Case-Studies

DPX がホルムアルデヒドの突然変異誘発性及び発がん性にどの程度寄与しているかは不明であ る (Recio、1997 年; Merk & Speit、1998 年; Speit ら、2000 年; Liteplo & Meek、2003 年)。DPX の存在は主にばく露の指標として考えられてきたが、これらの病変の特徴は前変異原性であり、 それゆえに直接的な遺伝毒性メカニズムのエビデンスであるという見方もある。しかし、DPX は 形成された細胞にダメージを与える可能性があり、高頻度で発生すると細胞死が起こる可能性が 高い。また、本研究では細胞への影響はそれほど深刻ではないものの、タンパク質-タンパク質架 橋 (PPX) が起こる可能性があることも示唆されている。もし主要なタンパク質が PPX の形成に 関与していれば、分化の制御を含む細胞の制御機構に影響を及ぼす可能性がある。化生領域が出 現しているため、このような変化は、ホルムアルデヒドにばく露されたラットの鼻腔上皮で生じ ている。遺伝毒性の MOA を示す有力なエビデンスがない限り、腫瘍は単に化生の一種と見なす ことができる。

Gaylor ら (2004 年) は、J 型濃度曲線を特定するように設計された統計手法を用いて、ラット におけるホルムアルデヒド誘発性細胞増殖の濃度-反応関係を解析し、異なるデータの解釈を提示 した。解析の際、がん発生率に関する定量的なデータが不十分であったため、細胞増殖のデータ を使用した。彼らの解析は、鼻腔腫瘍の発生に対する閾値を有する用量反応性が、低用量におけ る軽度な遺伝毒性の結果であり、これにより細胞毒性を有する高用量において J 字型の細胞増殖 曲線を呈するという仮説を支持するものである(Lutz、1998 年)。低用量では、漸増する DNA 損 傷は細胞増殖の減少によって打ち消される可能性があるため、明らかな閾値があるにもかかわら ず、データは遺伝毒性メカニズムと一致している。

ホルムアルデヒドにばく露されたラットにおいて、p53 遺伝子の進化的に保存された領域 II-V の cDNA 配列の GC 塩基対における点突然変異が、原発性鼻腔扁平上皮がん 11 例のうち 5 例で認 められた (Recio ら、1992 年)。この結果は、発がん過程におけるホルムアルデヒドにより誘発さ れた遺伝毒性過程を示すものと解釈される。しかし、出現した腫瘍における特定の突然変異の存 在は、それらが腫瘍の初期段階に存在していたエビデンスでも、それらが化学物質によって直接 誘導されたことを示すものではない。直接的な突然変異原性を示す可能性はあるが、これらの突 然変異は、化学物質によって誘発されたクロマチンタンパク質の機能的変化により間接的に生じ た可能性もある。これらの観察された突然変異が腫瘍の発生段階のどの段階で生じたかは推測の 域を出ない。これらの突然変異は一般的な事象であることは明らかであるが、すべて同じタイプ の腫瘍が発生するわけではないので、本質的な事象ではないこともまた明らかである。これらの 突然変異の発生は、遺伝毒性のメカニズムが排除されていないことを示しているが、必ずしも支 持するものでもない。

また、遺伝子発現の特異的な変化も生体内で観察されている。その結果、ホルムアルデヒドへ のばく露は、異物代謝、細胞周期制御、DNA 合成と修復、がん遺伝子、アポトーシスを含むいく つかの機能に関与する遺伝子の発現レベルに変化をもたらすことが示された(Hester ら、2003 年) これらの変化がホルムアルデヒドにどの程度特異的であるか、あるいは発がん性においてどのよ うな役割を果たしているのかは、現時点では明らかになっていない。

#### Harmonization Project Document No. 4

Harmonization Project Document No. 4

how specific these changes are to formaldehyde or what their role is, if any, in carcinogenicity.

## Glutaraldehyde

Glutaraldehyde has been less extensively tested than formaldehyde for genotoxicity in vitro and in vivo. It produces weak and inconsistent positive findings in tests in vitro and is not active in the vast majority of in vivo studies. The genetic toxicity of glutaraldehyde has been recently reviewed (Zeiger et al., 2005).

Glutaraldehyde induced DNA repair systems in bacterial cells and was a weak mutagen in *Salmonella* and *Escherichia coli*. Unscheduled DNA synthesis (UDS), DPX, and double-strand breaks were seen in human cell lines, but not in primary rat cells. There were weak and inconsistent responses in chromosomal aberration and sister chromatid exchange (SCE) studies with mammalian cells, and glutaraldehyde did not induce transformation in cultured Syrian hamster embryo (SHE) cells.

In vivo, glutaraldehyde induced S-phase DNA synthesis in nasal cells in rats and mice following direct nasal administration. Glutaraldehyde did not produce DNA damage in rat liver or cross-links in rat testes DNA or sperm cells. Tests for induction of chromosomal aberration in bone marrow cells in rats and mice were generally negative. Glutaraldehyde did not induce micronuclei in bone marrow cells or dominant lethal mutations in mice. Thus, glutaraldehyde does possess genotoxic potential, and, although the database is not as extensive as it is for formaldehyde, it might be anticipated that site of contact genotoxicity would occur. Consequently, if genotoxicity is a major carcinogenic MOA for formaldehyde, it remains to be explained why glutaraldehyde is not active.

# H. Uncertainties, inconsistencies, and data gaps

#### Formaldehyde

In most of the cancer bioassays for formaldehyde, data on intermediate end-points such as proliferative response as a measure of cytotoxicity and DPX are limited. Consequently, direct comparison of the incidence of intermediate lesions and tumours is restricted. Additionally, information on a direct relationship between DPX and mutation induction and the probability of converting a DPX into a mutation is desirable, while the mode by which regenerative cell proliferation is involved in the production of mutations required for tumour development needs to be determined.

Studies on the *hprt* mutation spectrum in formaldehyde-exposed human cells revealed that 50% of the mutations are deletions, whereas 50% are due to point mutation at the A:T base pair (Crosby et al., 1988; Liber et al., 1989). The finding of deletions as part of the formaldehyde mutation spectrum may explain the homozygous nature of base pair mutations observed in p53 in formaldehyde-induced squamous cell carcinomas. However, there is an inconsistency with regard to the base pair that is mutated. It was found to be A:T in *hprt* in human and mammalian cell lines and G:C at p53 in formaldehyde-induced squamous cell carcinomas are induced by formaldehyde in vitro, these types of mutation may not be fundamental to its carcinogenicity.

#### グルタルアルデヒド

グルタルアルデヒドは、ホルムアルデヒドに比べて in vitro 及び in vivo での遺伝毒性に関する 試験があまり行われていない。グルタルアルデヒドは、in vitro 試験では軽微かつ不規則な陽性所 見を示し、in vivo 試験の大部分では活性がない。最近、グルタルアルデヒドの遺伝毒性に関する レビューが発表された(Zeiger ら、2005 年)。

グルタルアルデヒドは細菌では DNA 修復系を誘導し、サルモネラ菌や大腸菌では弱い変異原 性を示した。不定期 DNA 合成(UDS)、DPX、二本鎖切断はヒト細胞株で認められたが、ラット 初代細胞では認められなかった。哺乳類細胞を用いた染色体異常及び姉妹染色体交換(SCE)試験 では、軽微かつ一貫性のない反応がみられ、培養シリアンハムスター胚(SHE)細胞においてグル タルアルデヒドは形質転換を誘導しなかった。

生体内では、ラット及びマウスの鼻腔内投与後、グルタルアルデヒドは鼻腔内細胞にS期のDNA 合成を誘導した。グルタルアルデヒドはラット肝臓ではDNA 損傷を生じず、ラット精巣 DNA や 精子細胞では架橋を生じなかった。ラット及びマウスの骨髄細胞を用いた染色体異常試験では、 概ね陰性であった。グルタルアルデヒドは、マウスの骨髄細胞に小核や優性致死性突然変異を誘 発しなかった。このように、グルタルアルデヒドは遺伝毒性を有する可能性があり、データベー スはホルムアルデヒドほど豊富ではないが、接触部位における遺伝毒性の発生が予想される。し たがって、遺伝毒性がホルムアルデヒドの主要な発がん MOA であるとすれば、なぜグルタルア ルデヒドが効果を発揮しないのかを説明する必要がある。

# H. 不確実性、矛盾、データギャップ

## ホルムアルデヒド

ホルムアルデヒドを用いたがんのバイオアッセイのほとんどは、細胞毒性の指標としての増殖 反応や DPX などの中間エンドポイントに関するデータが限られている。そのため、中間病変と腫 瘍の発生率を直接比較することには制限がある。加えて DPX と突然変異誘発との直接的な関係に 関する情報及び DPX が突然変異につながる確率に関する情報が望まれる。一方で、腫瘍の発生に 必要な突然変異の生成にはどの再生性細胞増殖が関与しているかを決定する必要がある。

ホルムアルデヒドばく露ヒト細胞における hprr 遺伝子突然変異スペクトルの研究により、突然 変異の 50%は欠失であり、50%は A:T 塩基対での点突然変異によるものであることが明らかに なった (Crosby ら、1988 年; Liber ら、1989 年)。ホルムアルデヒド誘発性扁平上皮がんにおいて、 ホルムアルデヒド突然変異スペクトルの一部として欠失が認められたことで、p53 遺伝子で観察 されるホモ塩基対変異の性質を説明できるかもしれない。しかし、変異している塩基対に関して は矛盾がある。ヒト及び哺乳類細胞株では hprr 遺伝子の A:T であり、ホルムアルデヒド誘発性 扁平上皮がんでは p53 の G:C であることが明らかになっている(Recio、1997 年)。in vitro では ホルムアルデヒドによってこのような突然変異が誘導されるが、このタイプの突然変異はホルム アルデヒドの発がん性の根本ではない可能性がある。

# Glutaraldehyde

Glutaraldehyde is clearly much more cytotoxic than formaldehyde, perhaps because it is a bifunctional alkylating agent. Intranasal instillation studies have demonstrated that, on a molar basis, glutaraldehyde is 10- to 20-fold more toxic than formaldehyde when delivered to the nasal mucosa as a single treatment in aqueous solution (St. Clair et al., 1990). Comparison of results from a 13-week inhalation study of glutaraldehyde (NTP, 1993) with similar inhalation studies with formaldehyde (Heck et al., 1990; Monticello, 1990; Monticello et al., 1991) shows that glutaraldehyde is about 20-fold more toxic than formaldehyde by this route also. Pulmonary damage and mortality occur at much higher glutaraldehyde concentrations. Cytotoxicity is manifest closer to the external nares in the case of inhaled glutaraldehyde. This difference in the site of toxic action may be particularly important because, if the only difference was toxic potency, then glutaraldehyde would be expected to produce effects similar to those of formaldehyde, although only at lower doses.

# I. Assessment of postulated mode of action

# Formaldehyde

From a weight-of-evidence point of view, the hypothesized MOA for formaldehyde-induced nasal tumours satisfies several criteria, including consistency, concordance of dose–response relationships across all key events, and biological plausibility and coherence of the database. Given the extensive experimental data that address and are consistent with the proposed MOA of formaldehyde in the induction of tumours in the nasal cavity, a high degree of confidence may be ascribed to it.

## Glutaraldehyde

The key events of cytotoxicity, cell proliferation, and DPX formation (in vitro) have been demonstrated with exposure to glutaraldehyde. However, glutaraldehyde has not produced nasal tumours in rats and mice. Therefore, if the proposed MOA for formaldehyde is to be maintained, an explanation for this discrepancy is necessary. A reason for the difference has not been identified, but a hypothesis can be proposed. The dialdehyde function of glutaraldehyde is an important factor that may inhibit the macromolecules with which it reacts from further reaction within the cellular environment. Should these macromolecules be proteins involved in the maintenance of survival, then their immobility perhaps more likely leads to cell death than to a change in differentiation state. This immobilization of macromolecules by glutaraldehyde is the property that makes it a better fixative for high-resolution microscopy (e.g. electron microscopy) than formaldehyde. It almost certainly contributes to the very much higher toxicity of the dialdehyde. The monoaldehyde function of formaldehyde also causes cellular damage, but a proportion of proteins involved in cellular differentiation may be able to continue in that role, although with an altered outcome that may be the beginning of a path to neoplasia. If, on the other hand, these aldehydes react with nucleic acids (the evidence for glutaraldehyde reacting in this way is not substantial), then the repair of the alkylated nucleotides may be more difficult or even impossible in the case of glutaraldehyde, whereas repair does occur following formaldehyde interaction with DNA. Thus, irrespective of whether the mode of formaldehyde action in carcinogenicity is as proposed or is primarily due to genetic toxicity, the different response to glutaraldehyde exposure can be explained.

## グルタルアルデヒド

グルタルアルデヒドは二官能性アルキル化剤であるためか、ホルムアルデヒドよりも明らかに 細胞毒性が強い。経鼻投与試験では、水溶液を鼻粘膜に単回投与した場合、モル比でグルタルア ルデヒドはホルムアルデヒドの10~20倍の毒性があることが実証されている(St. Clair 6、1990 年)。グルタルアルデヒドの13週間吸入試験(NTP、1993年)の結果とホルムアルデヒドの同様 の吸入試験(Heck 6、1990年; Monticello 6、1991年)との比較は、こ の経路でもグルタルアルデヒドはホルムアルデヒドより約20倍の毒性があることを示している。 肺障害及び壊死は、かなり高い濃度のグルタルアルデヒドで発生する。細胞毒性は、グルタルア ルデヒドを吸入した場合には外鼻に近いところで発現するため、主に影響を受ける組織はホルム アルデヒドを吸入した場合と同じではない。唯一の違いが毒性の強さであるならば、グルタルア ルデヒドは、低用量でもホルムアルデヒドと同様の影響をもたらすと予想されるため、毒性作用 部位における違いは特に重要かもしれない。

# I. 推定される MOA の評価

# ホルムアルデヒド

重要なエビデンスの観点より、ホルムアルデヒド誘発性鼻腔腫瘍の仮説 MOA は一貫して、key events すべてにおける用量反応関係の一致、データベースの生物学的妥当性と整合性など、いく つかの基準を満たしている。鼻腔内腫瘍誘発におけるホルムアルデヒドの推定される MOA は多 くの実験データと一致しているため、この MOA は信頼性が高いと考えられる。

# グルタルアルデヒド

細胞毒性、細胞増殖及び DPX 形成の key events (in vitro) は、グルタルアルデヒドへのばく露 で実証されている。しかし、グルタルアルデヒドはラットやマウスでは鼻腔内腫瘍を発生させな い。したがって、推定されているホルムアルデヒドの MOA を維持するためには、この矛盾を説 明する必要がある。この矛盾の理由は特定されていないが、仮説を提示することは可能である。 グルタルアルデヒドの二つのアルデヒド官能基は、細胞環境内で高分子のさらなる反応を阻害す る重要な因子である。これらの高分子は、生存に関与するタンパク質であり、それらの不動化は、 おそらく分化状態の変化よりも細胞死につながる。このグルタルアルデヒドの高分子を不動化さ せる特性が、ホルムアルデヒドよりも高分解能顕微鏡(例えば電子顕微鏡)用の優れた固定剤に なる理由である。そのことはほぼ確実にジアルデヒドの非常に高い毒性につながっている。また、 ホルムアルデヒドのアルデヒド官能基は細胞障害を引き起こすが、細胞の分化に関与するタンパ ク質は、腫瘍の初期変化となりうる分化方向の変化を伴うものの、その役割を維持することがで きるかもしれない。一方、これらのアルデヒドが核酸と反応する場合(グルタルアルデヒドがこ のように反応するというエビデンスは実質的なものではない)、ホルムアルデヒドが DNA と相互 作用した後にアルキル化されたヌクレオチドの修復が起こるのに対し、グルタルアルデヒドの場 合は、困難、あるいは不可能かもしれない。このように、発がん性におけるホルムアルデヒドの 作用様式が推定されている通りなのか、それとも遺伝毒性が主な原因なのかにかかわらず、グル タルアルデヒドばく露に対する反応の違いを説明することができる。

# 2. CAN HUMAN RELEVANCE OF THE MOA BE EXCLUDED ON THE BASIS OF FUNDAMENTAL, QUALITATIVE DIFFERENCES IN KEY EVENTS BETWEEN EXPERIMENTAL ANIMALS AND HUMANS?

# A. Formaldehyde

In rhesus monkeys exposed to formaldehyde at 7.2 mg/m<sup>3</sup> for between 1 and 6 weeks, formaldehyde-induced lesions were associated with increases in cell proliferation rates of up to 18-fold over controls and remained significantly elevated after 6 weeks of exposure. Histological lesions and increases in cell proliferation were most extensive in the nasal passages and were minimal in the lower airways, whereas the maxillary sinuses showed no evidence of a response to formaldehyde exposure. Based on the extent of lesions and cell proliferation data, it appeared that rhesus monkeys are more sensitive than rats to the acute and subacute effects of formaldehyde at 7.2 mg/m<sup>3</sup> (Monticello et al., 1989). The absence of response in the maxillary sinuses in rhesus monkeys is an observation deserving special attention in the design of epidemiological studies (or, perhaps, in the reporting of tumour sites). Most epidemiological studies of sinonasal cancer have not distinguished tumours arising in the nose from those developing in the nasal sinuses. Thus, the risk for nasal cancer specifically would tend to be diluted if there was no corresponding risk for cancer in the sinuses and could go undetected through lack of statistical power.

Many epidemiological studies have investigated formaldehyde exposure and cancer of the respiratory tract. The strongest evidence of an association has been observed for naso-pharyngeal cancers. A statistically significant excess of deaths from nasopharyngeal cancer has been observed in the largest cohort study of industrial workers (Hauptmann et al., 2004), with statistically significant exposure–response relationships for peak and cumulative exposure. An excess of deaths from nasopharyngeal cancer was observed in a proportionate mortality analysis of the largest cohort of embalmers in the United States (Hayes et al., 1990). An excess of cases of nasopharyngeal cancer was observed in a Danish study of proportionate cancer incidence among workers at companies that manufactured or used formaldehyde (Hansen & Olsen, 1995). Other cohort studies reported fewer cases of nasopharyngeal cancer than expected (Walrath & Fraumeni, 1983; Coggon et al., 2003; Pinkerton et al., 2004). Of seven case–control studies of nasopharyngeal cancer, five found elevations of risk for exposure to formaldehyde.

Several case–control studies have investigated the association between exposure to formaldehyde and sinonasal cancer. A pooled analysis of 12 studies showed an increased risk of adenocarcinoma in men and women thought never to have been exposed to wood dust or leather dust, with an exposure–response trend for an index of cumulative exposure (Luce et al., 2002). One other case–control study (Olsen & Asnaes, 1986) and a proportionate incidence study (Hansen & Olsen, 1995) showed an increased risk of sinonasal cancer, particularly squamous cell carcinoma. However, the three most informative cohort studies of industrial workers showed no excesses of sinonasal cancer (Coggon et al., 2003; Hauptmann et al., 2004; Pinkerton et al., 2004).

In evaluating this body of evidence, the International Agency for Research on Cancer (IARC) concluded that there was sufficient epidemiological evidence that formaldehyde causes

# 2. 実験動物とととの間の key evants の根本的、質的な違いに基づいて、MOA のととの 関連性を合理的に排除することができるか

## A. ホルムアルデヒド

7.2 mg/m<sup>3</sup>のホルムアルデヒドに 1~6 週間ばく露したアカゲザルにおいて、ホルムアルデヒド に誘発された病変は、対照群の最大 18 倍を示す細胞増殖率の増加を伴っており、6 週間のばく露 後も有意に高い値が続いた。組織学的な病変と細胞増殖の増加は鼻腔で最も広範囲に見られ、下 気道では最小限であったが、上顎洞ではホルムアルデヒドばく露に対する反応のエビデンスは認 められなかった。病変の程度及び細胞増殖のデータに基づいて、7.2 mg/m<sup>3</sup>の用量でのホルムアル デヒドの急性及び亜急性影響に対する感受性はラットよりもアカゲザルの方が高いと考えられた (Monticello ら、1989 年)。アカゲザルの上顎洞における反応がないことは、疫学研究において(あ るいは、腫瘍部位の報告において)特別な注意を払うに値する所見である。副鼻腔がんのほとん どの疫学研究では、鼻に発生した腫瘍と副鼻腔に発生した腫瘍を区別していない。そのため、副 鼻腔に発生するがんに対応するリスクがなければ、鼻腔がんのリスクは希釈される傾向にあり、 統計的に検出されない可能性がある。

多くの疫学研究では、ホルムアルデヒドばく露と気道がんとの関連が調査されている。最も有 力なエビデンスは、鼻咽頭がんで観察されている。工場労働者を対象とした最大規模のコホート 研究(Hauptmann ら, 2004 年)では、鼻咽頭がんによる死亡者数の増加が観察されており、最大 ばく露量と累積ばく露量についてばく露-反応関係を示している。死体防腐処理業者を対象とした 米国最大のコホート研究では、上咽頭がんによる死亡者の増加が死亡率分析で観察されている (Hayes ら、1990 年)。ホルムアルデヒドを製造または使用している企業の労働者を対象としたデ ンマークの研究では、鼻咽頭がんの症例数の増加が観察された(Hansen & Olsen、1995 年)。他の コホート研究では、予想よりも鼻咽頭がんの症例数は少なかったと報告されている(Walrath & Fraumeni、1983 年; Coggon ら、2003 年; Pinkerton ら、2004 年)。鼻咽頭がんに関する7件の症例 対照研究のうち、5件ではホルムアルデヒドばく露によるリスク増加が認められた。

いくつかの症例対照研究では、ホルムアルデヒドへのばく露と副鼻腔がんとの関連が調査され ている。12 件のプール解析では、木粉または革粉にばく露されたことがない男女における腺がん のリスク増加が示され、累積ばく露の指標に対し、ばく露用量反応性を示す傾向が示された(Luce ら、2002 年)。他の1 件の症例対照研究(Olsen & Asnaes、1986 年)と発生率研究(Hansen & Olsen、 1995 年)では、副鼻腔がん、特に扁平上皮がんのリスクの増加が示された。しかしながら、工場 労働者を対象とした 3 件の最も有力なコホート研究では、副鼻腔がんの増加は認められなかった (Coggon ら、2003 年; Hauptmann ら、2004 年; Pinkerton ら、2004 年)。

この一連のエビデンスを評価するにあたり、国際がん研究機関(IARC)は、ホルムアルデヒドがヒトで鼻咽頭がんを引き起こすという十分な疫学的エビデンスがあるが、ホルムアルデヒドがヒトで副鼻腔がんを引き起こすという疫学的エビデンスは限られている。

nasopharyngeal cancer in humans; only limited epidemiological evidence that formaldehyde causes sinonasal cancer in humans; and strong but not sufficient evidence for a causal association between leukaemia and occupational exposure to formaldehyde (Cogliano et al., 2005).

There are no publications describing DPX in nasal cells from formaldehyde-exposed personnel. Assessment of DPX in peripheral lymphocytes from formaldehyde-exposed workers demonstrated an association with overall exposure (Shaham et al., 2003). The single DPX study involved 399 workers from 14 hospital pathology departments, and formaldehyde exposure categories were low-level (mean 0.5 mg/m<sup>3</sup>, range 0.05–0.8 mg/m<sup>3</sup>) and high-level (mean 2.7 mg/m<sup>3</sup>, range 0.86–6.7 mg/m<sup>3</sup>). Adjusted mean DPX were significantly higher in the exposed groups. There appear to be some doubts regarding the sensitivity and reproducibility of the physical separation method used in this study (Heck & Casanova, 2004).

Some studies have investigated the histological changes within the nasal epithelium of workers occupationally exposed to formaldehyde; however, the extent to which nasal epithelial cell regenerative proliferation occurs is unresolved because the results are mixed and there was co-exposure to wood dust in some studies (Berke, 1987; Edling et al., 1988; Holmström et al., 1989; Boysen et al., 1990; Ballarin et al., 1992).

Mucociliary clearance in the anterior portion of the nasal cavity was reduced following exposure of volunteers to formaldehyde at  $0.30 \text{ mg/m}^3$  (Andersen & Mølhave, 1983).

The concordance of animal and human key events for formaldehyde is summarized in Table 3.

## Table 3. Formaldehyde concordance table.

Key event	Evidence in animals	Evidence in humans
Cytotoxicity	Positive in vivo (target cells)	Plausible
Proliferation	Positive in vivo (target cells)	Plausible (some evidence but confounded by co-exposure)
Genotoxicity	DPX (target cells in vivo)	DPX (non-target cells, i.e. lymphocytes)
Mutations	Positive in vitro; unconvincing in vivo	Positive (? cells)
Nasal tumours	Positive (mainly anterior lateral meatus)	Positive (nasopharyngeal) ? (sinonasal)

# **B. Glutaraldehyde**

There are few epidemiological studies for exposure to glutaraldehyde and human cancer. No increase in the number of cancer deaths was observed among 186 male glutaraldehyde production workers. The average time since first exposure to glutaraldehyde was 20.6 years, and the period of exposure was 3–7 years. During periods of monitoring exposure, glutaraldehyde concentrations in air ranged from 0.04 to 1.4 mg/m<sup>3</sup> (NICNAS, 1994). Studies of embalmers, pathologists, and members of the American Association of Anatomists for possible effects of glutaraldehyde have all shown increases in risk of cancer; however, all of

#### IPCS Framework for Analysing the Relevance of a Cancer Mode of Action for Humans and Case-Studies

また、白血病とホルムアルデヒドの職業ばく露との間に因果関係があるという十分なエビデンスはない、と結論づけた (Cogliano ら、2005)。

ホルムアルデヒドにばく露されたヒトの鼻の細胞における DPX について記述している論文は ない。ホルムアルデヒドにばく露された労働者の末梢リンパ球における DPX の評価では、全体的 なばく露との関連性が示された(Shaham ら、2003 年)。単一の DPX 試験では、14 の病院の各病 理部門で働く 399 人が参加し、ホルムアルデヒドばく露のカテゴリーは低レベル(平均0.5 mg/m<sup>3</sup>、 範囲 0.05~0.8 mg/m<sup>3</sup>)及び高レベル(平均 2.7 mg/m<sup>3</sup>、範囲 0.86~6.7 mg/m<sup>3</sup>)であった。調整後の 平均 DPX は被曝群で有意に高かった。この研究で用いられた物理的分離法の感度及び再現性には 疑問があるようである(Heck & Casanova、2004 年)。

いくつかの研究では、ホルムアルデヒドに職業ばく露された労働者の鼻腔上皮内の組織学的変 化を調査しているが、結果はまちまちであり、いくつかの研究では木粉への共ばく露があったた め、鼻腔上皮細胞の再生性増殖がどの程度起こるのかは未解明である(Berke, 1987年; Edling ら、 1988年; Holmström ら、1989年; Boysen ら、1990年; Ballarin ら、1992年)。

鼻腔前部の粘膜クリアランスは、ホルムアルデヒドの 0.30 mg/m<sup>3</sup> でのばく露後に減少した (Andersen & Mølhave、1983 年)。

ホルムアルデヒドに関する動物とヒトの key events の一致を表 3 にまとめた。

# 表 3. ホルムアルデヒドの用語索引表

key events	動物におけるエビデンス	ヒトにおけるエビデンス
細胞毒性	in vivo で陽性(標的細胞)	妥当性あり
細胞増殖	in vivo で陽性(標的細胞)	妥当性あり (エビデンスはあるが、共 ばく露によって交絡されている)
遺伝毒性	DPX (in vivo 標的細胞)	DPX (非標的細胞、リンパ球など)
突然変異	in vitro では陽性、in vivo では説得 力がない	陽性(?細胞)
鼻腔腫瘍	陽性(主に前外側鼻腔)	陽性(鼻咽頭) ?(副鼻腔)

# B. グルタルアルデヒド

グルタルアルデヒドへのばく露とヒトのがんに関する疫学的研究はほとんどない。グルタルア ルデヒド製造に携わる男性労働者 186 名のがん死亡者の増加は認められなかった。グルタルアル デヒドに初めてばく露されてからの平均期間は 20.6 年、ばく露期間は 3~7 年であった。モニタ リングばく露期間中、大気中のグルタルアルデヒド濃度は 0.04~1.4 mg/m<sup>3</sup> の範囲であった (NICNAS、1994 年)。グルタルアルデヒドの潜在的な影響について、遺体整復師、病理医及び米 国解剖学会のメンバーを対象とした研究では、すべての研究ががんリスクの増加を示している。 しかしこのグループはホルムアルデヒドにもばく露されていた(Walrath & Fraumeni、1983 年、遺 伝毒性変異;ホルムアルデヒドに関するコンセンサスワークショップ、1984 年; Stroup ら、1986 年)。

#### Harmonization Project Document No. 4

these groups were also exposed to formaldehyde (Walrath & Fraumeni, 1983; Consensus Workshop on Formaldehyde, 1984; Stroup et al., 1986).

There are no studies examining glutaraldehyde exposure and DPX formation, cytotoxicity, and cell proliferation in human nasal tissues.

The concordance of animal and human key events for glutaraldehyde is summarized in Table 4.

### Table 4. Glutaraldehyde concordance table.

Key event	Evidence in animals	Evidence in humans
Cytotoxicity	Positive	Plausible
Proliferation	Positive in vivo	Plausible
Genotoxicity	DPX in vitro	Unknown
Mutations	Positive in vitro	Unknown
Nasal tumours	Negative (no evidence at any site)	Unknown

# 3. CAN HUMAN RELEVANCE OF THE MOA BE EXCLUDED ON THE BASIS OF QUANTITATIVE DIFFERENCES IN EITHER KINETIC OR DYNAMIC FACTORS BETWEEN EXPERIMENTAL ANIMALS AND HUMANS?

## A. Formaldehyde

Quantitative differences between experimental animals and humans for the postulated MOA will be a function of the concentration of formaldehyde at the target tissue. It is formaldehyde per se, and not its metabolites, that causes cytotoxicity. Exogenous inhaled formaldehyde is rapidly metabolized upon absorption, to formate, by a number of widely distributed cellular enzymes, particularly formaldehyde dehydrogenase. In addition to this efficient metabolic detoxification mechanism, the mucociliary apparatus provides protection of the underlying epithelium from gases and vapours. Thus, in order to attain free formaldehyde concentrations that may be cytotoxic to the target tissue, relatively high concentrations of formaldehyde vapour must be delivered to the target site to overcome these protective mechanisms. Mechanistic events of clear significance for carcinogenicity occur at dose levels where formaldehyde detoxification mechanisms are saturated in rats (Casanova & Heck, 1987).

It is critical to take dosimetry into consideration when considering quantitative species differences for formaldehyde-induced toxicity in the respiratory tract. Inhaled formaldehyde is predominantly deposited and readily absorbed in the regions of the upper respiratory tract with which it comes into initial contact, owing to its high reactivity with biological macromolecules (Heck et al., 1983; Swenberg et al., 1983). A complex relationship between nasal anatomy, ventilation, and breathing patterns (nasal or oronasal) determines where in the upper respiratory tract formaldehyde absorption occurs in species. In rodents, which are obligate nasal breathers, deposition and absorption occur primarily in the nasal passage. In contrast, primates are oronasal breathers; although absorption and deposition are likely to occur primarily in the oral mucosa and nasal passages, they can also occur in the trachea and ヒトの鼻組織におけるグルタルアルデヒドばく露と DPX 形成、細胞毒性及び細胞増殖を検討した研究はない。

# 3. 実験動物ととトとの間の動態的または薬力学的要因のいずれかの量的差異に基づいて、MOAのとトへの関連性を合理的に排除することができるか

## A. ホルムアルデヒド

推定される MOA に関する実験動物とヒトとの間の定量的差異は、標的組織におけるホルムア ルデヒドの濃度がもたらす作用にある。細胞毒性を引き起こすのはホルムアルデヒドそのもので あり、その代謝物ではない。吸入された外因性のホルムアルデヒドは、広く分布する多数の細胞 酵素、特にホルムアルデヒド脱水素酵素によって急速に代謝されギ酸塩になる。この効率的な代 謝解毒メカニズムに加えて、粘膜絨毛機構が、その下の上皮をガスや蒸気から保護する。したが って、標的組織において細胞毒性が発生するのに十分な遊離ホルムアルデヒドの濃度を達成する ためには、これらの保護機構を克服することが必要であり、比較的高濃度のホルムアルデヒド蒸 気を標的部位に到達させる必要がある。明らかに有意な発がん性をもたらす薬力学的事象は、ラ ットのホルムアルデヒド解毒機構が飽和した用量で発生する (Casanova & Heck、1987 年)。

呼吸器系におけるホルムアルデヒド誘発性毒性の定量的な種差を考慮する際には、投与量を考 慮することが重要である。吸入されたホルムアルデヒドは、生体高分子との高い反応性のため、 最初に接触する上気道の領域に多く沈着し、容易に吸収される(Heck ら、1983 年; Swenberg ら、 1983 年)。鼻の生体機構、換気量、呼吸パターン(鼻または鼻腔)の間の複雑な関係が、種によっ て上気道のどこでホルムアルデヒドの吸収が起こるかを決定する。鼻呼吸であるげっ歯類では、 沈着と吸収は主に鼻腔内で起こる。対照的に霊長類は口鼻呼吸であり、吸収と沈着は主に口腔粘 膜と鼻腔で起こる可能性が高いが、気管と気管支でも起こる可能性がある(Monticello ら、1991 年)。

bronchus (Monticello et al., 1991). This hypothesis is supported by effects (histopathological changes, increased epithelial cell proliferation, and DPX formation) being observed farther along within the upper respiratory tract in monkeys.

Species differences in dosimetry have been taken into account in a two-stage clonal growth model that has been developed to predict the nasal carcinogenic risk of formaldehyde in humans (Conolly et al., 2004). The model also incorporates data on normal growth curves for rats and humans, cell cycle times, and cells at risk in the different regions of the respiratory tract.

Mice are better able to reduce both their respiratory rate and tidal volume upon repeated exposures; therefore, mice have less formaldehyde available for deposition than rats, resulting in less tissue damage and a lower rate of cell turnover in the nasal epithelium (Chang et al., 1981, 1983). These are characteristics that may help explain the lack of neoplastic response in the nose of mice.

Although there are likely to be quantitative differences between animal species and humans due to differences in dosimetry in the respiratory tract, there do not appear to be fundamental differences that would indicate that the proposed MOA does not occur in humans.

# **B. Glutaraldehyde**

Much less is known of the kinetics of glutaraldehyde in experimental animals compared with formaldehyde. Inhalation studies do not appear to have been conducted. The terminal half-lives for elimination are long for both intravenous injection (rat 10 h, rabbit 15–30 h) and dermal application (rat 40–110 h, rabbit 20–100 h), probably due to the binding of glutaraldehyde to protein and the slow excretion of metabolites. The metabolites have not been identified, but it has been proposed that the metabolism of glutaraldehyde dehydrogenase. The glutaric acid formed by oxidation is probably further metabolized by reaction with coenzyme A (CoA) to give glutaryl CoA, which is then oxidized by glutaryl CoA dehydrogenase to glutaconyl CoA, leading to its eventual degradation to carbon dioxide via acetate (Beauchamp et al., 1992; NTP, 1993; NICNAS, 1994; Ballantyne, 1995).

Glutaraldehyde reacts readily with proteins as a cross-linking agent, mainly between amino groups. The reaction is rapid and pH dependent (rate increases at pH >9), to give Schiff bases. Further reaction occurs to give a number of complex reaction products, with the mechanism of the cross-linking process not yet fully understood.

Little information is available on the interaction between glutaraldehyde and DNA, but it has been reported (Hopwood, 1975) that glutaraldehyde reacts with DNA only at >60 °C (summarized by NICNAS, 1994), and there are data implying that there is no reaction under physiological conditions (Sewell et al., 1984; Douglas & Rogers, 1998; Vock et al., 1999).

#### IPCS Framework for Analysing the Relevance of a Cancer Mode of Action for Humans and Case-Studies

この仮説は、サルの上気道内のより遠位まで病理組織学的変化、上皮細胞の増殖及び DPX 形成 が観察されることによって支持されている。

ヒトにおけるホルムアルデヒドの鼻腔発がんリスクを予測するために開発された 2 段階のクロ ーン増殖モデルでは、用量評価における種差が考慮されている (Conolly ら、2004 年) このモデル には、ラットとヒトの正常成長曲線、細胞周期の時間及び気道の異なる領域におけるリスクのあ る細胞に関するデータも組み込まれている。

マウスは反復ばく露により呼吸速度と一回換気量の両方を低下させることができるため、マウスはラットよりもホルムアルデヒドの沈着が少なく、その結果、鼻腔上皮の組織損傷と細胞の再 生率が低下する(Changら、1981年、1983年)。これらの特徴は、マウスの鼻で腫瘍発生がないこ とを説明するのに役立つかもしれない。

動物とヒトとの間には、気道の用量評価の違いによる定量的な違いがあると思われるが、推定 される MOA がヒトでは発生しないことを示すような根本的な違いはないようである。

# B. グルタルアルデヒド

実験動物におけるグルタルアルデヒドの動態は、ホルムアルデヒドに比べてあまり知られてい ない。吸入試験は実施されていないようである。半減期は、静脈内投与(ラット10時間、ウサギ 15~30時間)と経皮投与(ラット40~110時間、ウサギ20~100時間)の両方で長くなっている が、これはグルタルアルデヒドがタンパク質に結合し、代謝物の排泄が遅いためと考えられる。 代謝物は同定されていないが、おそらくグルタルアルデヒドの代謝は、アルデヒド脱水素酵素に よる対応するカルボン酸への初期酸化を伴うと推定されている。酸化によって産生されたグルタ ル酸は、コエンザイム A (CoA)と反応してグルタリル CoA を産生する。そして、グルタリル CoA デヒドロゲナーゼによってグルタコニル CoA に酸化され、最終的にはアセテートを介して二酸化 炭素に分解される(Beauchamp ら、1992年; NTP、1993年; NICNAS、1994年; Ballantyne、1995 年)。

グルタルアルデヒドは、主にアミノ基間の架橋剤としてタンパク質と容易に反応する。この反応は迅速でpHに依存しており (pH>9 で反応速度が増加)、Schiff塩基を生成する。さらに反応すると、多くの複雑な反応生成物が得られるが、架橋反応のメカニズムはまだ完全には解明されていない。

グルタルアルデヒドと DNA との相互作用についてはほとんど情報がないが、グルタルアルデ ヒドが DNA と反応するのは 60℃以上の場合のみであることが報告されており(Hopwood、1975 年)、生理的条件下では反応しないことを示唆するデータもある(Sewell ら、1984 年; Douglas & Rogers、1998 年; Vock ら、1999 年)。

# 4. STATEMENT OF CONFIDENCE, ANALYSIS, AND IMPLICATION

# A. Formaldehyde

Sustained cytotoxicity and cell proliferation are key events in the proposed MOA for the induction of several types of animal tumours. There are substantial data to support this postulated MOA for formaldehyde-induced nasal tumours in rats. Cytotoxicity, DPX formation, nasal epithelial cell regenerative proliferation, squamous metaplasia, and inflammation have been measured in rat studies and are site-specific, highly non-linear concentration–response processes in concordance with the incidence of nasal tumours.

Based on the weight of evidence, it is likely that the MOA is relevant to humans, at least qualitatively. Increased cell proliferation and DPX formation within epithelia of the upper respiratory tract have been observed in monkeys exposed to formaldehyde vapour. Increased human epithelial cell proliferation following in situ exposure to formaldehyde has also been observed in a model system in which rat tracheae populated with human tracheobronchial epithelial cells were xenotransplanted into athymic mice. Limited evidence on histopathological lesions in the nose of humans exposed primarily to formaldehyde in the occupational environment is consistent with a qualitatively similar response of the upper respiratory tract in experimental animals. In addition, several epidemiological studies have indicated an increased risk of nasal cancers with formaldehyde exposure.

Therefore, the MOA is considered relevant to humans, and animal nasal tumour and other supporting data should be taken forward to evaluate human risk. This process would include consideration of the data suggesting that formaldehyde induces tumours in a non-linear, dose-dependent manner. There may also be quantitative differences in response between species for the proposed MOA due to differences in dosimetry.

# **B. Glutaraldehyde**

The epidemiological studies for glutaraldehyde are very limited and do not show an association with nasal tumours. In animal studies, glutaraldehyde has been shown to cause cytotoxicity, cell proliferation, and DPX production, but not nasal tumours, in inhalation studies in rats and mice. The fact that glutaraldehyde is clearly more toxic than formaldehyde should not constitute a reason for the difference in carcinogenic potential. Although, dose for dose, glutaraldehyde exposure may tend to result in more cell death than formaldehyde exposure, if glutaraldehyde is a carcinogen, this should be demonstrable at doses lower than those used for formaldehyde.

The MOA postulated for formaldehyde—that is, sustained cytotoxicity and cell proliferation—would appear to be relevant to glutaraldehyde, but tumour formation has not been demonstrated. It has been tentatively suggested here that the difference in pathological responses to these aldehydes is due to formaldehyde being a monoaldehyde whereas glutaraldehyde is a dialdehyde. This difference may result in a different form of cross-linking so that glutaraldehyde cross-link products are neither likely to retain any biological function nor likely to be repairable. The case-study highlights the difficulties in applying the HRF when the animal tumour data are inadequate.

# 4. 信頼性、解析及び帰結の記述

# A. ホルムアルデヒド

持続的な細胞毒性と細胞増殖は、いくつかの動物種における腫瘍誘発に対して提唱されている MOA にとっての key events である。ラットにおけるホルムアルデヒド誘発性鼻腔腫瘍の MOA を 支持するデータは多数存在する。細胞毒性、DPX 形成、鼻腔上皮細胞の再生性増殖、扁平上皮化 生、炎症はラットの研究で観察されており、部位特異的で非線形の濃度反応過程であり、鼻腔腫 瘍の発生率と一致している。

エビデンスの重み付けに基づいて、動物 MOA は少なくとも定性的にはヒトに関連している可 能性が高い。ホルムアルデヒド蒸気にばく露されたサルでは、上気道上皮内の細胞増殖及び DPX 形成の増加が観察されている。また、ホルムアルデヒドへの組織ばく露後のヒト上皮細胞の増殖 は、ヒト気管支上皮細胞を移植したラット気管を胸腺欠損マウスに異種移植したモデル系でも観 察されている。主にホルムアルデヒドにばく露されたヒトの鼻の病理学的病変に関する数少ない エビデンスは、定性的に類似している実験動物の上気道の病変と一致している。さらに、いくつ かの疫学研究では、ホルムアルデヒドばく露に伴う鼻腔がんのリスク増加が示唆されている。

したがって、MOA はヒトに関連していると考えられ、ヒトのリスク評価のために、動物の鼻腔 腫瘍やその他の裏付けとなるデータを活用すべきである。このプロセスには、ホルムアルデヒド が非線形で用量依存的に腫瘍を誘発することを示唆するデータを考慮することが含まれる。また、 定量法の違いにより推定される MOA については種間の反応に量的な差異があるかもしれない。

# B. グルタルアルデヒド

グルタルアルデヒドの疫学研究は非常に限られており、鼻腔腫瘍との関連性は示されていない。 動物実験では、ラットとマウスの吸入試験において、グルタルアルデヒドは細胞毒性、細胞増殖、 DPX 産生を引き起こすことが示されているが、鼻腔腫瘍は引き起こさないことが示されている。 グルタルアルデヒドの方がホルムアルデヒドよりも明らかに毒性が強いという事実は、発がん性 の違いの説明にはならない。グルタルアルデヒドはホルムアルデヒドよりも低用量での細胞死が 多いため、発がん性があるとすれば、ホルムアルデヒドよりも低い用量でそのことが証明されな ければならない。

ホルムアルデヒドで推定される MOA、すなわち持続的な細胞毒性と細胞増殖は、グルタルアル デヒドに関連しているように思われるが、腫瘍形成では実証されていない。これらのアルデヒド に対する病理学的反応の違いは、ホルムアルデヒドがモノアルデヒドであるのに対し、グルタル アルデヒドはジアルデヒドであるためであることが暫定的に示唆されている。この違いが、グル タルアルデヒドの架橋生成物が生物学的機能を保持する可能性も修復する可能性もないように、 架橋の形態が異なるという結果になっているのかもしれない。この事例研究は、動物の腫瘍デー タが不十分な場合に HRF を適用することの難しさを浮き彫りにしている。

非発がん MOA のヒトへの関連性を解析するための IPCS フレームワーク

# **PART 2**

# IPCS FRAMEWORK FOR ANALYSING THE RELEVANCE OF A NON-CANCER MODE OF ACTION FOR HUMANS

# PREFACE

Following completion of the IPCS Framework for Analysing the Relevance of a Cancer Mode of Action for Humans (see Part 1), an expert meeting was convened in Geneva in 2006 to explore the question as to whether the IPCS framework could be applied in chemical risk assessment generally (i.e. to develop a non-cancer framework). The participants at this expert meeting concluded that the framework should be applicable to all end-points and proceeded to author a draft publication out of session. The draft was sent for peer review by the members of the Harmonization Project Steering Committee and subsequently revised by the authors, taking into account the peer review comments received.

ヒトに対するがん MOA の妥当性を解析するための IPCS フレームワーク(第1部参照)の完成 後、2006 年にジュネーブで専門家会議が開催され、化学物質リスク評価に IPCS フレームワーク を一般的に適用できるか否か(すなわち、がん以外のフレームワークを開発すること)という問 題が議論された。この専門家会議の参加者は、フレームワークはすべてのエンドポイントに適用 可能であるべきであると結論付け、会期外に出版物の草案を作成した。この草案は、ハーモナイ ゼーションプロジェクト運営委員会のメンバーによって査読され、その後、受領した査読コメン トを考慮して著者によって修正された。

IPCS Framework for Analysing the Relevance of a Non-Cancer Mode of Action for Humans

# LIST OF CONTRIBUTORS

Alan R. Boobis Section of Experimental Medicine and Toxicology, Division of Medicine, Imperial College London, Hammersmith Campus, London, United Kingdom

John E. Doe European Centre for Ecotoxicology and Toxicology of Chemicals (ECETOC), Brussels, Belgium

Barbara Heinrich-Hirsch Safety of Substances and Preparations, Federal Institute for Risk Assessment, Berlin, Germany

M.E. (Bette) Meek Existing Substances Division, Safe Environments Programme, Health Canada, Ottawa, Ontario, Canada

#### Sharon Munn

Toxicology and Chemical Substances, Institute for Health and Consumer Protection, Joint Research Centre, European Chemicals Bureau, Ispra, Italy

Mathuros Ruchirawat Chulabhorn Research Institute (CRI), Lak Si, Bangkok, Thailand

Josef Schlatter Nutritional and Toxicological Risks Section, Swiss Federal Office of Public Health, Zurich, Switzerland

Jennifer Seed Risk Assessment Division, Environmental Protection Agency, Washington, DC, USA

Carolyn Vickers International Programme on Chemical Safety, World Health Organization, Geneva, Switzerland

# IPCS FRAMEWORK FOR ANALYSING THE RELEVANCE OF A NON-CANCER MODE OF ACTION FOR HUMANS<sup>1</sup>

Alan R. Boobis, John E. Doe, Barbara Heinrich-Hirsch, M.E. (Bette) Meek, Sharon Munn, Mathuros Ruchirawat, Josef Schlatter, Jennifer Seed, & Carolyn Vickers

Structured frameworks are extremely useful in promoting transparent, harmonized approaches to the risk assessment of chemicals. One area where this has been particularly successful is in the analysis of modes of action (MOAs) for chemical carcinogens in experimental animals and their relevance to humans. The International Programme on Chemical Safety (IPCS) recently published an updated version of its MOA Framework in animals to address human relevance (cancer Human Relevance Framework, or HRF). This work has now been extended to noncancer effects, with the eventual objective of harmonizing framework approaches to both cancer and non-cancer end-points. As in the cancer HRF, the first step is to determine whether the weight of evidence based on experimental observations is sufficient to establish a hypothesized MOA. This comprises a series of key events causally related to the toxic effect, identified using an approach based on the Bradford Hill criteria. These events are then compared qualitatively and, next, quantitatively between experimental animals and humans. The output of the analysis is a clear statement of conclusions, together with the confidence, analysis, and implications of the findings. This framework provides a means of ensuring a transparent evaluation of the data, identification of key data gaps and of information that would be of value in the further risk assessment of the compound, such as on dose-response relationships, and recognition of potentially susceptible subgroups, for example, based on life stage considerations.

The framework described in this paper, a non-cancer Human Relevance Framework (HRF), was prepared by the International Programme on Chemical Safety (IPCS) (WHO/ILO/UNEP) project on the Harmonization of Approaches to the Assessment of Risk from Exposure to Chemicals. This global "Harmonization Project" aims to harmonize global approaches to chemical risk assessment through both increased consistency of risk assessment methodologies and development of international guidance documents. The project enables the achievement of commitments on harmonization of chemical risk assessment (United Nations Conference on Environment and Development (United Nations, 1992), the Intergovernmental Forum on Chemical Safety (1994), the World Summit on Sustainable Development (UNEP, 2002), and the Strategic Approach to International Chemicals are assessed, and hence the documents produced can be applied in the assessment of industrial chemicals, biocides, pesticides, veterinary chemicals, pharmaceuticals, cosmetics, natural toxicants, food additives, and environmental contaminants in food, water, air, and consumer products.

A main outcome of the Harmonization Project is the IPCS Conceptual Framework for Evaluating a Mode of Action for Chemical Carcinogenesis (Sonich-Mullin et al., 2001) and

its subsequent development into an IPCS Framework for Analysing the Relevance of a Cancer Mode of Action for Humans (IPCS cancer HRF) (Boobis et al., 2006; see also Part 1 of this document). The mode-of-action (MOA) analysis utilizes a weight-of-evidence approach based on the Bradford Hill criteria for causality (Hill, 1965). It aims to determine whether it is possible to establish an MOA for a carcinogenic response observed in an experimental animal study, through application of a weight-of-evidence approach that requires identification of key events along the causal pathway to cancer. When an MOA has been established in experimental animals, the cancer HRF provides an analytical tool to enable the transparent evaluation of the data in order to consider the human relevance of the MOA.

Following on from this, IPCS decided to consider whether the framework for cancer could be applied, with modifications, if necessary, to other end-points and their associated MOAs. Recognizing the work that the Risk Science Institute (RSI) of the International Life Sciences Institute (ILSI) had conducted in parallel to develop a similar framework and apply it to non-cancer risk assessment, IPCS convened an international meeting in Geneva in March 2006 to review and consider the ILSI publication (Seed et al., 2005), along with the IPCS cancer HRF (Boobis et al., 2006; see also Part 1 of this document), in order to explore the question as to whether the IPCS framework could be applied in chemical risk assessment generally. In summary, this IPCS meeting recognized that the framework should be applicable to all endpoints, both cancer and non-cancer, and recommended further work to put this into practice, including documenting the rationale for application of the framework more generally, which appears in the present paper, and steps to facilitate uptake and use of the framework.

The IPCS meeting recognized that the non-cancer HRF would have multiple uses in chemical risk assessment:

- It would provide an internationally harmonized approach to the establishment of an MOA in experimental animals and its relevance to humans.
- It would generate criteria for the MOA against which subsequent cases could be considered—that is, to show whether a compound shares an established MOA.
- It would enable clarification of key information relating to the human relevance of the MOA, and this would inform the assessment of other chemicals that share the MOA.
- In general, application of the framework would enable critical data deficiencies and research needs to be identified and inform qualitative and quantitative assessment.

## THE NEED FOR A NON-CANCER HUMAN RELEVANCE FRAMEWORK

The non-cancer HRF is a tool that provides a structured approach to the assessment of human relevance of a postulated MOA in animals in a weight-of-evidence context. Subsequently, it includes explicit consideration of the relevance of the proposed MOA to humans, often based on consideration of more generic information, such as anatomical, physiological, and biochemical variations among species. In this manner, the framework encourages maximum use of both chemical-specific and more generic information in a transparent and analytical fashion.

ーク (Sonich-Mullin ら、2001 年) と、それに続くがん MOA のヒトへの関連性を解析するための IPCS フレームワーク (IPCS cancer HRF) (Boobis ら, 2006 年;本文書の第1部も参照) がある。 MOA 解析は、因果関係の Bradford Hill 基準 (Hill、1965 年)に基づくエビデンスの重み付け (weight of evidence) アプローチを利用している。これは、腫瘍の原因に沿った一連の key events の特定を 必要とするエビデンスの重み付けアプローチを適用することで、動物実験で観察された発がん作 用に対する MOA を確立できるか判断することを目的としている。実験動物で MOA が確立され た場合、がん HRF は、MOA のヒトへの関連性を検討するために透明性のあるデータ評価を可能 にする解析ツールを提供できる。

これを受けて、IPCS は、必要に応じて修正を加えながら、他のエンドポイントとそれに関連す る MOA にもがんのフレームワークを適用できるか否かを検討することにした。国際生命科学研 究機構(ILSI)のリスクサイエンス研究所(RSI)は、がん以外のリスク評価に適用するために、 同様のフレームワークを開発した。また、IPCS は 2006 年 3 月にジュネーブで国際会議を開催し た。そこで、ILSI のフレームワークが一般的に化学物質のリスク評価に適用できるかという問題 を探るために、ILSI の出版物(Seed ら、2005 年)と、ILSI のがん HRF(Boobis ら、2006 年 ;本 文書の第1部も参照)を評価、検討した。要約すると、この IPCS 会議では、フレームワークが発 がんと非発がんの両方のエンドポイントに適用されるべきであり、これを実践に移すための更な る作業を推奨している。そしてこれには、本稿にも記載しているが、フレームワークのより一般 的適用のための根拠の文書化及びフレームワークの利用と利用を促進するための手順が含まれて いる。

IPCS 会議では、化学物質リスク評価において非発がん HRF は下記のような複数の有用性を持つことが認識された。

- 実験動物における MOA の確立とヒトとの関連性について、国際的に調和のとれたアプローチ を提供する。
- MOA の基準が作成され、後続のケースを考慮することができるようになる。すなわち、ある 化合物に確立された MOA を適合できるかを示すことができるようになる。
- MOAのヒトとの関連性に関する重要な情報が明らかになり、MOAを共有する他の化学物質の 評価に情報を提供できるようになる。
- 一般的に、このフレームワークを適用することで、重要データの不足や必要な研究が明らかになり、定性的・定量的な評価に役立てることができるようになる。

#### 非発がんとト関連性フレームワークの必要性

非発がん HRF は、動物 MOA のヒトとの関連性を評価するための体系化されたアプローチを提 供する手段であり、エビデンスの重み付けの文脈の中で、動物において推定される MOA のヒト への関連性を評価する。その後、推定される MOA のヒトへの外挿性を明確に検討することが含 まれており、多くの場合、種間の解剖学的、生理学的及び生化学的な差異などの一般的情報の検

108

Pivotal to transparency in determining human relevance using the framework are the delineation and consideration of the nature of evidence in various species of key events—that is, those in a postulated MOA that are measurable and critical to the induction of the toxicological response. Evaluation of the concordance of key events based on explicit consideration of variations between experimental animals and humans constitutes the principal basis of transparency in consideration of weight of evidence for human relevance.

While principally relevant to hazard characterization, the non-cancer HRF additionally contributes more generally to transparency in risk assessment through explicit delineation and consideration of data on appropriate key events that are also relevant to subsequent dose–response analysis for MOAs deemed relevant to humans. If the MOA in experimental animals is judged to be qualitatively relevant to humans, a more quantitative assessment is required that takes into account any kinetic and dynamic information that is available from both the experimental animals and humans in order to determine whether human relevance might be precluded on this basis.

These same data are critical to subsequent dose–response analysis for MOAs considered relevant in considering the adequacy of, for example, available information as a basis for replacement of default uncertainty factors in the development of chemical-specific adjustment factors (CSAFs) (IPCS, 2005). This information could, for example, constitute an adequate basis to consider interspecies variation in rates of formation of reactive metabolites in the target tissue, for replacement of the default subfactor for interspecies differences in toxicokinetics with a CSAF (IPCS, 2005).

Use of this non-cancer HRF also promotes harmonization of approaches to risk assessment for all end-points, bridging previously distinct approaches on, for example, cancer and noncancer effects. Harmonization in this context refers to a biologically consistent approach to risk assessment for all end-points, for which exploration of biological linkages is critical to ensuring maximal use of relevant information. Often, for example, organ toxicity is a critical key event in postulated MOAs for induction of tumours at the same site. The non-cancer HRF, then, sets the stage for identification of critical precursor non-cancer key events for which subsequent quantification of interspecies differences and interindividual variability in dose–response analysis is relevant. In other cases, a postulated MOA may lead to toxic effects in multiple organs, and these would be considered in the same non-cancer HRF analysis.

In addition, consideration in a transparent framework may identify factors that, while not themselves essential for the toxicological effect (and hence not key events), may modulate key events and, as a result, contribute to differences between species or individuals. Such factors include genetic differences in pathways of metabolism, competing pathways of metabolism, and cell proliferation induced by concurrent pathology.

Such an analysis may also provide an indication of those components of a proposed MOA that may operate only over a certain dose range. If a high experimental dose of a given compound is needed to result in an obligatory step in an MOA, then the relevance to human

討に基づいている。このようにして、フレームワークは、透明性のある解析方法で、化学物質に 特異的な情報と一般的な情報の両方を最大限に利用することを奨励している。

フレームワークを用いてヒトへの関連性を決定する際の透明性を確保するために極めて重要な のは、key events の様々な種におけるエビデンスの性質を明確にし、検討することである。すなわ ち、推定される MOA における、測定可能で毒性学的反応の誘発に重要であると想定される key events に関するエビデンスの性質を明らかにし、考慮することである。実験動物とヒトの差異を 明確に考慮した上での key events の一致性の評価は、ヒトとの関連性に関するエビデンスの重み 付けを考慮する上での透明性を保つための基礎となる。

主にハザード評価において、非発がん HRF は、その後のヒトに関連すると考えられる MOA の 用量反応解析に関わる適切な key events の明確な定義とデータの検討を通じて、リスク評価の透 明性を高めることにも貢献している。実験動物における MOA がヒトと定性的に関連があると判 断された場合には、ヒトとの関連性が否定されるか否かを判断するために、実験動物とヒトの双 方からの動態学的及び薬力学的情報を考慮に入れた、より定量的な評価が必要である。

これらのデータは、その後の関連があると考えられる MOA の用量反応解析に極めて重要である (IPCS、2005年)。例えば、化学物質特異的調整係数 (CSAFs)の定義づけにおいて、デフォルトの不確実係数を置き換えるための基礎として、利用可能な情報の妥当性を考慮する場合である。この情報は、標的組織における反応代謝物の形成速度の種差を考慮して、毒物動態の種間差に対するデフォルトのサブファクターを CSAF で置き換えるための適切な根拠となり得る (IPCS、2005年)。

また、この非発がんHRFの使用はすべてのエンドポイントのリスク評価適用の調和を促進する。 例えば、発がん影響と非発がん影響に関するこれまでの異なるアプローチの架け橋となる。ここ でいう調和とは、関連情報を最大限に活用するために生物学的関連性を探ることが重要であり、 すべてのエンドポイントのリスク評価における一貫したアプローチを意味する。例えば多くの場 合、臓器毒性は同一部位に腫瘍を誘発すると推定される MOA において key events となる。非発が ん HRF は、その後の用量反応解析における種間差及び個体間のばらつきの定量化に関連する、重 要な前がん病変の key events を特定するための段階を設定する。他にも、推定される MOA が複数 の臓器に毒性効果をもたらす可能性があれば同じ非発がん HRF 解析で検討されることになる。

さらに、透明性のあるフレームワークで検討することで、それ自体は毒性学的影響に必須では ない(すなわち key events ではない)が、key events を修飾し、種や個体間の差異に寄与する因子 を特定できる可能性がある。そのような要因には、代謝経路の遺伝的差異、競合する代謝経路、 及び同時進行する病理学的要因により誘発される細胞増殖が含まれる。

このような解析は、特定の用量範囲でのみ、作動する可能性のある推定される MOA の構成要

109

risk becomes a matter of exposure. Thus, the exposure assessment step of the risk assessment is critical to a comprehensive evaluation.

Importantly, then, application of the non-cancer HRF contributes to identification of any specific subpopulations (e.g. those with genetic predisposition) who are at increased risk and provides information relevant to consideration of relative risks at various life stages. In many cases, this is based not on chemical-specific information but rather on inference, based on knowledge of the MOA, as to whether specific age groups may be at increased or decreased risk. This requires explicit consideration of comparative developmental and ageing processes and events in humans and animal models. These considerations are critical to determination of focus in the remaining stages of risk assessment, such as dose–response analysis.

The transparent delineation of the weight of evidence for postulated MOAs and their relevance to humans (requiring explicit consideration of the strengths and weaknesses of the available database, as well as highlighting qualitative and quantitative similarities and differences among species and related uncertainties) also identifies any inconsistencies in the available data and defines critical data gaps and research needs. This derives from the requirement in each step to explicitly assess confidence in the quality and quantity of data underlying the analysis, consistency of the analysis within the framework, consistency of the database—that is, that studies are not contradictory of each other—and the nature and extent of the concordance analysis.

Iterative application of the non-cancer HRF, even before all of the data are available, to the analysis of a postulated MOA and its relevance to humans are beneficial as a basis for developing and refining research strategies as additional information becomes available. In this context, the framework should prove helpful in facilitating discussion between risk assessors and research scientists in jointly understanding the nature of data that would support human relevance analysis of a postulated MOA in animals and defining next steps in data acquisition. Iterative consideration of MOA in designing research strategies is also expected to increase efficiency by focusing resources in critical areas in more tiered and targeted approaches.

As knowledge advances, MOAs will become less chemical specific and based even more on the key biological processes involved, allowing greater generalization of human relevance from one compound to another. The need for chemical-specific data for established MOAs will be less, although it will always be necessary to establish rigorously that the key events comprising the MOA occur.

The transparency in the human relevance of a postulated MOA that results from application of the non-cancer HRF should promote confidence in the conclusions reached, through the use of a defined procedure that encourages clear and consistent documentation supporting the analysis and reasoning, highlights inconsistencies and uncertainties in the available data, and identifies critically important data gaps that, when filled, would increase confidence in outcome. This transparency not only is anticipated to facilitate discussion between the risk assessment and research communities, but may also contribute to greater convergence among different regulatory agencies. 素に関する指標も提供するかもしれない。MOA に必須な事象を引き起こすのに、対象の化合物の 高用量ばく露が必要とされる場合、ヒトのリスクとの関連性はばく露量に依存する問題となる。 このように、リスク評価におけるばく露評価は、包括的な評価を行う上で非常に重要である。

重要なことは、非発がん HRF を適用することで、リスクが高い集団(例えば遺伝的素因を持つ 人)を特定し、様々なライフステージにおける相対リスクに関連する情報を提供できるようにな るということである。これは多くの場合、化学物質固有の情報に基づくのではなく、MOA の知識 に基づき特定の年齢層でのリスクが増加しているか減少しているかを推論することに基づいてい る。このためには、ヒト及び動物モデルにおける発達及び老化過程を比較し、事象を明確に検討 する必要がある。これらの検討事項は、後続のリスク評価過程において用量反応解析など、どこ に重点を置くべきか決定する上で重要となる。

推定される MOAs のエビデンスの重み付けと透明性のあるヒトとの関連性を示すこと(利用可 能なデータベースの長所と短所を明確に検討し、種間の質的・量的な類似性と相違点及び関連す る不確実性を強調することを必要とする)は、利用可能なデータの矛盾を特定し、重要なデータ ギャップと研究の必要性を明らかにすることにもなる。これは、各ステップにおいて、解析の基 礎となるデータの質と量、フレームワーク内での解析の一貫性、データベースの一貫性(つまり 研究が互いに矛盾していないこと)、そして一致解析の質的・量的な信頼性を明確に評価する必要 があることに由来している。

すべてのデータが利用可能になる前であっても、推定される MOA 及びヒトとの関連性の解析 に、非発がん HRF を繰り返して適用することは、追加情報の獲得とともに研究戦略を策定・改良 するための基礎として有益である。すなわち、フレームワークは動物における推定される MOA の ヒトへの関連性解析を支援するデータの性質について、リスク評価者と研究者が共に理解を深め ること、データ取得に向け次の一手を決める手助けとなるに違いない。また、研究戦略を立案す る際に MOA を繰り返し検討することで、重要な分野に資源を集中させ、より階層的で集中的な アプローチを行うことができ、効率性を高めることが期待される。

知識の進歩に伴い、MOA は化学物質に特化したものから、関連する主要な生物学的プロセスに 基づいて、ある化合物から別の化合物へとヒトとの関連性をより一般化させることになるだろう。 MOA を構成する key events が発生していることを厳密に立証することが常に必要であるものの、 MOA を確立する際に化学物質固有のデータを必要とすることは少なくなるだろう。

非発がん HRF を適用した推定 MOA の透明性は、解析と推論を裏付ける明確で一貫性のある文 書化を奨励している。そして、それを満たすことで結果の信頼性を高める重要なデータギャップ を特定し、データの矛盾や不確実性を明らかにし、到達した結論に対する信頼性を向上させる。 このような透明性は、リスク評価者と研究者との議論を促進させるだけでなく、異なる規制機関 間の意見合意にも貢献すると期待される。 The non-cancer HRF also provides the basis for improved process and content for scientific peer input and peer review, specifying minimum criteria of clarity and transparency as a basis to acquire input and acceptance of postulated MOAs and their relevance to humans. Adherence to these criteria enables others to determine the basis of the conclusions reached with respect to the key events, the exclusion of other MOAs, and the analysis of human relevance.

# WHEN WOULD THE NON-CANCER HRF BE APPLIED?

The non-cancer HRF provides a valuable tool to assess an MOA, but it requires significant amounts of effort and experimental work, so it is not something that would be used during the course of the assessment of every chemical. Its main purpose would be to determine whether to apply the default assumption that all effects seen in animals are relevant to humans. This question increases in importance when the application of the default assumption during the course of a risk assessment indicates that adverse effects are likely to occur—for example, where there is a low margin of exposure between the point of departure for the effect under consideration and the estimated human exposure, especially if the human exposure estimate has already been refined. It then becomes important to know whether risk management measures will be required. This is of most concern when new data emerge, such as those identifying a new effect, additional data on the dose–response relationship of the chemical, or changes in use pattern or exposure estimation, which change the risk assessment of a chemical that is already in use.

Use of the non-cancer HRF may also be of value in the situation where the effects in animals would have potentially serious consequences if they occurred in humans, such as neuro-toxicity or teratogenesis. These effects are subject to very rigorous risk assessment procedures, so they comparatively frequently suggest the need for risk management measures.

Another situation in which use of the non-cancer HRF should be considered is where there are interspecies differences in either the type of effect or the dose levels at which an effect occurs. In these cases, it will be important to understand which species is the most appropriate upon which to base extrapolation to humans. This indication would also apply to differences between sexes or strains in the same species.

These situations indicate that further consideration is required, and the non-cancer HRF provides a way of doing this. The framework can be applied at any stage in the process of considering an effect. It should be applied in an iterative way during the course of investigating an effect to help guide the scientist. When an effect has first been observed and gives rise to concern, the framework allows the investigator to structure the work programme by prompting the questions to be addressed. As the investigation develops, it guides the investigator in assessing the data as they are generated and provides pointers in deciding whether and what other data would be required.

In situations where there is a large body of data, the framework allows the evaluator to weight the evidence according to its significance as well as its volume.

また非発がん HRF は、専門家の関与やピアレビューのために改善されたプロセスや内容の基礎 を提供し、推定される MOA 及びそのヒトへの関連性についての助言や承認を得るための基礎と して、解析の明確性や透明性の最低限の基準を明らかにする。これらの基準に従うことで、他者 が key events や他の MOA の除外、対象 MOA のヒトへの関連性の結論の根拠を、明確に認識でき るようになる。

# 非発がん HRF はどのような場合に適用されるのか

非発がん HRF は MOA を評価するための貴重なツールを提供するが、かなりの労力と実験的作 業を必要とするため、すべての化学物質の評価に用いられるものではない。HRF の主な目的は、 動物でみられるすべての影響がヒトに関連するというデフォルトの仮定を適用するか否かを決定 することであろう。この疑問は、リスク評価の過程で上記の仮定を適用した場合に評価結果がヒ トに有害な影響が発生する可能性が高いことを示す場合に重要性が増す。例えば、検討中の影響 が発生する最低用量とヒトの推定ばく露量との差が小さい場合、特にヒトのばく露量の推定値が 既に精緻化されている場合である。そしてその場合、リスク管理対策が必要かを知ることが重要 になる。このことは、新たな影響を特定したデータ、化学物質の用量反応関係に関する追加デー タ、または使用パターンの変更やばく露推定値の変更など、既に使用されている化学物質のリス ク評価を変更するような新たなデータが出てきた場合に最も懸念されることである。

非発がん HRF の使用は、動物での影響が神経毒性や催奇形性など、ヒトで発生した場合に重大 な影響を及ぼす可能性がある場合にも有用である。これらの影響は非常に厳格なリスク評価プロ セスの対象となるため、比較的頻繁にリスク管理措置の必要性が示唆される。

がん以外にHRFの使用を検討すべきもう一つの状況は、影響の種類または影響が発生する用量 レベルのいずれかに種差がある場合である。このような場合には、どの種がヒトへの外挿におい て最も適切なものであるかを理解することが重要である。この指針は、同一種の性別又は系統間 の違いにも適用される。

これらの状況は、さらなる検討が必要であることを示しており、非発がん HRF はこれを行う方 法を提供している。このフレームワークは、影響を検討するプロセスのどの段階でも適用でき、 科学者の道しるべとなるよう、影響を調査する過程で反復的に適用されるべきである。最初に影 響が観察され、懸念が生じたとき、フレームワークは、調査者が対処すべき問いを示すことによ って作業プログラムを構成できるようにする。研究の進展とともに、HRF はデータが作成された ときには、データを評価する研究者を導き、また他のデータが必要かどうか、どのようなデータ が必要かを決定する際の指標となる。

大量のデータがある状況では、フレームワークにより、評価者はその重要性と量に応じてエビ デンスの重み付けが可能となる。

The non-cancer HRF can also be useful when a chemical is observed to cause an effect suspected of being caused by an MOA that has already been established using the framework or shares structural similarity to a chemical or class of chemicals with an established MOA. The earlier use of the non-cancer HRF to establish this MOA will have identified the key steps that need to be investigated in order to ascribe the MOA to the new chemical. This will prove valuable both in a prospective way in designing new research or testing programmes and retrospectively in evaluating a data set.

# **CONSIDERATION OF THE NON-CANCER HRF**

The non-cancer HRF is an analytical tool that enables a structured approach to the assessment of the overall weight of the evidence for the postulated MOA and its relevance to humans. The framework is not designed to provide an absolute answer on sufficiency of the information, as this will vary, depending on the circumstance. It must be emphasized that it is not a checklist of criteria but an approach to data evaluation and presentation. The output from the application of the framework serves as the basis for the continuation of the risk assessment of the compound.

It is envisaged that the non-cancer HRF will be applicable to a wide range of toxicological end-points, encompassing changes in structure and function of organs, tissues, and cells, including physiological and neurobehavioural effects. The types of toxicity that could be addressed using the framework include, but are not limited to:

- *Organ toxicity*: Examples include benzene-induced haematotoxicity (aplastic anaemia), paraquat-induced lung toxicity, chloroquine-induced ocular toxicity.
- *Reproductive toxicity:* Examples include phthalate-induced male infertility, dioxininduced dysregulation of female fertility.
- *Developmental toxicity*: Examples include methylmercury-induced developmental neurotoxicity, retinoid-induced teratogenesis.
- *Neurotoxicity*: Examples include lead-induced peripheral neuropathy, acrylamide-induced axonopathy, 1-methyl-4-phenyl-1,2,3,6-tetrahydropyridine (MPTP)-induced Parkinson disease.
- Immunotoxicity: Examples include organotin-induced immunosuppression, isoniazidinduced systemic lupus erythematosus (SLE)-like syndrome, contaminated L-tryptophaninduced eosinophilia-myalgia syndrome (EMS).

# **Introduction to MOA**

Prior to embarking on a non-cancer HRF analysis, there needs to be careful evaluation of the weight of evidence for a toxicological response on exposure to a chemical in experimental animals. The nature of the non-cancer HRF is such that only one MOA is analysed at a time; hence, for example, different toxicological effects associated with chemical administration, even if observed in the same animals, will require separate framework analyses to discern the MOA for each effect. Consistent with species- and tissue-specific variation in metabolic activation and detoxication, there may be poor site concordance for some toxicants. This will need to be kept in mind when comparing animal and human data.

非発がん HRF は、既にフレームワークを用いて確立されている MOA によって、化学物質が影響を 起こすことが観察された場合や、化学物質が既に確立された MOA を持つ化学物質と構造的類似があ る場合にも有用である。MOA を確立するために非発がん HRF を早期に使用することで、MOA を新し い化学物質に適用させるために調査する必要がある重要なステップを特定することができる。これは、 新しい研究や試験を設計する際の前向きな方法としても、データを遡及的に評価する方法でも、価値 あるものになるだろう。

#### 非発がん HRF の検討

非発がん HRF は、推定される MOA とヒトとの関連性を評価するための全体的なエビデンスの重み 付けのための手段を体系化する解析ツールである。このフレームワークは、状況に応じて異なるため、 情報が十分であるか否かに対する絶対的な答えを提供するようには設計されていない。これは基準の チェックリストではなく、あくまでもデータの評価と提示の手段である。フレームワーク適用による 成果は、化合物のリスク評価を継続するための基礎となる。

非発がん HRF は、臓器、組織、細胞の構造と機能の変化(生理学的影響や神経行動学的影響を含む) を含む幅広い毒性学的エンドポイントに適用されることが想定されている。このフレームワークを用 いて対処できる毒性の種類には、以下のものが含まれるが、これらに限定されるものではない。

- ・臓器毒性:例)ベンゼンによる血液毒性(再生不良性貧血)、パラコートによる肺毒性、クロロ キンによる眼毒性など
- 生殖毒性:例)フタル酸による男性不妊、ダイオキシンによる女性の受胎能力障害など
- 発達毒性:例)メチル水銀による発達神経毒性、レチノイドによる催奇形性など
- 神経毒性:例)鉛による末梢神経障害、アクリルアミドによる軸索障害、1-メチル-4-フェニル
   -1,2,3,6-テトラヒドロピリジン(MPTP)によるパーキンソン病など
- 免疫毒性:例)オルガノチンによる免疫抑制、イソニアジドによる全身性エリテマトーデス(SLE) 様症候群、汚染されたL-トリプトファンによる好酸球増多症症候群(EMS)など

#### MOA の紹介

非発がん HRF 解析に着手する前に、実験動物における化学物質へのばく露による毒性学的反応のエ ビデンスの重みを慎重に評価する必要がある。非発がん HRF の特徴は一度に1つの MOA のみを解析 する点である。したがって、例えば、化学物質の投与に関連した異なる毒性学的影響は、たとえ同じ動 物で観察されたとしても、各影響の MOA を識別するために別のフレームワーク解析を必要とする。代 謝的活性化と解毒における種や組織の違いと同様に、一部の毒性物質では毒性発現部位の一致性が低 い場合がある。動物とヒトのデータを比較する際には、この点に留意する必要がある。

# 推定されるMOA(事例における仮説)

ここで、被験物質の毒性学的影響の原因となっていると推定される MOA における一連の事象 112

# Postulated mode of action (theory of the case)

This comprises a brief outline of the sequence of events in the MOA postulated to be responsible for the toxicological effect of the test substance. This description leads into the next section, which identifies the events considered "key" (i.e. necessary and measurable) in the MOA.

## Key events

The "key events" in the MOA are briefly identified and described. Key events are those events that are critical to the induction of the toxicological response as hypothesized in the postulated MOA and are also measurable. To support an event as key, there needs to be a body of experimental data in which the event is characterized and consistently measured. The types of information that might be relevant include, for example, toxicological response and relevant key events in the same cell type, sites of action logically related to the event(s), specific biochemical events, changes in the expression or activity of enzymes, receptor–ligand interactions, effects on cofactor levels, specific changes in histology, changes in cell proliferation (increased or decreased), perturbations in hormone homeostasis or other signalling pathways (either intracellular or extracellular), second messengers, or ion fluxes, increased degradation of macromolecules, and changes in membrane permeability or integrity.

# Concordance of dose–response relationships

The dose–response relationships for each of the key events and for the toxicological response should be characterized and their interrelationships discussed with respect to the Bradford Hill criteria (Hill, 1965). Ideally, it should be possible to correlate the dose dependency of the increases in the magnitude (or frequency) of a key event with increases in the severity (e.g. lesion progression) of other key events occurring later in the process and with the ultimate toxicological response. Comparative tabular presentation of the magnitude of changes in key events and toxicological response is often helpful in examining dose–response concordance.

It is important to consider whether there are fundamental differences in the biological response (i.e. dose transitions) at different parts of the dose–response curve (Slikker et al., 2004). If so, key events relevant to the different parts of the dose–response curve will need to be defined and used in the framework analysis.

## Temporal association

The temporal relationships for each of the key events and for the toxicological response should be characterized. Key events should be observable before toxicity is apparent and should be consistent temporally with each other; this is an essential step in deciding whether the data support the postulated MOA. Observations of key events at the same time as the toxicological response (e.g. at the end of a study) do not permit conclusions as to temporal association, but can contribute to the analysis described in the next section.

# Strength, consistency, and specificity of association of toxicological response with key events

The weight of evidence linking the key events, any precursor lesions, and the toxicological response should be addressed (see Weed [2005] for a discussion of what is meant by weight of evidence). Stop/recovery studies showing absence or reduction of toxicity when a key

の概要を簡単に説明している。この記述は次のセクションにつながり、MOAの中で「重要」と考 えられる事象(すなわち、必要かつ測定可能な事象)を特定するものである。

## Key events

MOAにおける「key events」を簡潔に説明する。key events とは、推定される MOA で仮定され た毒性学的反応の誘発に重要な事象であり、測定可能な事象である。ある事象を key events とし て支持するためには、その事象を特徴づける、一貫した測定実験データが必要である。関連する 可能性のある情報の種類には、例えば、類似の細胞における毒性学的反応と関連する key events、 理論上関連する作用部位、特定の生化学的事象、酵素の発現または活性の変化、受容体とリガン ドの相互作用、補因子レベルへの影響、組織学における特異的変化、細胞増殖の変化(増加また は減少)、ホルモンのホメオスタシスまたは他のシグナル伝達経路(細胞内または細胞外)、セカ ンドメッセンジャー、またはイオン流束、高分子の分解性の増加、さらには膜透過性または膜統 合性の変化などがある。

# 用量反応関係の一致

それぞれの key events と毒性学的反応の量的反応関係を特徴づけ、Bradford Hill 基準 (Hill、1965 年)を参考にして相互関係を検討すべきである。理想としては、key events の大きさ(または頻度) の増加の用量依存性と、その後に発生する他の key events の重症度(例えば、病変の進行)の増 加、最終的な毒性学的反応に関連づけられるべきである。key events と毒性学的反応の変化の大き さを比較することは、用量反応の一致を検討するのに役立つことが多い。

用量反応曲線の異なる部分において生物学的反応に根本的な違いがあるか否かを考慮すること が重要である (Slikker ら、2004 年)。もしあれば、用量反応曲線の異なる部分に関連する key events を定義し、フレームワーク解析に用いる必要がある。

# 時間的関連性

各 key events と毒性反応の時間的関係を特徴付ける必要がある。key events は毒性が明らかにな る前に観察可能であり、時間的に互いに一貫している必要がある。これは、データが推定される MOA を支持しているか否かを判断する上で不可欠なステップである。毒性反応と同時に(試験終 了時など) key events を観察しても、時間的関連性についての結論は出ないが、次のセクションで 説明する解析に貢献することができる。

# key events と毒性学的反応との関連の強さ、一貫性及び特異性

key events、前駆病変及び毒性学的反応を結びつけるエビデンスの重みに注目すべきである(エ ビデンスの重みの意味についての考察は Weed [2005 年]を参照)。key events を遮断または減少さ せた場合に毒性が発現しない、または減少したことを示す中止/回復試験は関連性の試験として特 に有用である。

様々な実験計画は未知のバイアスや交絡を減らすことができるため、実際デザインの異なる多

event is blocked or reduced are particularly useful tests of the association. Consistent observations in a number of studies, with different experimental designs, increase support for the MOA, since different designs can reduce any unknown bias or confounding. Consistency, which is the repeatability of the key events in the postulated MOA in different studies, is distinct from coherence, however, which addresses the relationship of the postulated MOA with observations more broadly (see next point). Observations that may be of value here include toxicological response and relevant key events in the same cell type, sites of action logically related to event(s), and results from stop/recovery studies.

# Biological plausibility and coherence

One should consider whether the MOA is consistent with what is known about the biology of the target process/site in general (biological plausibility) and also in relation to what is known specifically about the overall biological effects of the substance (coherence). For the postulated MOA and its associated key events to be biologically plausible, they need to be consistent with current understanding of biology. However, when using biological plausibility as a criterion against which weight of evidence is assessed, it is important to consider the potential for gaps in our knowledge. Coherence, which addresses the relationship of the postulated MOA with chemical-specific observations more broadly—for example, association of the MOA for the toxicological response with that for other end-points—needs to be distinguished from consistency (addressed in the preceding point). In assessing coherence, information on structural analogues may be of value (i.e. structure–activity analysis). Information from other compounds that share the postulated MOA may also be helpful, such as sex, species, and strain differences in sensitivity and their relationship to key events. Additionally, this section should consider whether the database on the agent is internally consistent in supporting the proposed MOA.

#### Other modes of action

Alternative MOAs that logically present themselves should be considered. If alternative MOAs are supported, they will need a separate non-cancer HRF analysis. These should be distinguished from additional components of a single MOA, since these would be addressed as part of the MOA under consideration.

### Uncertainties, inconsistencies, and data gaps

Uncertainties should be stated fully and explicitly. They should include those related to the biology of the toxicological response and those for the database on the compound being evaluated. Any inconsistencies should be noted and data gaps identified. It should be clearly stated whether the identified data gaps are critical in supporting the postulated MOA.

#### Assessment of postulated mode of action

There should be a clear statement of the outcome of the analysis, indicating the level of confidence in the postulated MOA—for example, high, moderate, or low. If a novel MOA is being proposed, this should be clearly indicated. However, if the MOA is the same as one previously described, the extent to which the key events fit this MOA needs to be stated explicitly. Any major differences should be noted and their implications for acceptance of the MOA discussed.

くの研究で一貫した結果が得られることは、MOA の支持を高める。一貫性(Consistency)は、異 なる研究において仮定された MOA の key events の再現性であるが、整合性(coherence)とは異な るものであり、仮定された MOA と観察との関係をより広く扱うものである(次のポイントを参 照)。ここで価値があると思われる観察には、類似の細胞における毒性学的反応や関連する key events、論理的に関連する作用部位、中止/回復試験の結果などが含まれる。

# 生物学的妥当性及び整合性

MOA が、ターゲットとなる順序/場所の生物学一般についての知見と一致しているかどうか (生物学的妥当性)、また物質の全体的な生物学的影響について具体的に知られていることとの関 連性(整合性)を考慮すべきである。推定される MOA とそれに関連する key events が生物学的に 妥当であるためには、現在の生物学的知見と一致している必要がある。しかし、生物学的妥当性 をエビデンスの重みを評価する基準として用いる場合には、我々の知識との間にギャップが生じ る可能性を考慮することが重要である。推定される MOA と化学物質固有の観察結果との関係を より広く、例えば、毒性学的反応の MOA と他のエンドポイントの MOA との関連性などは、整合 性(前項で述べた)とは区別する必要がある。一貫性を評価する際には、構造類似体に関する情 報に価値があるかもしれない(すなわち、構造活性解析)。また、推定される MOA を共有する他 の化合物から得た性差、種差、系統の違いや key events との関係などに関する情報も有用であろ う。さらに、このセクションでは、推定される MOA を支持するために、その物質に関するデータ ベースが内部的に一貫しているかどうかを検討すべきである。

#### その他のMOA

論理的に存在する代替 MOA を検討すべきである。代替 MOA が支持される場合、それらは 別の非発がん HRF 解析を必要とする。これらは、検討中の MOA の一部として扱われるため、 単一の MOA の追加的な構成要素とは区別されるべきである。

# 不確実性、矛盾及びデータギャップ

不確実性は完全かつ明示的に記載すべきである。不確実性には、毒性反応の生物学的性質に関 連するものと、評価対象の化合物のデータベースに関するものが含まれるべきである。矛盾する ものはすべて記載し、データギャップを特定すべきである。また特定されたデータギャップが、 推定される MOA を支持する上で重要であるか否かも明記すべきである。

# 推定されるMOA の評価

推定される MOA に対する高、中、低など信頼度を示す解析結果の明確な記述があるべきであ る。新規 MOA が推定されている場合は、これを明確に示すべきである。しかし、MOA が以前に 説明されたものと同じである場合は、key events がこの MOA に適合する程度を明示的に記載する 必要がある。主要な相違点はすべて記載し、MOA の適用が与える影響を議論すべきである。

114

## Life stage considerations

Since the response of an organism to a chemical exposure may vary through its lifespan, consideration of life stage is important for the MOA analysis of all toxic end-points. This is particularly true for effects that result from developmental exposures, since organ susceptibility may be restricted to critical periods of development, may depend on the ontogeny of key metabolic enzymes, or may depend on the interaction of the developing organism with its mother (see Zoetis & Walls, 2003). In addition, disruption of developmental processes may have downstream consequences.

Consideration of the ageing process is also important, for several reasons. First, developmental exposures can result in toxicities that are not detected until much later in life. In addition, there can be species-specific patterns of ageing for different organ systems. For example, reproductive senescence has a different etiology in rodents and humans and can even differ among different strains of rodents.

#### Human relevance

If it is possible to establish an MOA in animals for a toxicological effect, the next stage is to evaluate its relevance to humans. The IPCS non-cancer HRF is presented as an approach to answering a series of three (or four) questions, leading to a documented, logical conclusion regarding the human relevance of the MOA underlying the toxicological effect. The application of the guidance results in a narrative with four (or five) sections, which may be incorporated into the hazard characterization of a risk assessment.

1. Is the weight of evidence sufficient to establish a mode of action (MOA) in animals? This question is addressed by performing an MOA analysis as described above, the steps of which are based on the Bradford Hill criteria for causality (Hill, 1965). The weight of evidence for possible alternative MOAs needs to be considered and a conclusion reached on the overall strength of evidence supporting the MOA under consideration. The approach also identifies any critically important data gaps that, when filled, would increase confidence in the proposed MOA. If the postulated MOA has already been described for other chemicals, its human relevance will already have been evaluated. If the proposed MOA is novel, human relevance will need to be assessed de novo.

2. Can human relevance of the MOA be reasonably excluded on the basis of fundamental, qualitative differences in key events between experimental animals and humans? This step involves a qualitative assessment of the relevance of the MOA to humans. Listing the critical key events that occur in the animal MOA and directly evaluating whether or not each of the key events might occur in humans facilitate the evaluation and increase the transparency of the process. Presentation in tabular form, referred to as a concordance table, can be particularly useful. The information in such tables should be relatively brief, as a narrative explanation should always accompany the table. In one column, the effect on humans for each of the key events is evaluated. Another column for the results in a different strain, species, or sex or for a different route of administration that does not result in toxicity can be useful for comparative purposes. Factors may be identified that, while not key themselves, can modulate key events and so contribute to differences between species or individuals. Examples include genetic differences in pathways of metabolism, competing pathways of

#### ライフステージの考察

化学物質ばく露に対する生物の反応は、その一生を通じて変化する可能性があるため、すべて の毒性エンドボイントの MOA 解析において、ライフステージを考慮することが重要である。器 官の感受性は臨界期、主要な代謝酵素の発生時期、あるいは母体と胎児の相互作用に依存するか もしれないため、特に発生期のばく露で生じる影響において重要である(Zoetis & Walls、2003 年 を参照)。さらに、発生過程の障害はその下流に影響をもたらす可能性がある。

老化を考慮することも、いくつかの理由から重要である。第一に、発育期のばく露では、かな り後にならないと毒性が検出されないことがある。さらに、器官系ごとに種特異的な老化パター ンが存在する可能性がある。例えば、生殖器はげっ歯類とヒトでは病因が異なり、げっ歯類の系 統によっても異なることがある。

# ヒトとの関連性

動物において毒性学的影響の MOA を確立することができれば、次の段階でヒトへの関連性を 評価する必要がある。IPCS の非発がん HRF は、一連の 3 つの(または 4 つの)問いに答えるア プローチとして提示されており、毒性学的影響の根底にある MOA のヒトへの外挿性に関する文 書化された論理的な結論を導き出すことができる。このガイダンスを適用すると、4 つ(または 5 つ)のセクションで構成された説明文が作成され、リスクアセスメントのハザード評価に組み込 むことができる。

1. 動物における MOA を確立するのにエビデンスの重み付けは十分か。この問いは、因果関係 の Bradford Hill 基準 (Hill、1965 年)に基づいた、上記のような MOA 解析を行うことで解決され る。可能性のある代替 MOA におけるエビデンスの重みを考慮し、検討中の MOA を支持するエビ デンス全体の強さに基づいて結論を出す必要がある。このようなアプローチは、重要なデータギ ャップを特定する。このデータギャップが埋められることにより、提示された MOA はより信頼 性を高めるであろう。推定される MOA が他の化学物質について既に記述されている場合、その ヒトへの外挿性は評価されているだろう。推定される MOA が新規である場合、ヒトへの外挿性 は新たに評価する必要がある。

2. 実験動物とヒトとの間のkey events の根本的、質的な違いに基づいて、MOA のヒトとの関連 性を合理的に排除することができるか。この問いでは、ヒトに対する MOA の関連性の質的評価 を行う。動物の MOA で発生する重要な key events をリストアップし、各 key events がヒトで発生 する可能性があるかどうかを直接評価することで、評価が容易になり、プロセスの透明性が高ま る。一致表と呼ばれる表形式での提示は特に有用である。この表に従って証明するため、表の情 報は比較的簡潔でなければならない。1 つの列には、key events のそれぞれについてのヒトへの影 響が評価されている。毒性をもたらさない異なる系統、種、性、または異なる投与経路の結果に 関する列は、比較するのに有用である。それ自体は重要ではないが、key events を修飾し、種差ま たは個体差に寄与する因子が同定される場合がある。例としては、代謝経路における遺伝的差異、

metabolism, and effects induced by concurrent pathology. Any such factors identified should be noted in a footnote to the concordance table.

The evaluation of the concordance of the key events for the MOA for a given chemical in humans is an evaluation of the MOA in humans, rather than an evaluation of the specific chemical. In general, details of the initial key events are likely to be more chemical specific. Later events will be more generic to the MOA. While information for evaluating the key events in humans can come from in vitro and in vivo studies on the substance itself, basic information on anatomy, physiology, endocrinology, genetic disorders, epidemiology, and any other information that is known regarding the key events in humans can be of value.

In answering this question, a narrative describing the weight of evidence and an evaluation of the level of confidence for the human information should be prepared. Examples of specific types of information that can be useful include:

- where appropriate, background incidences of the effect at the anatomical site and cell type of interest, including age, sex, ethnic differences, and risk factors, including chemicals and other environmental agents;
- knowledge of the nature and function of the target site, including development, structure (gross and microscopic), and control mechanisms at the physiological, cellular, and biochemical levels;
- human and animal disease states that provide insight concerning target organ regulation and responsiveness;
- human and animal responses to the chemical under review or structural analogues following short-, intermediate-, or long-term exposure, including target organs and effects.

Obviously, a substantial amount of information is required to conclude that a given MOA is not relevant to humans. If such a conclusion is strongly supported by the data, exposure to chemicals producing toxicity only by that MOA would not pose a risk to humans, and no additional risk characterization for this end-point is required.

The question of relevance considers all groups and life stages. It is possible that the conditions under which an MOA operates occur primarily in a susceptible subpopulation or life stage—for example, in those with a pre-existing viral infection, hormonal imbalance, or disease state. Any information suggesting qualitative or quantitative differences in susceptibility is highlighted for use in risk characterization.

There are several aspects relating to life stage that should be considered in the non-cancer HRF analysis. First, the analysis should consider the comparative developmental processes and events that occur in humans and the animal model(s) (see Zoetis & Walls, 2003). This comparison will demonstrate the extent to which developmental processes are similar in humans and the animal model(s). In general, development is highly conserved; where this is the case, it would lead to a conclusion that the MOA in animals is also plausible in humans. However, there are some developmental processes that are unique to some species, which may therefore lead to a species-specific MOA that will not be plausible in humans.

#### Harmonization Project Document No. 4

競合する代謝経路及び同時並行的な病態によって誘発される影響などが挙げられる。特定されたそのような要因はすべて、一致表の脚注に記載する必要がある。

代謝経路における遺伝的差異、競合する代謝経路及び同時並行的な病態によって誘発される影響などが挙げられる。特定されたそのような要因はすべて、一致表の脚注に記載する必要がある。 ある化学物質のヒトにおける MOA の key events の一致性の評価は、特定の化学物質の評価という よりは、ヒトにおける MOA の評価である。一般的に、初期の key events の詳細は、より化学物質 に特化したものになる可能性が高い。その後の事象は、MOA により一般的に当てはまる事象とな る。ヒトにおける key events を評価するための情報は、物質そのものに関する in vitro 及び in vivo 研究から得られるが、解剖学、生理学、内分泌学、遺伝的疾患、疫学、その他ヒトにおける key events に関して知られているあらゆる基本的な情報が重要となる。

この問いに答える際には、エビデンスの重みとヒトの情報における信頼度の評価を記述した説 明文を作成する必要がある。有用な情報の具体例としては、以下のようなものがある。

- 必要に応じて、年齢、性別、人種差、化学物質やその他環境因子などの危険因子を含む、対象 となる解剖学的部位や細胞種における発生率の背景値
- 生理的、細胞的、生化学的レベルの制御機構や発生、構造(肉眼、組織)を含む標的部位の性質と機能に関する知識
- 標的器官の制御と応答に関する考察をもたらすヒト及び動物の疾患状態
- 対象となる臓器や影響を含む、短期、中期、または長期ばく露後の、評価対象の化学物質また は構造類似体に対するヒト及び動物の反応

MOA がヒトには関連性がないと明確に結論づけるためには、相当量の情報が必要である。その ような結論がデータによって強く支持されている場合、その MOA のみで毒性を生じる化学物質 はヒトにリスクをもたらさず、このエンドポイントに関する追加のリスク評価は必要ない。

関連性の問題は、すべての集団とライフステージを考慮している。MOA が作動する条件が、主 に感受性の高い集団やライフステージにいる人に発生する可能性がある。例えばすでにウイルス に感染しているか、ホルモンバランスの不均衡を有する人または疾患を持っている人である。感 受性の質的または量的差異を示唆する情報は、リスクの特徴付けに使用するため強調される。

非発がんHRF解析では、ライフステージに関連して考慮すべきいくつかの側面がある。第一に、 解析ではヒトと動物モデルで起こる発生過程と事象を比較検討すべきである(Zoetis & Walls、2003 年参照)。この比較は、ヒトと動物モデルにおいて発生過程がどの程度類似しているかを示すもの である。一般的に、発生過程はそんなに変化しておらず、このような場合には、動物 MOA はヒト MOA にも当てはまるという結論が導き出される。しかし、いくつかの種には特有の発生過程があ り、その場合種特異的な MOA となり、ヒトにもあてはまるとは限らない。 Second, the analysis should consider the phase specificity or relative timing of the developmental processes or events in humans and the animal model(s). Critical developmental events may occur at different times during ontogeny. Some developmental events may occur early during the prenatal development of the animal and relatively late in human prenatal development. Other developmental events may occur prenatally in humans and postnatally in the animal, or vice versa. Differences in timing of the developmental events can have an impact on the dose metrics if there are substantial differences in placental versus lactational transfer. Similarly, a comparison of the ontogeny of key metabolic enzymes relative to the key developmental process may reveal substantial differences between humans and the animal model. Such considerations may lead to a conclusion that the animal MOA is not plausible in humans.

3. Can human relevance of the MOA be reasonably excluded on the basis of quantitative differences in either kinetic or dynamic factors between experimental animals and humans? If the MOA in experimental animals cannot be judged to be qualitatively irrelevant to humans (no to question 2), a more quantitative assessment is undertaken, taking into account any kinetic and dynamic information that is available from experimental animals and humans. Such data will of necessity be both chemical and MOA specific and where possible should include the biologically effective doses required to produce the dynamic effects giving rise to the toxicity. Kinetic considerations include the rate and extent of absorption, tissue distribution, metabolism, and excretion. Differences in ontogeny can result in substantial species differences in placental and lactational transfers, which will affect the dose metrics. This may therefore result in a quantitative difference in the MOA between humans and experimental animals. Similarly, the differential ontogeny of key metabolic enzymes can result in substantial quantitative differences between humans and experimental animals. Dynamic considerations include the consequences of the interaction of the chemical with cells, tissues, and organs. Only infrequently is it likely that it will be possible to dismiss human relevance on the basis of quantitative differences. Since quantitative exposure assessment is part of the subsequent risk characterization rather than the HRF, the difference would have to be of such a magnitude that human exposure could not possibly be envisaged to reach such levels. In most cases, it will not be possible to reach such a conclusion without undertaking formal exposure assessment in the subsequent risk characterization. Hence, the answer to the question will be no, but it may still be concluded that the risk is negligible in the subsequent risk characterization. Melamine-induced urinary bladder carcinogenesis provides a useful case-study illustrating this point (Meek et al., 2003). Again, tabular comparison of the data from experimental animals and humans can help in the evaluation. Information from studies of other compounds acting by the same or a similar MOA can be of value. As understanding of the basis for differences in responses between experimental animals and humans improves, differences in key events thought to be qualitative may be shown to be due to specific quantitative differences.

While it may not be possible to conclude that the MOA for toxicity is not relevant to humans on the basis of quantitative differences, during the evaluation it may become apparent that the magnitude of those differences is sufficient to impact markedly on the risk assessment. Hence, it is particularly important that the narrative for the answer to this question be comprehensive and capture as much quantitative information as possible. 第二に、解析では、ヒトと動物モデルにおける発生過程や事象の相対的な時期や段階の特異性 を考慮する必要がある。重要な発生過程における事象は、発生期の異なる時期に生じる可能性が ある。いくつかの発生過程における事象は、動物では出生前の早い時期に発生し、ヒトでは出生 前の遅い時期に発生する可能性がある。その他発生過程における事象は、ヒトでは出生前に発生 し、動物では出生後に発生することもあれば、その逆もある。胎盤移行と乳汁移行に大きな差が ある場合には、発生時期の違いが線量基準に影響を与える可能性がある。同様に、発生過程に関 連する主要な代謝酵素の発生時期を比較すると、ヒトと動物モデルの間にかなりの差があること が明らかになる可能性がある。このような考察から、ヒトでは動物モデルの MOA は妥当ではな いという結論が導き出されるかもしれない。

3. 実験動物とヒトとの間の薬力学的または動態的要因のいずれかの量的差異に基づいて、MOA のヒトヘの関連性を合理的に排除することができるか。実験動物における MOA がヒトと定性的 に無関係であると判断できない場合(問い2に「No」)、実験動物とヒトから得られるあらゆる動 態学的及び薬力学的情報を考慮して、より定量的な評価が行われる。このようなデータは、必然的 に化学物質と MOA に固有のものであり、可能であれば、毒性を引き起こす薬力学的影響が発現 する用量を含むべきである。動態学的考察には、吸収の速度及び程度、組織分布、代謝及び排泄が 含まれる。胎生の違いは、胎盤移行及び乳汁移行において実質的な種差をもたらす可能性があり、 これは定量的な影響を及ぼす。したがって、これによりヒトと実験動物との間で MOA の量的差 異がもたらされる可能性がある。同様に、主要な代謝酵素の発現時期の違いにより、ヒトと実験 動物の間ではかなりの差が生じる可能性がある。薬力学的な考慮事項には、化学物質と細胞、組 織及び器官との相互作用が含まれる。量的差異に基づいてヒトへの外挿性を否定することができ るのは、ごくまれである。定量的ばく露評価は HRF よりもむしろその後のリスクの判定の一部で あるため、その差はヒトへのばく露がそのようなレベルに達するとは考えられないほどの大きさ でなければならない。ほとんどの場合、後続のリスクの判定で正式なばく露評価を行わなければ、 そのような結論に達することはできない。したがって、問いの答えは「No」であるが、その後の リスク評価では、リスクは無視できる程度であると結論づけられるかもしれない。メラミン誘発 性膀胱発がんは、この点を説明する有用な事例研究を提供している(Meek ら、2003 年)ここで も、実験動物とヒトからのデータを表形式で比較することが評価に役立つ。同様または類似の MOA によって作用する他の化合物の研究から得られた情報も価値がある。実験動物とヒトの間の 反応の違いの基礎的な理解が深まれば、定性的であると考えられていた key events の違いが、定 量的な違いによるものであることが示されるかもしれない。

量的差異に基づいて毒性 MOA がヒトと関連性がないと結論づけることはできないかもしれな いが、評価の中で、これらの差異の程度はリスク評価に顕著な影響を与えるのに十分である。し たがって、この問いへの回答の説明文は包括的であり、可能な限り定量的な情報を把握しておく ことが重要である。

As with question 2, if the response to this question is *ves*, then exposure to chemicals producing toxicity only by this MOA would not pose a risk to humans, and no additional risk characterization is required.

The preceding three questions comprise a decision tree (see Figure 1).

		Is the weight of evidence sufficient to establish a mode of action (MOA) in animals?	$\mathbf{NO}$ $\rightarrow$	Continue with risk assessment
		$\downarrow$ YES		
MOA not relevant	YES ←	Can human relevance of the MOA be reasonably excluded on the basis of fundamental, qualitative differences in key events between experimental animals and humans?		
		$\downarrow$ NO		
MOA not relevant	YES ←	Can human relevance of the MOA be reasonably excluded on the basis of quantitative differences in either kinetic or dynamic factors between experimental animals and humans?	$\mathbf{NO}$ $\rightarrow$	Continue with risk assessment

Figure 1. Decision tree for determining human relevance of an MOA for toxicity observed in experimental animals.

#### Potential implications for dose-response assessment

Should it not be possible to exclude human relevance of the MOA for toxicity prior to proceeding with the risk assessment, a further question should be addressed. This is: 4. Are there any quantitative differences in the key events such that default values for uncertainty factors for species or individual differences could be modified? Such information, on either kinetics or dynamics, could be used to calculate a CSAF, in which one or more of the default values for species or interindividual differences in kinetics or dynamics are replaced by a value based on chemical-specific information (IPCS, 2005). The other components of the adjustment factor would retain their default values. Such information may lead to either an increase or a decrease in the adjustment factor relative to the normal default.

#### Published case-studies

In developing a framework for assessing the human relevance of MOAs for non-cancer endpoints, ILSI/RSI also developed a series of illustrative case-studies. These were on molinateinduced inhibition of spermatogenesis (Kavlock & Cummings, 2005a), renal and developmental effects of ethylene glycol (Corley et al., 2005), developmental neurotoxicity of nicotine (Slikker et al., 2005), phthalate ester effects on male reproductive development (Foster, 2005), vinclozolin-induced malformations (Kavlock & Cummings, 2005b), developmental effects of valproic acid (Wiltse, 2005), haemoglobin-based oxygen carriers (HBOC)-related congenital malformations (Holson et al., 2005), developmental effects of angiotensinconverting enzyme (ACE) inhibitors (Tabacova, 2005), developmental ototoxicity of polyhalogenated aromatic hydrocarbons (Crofton & Zoeller, 2005), and propylthiouracilinduced effects on neurological development (Zoeller & Crofton, 2005). While these cases

問い2と同様に、この質問への回答が「Yes」であれば、この MOA のみで毒性を示す化学物質 へのばく露はヒトにリスクをもたらさず、追加のリスク特性評価は必要ない。

前述の3つの質問は、決定ツリーを構成している(図1参照)。

# 図1.実験動物で観察された毒性に対する MOA のヒトへの関連性を判断するための 決定ツリー

# 用量反応評価への影響

リスク評価を進める前に、毒性に対する MOA のヒトへの関連性を除外することはできないが、 更なる問いに対処すべきである。それは以下の点である。これは、4. 種や個体差の不確実性因子 のデフォルト値を変更できるような、kev events に量的な違いがあるか。このような情報は、動態 学又は薬力学のいずれかに関するものである。これは CSAF を計算するために使用することがで き、その場合動態学又は薬力学における種又は個体差のデフォルト値の1 つ以上が、化学物質固 有の情報に基づく値に置き換えられる(IPCS、2005年)。調整係数の他の要素は変更しない。この ような情報は、通常のデフォルト値と比較して調整係数の増加または減少をもたらす可能性があ る。

## 発表された事例研究

がん以外のエンドポイントに対する MOAs のヒトへの関連性を評価するためのフレームワーク を決定するにあたり、ILSI/RSI はまた、一連の例示的な事例研究を実施した。これらの事例研究 は以下の通り。

118

モリネートによる精子形成阻害(Kavlock & Cummings、2005 年 a)、

エチレングリコールの腎及び発育への影響(Corley ら、2005年)、

ニコチンの発達神経毒性 (Slikker ら、2005 年)

フタル酸エステルの男性の生殖発達に対する影響(Foster、2005年)、

ビンクロゾリン誘発性奇形 (Kavlock & Cummings、2005 年 b)、

バルプロ酸の発育への影響(Wiltse, 2005年)、

1492

IPCS Framework for Analysing the Relevance of a Non-Cancer Mode of Action for Humans

covered a range of end-points, most involved effects during development. Hence, there is a need for additional case-studies on other end-points, such as those indicated above. As experience is obtained in using this framework, some of the published cases could be further refined to provide valuable illustrative examples for training in the application of the framework.

In general, the cases have been very useful in highlighting a number of the key issues on which this non-cancer HRF is based. Examples include the importance of the concordance analysis, the value of quantitative information identified during the application of the framework when it is not possible to exclude human relevance, the need for a transparent and comprehensive narrative when reporting the conclusions of a framework analysis, the importance in identifying key data gaps (e.g. case-study on molinate and HBOC), identification of research needs (e.g. case-study on vinclozolin), the importance of understanding the formation of a specific metabolite, and the importance of establishing a robust MOA through the application of the Bradford Hill criteria (Hill, 1965) to the key events.

#### Statement of confidence, analysis, and implications

Following application of the non-cancer HRF and answering the three (or four) questions, a statement of confidence should be provided that addresses the quality and quantity of data underlying the analysis, the consistency of the analysis within the framework, the consistency of the database, and the nature and extent of the concordance analysis. Alternative MOAs should have been evaluated, when appropriate, with the same rigor. A critical outcome is the identification of specific data gaps that could be addressed experimentally to increase confidence in the analysis.

The output of the non-cancer HRF provides information that is useful for more than just determining whether or not the MOA for toxicity in experimental animals is relevant to humans. It can also provide much information that is critically important in subsequent steps in the risk characterization for relevant effects. For example, it may be possible to develop CSAFs on the basis of the information provided. Application of the framework can also provide information on relevant modulating factors that are likely to affect risk. In addition, it can identify those elements of a proposed MOA that operate only over a certain dose range. Where an obligatory step in an MOA occurs only following a high experimental dose of a compound, the relevance of the MOA to human risk is determined by the exposure. Thus, effective exposure assessment is particularly important to the evaluation of human risk from such toxicity.

The analysis also contributes to the identification of any specific subpopulations (e.g. those with genetic predisposition) who may be at increased risk and often provides information useful in considering relative risk at various life stages. This may be based not always on chemical-specific information but rather on inference, on the basis of knowledge of the MOA, as to whether the risk in specific age groups might be expected to differ.

The data and their analysis using the non-cancer HRF should be reported in a clear and comprehensive manner, so that others can determine the basis of the conclusions reached.

ヘモグロビン系酸素運搬(HBOC)関連先天性奇形(Holson ら、2005年)、

アンジオテンシン変換酵素 (ACE) 阻害剤の発生影響 (Tabacova、2005 年)、

ポリハロゲン化芳香族炭化水素の発達聴器毒性(Crofton & Zoeller、2005年)、

プロピルチオウラシルが神経発達に及ぼす影響(Zoeller & Crofton、2005 年)などがある。

これらの事例は、様々なエンドポイントを対象としているが、そのほとんどは発生段階の影響 を対象としている。したがって、上記のような他のエンドポイントに関する追加の事例研究が必 要である。このフレームワークの使用経験の積み重ねにより、公開された事例のいくつかは、フ レームワーク適用ための例示的事例を提供できるように、さらに洗練されていく可能性がある。

一般的に、これらの事例は、この非発がん HRF の基礎となっているいくつかの重要な問題を強 調する上で非常に有用である。例としては、一致解析の重要性、ヒトへの関連性を排除できない 場合のフレームワーク適用中に特定された量的情報の価値、フレームワーク解析の結論を報告す る際の透明性のある包括的な構成の必要性、重要なデータギャップの特定(例:モリネートと HBOC の事例研究)、研究ニーズの特定(例:ビンクロゾリンの事例研究)、特定の代謝物の形成を理解 することの重要性、Bradford Hill 基準(Hill、1965 年)を key events に適用して堅牢な MOA を確 立することの重要性などが挙げられる。

## 信頼性、解析及び帰結の記述

非発がん HRF を適用し、3 つ(または4つ)の質問に回答した後、解析の基礎となるデータの 質と量、フレームワーク内での解析の一貫性、データベースの一貫性及び一致性解析の性質と程 度に対応した信頼性を示す文書を提供すべきである。必要に応じて代替的な MOAs は、同様に厳 密に評価されるべきである。重要な成果は、解析の信頼性を高めるために実験的に対処できるデ ータギャップを特定することである。

非発がん HRF を行うことにより、実験動物における毒性 MOA がヒトに関連するかどうかを判 断するだけでなく、それ以上に有用な情報が得られる。また、関連する影響のリスクの判定の次 の段階で重要な情報を得ることができる。例えば、得られた情報に基づいて CSAFs を開発するこ とができるかもしれない。フレームワークを適用することで、リスクに影響を与える可能性のあ る調節因子の情報も提供できる。さらに、推定される MOA の要素のうち、特定の用量範囲での み作用するものを特定することができる。MOA で必須の段階が、ある化合物の高用量投与後にの み発生する場合、ヒトのリスクに対する MOA の関連性はばく露量によって決定される。したが って、効果的なばく露評価は、このような毒性によるヒトリスクの評価にとって特に重要である。

解析もまた、リスクが増加する可能性のある集団(例えば、遺伝的素因を持つ人々)の特定に 寄与し、多くの場合様々なライフステージにおける相対的なリスクを考慮するのに有用な情報を 提供している。これは必ずしも化学物質固有の情報に基づくものではなく、むしろ MOA の知識 に基づいて、年齢によってリスクが異なるかどうかについての推論に基づくものである。

Although the specific form of presentation will vary with the type of data available, a structured report, including the key headings from the framework, should be provided where possible. Presentation should include sufficient details on the context and thought processes to ensure transparency of the conclusions reached. The inclusion of concordance tables is strongly encouraged. This increases transparency and facilitates peer engagement.

# **USE OF THE FRAMEWORK AND ITS OUTPUTS**

The IPCS non-cancer HRF, which is based principally on robust concordance analysis of key events in postulated MOAs, is envisaged to be of value to both the risk assessment and research communities as a basis to contribute to harmonization in several areas, including:

- adequacy and nature of weight of evidence for postulated MOAs in animals and their relevance to humans;
- MOA integration across end-points;
- criteria for transparency to ensure sufficiency of peer input and review.

Among the strengths of the non-cancer HRF are its flexibility, transparency, and general applicability across end-points. This includes determination of the nature and shape of the dose–response curve, the identification and location of biological thresholds for individual key events, and their consequences. In addition, consideration of the kinetic and dynamic factors involved in each key event is informative regarding the relevance or not to specific subpopulations—for example, in early life, in those with particular diseases, or in those with specific polymorphisms. Alternatively, application of the framework can provide quantitative information on the differences between such groups. Human relevance analysis may also indicate that a species is inappropriate for evaluating a potentially relevant end-point because of dose limitations.

# **NEXT STEPS**

To ensure effective adoption of the non-cancer HRF, there will be a need to train individuals in its application and in the interpretation of its outputs. Experience is being gained in the use of the cancer HRF, and the expertise gained would be applicable in the training of others in the use of the non-cancer HRF. Training would be facilitated by the availability of a number of suitable case-studies. Those published to date would be a sound basis for further development for this purpose (Seed et al., 2005). In addition, cases on a wider range of end-points need to be developed. It would be helpful if organizations with experience in non-cancer HRF analysis could develop courses and make the materials available to others with suitable expertise to help in training.

A database of generally accepted MOAs should be compiled and maintained, together with informative case-studies. Such a database would be of particular importance as experience continues to evolve in the development of MOAs and in determining whether the MOA for a compound is novel or has been described previously for other compounds.

#### Harmonization Project Document No. 4

非発がん HRF を用いたデータとその解析は、他の人が到達した結論の根拠を判別できるように 明確かつ包括的な方法で報告されるべきである。

提示の具体的な形式は利用可能なデータの種類によって異なるが、可能であれば、フレームワ ークの主要な見出しを含む形式的な報告書を提供すべきである。発表は、到達した結論の透明性 を確保するために、文脈と思考プロセスの詳細を含めるべきである。一致表を含めることが強く 推奨される。これにより、透明性を高め専門家同士の協力が容易になる。

# フレームワークとその成果の利用

IPCS の非発がん HRF は、主に推定される MOA の key events の堅牢な一致解析に基づいてい る。以下のようないくつかの分野で調和に貢献するための基礎として、リスク評価と研究コミュ ニティの双方に価値があると考えられている。

- 動物における推定 MOA の妥当性とエビデンスの重み付けの性質及びヒトへの関連性
- ▶ エンドポイント間の MOA の統合
- 専門家の参加とレビューを十分に確保するための透明性のある基準

非発がん HRF の強みは、その柔軟性、透明性及びエンドポイント間で適用できることである。 これには、用量反応曲線の性質と形状の決定、個々の key events に対する生物学的閾値と位置の 特定及びそれらの影響が含まれる。さらに、各 key events に関与する動態学的及び薬力学的要因 を考慮することは、特定の集団、例えば、若年期、特定の疾患を有する人々、または特定の多型 を有する人々への関連性の有無に関して有益である。あるいは、フレームワークを適用すること で、そのようなグループ間の差異に関する定量的な情報を提供することもできる。また、ヒトへ の関連性の有無についての解析において、ある種の生物が、用量制限のために潜在的に関連する エンドポイントの評価には不適切である場合もある。

# 次のステップ

非発がん HRF を効果的に適用するためには、その適用及びその利用の解釈において個人を訓練 する必要がある。発がん性 HRF の利用においては経験が得られており、その得られた専門知識は、 非発がん HRF 使用における訓練にも適用できる。訓練は、適切な事例研究がより多く利用可能と なることによって促進されるであろう。これまでに発表された事例は、この目的のための適切な 基盤となる (Seed ら、2005 年)。さらに、より広範囲のエンドボイントに関する事例を調査する必 要がある。非発がん HRF 解析の経験を持つ組織が指針を作り、訓練を支援するために適切な専門 家がその教材を利用できるようにすることは有用であろう。

一般的に受け入れられている MOA のデータベースを、有益な事例研究とともに編集し、持続 させるべきである。このようなデータベースは、MOA の開発において事例は更新され続けられ、 ある化合物の MOA が新規か、あるいは他の化合物について以前に記載されていたものかを判断 The current non-cancer HRF, which arose out of the IPCS cancer HRF, is focused on noncancer end-points. However, there are marked similarities in the philosophy and strategy to evaluating cancer and non-cancer effects. It is strongly recommended that one of the next steps in harmonization of risk assessment of chemicals should be the preparation of a unified HRF that is applicable to all toxicological end-points, including cancer. The integration of framework approaches into the risk assessment process should be further elaborated, in which illustrative examples would be of value. Some guidance on problem formulation before embarking on an HRF analysis should be included in such a framework document, as should guidance on the use of the outputs of HRF analysis in risk assessment. For example, during application of the framework, a much deeper understanding of dose–response relationships is often developed, which should be taken forward into hazard characterization. As indicated above, knowledge of any dose transitions is invaluable in interpreting exposure data. Identification of key events in the MOA can provide insight into the sources and magnitude of interspecies and interindividual differences.

#### する上でも重要なものとなるだろう。

IPCS の発がん性 HRF から生まれた現在の非発がん HRF は、がん以外のエンドポイントに焦点を 当てている。しかし、発がんと非発がんの効果を評価するための哲学や戦略には顕著な類似点が ある。化学物質のリスク評価の調和における次のステップの一つとして、がんを含むすべての毒 性学的エンドポイントに適用可能な統一的な HRF を作成することが強く推奨される。リスク評価 過程へのフレームワーク適用は、さらに精緻化されるべきであり、その際には、例示が価値ある ものとなるであろう。このようなフレームワーク文書には、リスク評価における HRF 解析の使用 に関するガイダンスと同様に、HRF 解析に着手する前の問題の定式化に関するガイダンスが含ま れるべきである。また、フレームワークを適用することで、用量反応関係の理解が深まることが 多いが、これはハザード評価に反映されるべきである。上述のように、用量の変化に関する知識 は、ばく露データを解釈する上で非常に重要である。MOA における key events を特定することで、 種差及び個体差の原因や程度に関する知見を得ることができる。

# 概要

ヒトの健康に対する化学物質の有害影響を判断する際に重要となる毒性試験から得られる量的成果 に対して、統計学的あるいはそれ以外の観点も含めて意義のある有害影響を起こさない最高用量/濃度 を決定することが重要である。そのような毒性試験からの所見に対する首尾一貫した解釈が重要であ り、それはこれらのデータがヒトの健康リスク評価、特に「安全な」ばく露レベルを決定する重要な意 味を有しているためである。したがって、毒性試験において観察された影響が毒性か否かを判断する ことはヒトの健康リスク評価において最も重要かつ、論争上の課題の一つである。観察された影響が一過 性、可逆性あるいは軽度な場合、恒常性を損なわない限り、毒性ではないと判断する。

肝臓の肥大の毒性学的解釈については,病理組織学的な障害性変化(壊死,炎症,線維化等)または 生化学的に肝障害を示す変化(AST, ALT, ALP, ビリルビンの高値等)を伴わない場合は適応性変化 と考える。肝臓の肥大が適応反応か毒性かを判断する情報が不十分な場合,あるいは追加的な負荷に 対応する機能障害をきたしうる場合(例:累積的影響)や他の化学物質の影響に対する感受性の増加を もたらす可能性がある場合は,その影響は有害影響と仮定することをデフォルト,すなわち標準的な 方針とする。設定された参照値(例:ADI)は薬物代謝酵素誘導のLOELを超えてはならない。

統計学的に有意差があっても生物学的に意義がない影響がある。一方で,軽微ではあるが生物学的 に意義のある変化あるいは低用量での毒性影響は検出力の低い試験法では検出できない可能性がある。 "統計的に有意"とされる変化は、その影響の重要性または生物学的関連性と必ずしも直接結びつくわ けではない。軽微,軽度,中等度,重度に分類された組織学的所見などの実験データを考察する場合, 程度を考慮した統計解析を行うことで,総発生数だけでなく,程度についても用量反応性の有無を調 べることが出来る。統計学的に有意な所見は、投与との関連を示唆するが、それをそのまま生物学的な 毒性影響とか、毒性学的に意義ある影響とは結論付けられない。実際,正常な生物学的変動の範囲内で あっても統計学的には有意差があると判定される可能性がある(例:再生反応の兆候がない赤血球数 の減少)。これに対して、生物学的あるいは毒性学的に検討することで統計学的な結果が覆ることがあ る(例:1群4匹のみで実施するイヌ試験の場合)。しかし、統計学的に有意でない結果に対して生物 学的意義を主張する場合には常に注意が必要である。統計学的な有意差はないが用量との関連性のあ る軽度な病理組織所見は、投与と関連があるか否か、毒性か否かを判断するのが難しい場合がある(例: 肝細胞内の空胞の軽度な増加、脾臓における髄外造血の軽度な増加は毒性学的に重要とはみなさなく てよい)。全ての毒性試験において LOAEL で認められる軽度な所見は、ケースバイケースで包括的な 議論が必要になる。

投与期間中に消失する影響は一過性の影響として一般的に認められ,次のようなことに起因しうる。 1) 投与に対する非特異的反応(例:投与開始直後の摂餌忌避),2) 強制経口投与によるストレスが原 因の体重減少,3)年齢や体重増加に伴う摂餌量の減少。

投与期間中に消失する一過性の影響と投与終了後に回復する影響とを区別する必要がある。前者に ついては、急性ばく露でみられ、投与期間中に消失した一過性の影響が有害影響である可能性がある ため急性参照用量(ARfD)の設定に重要であり、後者の投与期間終了後に回復する影響については、 少なくとも継続的ばく露の場合では、投与期間中に現れる影響が有害影響である可能性があるため、 慢性参照用量を設定するためにそれぞれ重要である。

体重に対する一過性の影響(例:餌の嗜好性の変化による摂餌量の低下,体重減少が起こるが実験動物 の適応とともに影響が消失する場合)は毒性とは考えない。しかし,この結論は動物の成長の抑制が餌 の嗜好性低下によって直接もたらされた影響であることを証明することが可能な場合にのみ導き出さ れるということが重要である。

毒性試験から得られる最も重要な定量的アウトプットの一つは、ヒトの健康リスク評価に妥当であ る(relevant)と考えられる投与に関連した影響を引き起こさない最も高いばく露レベル(用量または 濃度)の特定である。しかし、規制当局及び他の科学文献ならびに現状の実務をレビューした結果、下 記のような頻繁に使用される用語の定義や適用に一貫性がないことが判明した。さらに、有害影響と 有害でない影響の評価や鑑別を含め、毒性試験結果の解釈の指針となるような首尾一貫した基準は認 められなかった。

そこで、まずは毒性試験の結果を記述するために頻繁に使用される主要用語の定義を提案する。 <u>無作用量(NOEL)</u>:適切な対照群と比較して、ばく露群において(有害・有害でない)影響が観察され ない最高のばく露量。

<u>無毒性量(NOAEL)</u>:適切な対照群と比較して,ばく露群において有害影響の頻度・重症度に統計学的 あるいは生物学的に有意な増加が認められない最高のばく露量。このばく露量において何らかの影響 が生じる可能性はあるが,それらは有害影響や有害影響の前駆状態(precursor)とは考えない。

<u>最小毒性量(LOAEL)</u>:適切な対照群と比較して,ばく露群において有害影響の頻度・重症度に統計学的あるいは生物学的に有意な増加が認められる最低のばく露量。

<u>有害影響</u>:単独あるいは複合的に生体全体のパフォーマンスに有害影響を及ぼす,あるいは環境変化 への生体能力を低下させる,(刺激に対する)生化学的,形態学的あるいは生理学的変化。反対に,有 害でない影響は,生体の全身状態,成長,発達,寿命に影響を与えるような生化学的,形態学的あるい は生理学的変化を引き起こさない生物学的影響と定義できる。

<u>生物学的・毒性学的に意義のある影響:</u>生体システムの健康に(正または負の)重要あるいは顕著な影響を与えると考えられる(刺激に対する)反応。この概念は、(生体の全身状態に対しては意義のある場合とない場合がある)統計学的に有意な影響・変化とは区別されるべきである。

次に,毒性学者が一貫性のある試験結果の解釈を行なうことを支援する首尾一貫したフレームワーク(図1参照)を概説する。このフレームワークのプロセスには以下の2つの主要なステップがあり, それぞれにおける一貫した判断を行なうための基準が記載されている。

- 対照群の値との差が投与の影響によるものか、偶発性のものかを判断する。
   次の場合は投与による影響の可能性は低い:明らかな用量反応関係性がみられない。差の原因が外れ値にある。測定精度が悪い。正常な生物学的変動の範囲内である。生物学的妥当性に欠ける。
- 2) 投与による影響であると判断された変化についてはさらに評価し、有害影響であるかどうかを判断 する。

次の場合は有害影響の可能性は低い:生体あるいは影響を受けた臓器・組織の機能障害がない。適応反応である。一過性のものである。重篤度が低い。影響が単独発現している(その影響に通常関

連する他のパラメータの変化を伴わない)。有害影響に進行する前駆状態ではない。他の有害影響 の二次的影響である。影響が投与方法に起因する。

複雑な試験結果を解釈する際には、これらの基準を組み合わせて総合的な判断を下す証拠の重み付け アプローチが最適な方法であると考えられる。そして、このようなスキームを使用することで、ハザー ドとリスク評価の基礎となる試験結果の解釈について一貫性を向上させることができると考えられる。

実験動物が生物学的な影響の出るレベルの化学物質[内因性あるいは外因性(合成あるいは天然由 来)]にばく露されると、様々な組織単位で化学的摂動(変化またはかく乱)に対処するための反応が 誘発される。ある種の化学物質では、初期反応は適応反応を構成し恒常性を維持するが、どの組織レベ ルにおいてもそれが崩れると毒性(有害)影響が生じる。

実験動物やヒトの肝臓は,他の臓器と同様に,細胞の増殖に続く分化を特徴とするプログラムされ た段階的な成長,発達を経るが,分化した細胞は恒常性を維持するための機能及び生体のニーズに応 えるための特殊化した機能を持つようになる。成熟後の肝臓は,肝細胞(中間細胞に分類され,複製頻 度は低いもののシグナルに応答して複製することができる),複製細胞である幹細胞,内皮細胞,クッ パー細胞,星細胞(伊東細胞,周皮細胞),胆管上皮及び顆粒リンパ球(ピット細胞)で構成される。 これらの様々な細胞において,化学物質による分子レベルの定量可能な変化が細胞小器官レベルでの 変化の根底にあり,細胞小器官レベルでの変化は細胞レベルでの変化を誘導し,最終的には全身性の 変化につながる。この定量可能な変化には,細胞レベルで生じる複製,壊死・アポトーシス,分化のよ うに計数的(2値的,すなわち all or none)なものがある一方,細胞内あるいは細胞外レベルで生じる 酵素誘導,細胞小器官の肥大,細胞外基質の生成のように,段階的あるいは連続的(非2値的 nonbinary) なものもある。そして,あらゆるこのような変化によって反応や影響は構成される。肝臓におけるそれ ぞれの種類の細胞は,その局在と機能に応じて刺激に反応するが,一般的に再生を行なっている細胞 は,ほぼ静止している中間細胞と比較して化学的損傷に対しより脆弱である。

肝臓の適応反応では通常,化学物質が(多くの場合受容体を介して)細胞の制御経路に作用することで、遺伝子発現が変化し、最終的にメタボローム(metabolome)が変化する。この反応は、様々な細胞及び細胞外機能の調節を通じて、恒常性を維持しようとするためのものである。また適応反応は、あらゆる組織レベルで化学物質によるストレスへの応答能力を高め、可逆的であり、生存能力を維持するという点で有益である。毒性影響が生じる閾値を下回るばく露でのこのような適応反応は、ホルミシス(hormesis)とも呼ばれている。一方、肝臓における毒性(有害)影響では、化学物質が細胞の高分子と反応することで、恒常性の崩壊が起こる。このような影響は、ストレスへの応答能力を低下させ、非可逆的となり得、また生存能力を低下させ得る。通常は適応反応を誘導するレベルのばく露量でも、ばく露期間の長期化、もしくは高用量のばく露により閾値を上回った場合は、用量の変化につれて作用機序が変化し毒性影響が現れうる。従って、影響を及ぼす用量の変化とともに作用機序も変化していることになる。肝臓では様々な適応反応及び毒性影響が確認されており、前者を誘導するものとしてフェノバルビタールやシプロフィブラートが、後者を誘導するものとして*p*-ジクロロベンゼンや2-アセチルアミノフルオレンが挙げられる。肝臓への化学物質の影響は、例外はあるものの概して実験

動物とヒトで類似しているため,適応反応と毒性影響の鑑別とモニタリングは安全性評価上不可欠で ある。

病理学者は、毒性試験において認められた病理組織学的所見の回復性を予測するためには、組織の 種類、細胞外基質の関与及び病変形成過程の性質ならびに重症度を考慮すべきである。

組織は、その構成細胞の増殖能に応じて不安定組織、安定組織及び永久組織のいずれかに分類され る。不安定組織は高い回復力を有し、細胞外基質(細胞を囲む間質基質と基底膜で構成されるネットワ ークであり、水分とミネラルを隔離する機能を持ち、細胞が付着する足場を提供し、さらに増殖因子の 貯蔵庫としての役割を果たす)が無傷である限り、同種の細胞の複製及び再増殖による再生を行なう。 安定組織は、不安定組織と同様に反応及び再生ができるものの、その程度は低い。また、正常な機能や 修復のためには、細胞外基質が正常・無傷であることが必要である。細胞外基質の間質フレームワーク が損傷した場合、再生した実質細胞が臓器内に不規則に散乱し、効果的な修復ができず、再生がうまく いかない。永久組織が致命的な傷害を受けた場合、同種の細胞による置換は行なわれず、通常は結合組 織で修復される。これらの組織の増殖(再生)能とその例を以下にまとめた。

- 1. 不安定組織(絶えず細胞分裂している組織)
  - a. 細胞は生涯にわたって増殖する
  - b. 傷害後, 容易に再生する
  - c. 幹細胞を含んでいる
  - d. 例:骨髄,造血組織,表面上皮(皮膚,消化管上皮)
- 2. 安定組織(静止状態の組織)
  - a. 低レベルの複製
  - b. 元の組織を再生・再構築することができる
  - c. 刺激に反応して急速に分裂することができる
  - d. 例: 肝臓, 腎臓, 膵臓の実質細胞; 線維芽細胞, 平滑筋, 内皮, リンパ球, 骨細胞, 筋衛 星細胞, 軟骨細胞などの間葉系細胞
- 3. 永久組織(細胞分裂しない組織)
  - a. 出生後,通常は細胞分裂しない
  - b. 再生できない
  - c. 例:神経細胞,心筋

再生過程における細胞外基質と細胞の関連性や相互作用は極めて複雑であり,例外もあるものの,

回復性の予測においては一般的に以下のことが適用できる。

- 1. 細胞外基質が影響を受けず、組織傷害が不安定性組織あるいは安定性組織に生じた場合、回 復の見込みがある。
- 組織傷害によって細胞外基質が損傷あるいは損失した場合は、その損傷や損失は回復せず、 無秩序で機能を喪失する再生、線維化あるいは鉱質沈着が生じる可能性が高い。

概要

げっ歯類を用いた亜慢性(亜急性)及び慢性の毒性試験において薬物や化学物質によって引き起こ される肝臓の腫大は、同程度の用量での生涯試験における肝毒性や発がん性、あるいはヒトとの関連 性についての認識の点で長年にわたり毒性学の専門家を悩ませてきた。

肝肥大とは、病理組織学者にとっては明確に認識され組織学的に十分定義されている一方、毒性学 者にとっては器官重量の増加、肝細胞の平均サイズの増加(肝細胞の肥大)、そして(時に機能的な「亢 進性」肥大とも言われる)肝酵素の誘導さえも含まれる意味の言葉として捉えられている。前臨床毒性 試験において、実験動物に長期間(終身)肝酵素誘導剤をばく露した結果、肝重量の増加、肝細胞の肥 大、細胞増殖、そして長期試験における高頻度の肝発がんといった特徴を示す毒性学的変化が生じる ことが報告されている。近年の進歩により、多くの外因性化学物質は、CAR、PXR、PPARa といった 核内ホルモン受容体の活性化を介した共通の作用機序により、これらの変化が誘導される可能性があ ることが明らかになってきた。これらについて改変された核内ホルモン受容体を発現する遺伝子組み 換えマウスを作製し、他の研究とも複合的に検討したところ、これらの作用の多くがげっ歯類に特異 的であることが明らかになった。これらのデータは、ヒトについて得られた信頼できる利用可能な疫 学的及び経験的なエビデンスと一致しており、これらの変化はヒトではほとんど起こらないという科 学的見解を裏付けるものである。そのため ESTP は、肝細胞肥大に関連して何が有害と考えられるかを 毒性病理学者がより明確に定義するために、国際的な専門家パネルを招集し、エビデンスについて議 論した。このワークショップの結果、肝毒性を示す組織学的または臨床病理学的変化を伴わない肝細 胞肥大の結果としての肝肥大は適応性であり、有害反応ではないと結論づけられた。

肝重量の増加によってもたらされる組織学的変化を評価する際,その変化が有害か否かを判断する ために多くの段階を経て検討する必要がある。まず肝細胞の壊死,線維化,炎症や脂肪性の空胞変性, 胆管/卵形細胞の増殖,変性,線維化,胆汁うっ滞,他の肝臓構成細胞の壊死や変性といった構造的変 性や壊死性変化の組織学的証拠があるかを検討する。組織学的変化がない場合,ALT の少なくとも 2 倍から 3 倍の増加や他の肝胆管傷害の指標(ALP,AST,γGT,GLDH等)の生物学的に有意な変動。 さらに別の肝臓の異常を示す臨床検査マーカー(アルブミン,ビリルビン,胆汁酸,凝固因子,コレス テロール,過酸化脂質等)の生物学的に有意な変動のうち,少なくとも 2 つの肝臓の検査項目が用量 依存的であり生物学的に有意かつ継続的に変動しているとして特徴付けられる肝細胞傷害の臨床病理 学的証拠があるかを検討する。以上述べた有害作用の基準に達する変化が認められない場合,臓器重 量の増加や肝細胞肥大が薬物代謝酵素誘導に関連した適応反応であり,ヒトには毒性学的意義がない と判断しうる段階となる。その発現メカニズムにAhR\*や既知の毒性メカニズムが関与している場合は 有害作用と判断され, CAR, PXR, PPARa の活性化\*\*あるいは未知のメカニズムであってもその他の 毒性メカニズムを示す証拠がない場合,有害作用とはみなされないと判断する。

\*げっ歯動物に遺伝子毒性がないダイオキシンを与えると、AhRの活性化を通じた肝肥大や肝細胞の変 異増殖巣,及び肝発がんが認められる。AhR介在性の発がんのヒトへの外挿性は否定できない。

\*\*CAR, PXR, PPARa の活性化はげっ歯動物の肝細胞を増殖に向かわせる。ヒトでこれら核内受容体の活性化が起こったとしてもヒトの肝細胞の増殖性は惹起され難い。

背景データ(Historical control data)は、腫瘍や発生異常の評価に利用することが多いが、それらの 結果が正常な生物学的範囲内に収まることを示すことが目的である。背景データは、比較対象とする 試験と同じ系統の動物を対象とし、ほぼ同時期に、同じ試験施設で実施した試験から得られたもので なければならない(理想的には、試験開始2年前から試験終了後2年までの間)。これらの基準に合わ ない場合は、その旨を本文中に記載する。可能なら、各試験の結果を別々に見ることが出来るような形 式で提供する必要がある。最低限、試験数、平均値、最小値~最大値の範囲を記載する。当該試験と背 景データの間で、解釈上または検査上の方法に違いがないことも確認する必要がある。提出された背 景データがこれらの基準を満たさないなら、その不足部分を補うよう、対応を依頼する必要がある。

長期試験では、当該試験の対照動物における非腫瘍性あるいは腫瘍性病変の発生率が正常より低い 場合、投与群におけるそれら病変の発生率が有意な高値を示すことがある。逆に、正常より高い場合は 投与群における毒性あるいは発がん性を隠してしまう。背景データは、同じ試験施設の同じ条件下で 飼育された同じ種及び系統の動物を使って行われた試験から得られたものでなければならない。背景 データには次の情報が示される必要がある。

1)動物種,系統の同定,生産者名,繁殖地の識別(生産者が複数の地理的場所にある場合)

2) 試験施設の名称及び試験実施日

- 3)動物の一般飼育条件(飼料の種類及び銘柄,可能なら消費量)
- 4) 試験開始時及び計画解剖時または死亡時の対照動物の大体の年齢(日数)及び体重
- 5) 試験中または試験終了時に観察された対照群動物の死亡パターン及び他の関連する所見(例:病気, 感染)
- 6) 試験からの病理学的データの収集及び解釈を担当した試験施設名及び検査担当科学者の氏名
- 7) 発生率データを作成するために合計された可能性のある腫瘍の種類の記載

背景データは,試験ごとに絶対値や相対値など評価に役立つ値が示されるべきである。集計値には, 値の範囲,平均値,中央値及び標準偏差を含むべきである。げっ歯類の稀な腫瘍の評価には文献データ が適用できる場合もある。肝臓,下垂体及び副腎の腫瘍のように通常みられる腫瘍の場合は,発生率の 範囲が広いために,投与群も含めた腫瘍の発生率が背景データの範囲内に収まることが多く,範囲だ けでは評価が困難であり平均や分布が有用である。被験物質と類似の構造または作用機序を示す他の 化学物質に関する組織学的データも有用である。もし,背景データの範囲内だが腫瘍発生数の軽度な 増加が被験物質の標的臓器でみられた場合,前腫瘍性病変やその標的臓器への連続的な障害の有無に ついて注意深く評価する必要がある。 (胎児の異常)対照群のデータは試験ごとに必要である。これに対し、複数の試験から得られた陰性 (溶媒)対照群のデータで構成される背景データは、日常的に必要とされるものではないが、試験の所 見を解釈するために有用で適切と考えられている。投与群のデータと比較する場合、背景データより も当該試験の対照群のデータが優先されるべきである。胎児の異常に関する背景データも長期試験の 背景データで上述した基準1)から6)に加え、7)奇形や変異の評価基準が示される必要がある。

## OECD TGs における統計学的手法の記載

- ・OECD TGs 451, 452, 453 の共通項(275)
  - ・数値結果は適切で一般的に許容される統計的方法で評価されるべき
  - ・統計的手法及び分析すべきデータについては、試験計画の段階で選択されるべき
  - ・必要に応じて、生存率で調整する規定を設けるべき
- ・TG451及び453の共通項(276)
  - ・実験計画と目的を考慮し、最も適切な統計的方法は、試験開始前に確立されるべき
  - ・生存率の補正,生存期間に対する累積腫瘍リスクの分析,腫瘍発生時期の分析,及び1つまたは 複数の群が途中で終了した場合の解析を統計手法に含めるか考慮する
  - 適切な統計分析に関するガイダンス及び国際的に認められた統計手法の主な参照事項は、OECDの試験ガイドラインの公開サイトで入手可能な慢性毒性及び発がん性試験の設計及び実施に関するガイダンス文書、ならびに慢性毒性及び発がん性試験の分析及び評価に関するガイダンス文書No.35に記載されている
- OECD TGs 452 (276)
  - ・生存率の補正及び1つまたは複数の群が途中で終了した場合の解析を統計手法に含めるかを考慮 する

### EPA 発がん性物質リスクアセスメントのガイドラインにおける統計学的手法の記載

- ・長期試験の統計解析は、腫瘍の種類ごとに個別に行うべき
- ・同じ細胞由来の良性病変と悪性病変の発生率は、それぞれ別々に検討された後、科学的に説明可能な場合には組み合わせて検討される(McConnell ら、1986年)
- ・傾向検定及び pairwise 比較検定は、腫瘍発生率の明らかな増加が、被験物質投与に関連した影響というよりはむしろ偶発性であることを証明するために推奨される検定である
- ・Cochran-Armitage 検定(Snedecor & Cochran, 1967 年)のような傾向検定は、すべての投与群の結果 が投与量の増加に伴って増加するかどうかを問うものである
- ・Fisher exact 検定(Fisher, 1950年)のような pairwise 比較検定では、ある1つの投与群の発生率が対 照群よりも増加しているかどうかを問うものである
- ・統計的に有意な差とは、発生率の増加が偶発性であることを示すpが 0.05 未満のものである
- どちらの種類の検定でも、結果が偶然によるものであるという仮説を棄却するには、有意性があれば

+分である。統計的に有意な反応は、生物学的に有意である場合もあれば、そうでない場合もあり、そ の逆もある。有意水準の選択は、偽陽性と偽陰性のリスクの間のトレードオフに基づいている。有意水 準が5%以上または以下(最も一般的な有意水準)の場合、他の科学的情報を確認できるかどうかを検 討する。評価が単純な5%レベルから逸脱する場合は、リスク判定の際に強調する必要がある。両側検 定または片側検定を使用することは可能であるが、いずれの場合も根拠を示すことか必要である。

## グレーディングシステム/程度評価

- ・病変の程度は、変化の度合い(その所見に付随する変化がどれくらい存在するか)、分布(局所~び まん性)、及び実際の重症度の組み合わせを反映して選択されるべきである。
- ・グレーディングシステムは、研究施設により様々であり、病変の分布、病期、及び病変の範囲をどの ように組み入れるかで異なる場合があるため、普遍的なグレーディングシステムを構築することは 困難である。
- ・最も一般的に使用されているグレーディングシステムは、4~5 段階の明確な半定量的評価法(表) である。
- ・被験物質の影響及び用量相関性の判断は,統計学的分析よりも担当病理医が実施することが適切で ある。
- ・同一化合物に関する試験内又は試験間での程度付の整合性は、病理学的評価の品質保持のため重要であり、試験内での程度付の不整合性又は「ドリフト(drift)」(診断基準が経時的に変化する傾向)は、被験物質の影響を検出する感度が損なわれるか、または実際には被験物質の影響がないにもかかわらず、それがある(偽陽性)ことにつながる可能性がある。
- ・投与に関連した影響や用量反応性を伝えるために、毒性病理医は試験内のスコアの基準を変更したり、「分割(split)」したりすることがあるが、この場合は病理報告書の方法のセクションでそのプロ セスと基準を明記すべきである。
- ・Peer review において, reviewer は, 試験内でのグレーディングの一貫性を評価すべきである。

## 程度のない病変

- ・病変によっては、付加的な情報が得られないことから、程度付けを行わないことがある。
- ・これらの病変は通常,重症度の評価ではなく「存在する (P)」として記録される。
- ・例としては、腫瘍、嚢胞、自己融解、先天性異常などが挙げられる。
- ・一方で、病理データ入力システムの中には、すべての病変について等級を入力することを要求する ものもある。

表1 4 点採点システムの説明

- ・被験物質の投与の影響を判断する最も関連性の高い対照データは、同時対照群のデータではあるが、 特定の状況においては背景データ Historical control data (HCD)の評価も有用である。これには、自 然発生腫瘍、希少腫瘍、一般的な腫瘍、発生数が激しく変動する腫瘍、同時対照群と比較して発生数 がわずかに増加している腫瘍、または対照動物における腫瘍発生数の予期せぬ増減などの評価が含 まれる。
- ・HCD は化合物の潜在的な発がん性を評価する際に,「根拠の重み」付けを補足できる多くの情報源の 1つとして使用されるべきである。考慮すべき他の情報としては,類似の細胞由来の他の病変,体重, 生存率,腫瘍の発生時期,その腫瘍が両種または雌雄に発生している場合,用量相関性がある場合, または両側性臓器の両側に発生している場合である。
- ・腫瘍発生数を HCD と比較する方法は 2 つあり、一方はデータの探索的(非公式)分析(exploratory analysis)、他方はより正式な統計的アプローチ(more formal statistical approach)分析である。
- ・箱ひげ図は,HCD の分布に関して現在のデータを説明する探索的なツールとして用いる。平均値, 標準偏差,範囲などの標準的な方法ではわからない,潜在的な異常値を特定することができる。
- ・ここで述べられている HCD の統計解析に関する様々なオプションは、必ずしも標準的な手法を示す ものではなく、これら以外にも種々の統計手法が存在している。

### 主要試験項目の分析と評価

試験項目の分析と評価において,観察された被験物質の変化のすべてが必ずしも毒性作用ではない ことを念頭に置くべきである。肝酵素誘導による肝肥大のような適応反応や感染症の治療に使用され た抗生物質投与による白血球減少のような薬理作用などが例として挙げられる。

パラメータの中には加齢に伴って、計時的に値が変動するものがあるため、週齢の一致した対照群 と比較すべきである。背景データを用いる場合でも背景データとの統計学的な比較は適切ではない。 老齢げっ歯類に観察される慢性進行性糸球体腎炎やアミロイドーシスなどのような加齢性病変につい ては、被験物質投与に影響を受ける可能性があるとされている。

背景データは、当該試験の対照群に異常がないかの確認にも有用である。対照群の背景データから の逸脱がみられる場合には、報告書においてその解析結果に対して何らかの考察が必要である。背景 データとの間に一貫して差が認められる場合には、その動物の由来を含めて検討すべきである。

背景データを利用する場合には、以下の条件が必要である。

- ・試験から得られたデータは同じ試験実施場所で検査されたものであること。
- ・当該試験の動物は同じブリーダーからの同じ系統、年齢及び性別であること。
- ・当該試験の前後2~3年以内に実施されたものであること。
- ・試験条件(絶食・非絶食の条件,試験パラメータの想定方法,病理組織学的な判断基準,最終と殺 時の年齢)なども明らかにする。

溶媒を用いた場合には、溶媒対照群を投与しない対照群も設定することで溶媒の影響の有無を知る ことができる。また、動物に対する取扱い方法の違いによっても検査値に影響する場合がある(例え ば、マウスにおいて保定による血清ALT上昇が報告されており、対照群も同様に処置する必要がある)

基本的な検査項目(体重増加,食物消費量,変換効率など)は多くの場合,低用量で影響を受ける最 も重要なエンドポイントである。評価者は,さらに,臓器重量,病理組織学的検査結果,血液生化学的 検査値や神経毒性に関する項目も含め,さらに特定の生物学的または毒物学的影響に対する用量反応 関係を慎重に考慮して評価に重要なエンドポイントを判断すべきである。

### 統計解析の方法

毒性試験の目的は生物学的に重要な反応を示すことであることを念頭に置く必要があることから統 計結果を評価に用いる場合には以下の点に注意する。

- (1) 統計は質の悪い検査データを良くすることはできない。
- (2) 統計的有意性は生物学的な意義を意味するものではない。

- (3) 生物学的に意義のある影響であっても、統計的には有意でない場合がある。
- (4) 統計的有意性がないことが安全性の証明にはならない。

付録Vには、一般的に使用される統計的検定がいくつか記載されている。

なお,統計解析において以下の場合にはその旨を報告書に記載し,必要に応じて,データの再分析な どの他の措置をとる必要性がある。

- 統計的検定が使用されていない場合,
- ・不適切な検定が使用されていると思われる場合,
- ・一般的に使用されていない検定が使用されている場合には、その旨を報告書に記載する。
- 付録 V 適用可能な統計的検定の一覧

非正規性の検定

- カイ二乗
- Kolmogorov-Smirnov
- Shapiro-Wik

分散の同質性の検定

- バートレットの検定
- Levene の検定

正規分布データの仮定

- 1. 全体的な検定
- 分散分析 (ANOVA, 固定効果モデル, Model 1 ANOVA が最も一般的だが, 他のモデルもあり得る)
- 共分散分析(ANCOVA)
- Pearson の相関係数 (Pearson's Correlation Coefficient)
- 用量効果の傾向を調べるための線形回帰(従属データである2つのパラメータの関係をテストする。
   回帰スロープの有意性を検証する。例:男女間の反応は似ているか?)
- 2. ペアワイズ比較
- Duncan の多重範囲検定
- Dunnett の t-検定(コントロールと他のグループの平均値を比較する)
- Scheffeの検定(多重比較, Newman-Keulsの多重範囲検定よりも検出力が弱い)
- Williams の t-テスト
- Studentのt-テスト
- Fisher の最小有意差(LSD) 検定

ノンパラメトリック手続き(パーセント値,順位など)

- Kendallの順位相関係数
- Mann-Whitney U-Test (t-test に類するもの
- Wilcoxon signed-rank 検定 (ペア, マッチドペアデータ)
- Kruskal-Wallis ANOVA
- 分布によらない多重比較検定(例: Dunn の検定, Shirley の検定)
- Jonckheere の検定

定量的データ(死亡率,病理所見など)

- Fisher の正確検定
- R×Cカイ二乗検定
- Litchfield & Wilcoxon ED50 などの信頼限界

多変量解析法

- ホテリングの T<sup>2</sup>法
- 多変量分散分析(MANOVA)

血液学,血液生化学及び尿検査の毒性評価では,関連するパラメータが一貫して同じ方向(増加ある いは減少)に向かっているか,用量と関連しているか(又は,「用量依存的であるか」)を判断すること が重要である。血液学,血液生化学及び尿検査の背景データとしては,過去10年以内のデータや同一 試験施設で実施された毒性試験と同時期のものが適切である。背景データは,統計的範囲(±1標準偏 差)で表すことが望ましい。年齢,系統,取り扱いや給餌の技術,測定に使用する機器など,多くの要 因が背景データに影響を与える可能性がある。イヌでは,個体値のばらつきが大きいので,平均値より も投与開始前を含めた試験期間中の個々の値の変化の方が有用である。また,構造的に類似した化学 物質または類似の作用機序を示す化学物質の血液学,血液生化学及び尿検査パラメータに関する情報 も有用である。尿検査結果は,特に全身の栄養状態に影響するような高い濃度で投与する場合に,常に 他のエンドポイントと併せて解釈する必要がある。

毒性と考えらない影響には次のようなものがある。(血液検査)1)総白血球数の変化を伴わないリン パ球と好中球の数の変化,2)白血球の中のマイナーな細胞集団(好塩基球,好酸球,単球)の数の3 倍以内の変化,3)赤血球数,ヘマトクリット値またはヘモグロビン濃度の10%以内の増加または減少, 白血球数及び血小板数の20%以内の増加または減少,4)高用量で肝毒性によって二次的に起こった軽 度な貧血(血液生化学検査)1)組織・臓器に由来する酵素の僅かな増減(AST,ALT,ALP,γ-GTP, CK等):50%以上で毒性指標を考慮,2)若齢動物のγ-GTP活性を対照群との百分比で表した場合(誤 った解釈につながる),3)総タンパク濃度またはアルブミン濃度の変化を伴わないアルブミン/グロ ブリン比,4)10%以下の総タンパク濃度またはグルコース濃度(尿検査)1)排泄される酸性または塩 基性化合物に関連する pH の変化,2)水分消費量または体液減少(嘔吐または下痢など)の変化に関 連する尿量及び/または比重の変化。

軽度ではあるが毒性学的に有意な変化には次のようなものがある。(血液検査)1) 平均赤血球容積の 5%以上の増加は赤血球の形態学的異常を示す可能性がある、2) ヘモグロビン濃度が約 10%以上低下 した場合は貧血の指標となる、3) メトヘモグロビンは正常でも存在するが、投与群において、イヌで 5%以上、ラットで 1.5%以上の上昇は毒性と考えられる、4) スルファメトヘモグロビンは正常では存 在しないため、検出されれば異常である。(血液生化学検査) IgG 濃度の低下は免疫抑制の指標となる。

(尿検査)1)細胞(血液細胞,腎臓上皮細胞または膀胱上皮細胞)数の増加は腎臓・尿路系の障害の 指標となる,2)尿中の血液は、全身の出血や腎臓、尿路、雄性生殖器系における局所的な障害を示す ことがある。

肝細胞  $\gamma$ GT ( $\gamma$ -glutamyltranspeptidase)の誘導は、フェノバルビタールナトリウムを含むいくつかの 化学物質でも報告されており、フェノバルビタールナトリウムは肝重量の増加を引き起こし、肝臓で の代謝亢進を誘導することが知られている。ワークショップで発表された事例研究では、ラットを用 いた反復投与(7日間)の経口毒性試験において、肝 $\gamma$ GT のメッセンジャーRNA (mRNA)が誘導され ることが示され、小葉中心性肝細胞肥大、肝重量の増加、CYPs(主に2B2と3A3)の増加、第2相酵 素活性(主にGSTA3とUGT1A6)の増加が観察された。しかし、これは循環血中の $\gamma$ GT活性の増加に のみ影響し、肝 $\gamma$ GT mRNA の顕著な誘導(50倍以上)が観察された。フェノバルビタールを5日間投 与したラットでは、肝 $\gamma$ GT 活性は増加したが、血清 $\gamma$ GT 活性は増加しなかったことから、実験動物の 肝胆道変化の指標としての血清由来 $\gamma$ GT は、肝 $\gamma$ GT の測定と比較して相対的に感度が低いことが示唆 された(Goldberg et al. 1981)

しかし, 肝内胆管の部分的な閉塞による胆汁閉塞も同様に γGT 酵素活性の変化を引き起こす可能性 がある。したがって, γGT の増加を酵素誘導によるものとする判断は, 肝重量の増加, 生物学的に意義 のあるトランスアミナーゼ活性の増加がないこと, 及び病理組織学的に有害な事象を示す変化がない ことを十分に考慮した上で, 証拠の重み付けに基づいて行われるべきである。

γGT と ALP は、 ラット、 マウス、 イヌにおいて異なる組織分布を有する (Clampitt and Hart 1978; Keller 1981)。例えば、 イヌでは、 肝型が血中の ALP 活性の主体となるが、 ラットでは比較的活性が低く、 このため、この種では診断感度が低い。さらに、 レギュラトリーな毒性試験に一般的に用いられる幼若 な動物では、 血清 ALP 活性は主に骨のアイソザイムに由来し、 肝臓には由来しない (Hoffmann et al. 1994)。したがって、 肝臓酵素の誘導に加えて、 他の臓器での変化も考慮した評価をする必要があるか もしれない。

前述の化学物質による酵素の誘導もまた,種特異性があると考えられる:イヌでは,コルチコイド誘発性 ALP アイソザイム活性がしばしば増加するのに対し(Gaskill ら 2005),マウスでは肝 ALP が増加する(Kawasaki, Mataki, and.Takano 1994)。ラットでは,肝酵素誘導剤に反応して肝  $\gamma$ GT が誘導される(Gallagher ら 1998; Satoh ら 1982)。妊娠 6 日目(GD6)から GD20 までの妊娠ラットでは,酵素誘導剤を投与すると, $\gamma$ GT 活性ではなく ALP 活性が上昇する(Strauss, pers.comm. 2011)。マウスでは,ラットとは対照的に,肝細胞毒性の病理組織学的徴候を伴わない肝酵素誘導剤を投与した場合には,ALT が増加することが多い(Strauss, pers. comm. 2011)。

また,市販のヒト用 γGT キットの検出限界は約 3 U/L であることに注意が必要である。(37℃ で 50 nkat/L,例として γGT, Szasz mod., 2010-06, V7:ロシュ取扱説明書)。正常なラット血清 γGT 活性は, 一般的にこの検出限界以下であるので,中等度の γGT 増加は,これらの検査では検出できない。

血清アルカリホスファターゼ (ALP) 活性の上昇は、ヒトや実験動物における肝障害の指標となる。 実際には、イヌを用いた農薬の毒性試験において、他の肝障害の変化を伴わないALPの上昇がしばしば 認められる。本研究では、食品安全委員会がリスク評価の過程で毒性評価報告書として評価した206種 の農薬について、ALP上昇の毒性学的意義を解析した。その結果、ラット (36/206)よりもイヌ (108/206) の方がALPの上昇が認められる試験の割合が高かった。108農薬中87農薬では、イヌで肝毒性を伴うALP 上昇が認められた。しかし、ALPの増加には、特定の種類の肝毒性との特異的な関連は認められず、肝 毒性のマーカーとしては高感度(または鋭敏)とはいえなかった。肝毒性を示した87種の農薬の約50% は、肝肥大も誘発した。残りの21種類の農薬では、肝重量の増加や肝肥大以外に肝毒性の変化はみられ なかった。これら21種類の農薬のほとんどは、齧歯類におけるフェノバルビタール様肝代謝酵素誘導 剤であった。これらの結果から、肝毒性所見がない場合、ALPの上昇はイヌにおける肝毒性の指標には ならないことが示唆された

解析の結果,イヌにおける ALP の上昇についてその毒性学的意義を決定する要因が明らかとなった。 まず ALP の上昇が肝毒性や肝肥大といった異常所見を伴っているかについて確認する。肝毒性に加え 肝肥大が認められる場合、ALP の増加が認められる用量と肝毒性が認められる用量を比較し、ALP 増 加が認められる用量が肝毒性のそれに比べ同等あるいはより高い場合,ALPの上昇は有害影響であり, 肝毒性の NOAEL には影響を与えない。ALP 増加がみられる用量が、肝毒性がみられる用量より低い 場合, さらにその用量について肝肥大を示す用量との比較を行う。ALP 増加がみられる用量と肝肥大 がみられる用量が同等であった場合, ALP の上昇は有害影響とはならず, 肝毒性の NOAEL に影響を 与える。同等でなかった場合には、期間の延長により毒性が増強されることを示す証拠があるかを考 慮し、証拠が認められる場合 ALP の上昇は有害影響であり、肝毒性の NOAEL には影響を与え、認め られない場合は ALP の上昇は有害影響とはならず, 肝毒性の NOAEL に影響を与える。肝毒性のみ認 められる場合, ALP の増加が認められる用量において肝毒性が認められる用量に比べ同等か高いこと, あるいは期間の延長により毒性が増強された証拠の有る、といった条件のいずれかに当てはまる場合 ALP の上昇は有害影響であり、肝毒性の NOAEL には影響を与えず、何れにも当てはまらないのであ れば、ALP の上昇は有害影響ではなく、肝毒性の NOAEL に影響を与える。肝肥大のみ伴っている場 合, 肝代謝酵素の誘導や肝肥大を示す証拠があれば ALP の上昇は有害影響ではなく, 肝毒性の NOAEL に影響を与える。そういった証拠がない場合、期間の延長によりさらに低い用量での毒性の増強を示 す証拠の有無を確認し、有る場合は ALP の増加はおそらく有害影響であり、肝毒性の NOAEL に影響 を与えることになる一方, 無い場合は ALP の上昇は有害影響ではなく, 肝毒性の NOAEL に影響を与 える。他の肝臓所見が見られない場合も同様の考察が可能であり、この解析はイヌにおける ALP の毒 性学的意義の新たな解釈を提供し、農薬の毒性学的評価に寄与する可能性がある。

基準間隔Reference intervals (RI) は, 検査室での診断検査や臨床上の意思決定に不可欠な要素であり, 同等の個人の健康な集団からの基準値Reference values (RV)の推定分布を表す。診断の追求や治療開 始の意思決定は,しばしばRIに含まれない値に基づいて行われるため,RV値の収集と分析には細心の 注意を払う必要がある。

慣例上, RIはRVの中心95%を含み,基準値の上限と下限で区切られる。基準限界値を決定するため に選択された統計的方法は,RVの数と分布に基づく(表1)。ノンパラメトリック法は、少なくとも120 個のRVが利用可能な場合に推奨される。2.5分の1と97.5分の1のフラクタイルfractilesがそれぞれ基準値 の下限と上限として機能する。利用可能なサンプル数が120未満の場合,90%信頼区間を決定するため には、代替の方法(ブートストラップ等)が必要となる。39個は、95%ノンパラメトリックRIを決定で きる最小サンプル数であるが、この場合、極端な値が下限値と上限値となる。ノンパラメトリックRIを決定で きる最小サンプルサイズで使用しなければならない場合は、両極端の潜在的な外れ値をトリミングでき るように十分なサンプルを収集する必要がある。あるいは、ロバスト法またはパラメトリック法を使 用するべきである。ロバスト法は、≧40及び≦120の参照サンプルが利用可能な場合に推奨され、デー タの位置と広がりを推定するために反復プロセスを利用する。またガウス分布を必要としないが、デ ータが対称的に分布している場合、より良いパフォーマンスを発揮する。ブートストラップ法は90%信 頼区間を決定するために使用されるべきである。

データがガウス分布を持つか、またはガウス分布に変換できる場合、≧40及び≦120の基準サンプル が利用可能な場合、パラメトリック法を使用することができる。パラメトリック法は、値の中心95%よ りもわずかに多くの値を包含し、それぞれ平均+2SD及び平均-2SDで上限及び下限の基準限界を確立す る。パラメトリック法は、基準値の90%信頼区間を決定するために使用されるべきである。

獣医学では、特殊種や野生で捕獲された種、新生児など、基準サンプルの収集数が限られる場合があ る。20~40サンプルの基準サンプルの場合、RIはロバストまたはパラメトリックな方法で計算する必 要がある。小さなサンプルサイズに内在する不確実性を強調するために、90%信頼区間を計算すべきで ある。さらに、情報に基づいた臨床的意思決定を可能にするために、ヒストグラム、平均値や中央値、 最小値及び最大値を報告すべきである。あるいは、ヒストグラムと共にすべての値を列記した表の提 供に代替され得る。

10 人以上 20 人未満の基準サンプルが入手可能な場合は、ヒストグラム、平均値または中央値とともに昇順 値の表を報告すべきであるが、少ないサンプル数に基づく限界値の不確実性を考慮して、RI を決定すべきで はない。参照個体が非常に少ない場合には、被験者ベースの RI を考慮すべきである。一般に、利用可能な 参照個体が 40 人未満の場合, 適切な参照被験者の選択に細心の注意を払い, 標準化された収集技術と十分に管理された分析方法を遵守して, 外れ値のないサンプルを収集することに重点を置くべきである。 外れ値の存在を評価することは特に重要で, 単一の外れ値の存在は推定基準値に強い影響を与えるためである。 外れ値が識別された場合は, 代替サンプルを収集するためにあらゆる努力をすべきである。

正常な生物学的変動内での影響に関する一般的な結論

主に体重または体重増加, 臓器重量変化, 血液学的・生化学的・尿検査パラメータに関する影響であ る場合, 文献で公表されている正常範囲の値は, 当該試験で使われた方法と同等であることを保証す るために, それらが得られた方法が明記されている場合にのみ使用すべきである。それらの影響のパ ターンを考慮すると, 毒性学的影響の概算の変化の大きさは, 1) 10%の体重または体重増加, 2) 20% のアセチルコリンエステラーゼ阻害, 3) 臓器重量の変化がある。

臓器重量の変化は、毒性試験で観察された被験物質投与に関連した影響のうち、しばしば最も感度 の高い指標となる。臓器重量の解析は、絶対重量、相対重量の両方を基に行うべきである。臓器重量の 変化は, 絶対値及び相対値の両方とも, 対照群と投与群との差をパーセンテージで表したものである。 体重変化が大きい場合、相対重量は体重よりも脳重量との相対値で表す方が好ましい場合がある。臓 器重量の変化は, 絶対重量, 相対重量, またはその両方が変化しているかどうかという観点で評価すべ きである。その変化は、適切な対照群の平均値と比較した百分比(増加または減少)として表現すべき である。臓器重量の適切な評価には、個々の動物の値と群の平均値の両方が必要である。ラットにおけ る標的臓器毒性を最も正確に検出しやすいエンドポイント(臓器重量、臓器重量体重比、臓器重量脳 比)を決定するために実施された評価では、臓器重量体重比は、肝臓及び甲状腺、臓器重量脳比は卵巣 及び副腎への影響を評価するのにそれぞれ役立つ。脳、心臓、腎臓、下垂体及び精巣の重量はいずれを 選んでも適切に評価できないので,共分散分析などの代替方法を利用すべきである。マウスにおいて 投与に関連した臓器重量の変化を明らかにするためには、肝臓、腎臓、肺及び心臓の絶対重量の加齢に 伴う増加,及び脳と精巣の重量が比較的安定であることを考慮しなければならない。マウスにおける, 絶対重量のばらつきの一般的な傾向として,脳 < 精巣 < 腎臓 < 心臓 < 肝臓 < 肺 < 脾臓 < 胸腺 と報告されている。ラットについては、脳、肝臓、腎臓、肺、心臓、甲状腺及び精巣の加齢による絶対 重量の増加と相対重量の減少を考慮しなければならない。ラットにおける絶対重量のばらつきの一般 的な傾向として,脳 < 精巣 < 心臓 < 腎臓 < 肝臓 < 肺 < 胸腺 < 甲状腺と報告されている。

臓器重量データは、剖検所見、臨床検査結果及び病理組織所見とともに総合的に解釈しなければな らない。対応する肉眼所見や組織所見を伴わない臓器重量の変化は注意して解釈する必要がある。臓 器重量の変化が投与に関連したものかどうかを判断するためには以下の付加的な点を考慮すべきであ る。1)用量相関性、2)統計学的有意差があるか、3)両性で起こっているか、片性のみか、4)各投与 群での発生率はどうか、5)対照群の範囲外か、6)臓器重量の変化が体重の変動に依存しているか、7) 回復期間内で部分的または完全に回復するか、8)臨床検査結果、剖検所見、組織所見と関連があるか、 である。

毒性試験の目的は、被験物質によって引き起こされた標的臓器の有害影響を特定することであり, 高用量で観察される被験物質投与に直接的に起因する影響(一次的影響)は二次的にストレスをもた らすのに十分な程度と持続時間をもつ。被験物質の一次的影響は一般的に投与用量に比例するため, ストレスに起因する変化も用量に比例すると考えられる。このため、毒性試験における被験物質の一 次的影響とストレスに関連した二次的影響とを区別することは困難である。ストレスが脳で感知され ると,主に交感神経-副腎髄質系の活性化によるカテコールアミンの放出及び視床下部-下垂体-副腎系 (HPA 系) を介した血清グルココルチコイドの上昇が起こる。これらの神経内分泌シグナルにより, 下流では総体重または体重増加量, 摂餌量ならびに活動量の減少, 臓器重量の変動 (胸腺及び脾臓重量 減少,副腎重量増加),胸腺及び脾臓のリンパ球減少,循環白血球数の変動(リンパ球数及び好酸球数 の減少を伴う好中球数の増加),生殖機能の変化など,多臓器にわたり幅広い影響がもたらされる(表 1)。これらの所見の一部またはすべてが発生した場合、それらはストレスに起因する可能性が高い。毒 性試験でストレスを示す最も感度の高いパラメータは、循環白血球数、リンパ球サブセット、副腎及び 胸腺重量であり、ストレスに対する感受性は動物種、ストレスの種類、動物の状態や個体差によって異 なる。また, 急性ストレスに関連した影響は臓器外観の変化ではなく, 臨床病理パラメータの変化(例: ストレス性の白血球像)及び/または感受性の高い細胞集団の組織学的変化(例:グルココルチコイド 誘発胸腺リンパ球のびまん性アポトーシス)として表れる。これに対し、慢性ストレスは体重及び臓器 重量に影響を与える可能性がある(体重、胸腺、副生殖器及び脾臓重量の減少ならびに副腎重量の増 加)。

毒性試験でみられる変化が被験物質ばく露に起因するものか、ストレスに起因するものかどうかを 区別するためにはデータを総合的に評価する必要があり、以下に示す証拠の重み付けアプローチ

(weight-of-evidence approach) が有用である。

・<u>被験物質の標的臓器を考慮する</u>:被験物質がストレスを受けやすい臓器に影響を及ぼす場合,その 変化がどちらの影響によるものなのかを特定することは難しいため,低用量での被験物質の影響から 判断材料を得られる可能性がある。

・<u>ストレスによる影響を受けやすいパラメータや臓器におけるストレス反応の大きさを評価する</u>: ストレス反応の大きさは与えられたストレスの大きさに見合ったものでなければならない(例:1ヵ月 程度の軽度の反復ストレスを与えられた動物は副腎の重量及び組織に軽微から軽度の影響がみられる 可能性がある)

・<u>ストレスに関連した変化の用量反応と被験物質に関連した変化の用量反応との比較</u>:ストレスに

関連した変化は一般的に被験物質の影響がみられない用量では起こりえない(例:中間用量及び高用 量群で投与用量に関連した循環リンパ球及び胸腺リンパ球の減少,副腎重量の増加及び体重減少が認 められ,低用量群では副腎重量の増加のみみられる試験では,低用量の変化は被験物質投与の直接的 な影響である可能性がある)。

・<u>他の解釈の可能性を考慮する</u>:ストレスに起因する変化のほとんどは、別の解釈をもつ。データの 解釈を行う前に、別の解釈とそれを支持または反論する証拠について十分に検討する必要がある(例: 副腎皮質の肥大/過形成はストレスまたはグルココルチコイドの産生を抑制する副腎毒性物質が原因で ある可能性が考えられるが、他にストレスに関連した変化が認められない場合は副腎皮質ホルモン合 成に対する影響である可能性がある)。

・<u>証拠の重み付けの強さを評価する</u>:一般的に感度の低いストレスの指標は,感度の高いストレスの 指標が認められない場合には起こりえない(体重やリンパ系への影響等がなく生殖器系の影響のみが みられる場合,ストレスの影響ではない可能性がある)。

試験段階	影響を受ける システム	パラメータ	起こり得るストレス影響 (影響がない場合もある)
In-life		体重または体重増加量	(影音//など/場合もめる) 減少
III IIIC		摂餌量	減少
	循環血液細胞	好酸球数	減少
		リンパ球数	増加または減少
		好中球数	增加
	免疫系	マクロファージの貪食作用	減少
臓器重量 a	内分泌系	副腎	増加
	免疫系	胸腺	減少
		脾臓	減少
	生殖器系	精巣 <sup>b</sup>	変化なし (ラット) または減少 (マウス)
		精巣上体	減少
		精嚢	減少
		前立腺	減少
		卵巣	減少
		子宮	減少
臓器組織学	消化器系	胃潰瘍	增加
	リンパ系	胸腺細胞数	減少
		脾臓細胞数	減少
	生殖器系	精巣	変化なし (ラット) または変性 (マウス)
		精巣上体, 前立腺, 精嚢	萎縮の可能性あり
		卵巣,子宮	機能低下
		膣	萎縮,粘液産生
	内分泌系	副腎皮質	肥大/過形成

表 1. 毒性研究でよく評価される In-life 及び病理学的パラメータ:ストレスに対する典型的な反応

注: ストレスの影響を受けるパラメータは,動物種,性別,週齢及びストレス因子の種類と持続時間に 依存する。種特異的反応については,該当部分を参照のこと。

a: 絶対重量,体重に対する相対量,及び/または脳重量に対する相対量

b: 絶対重量のみ

### ・免疫系とストレス

免疫系に対するストレスの生理学的及び形態学的影響は、血液、胸腺、脾臟、骨髄で見られる。リン パ系組織の中では、胸腺が最も感受性が高く、ストレスに対する反応は数時間以内に誘発される。グル ココルチコイドは、リンパ球の再分布、細胞応答の変化、及びリンパ球の破壊を引き起こす可能性があ る。臓器重量が約 20%以上減少した場合にリンパ球減少の組織学的所見と関連が認められる。未熟リ ンパ球はストレスの影響を最も受けやすいため、胸腺の皮質はリンパ球減少の結果、しばしばサイズ が減少するが、骨髄や脾臓では胸腺に比べて成熟リンパ球が優勢であるため、これらの臓器でのスト レス反応はそれほど明瞭ではない。ストレスに関連した変化は、他の二次リンパ系臓器ではあまり一 貫性が認められない。

### ・胸腺

胸腺では、ストレスは皮質リンパ球の減少に起因する皮質のサイズの減少をもたらし、未熟な皮質 リンパ球が最も影響を受ける。重度の急性ストレスは、多数の"tingible-body"マクロファージと細胞の 破片(すなわち, starry sky 像)の出現を特徴とするびまん性のアポトーシスを引き起こす可能性があ る。対照的に、軽度な慢性ストレスは皮質のサイズの明らかな減少をもたらすかもしれないが、アポト ーシスの証拠は限られているか、全くない。胸腺リンパ球のアポトーシスはラットの拘束ストレスの2 時間後に始まるが、胸腺重量は拘束後 8 時間まで変化しない。ラットの胸腺リンパ球数と重量は、毎 日の強制水泳ストレスを 21 日間受けると減少する。マウスの胸腺重量は、ケージラックを短時間移動 させた 12 時間後と 24 時間後にそれぞれ 12%と 15%減少した。胸腺に対する効果は可逆的であり得る。 例えば、マウスにデキサメタゾンを単回投与すると、胸腺萎縮が生じ(細胞数及び増殖の減少によって 示される)、これは処置後 3 日目までに最も顕著であるが、12 日目までに完全に回復する。

#### ・脾臓

毒性試験では、一般に脾臓に影響を及ぼすほどの十分に強いストレス因子は、リンパ球のアポトーシスの有無に関係なく、白脾髄領域の減少を伴う脾臓重量の減少をもたらす。ストレスに関連した変化は胸腺に比べて脾臓では一般的に一貫性がなく軽度である。1回の急性ストレスが脾臓重量に一過性の影響を与えることがマウスで報告されている。1日2時間のストレスに7日間連続でばく露されたラットでは、Tリンパ球領域の増殖が低下して白脾髄量が減少する。さらに、アポトーシスの増加によりBリンパ球領域が減少する。前述したように、循環Bリンパ球はストレス時にリンパ系器官に再分配し、その結果、ストレス下での脾臓のBリンパ球領域の可変的な変化に寄与している可能性がある。 脾臓重量を増加させる被験物質の薬理学的または毒性学的効果は、ストレスに関連した脾臓重量の減少を隠蔽する可能性がある。

本研究は味の悪い餌や食欲不振によって起こる短期の摂餌量減少が引き起こす変化を特定すること を目的とし、4-5 週齢の Sprague-Dawley SD ラット (Charles River) 各群雌雄 10 匹ずつの 4 グループに、 2週間にわたり異なる量の餌 [グループ1:自由摂取(対照群), グループ2:前日の対照群の摂餌量の 75%(軽度食餌制限),グループ3:前日の対照群の摂餌量の50%(中等度食餌制限),グループ4:前 日の対照群の摂餌量の25%(重度食餌制限)]を与え、血液学的検査、血液生化学的検査、臓器重量測 定(副腎,脳,心臓,腎臓,肝臓,精巣及び胸腺)及び組織学的検査(臓器重量測定を行った臓器に加 え,骨及び骨髄(胸骨),ならびに胃)を実施した。その結果,いずれの群にも動物の死亡は認められ ず、すべての食餌制限群において発育遅延以外の臨床症状は観察されなかった。試験終了時の最終体 重は、雄ではグループ2、3及び4においてそれぞれ対照群と比較して77%、62%、38%であり、雌で は82%,66%,42%であった。血液学的検査では、赤血球数はヘマトクリット値及び血色素量とともに 食餌制限の程度に比例して増加し、血小板数はすべての食餌制限群で減少した。白血球数はグループ4 で著しく減少し,特にリンパ球数の減少が目立った。血液生化学的検査では,グループ4の雌雄で血 清ビリルビンの増加,電解質異常及びコレステロールの減少(雌のみ)がみられた。臓器重量では、体 重への著しい影響に伴い、グループ 4 のすべての臓器の絶対重量が減少していた。胸腺はグループ 4 の雌雄及びグループ3の雄で、肝臓はすべての食餌制限群で絶対及び相対重量が減少した。その他の 臓器の相対重量については、変化しないか、もしくは増加していたが、これは減少した体重の大部分が 脂肪、筋肉及び水分の喪失によるものであったことを示唆していた。食餌制限に関連した組織学的所 見は骨髄, 胸腺, 胃及び精巣で観察された [発生頻度は雌雄合算し(n=20), 病変の程度は軽微(1), |軽度(2),中等度(3),高度(4),重度(5)の5段階で評価した]。食餌制限により最も生物学的に重 大な組織学的変化が観察されたのは骨髄であり、グループ2及び3では軽微から中等度の造血組織の 減少(骨髄腔の脂肪増加)、グループ4では脂肪がみられず、中等度から重度の造血及び間質成分の変 性及び壊死が観察され、造血組織は対照群の10~25%であった。胸腺ではグループ4のすべての動物 に退縮または萎縮が認められ、雌でより強い影響がみられた(重度の萎縮は雄1/10及び雌7/10に観察 された)。重度の胸腺萎縮では、ハッサル小体とわずかに残るリンパ球とともに泡沫状マクロファージ が充満する間質しか残っておらず,正常構造は失われていた。グループ 4 の残りの動物の胸腺には, マクロファージ (星空像を呈する可染体マクロファージ),皮質のリンパ球減少,ハッサル小体の増加 及び皮髄境界部の不明瞭が観察され、より程度の弱い萎縮像と考えられた。グループ2及び3では、 少数の動物に皮質における泡沫状マクロファージの軽微な増加が観察された。精巣の組織学的変化は, グループ4において4例にみられ、このうち2例では軽度な精上皮変性(精上皮の脱落及び巨細胞の

形成)が,残りの2例では精子数の減少が観察された。胃では,剖検時にすべての食餌制限群で粘膜の 局所的な赤色化もしくは血様内容物が認められ,組織学的に観察された軽度なびらんの発生頻度は食 餌制限群で高かった(グループ 1-4:1/20,5/20,2/20,5/20)。副腎,脳,心臓,腎臓,または肝臓で は,食餌制限に関連する組織変化は観察されなかった。

以上の結果より、生物学的に特に重要であると考える変化を以下に示す。

・摂餌量が対照群の75または50%の場合、胸骨骨髄における造血組織の減少及び脂肪の増加

・摂餌量が対照群の25%しかない場合,骨髄の壊死,胸腺萎縮(特に雌で強い),骨髄及びリンパ組織へ影響を反映した好中球,リンパ球及び血小板減少,脱水の影響による血液濃縮及び血清電解質の 異常,ならびに肝萎縮(絶対及び相対重量の減少)。その他の変化については,それほど重要ではない と考えられた。

(翻訳注:肝臓の萎縮については相対重量の変化は統計学的に有意ではなく,組織学的な変化は観察されていないが,生体異物の代謝に影響を及ぼすかもしれないので無視出来ないとしている。)

Society of Toxicologic Pathology (STP) は、各分野の規制ガイドラインの間には一定の違いがあるこ とを認識しており、その中で、臓器重量の現行の評価方法が大きく異なることを認識している。そのた め、STPは毒性試験における臓器重量に関する評価の方法を調査するためのワーキンググループを招集 した。調査は、ヨーロッパ、北米、日本の製薬、獣医、化学、食品/栄養、消費者製品の種々の分野の 企業にアンケートを配布し、意見を求めた。

調査では、げっ歯類及び非げっ歯類を使った様々な種類の毒性試験で日常的に測定されている臓器 を特定し、臓器重量の評価法を比較し、臓器重量測定の有用性についての見解をまとめた。結果とし て、脾臓及び胸腺重量は免疫毒性、ストレス及び生理学的なかく乱の鋭敏な指標であると考えられ、さ らに脾臓及び胸腺の病理組織学的変化は臓器重量の変化と相関があるとされた。一方、これらの重量 測定にはほとんど価値がないという見解もあり、その理由として、胸腺では解剖時の技術的な問題や 加齢に伴う退縮、ストレスに関連した影響などによるばらつきの大きさが挙げられた。脾臓では、動物 間の変動性、ストレス関連の影響及び非げっ歯類(特にイヌ)における安楽死に関連した脾臓のうっ血 のような投与とは無関係の生理的な要因のため、その価値は限定的であると考えられた。さらにその 価値が限定的であると考える人には、脾臓及び胸腺の重量変化はしばしば病理組織学的所見と相関し ないことが多く、病理組織学的検査は被験物質投与による影響のより鋭敏な指標と考えられていた。

今回の STP 調査の回答では、一般的には、臓器重量は毒性試験における被験物質投与との関連性を 評価するために有用なスクリーニングツールであると考えられていた。しかし、個別の臓器ごとの評 価に関しては、実施した試験の目的に応じてその有用性の重要度については意見が大きく異なってい た。また、臓器重量データは、体重変化、被験物質の薬理作用、臨床病理学的データ、動物の絶食状態 または絶食した場合の情報及び肉眼的・組織学的所見などのデータを含めた試験全体の流れの中で評 価すべきであると強調する意見もあった。

フィッシャー344 (F344) ラットは、米国国立がん研究所 (NCI) 及び米国国家毒性プログラム (NTP) による毒性試験に使用される標準的なラット系統である。臓器重量の影響は、規制当局がヒトの健康 リスク評価の毒性参照値 (TRV) を設定するために使用する重要なエンドポイントであり、加えて相対 臓器重量を利用する生理学的薬物動態 (PBPK) モデルが TRV の策定に使用されるようになってきて いる。このように F344 ラットの集計された臓器重量は TRV 設定と PBPK モデリングに有益なデータ になり得るため、本研究では、NCI/NTP の混餌、飲水、吸入試験から、被験物質非投与の対照群の F344 ラットの利用可能なすべての絶対及び相対臓器重量データを収集し、週齢別にまとめた。

得られた知見が示しているのは,月齢に応じて絶対重量が増加し,相対重量が減少するのは脳,肝 臓,右腎,肺,心臓,甲状腺,右精巣である。結果によると,絶対臓器重量における一般的な変動傾向 は、小さいほうから脳,右精巣,心臓,右腎,肝,肺,胸腺,甲状腺の順であることが示唆される。

2 つのブリーダーの生後 23 週齢から 108 週齢までの未処理の雄のビーグル犬の前立腺の重量と組織 学的所見を評価した。27 のガイドライン試験で得られた 125 頭の対照ビーグル犬のデータを使用した。 年齢,最終体重及び前立腺重量を測定した。前立腺について病理組織学的変化(腺房の発達,分泌量, 拡張や炎症のパターンなど)を観察し,必要に応じて等級付けを行った。前立腺の重量及び組織学的所 見に及ぼす年齢,最終体重及びブリーダーの影響,及び動物間の変動の程度を評価した。

前立腺は精巣から分泌されるテストステロンによって発達することから,精巣及び精巣上体の組織 学的検査により性成熟の評価を行った(図1)。その結果,前立腺の成熟度と精巣及び精巣上体の成熟 度との間には強い相関関係があることが明らかとなった。さらに,Harlan Franceの31-40週齢の動物は 90%が性成熟していたのに対し,Marshall Farms USA の同じ週齢の動物では10%しか性成熟しておら ず,ブリーダーにより性成熟期のずれがあることが示唆された。同じ週齢の平均最終体重はMarshall Farms USA より Harlan Franceの動物の方が統計学的に有意に高く,これは生産コロニーの遺伝的背景 が異なるためと考えられた。これらのことから,前立腺重量のばらつきの要因をまとめると以下のよ うになる。

- 性成熟期の個体差(Marshall Farms USAの動物は41-50週齢, Harlan Franceの動物では31-40週齢の 間に性成熟に達した)
- ② ブリーダーの違い(Harlan Franceの動物はMarshall Farms USAより同じ週齢でも体重が重く、早く性成熟を迎えていたが、同じ成熟段階の前立腺にブリーダー間の組織学的な差はなかった)

③ 同じ性成熟段階における個体差

## Marshall Farms USA

Harlan France

図 1. 週齢別の未成熟及び成熟精巣の割合: Harlan France のイヌでは,未成熟と診断された最高齢のイ ヌは 31 週齢であったのに対し, Marshall Farms USA のイヌでは 41 週齢であった。この結果から, Harlan France のイヌは Marshall Farms USA のイヌよりも早く性成熟を迎えることが確認された (Marshall Farms USA [n=97], Harlan France Harlan France [n=28])。

本研究では 1992 年 1 月から 1999 年 7 月までの期間に Wyeth Research で実施された, Crl:CD<sup>®</sup>[SD]BR (Charles River Laboratories) ラットを用いた 26 本の 1 ヵ月間試験の対照動物(雄 307 匹,雌 266 匹) において,様々な臓器がどの程度,臓器重量と体重あるいは脳重量との間に比例関係があるかを調査 し,これらの結果に基づき,どのエンドポイント(臓器絶対重量,臓器重量/体重比または臓器重量/脳 重量比)が標的臓器毒性を正確に検出できるかを検証した。

その結果を表1に示す。雌雄の肝臓及び甲状腺重量は体重との間に比例関係が存在し、雌雄の副腎 及び雌の卵巣重量では脳重量との間に比例関係が認められた。従って、臓器重量/体重比は肝臓及び甲 状腺重量を評価するのに適しており、臓器重量/脳重量比は副腎及び卵巣重量を評価するのに適してい ると考えられた。脳、心臓、腎臓、下垂体及び精巣の臓器重量については絶対重量、臓器重量/体重比 または臓器重量/脳重量比を用いた解析に適合していないことから、共分散分析のような別の統計手法 を利用すべきであろう。

臓器	体重比	脳重量比	別の統計手法
副腎		$\checkmark$	
心臓			$\checkmark$
腎臓			$\checkmark$
肝臓	$\checkmark$		
下垂体			$\checkmark$
甲状腺	$\checkmark$		
精巣			$\checkmark$
卵巣		$\checkmark$	
旭			$\checkmark$

表1. 絶対臓器重量, 臓器重量/体重比及び臓器重量/脳重量比の最適な利用

✓統計解析で、このエンドポイントに相当するモデルがデータに適合していることを示す。
 このエンドポイントは、群間に体重差が存在する場合に臓器重量差の評価に推奨される。

✓統計解析で、モデルが絶対重量、臓器重量/体重比または臓器重量/脳重量比の解析に適合していないことを示す。臓器重量の解析には、別の統計手法を利用すべきである。

毒性試験における臓器重量の評価は、医薬品、化学物質、医療機器の評価に不可欠である。米国毒性 病理学会は、7日間から1年間のGLPでの一般毒性試験において重量測定が推奨される臓器を提案す る(付表1)。

脾臓及び胸腺はげっ歯類を対象とした試験では測定すべきである。胸腺重量は非げっ歯類でも価値 があるが、生理的な胸腺の退縮は思春期以降のイヌやサル、特に期間が3ヶ月を超える試験では解釈 を複雑にする。さらに非げっ歯類の脾臓重量は麻酔の方法や放血の程度により影響を受けることがあ る。脾臓及び胸腺重量は、リンパ系臓器重量に固有のばらつきがあるため、常に病理組織学的結果と併 せて解釈すべきである。

ラット	マウス	非げっ歯類
肝臓	肝臓	肝臓
腎臓	腎臓	腎臓
心臓	心臓	心臓
副腎	副腎	副腎
月凶	月凶	月送
精巣	精巣	精巣
前立腺		
精巣上体		
脾臓	脾臓	
胸腺	胸腺	
甲状腺/上皮小体		甲状腺/上皮小体
下垂体		下垂体

### 体重変化、食物及び水の消費量

試験期間中の個々の動物や動物群の体重変化(増加または減少)を,対照群の変化と比較すること は,かなり重要な基準となる。体重変化は通常,飼料摂取量に関連しており,両者の評価を併せて行う ことが必要である。体重の減少は必ずしもそれ自体が毒性と関連しているとは限らない理由としては, 被験物質を含む飼料に対して動物の飼料に対する嗜好性が低下することにより,飼料摂取量に影響す ることがある。動物の忌避がみられた場合に餌の容器からの飼料のこぼしが増加することがあり,被 験物質摂取量について配慮が必要となる。被験物質を飲料水によって投与する場合も同様に考慮する 必要がある。

この忌避の作用は、多くの場合、最初の2~3週間の投与で明らかになるが、それ以降、これら動物 は被験物質を含む飼料に適応できるようになり、体重増加が徐々に回復することがある。その際、亜急 性毒性試験では、摂取した飼料1グラムあたりの個々の動物の増加量(食餌効率)が好転し、それに遅 れて投与群の体重増加が続く場合があり、被験物質の毒性とは無関係に被験物質投与群と対照群間に 投与初期に統計的に有意差を生じることがある。

被験物質の添加によって餌中の1つまたは複数の必須栄養素と相互作用することで、体重増加の減 少や毒性反応の変化が生じることもある。この現象が亜急性毒性試験で観察された場合には、それに 続く慢性毒性試験を開始する前に許容可能な手段(acceptable means)で克服することができる。まれに 対照群の体重増加が低いために、他の群の増加値が高いようにみえることがあります。

飼料組成,飼料及び水の摂取量,体重の増加は,代謝,ホルモン,恒常性維持機構の変化や病歴,成 熟などの動物の状態に重要な影響を与えることがあり,臓器やその他の重要なシステムに異常な所見 がないにもかかわらず,これらの悪影響が観察された場合には考慮すべきである。

### 臓器重量の絶対値と相対値

これまで, 亜急性毒性試験では, 肝臓, 腎臓, 体重の変化が毒性のエンドポイントであるとされてき た。一般的には, 臓器や体重の変化よりも病理組織学の方が最小中毒量を確定するのに適していると 考えられているものの, 臓器重量も通常, 絶対臓器重量及び相対臓器重量(体重ないし脳重量に対する 相対)が評価に用いられる。

実験者が制御可能なものと制御できない両方の要因(概日リズム,食物摂取量,脱水,食餌の性質,動物の年齢,臓器の作業量,ストレス,殺処分方法など)も,臓器重量や体重に影響する。

殺処分時に放血処理をしなかった場合には,肝臓や腎臓の絶対あるいは相対重量を減少させるが, 心臓,脳,脾臓重量には影響はないとされている。

被験物質が体重減少あるいは体重増加抑制に大きな影響を与えている毒性試験では、脳の相対量の

増加は評価上意味がなく、また、脳だけでなく他の臓器においても体重に依存して相対重量に影響した可能性があるため、これらは毒性影響による変化と区別するべきである。

また臓器重量変化に対する判断は,対照値との間の統計的に有意な差の有無だけでなく,病理組織 学的データや代謝・トキシコキネティクスデータを含めて考慮する必要がある。
