海外のリスク評価機関における評価結果等に関する調査

報告書

令和3年3月

一般財団法人残留農薬研究所

#### 調査の概要

2018年12月に改正された農薬取締法に基づき、2021年度から農薬の再評価制度が 開始される。これに伴い、食品安全委員会は、リスク管理機関からの諮問を受け、既 登録農薬の再評価を行うことになる。

我が国で再評価が予定されている農薬に関し,再評価制度を先んじて導入していた 海外のリスク評価機関である欧州食品安全機関(以下「EFSA」という。)及び米国環 境保護庁(以下「EPA」という。)でのこれまでの再評価に関する情報は,我が国での 再評価に向けて、大変有益である。このため、両機関における、再評価の評価書及び 再評価の関連文書を収集するとともに、農薬(有効成分)及び機関ごとにそれらを整 理した。

### 海外のリスク評価機関における評価結果等に関する調査報告書

#### 1. 調査の目的

2018年12月に改正された農薬取締法に基づき、2021年度から農薬の再評価制度が 開始される。これに伴い、食品安全委員会は、リスク管理機関からの諮問を受け、既 登録農薬の再評価を行うことになる。

我が国で再評価が予定されている農薬に関し,再評価制度を先んじて導入していた 海外のリスク評価機関である欧州食品安全機関(以下「EFSA」という。)及び米国環 境保護庁(以下「EPA」という。)でのこれまでの再評価に関する情報は,我が国での 再評価に向けて、大変有益である。このため、両機関における、再評価の評価書及び 再評価の関連文書を収集するとともに、農薬(有効成分)及び機関ごとにそれらを整 理し、評価書ごとにその結果の概要を一覧表に取りまとめる。

#### 2. 再評価の評価書及び関連文書の収集

本調査では、再評価が予定されている既登録農薬のうち、内閣食品安全委員会事務 局担当官が指定する4有効成分(表1)を調査対象とし、これらの有効成分の欧州委 員会(以下「EC」という。)又はEPAでのこれまでの農薬登録の有無を調査し、過去 に登録されたことのある農薬については、以下に示す再評価の評価書及び関連文書を 収集し整理した。

整理項目としては、下記のとおりである。

- 再評価開始前の事前のやり取り(企業と政府機関との相談・連絡)に関する文書
- ② 再評価時に追加要求された試験項目及びその内容に関する文書
- ③ ②の試験成績の提出の有無及びそれに係る再評価での結果に関する文書
- ④ 再評価前の評価書、再評価の評価書(例えば,欧州の場合ならDAR/RAR及び EFSA評価書は少なくとも入手、公表文献の評価に関する文書もあれば入手)、 再評価後の評価書の追補文書(存在する場合のみ)
- ⑤ 再評価結果を反映した規制の内容(欧州にあっては再評価結果を踏まえた EC に よる登録状況(再評価前、再評価後、現在)、その他の規制の内容及び EU 各国 での規制の内容)に関する文書

番号	農薬名	英名	種類
1	フィプロニル	fypronil	フェニルピラゾール系殺虫剤
2	フェンメディファム	phenmedipham	カーバメート系除草剤
3	プロスルフォカルブ	prosulfocarb	カーバメート系除草剤
4	ピメトロジン	pymetrozine	ピリジンアゾメチン系殺虫剤

表1 調査対象の農薬

なお、該当する情報を収集するために現地のレギュラトリー制度に精通している専門家 のスキルが必要となり、ヒト健康影響評価に資する農薬の再評価の評価書及び再評価の 関連文書の情報収集における正確性、信頼性を確保するため、以下の会社に再委託を行 った。

- 米国: Landis International 社 (3185 Madison Highway, Valdosta, Georgia, 31603-5126, USA)
- 欧州: Mendel-Kreusel Consult 社 (Auf der Heide 8, 53783 Eitorf, Germany)

### 3. 一覧表の作成

2項で収集した情報について、それぞれの概要についてエクセル及びワードを用いてまとめた一覧表を作成した。

## 4. ガイダンス等の翻訳

以下のガイダンス等について、和文和訳(図表等を含める)を作成した。

- US EPA: U.S. : Office of Pesticide Programs 'Framework for Incorporating Human Epidemiologic & Incident Data in Risk Assessments for Pesticides. (2016)
- EFSA: Scientific Opinion of the PPR Panel on the follow-up of the finding of the External Scientific Report 'Literature review pf epidemiological studies linking exposure to pesticides and health effects'. EFSA Journal 2017; 15(10): 5007
- EFSA: Literature review on epidemiological studies linking exposure to pesticides and health effects. EFSA supporting publication 2013: EN-497
- LaKind JS, et.al.: A proposal for assessing study quality : Biomonitoring, Environmental Epidemiology, and Short-lived Chemicals (BEES-C) instrument. Environment International 73 (2014) 195–207
- IPCS Harmonization Project Document Document No.4 (2007)
   PART 1: IPCS FRAMEWORK FOR ANALYSING THE RELEVANCE OF A CANCER MODE OF ACTION FOR HUMANS AND CASE-STUDIES
   PART 2: IPCS FRAMEWORK FOR ANALYSING THE RELEVANCE OF A NON-CANCER MODE OF ACTION FOR HUMANS

#### 5. 残留農薬のリスク評価に当たっての毒性試験結果の解釈に係る知見の収集

以下の4点について、海外のリスク評価機関や残留農薬のリスク評価に関する国際 機関のガイダンス等の文書、信頼性の高い公表文献等を対象に情報を収集し、それぞ れの概要(入手資料の該当ページに関する情報を含む)を日本語で作成した。

- ① 各種毒性試験における毒性を解釈する上で共通する考え方(適応性変化等)
- ② 毒性判断に用いる統計学的手法、背景データの利用
- ③ 血液学的検査、血液生化学的検査及び尿検査に対する基本的な考え方及びこれらの検査において統計的に得られる正常範囲
- ④ 体重、摂餌量及び臓器重量に対する基本的系な考え方及びこれらの重量について統計学的に得られる正常範囲

#### 6. 作業実施者の要件

3~5項に規定する概要及び翻訳の作成に当たっては、作業内容に応じて、以下の 要件を一つ以上満たした作業者が実施した。

- ・毒性学、体内動態学に関する科学的知見を有する者(学位等)
- ・化学物質のリスク評価(手法)に関する調査等の実務経験を有する者
- ・毒性学、生化学、農芸化学、生物学、有機化学、医学、薬学等の分野における論 文(英文、邦文)の検索・要約作成等の業務経験(研究等を含む)を有する者

#### 7. 専門家の意見の聴取

(ア) 2項で収集した情報の取捨及び3項の一覧表の概要の作成に当たっては、農薬の再評価制度に加えて以下の分野についての専門知識を有する者(各分野で1名程度)の意見を聴取の上、行った。(表 2)
 ・動物代謝 ・毒性 ・遺伝毒性 ・疫学

専門分野	氏名	肩書	所属
動物代謝	永田 清	教授	東北医科薬科大学
			薬学部 環境衛生学系 環境衛生学教室
毒性	山手 丈至	教授	大阪府立大学生命環境科学研究科

			的発達の遅れに基づく。
			・短期間の発達神経毒性試
			験では、授乳中の子犬の体
			重の有意な減少、およびオス
			の性発達遅延の兆候に基
			づき、LOAEL は
			0.90mg/kg/day。
			0.90mg/kg/day。 ◇動物代謝
			・経皮吸収はラットを用いた試
			験において1%未満
			・ヒト、ウサキ、、ラットの皮膚表皮
			を用いた <sup>14</sup> C-フィフ <sup>ロ</sup> ニルの in
			vitro 試験では、200g/L 溶
			液塗布の8時間後の浸透
			率は、0.08%(ラット)、0.07%
			(ウサギ)及び 0.01%(ヒト)で
			あった。0.2g/L の溶液塗布
			では、0.9%(ラット)、13.9%
			(ウサキ*)、0.9%(ヒト)の吸収
			率であった。別の in vitro 試
			験では、24 時間後にとトの皮
			膚表皮で 0.15~3.00%、ラット
			の皮膚表で1~35%)の浸
			透性であった。
			・犬と猫を対象とした <sup>14</sup> C-7ィ
			プロニルのスポットオン処理で
<u> </u>			ノロールのスホットオン処理で

		は、有効成分は主に皮膚表
		層に分布し、真皮や表皮下
		層(脂肪組織)では検出され
		なかった。
		<ul> <li>・ラット皮膚に<sup>14</sup>C-フィフ<sup>°</sup>ロニルテ<sup>°</sup></li> </ul>
		ススルフィル(光分解物)0.08~
		7.20mgを処理すると24 時
		間後に塗布した量の約 0.2
		~7.0%皮膚に浸透した。
		・標識したフィプロニルを 0.05、
		2.00、10.00ppm の用量でヤ
		ギの飼料経由で7日間投
		与したところ、吸収率は 15
		~33%であった。ラットを対象
		とした研究では、経口投与
		後の吸収率は 30~50%で
		あった。
		【分布】
		・本有効成分は哺乳類の体
		内に広く分布し、主に脂肪
		組織に検出される。単回経
		口投与されたラットでは、胃、
		消化管(GI)、脂肪、副腎で
		の濃度が最も高かった。中
		等度の濃度は肝臓、膵臓、
		甲状腺、卵巣に認められ
		た。低濃度は筋肉、脳、心
		臓、心臓の血液中に認めら
		nte.
		・犬と猫を対象としたスポットオ
		ン処理では、治療後2ヶ月
		後に皮脂腺、毛の周囲の上
		皮層、毛軸の露出部に <sup>14</sup> C-
		フィプロニルが検出され、毛と
		皮膚を覆う皮脂中に拡散し
		ていることが示唆された。ス
		ポットオン型のフィプロニル製品を
		犬に塗布し、毎日5分間、
		綿の手袋を使って犬を激し
		く撫でた。手袋に移行した残
		留物は、処理後24時間後
		に 589(±206)ppm でピーク
		を迎え、時間の経過とともに
		減少し(8日後には448±
		118ppm)、36 日後には検出
		されなくなった。
		【代謝】
		・ラットにおける全血中の半減
		期は、4mg/kgの経口投与
		で約 6.2~8.3 日であり、
		150mg/kg の経口投与では
		2.1~2.3 日。
		【排泄】
		・経口投与したラットでは、糞
		中に 45-75%、尿中に 5-
		25%のフィプロニルが排泄され
		た。親化合及びフィプロニルスル

				ホンは、糞及び尿共に検出さ
				れた。
				・授乳中のヤギにフィプロニルを
				7日間摂取させた場合に
				は、18~64%が糞中に、1~
				5%が乳中に排泄され、8~
				25%が体組織中に残存し
				た。
				・フィプロニルデススルフィルをヤキ゛
				に投与した場合には、糞中
				に 20~50%、尿中に 3~
				7%を排泄した。

【人の健康影響評価についての要約】

- ▶ 米国
- ✓ EPA レビューページ(別紙1)

Regulations.gov - Docket Folder Summary

年月	評価資料	食品経由での人健康影響エンドポイント
		・追加要求
2020年7月	Interim Registration Review Decision	◇ヒト健康影響及び生態影響リスク評価
		の結論は、PID(Proposed Interim
	(PYU1)	Registration Review Decision) $\mathcal{E}$
	EPA-HQ-OPP-201 3-0368-0060_cont	ID (Interim Registration Review
		Decision)の間で変更されなかった。ヒ
		ト健康影響に関する追加データ不要
		◇EPA は、PID に対して提出された意見
		を検討した結果、以下のように決定した。
		・ジャガイモ及びペカンの単回最大散布率
		及び年間最大散布率低減を要求しな
		ί, ۱°
		・観葉植物の屋内散布の年間最大散布
		量を、1 エーカーあたり 3.125 ポンドの有
		効成分で維持する。
		・PID に記載されている空中散布を禁止
		しない。
2018年12月	Proposed Interim Registration Review	◇ヒト健康影響リスク評価では、飲料水
	Decision	用途の地下水に含まれるピメトロジン残
		留物による急性、慢性及び発がん性の可
	(PYU2)	能性が示唆される。
		・急性及び慢性のヒト健康へのエンドポイ
	EPA-HQ-OPP-201	ントは、ラット発達神経毒性試験で観察
	3-0368-0036_cont	された脳形態学的変化である。
		・発がん性のエンドポイントイは、マウスのオ
		スにおけるヘパトーマおよび/または肝細胞
		・飲料水中の残留物暴露は、リスク評価
		において主な原因であった。食品への暴
		露だけでは、急性、慢性、または発がん性

*個の合きや フリフ りは 仕じ キンロ・ギー 金切り し
が懸念されるリスクは生じないが、飲料水
を食事暴露の計算に含めると、懸念レベ
ル(LOC=急性母集団調整線量
(aPAD)または慢性母集団調整線量
(cPAD)の100%を超えていた。
◇以下の緩和策を提案する。
・コンテナ栽培の観葉植物を除くすべての
用途について、軟弱土壌で栽培された作
物への使用禁止
・コンテナ栽培の観葉植物(屋外栽培)
について、深度が浅い地下水の場合、水
管理の実施または集水システムから 900
フィート以内での使用禁止。
・ジャガイモ、ペカン及び花卉類への処理
量低減
・職業リスクを軽減するため、空中散布の
禁止。
◇非標的生物に対するリスクを軽減する
ためのラベル変更
◇耐容摂取量の再評価に基づく適用変
更
◇DCI について追加データ要求はない。
ただし、ミツバチに対する潜在的リスクを考
慮し、ポリネーターに関する追加要求を行
う可能性がある。
◇疫学データ
OPP (The Office of Pesticide
program) の IDS(Incident Data
System)及び CDC(Centers for
Disease Control) /NIOSH
(National Institute for
Occupational Safety and Health)
$\mathcal{O}$ SENSOR (Sentinel Event
Notification System for
Occupational Risks ) -Pesticides
データベースを用いて検討。2012年1
月1日から2017年6月7日までの間
に、1 件の軽度の症例 IDS に報告され

		ていた。1998 年から 2013 年の間に SENSOR-Pesticides で 5 件の事例が 確認された。この事例はすべて複数の有 効成分が関与していた。本有効成分につ いて報告された事例の頻度と重症度が低 いことを考えると、現時点での懸念はな い。
2018年12月	Addendum to the Draft Human Health Risk Assessment for Registration Review (PYU3) EPA-HQ-OPP-201 3-0368-0032_cont	<ul> <li>◇懸念されるリスクは、主に飲料水への残留。そのための緩和策を提案。</li> <li>・最大散布量を低減</li> <li>・空中散布を禁止するか、保護マスクの 要件を追加する</li> <li>◇緩和策での急性および慢性の食品経 由(飲料水を含む)暴露評価では、懸 念すべきリスクはない。</li> </ul>
	Update to the Drinking Water Assessment for registration Review of Pymetrozine dated August 24,2017 (PYU4) EPA-HQ-OPP-201 3-0368-0030_cont	◇飲料水経由でのリスク評価(2017 年8月)の更新
2018年11月	Syngenta & EPA Registration Review Risk Management Discussion (PYU5) EPA-HQ-OPP-201 3-0368-0035_cont	◇シンジェンタ社は、保護マスクに関する 追加記載、散布ドリフトに関する記載の 標準し、軟弱土壌に対する散布量低減 と散布制限に関する議論に合意
	Response to Public Comments on the Drinking Water Assessment and Preliminary Ecological Risk Assessment	◇飲料水経由のリスク評価及び生態影 響に関する予備的リスク評価のパブコメに 対するコメント

	(PYU6) EPA-HQ-OPP-201 3-0368-0031_cont Response to OPP's Pymetrozine Mitigation Proposals (PYU7) EPA-HQ-OPP-201 3-0368-0034_cont	◇ADAMA は特定されたリスクを軽減す るために、空中散布用途禁止、軟弱土 壌への散布制限及び一部の作物への散 布量を低減ことに合意。
2017年12月	Draft Human Health Risk Assessment for Registration Review (PYU9) EPA-HQ-OPP-201 3-0368-0017_cont	<ul> <li>◇FQPA (Food Quality Protection Act) に基づきとトの健康影響リスク評価 に係る毒性データベースは十分。</li> <li>◇免疫毒性試験と亜急性吸入毒性試 験は実施していないが、HED はこれらの 試験は必要ないと判断。</li> <li>◇哺乳類では、標的臓器は肝臓。さらに 急性、亜慢性及び発達神経毒性試験で 神経影響がみられた。</li> <li>◇ラット及びウサギにおける発生毒性試 験あるいは発達神経毒性試験において、 出生前の感受性の増加が認められた。ラ ットの生殖毒性試験では認められなかった。</li> <li>◇毒性および暴露データを評価した結 果、FQPA 安全係数 (SF)をX10と 設定した。</li> <li>◇HED は、本有効成分を「とト発がん性 物質の可能性が高い」と分類し、マウス (オス、メス)及びラット(メス)における 複合肝腫瘍(良性肝腫及び/またはがん 腫)について、発がん性リスクの定量化を 求める。</li> <li>◇食品経由暴露評価に基づき、急性、</li> </ul>

	Acute, Chronic, and Cancer Dietary Exposure and Risk Assessments in Support of the Registration Review Risk Assessment (PYU10)	慢性及び食品経由の発がん性リスクは、 一般的に懸念レベルを超過している。その 原因は食品経由ではなく飲料水に含まれ る残留物である。
	EPA-HQ-OPP-201 3-0368-0018_cont	
2017年8月	Drinking Water Assessment for Registration Review (PYU11) EPA-HQ-OPP-201 3-0368-0028_cont	<ul> <li>◇EFED (Environmental Fate and Effects Division) は、食品経由リスク 評価において、HED が使用している地下 水の最高濃度 404µg/L 及びその後の 平均値を 367µg/L とすることを推奨す る</li> </ul>
2017年7月	Tier I Update Review of Human Incidents and Epidemiology for Draft Risk Assessment (PYU12) EPA-HQ-OPP-201 3-0368-0019_cont	◇疫学データ 2012年1月から2017年6月のIDS及び SENSOR-Pesticideのデータベースにお いて、本有効成分による事故は報告され ていない。
2014年5月	GENERIC DATA CALL-IN NOTICE (PYU14) EPA-HQ-OPP-201 3-0368-0014_cont	<ul> <li>◇ 公開された PWP (Preliminary Work Plan) で概説されたデータギャップ についての追加要求であり、FWP (Final Work Plan) で満たされている と指摘されたデータギャップは不要。</li> <li>◇追加要求データ</li> <li>・好気的水中代謝試験</li> <li>・発芽影響</li> <li>・植物体影響</li> <li>・鳥類経口急性毒性</li> <li>・分析バリデーション</li> <li>・ミッバチ半野外影響</li> </ul>
2013年12月	Final Work Plan	◇エビデンスの重み付け(WOE)に基づき、免疫毒性試験は不要と結論付けた。

	(PYU15)	パブコメ結果から、加水分解試験及び土
	POF 2	壌分解試験は不要となった。
	EPA-HQ-OPP-201	◇データギャップ更新

		するよう要求。
	Pymetronzine_Re quest of the appli	•Technical guidance on the
		interpretation of points 3.6.3. to
		3.6.5, and 3.8.2 of Annex II to
		Regulation (EC) No 1107/2009, in particular regarding the assessment
		of negligible exposure to an active
		substance in a plant protection
		product under realistic conditions of use"; SANCO-2014-12096.
		•EFSA Guidance on the assessment
		of exposure of operators, workers,
		residents and bystanders in risk
		assessment for plant protection
		products (EFSA Journal 2014;
		12(10):3874).
		◇主な変更点
		・技術的に可能な限りばく露を低減するための
		緩和策の検討
		・急性 AOEL の設定と、操作者、作業者、傍 観者、居住者の関連暴露量の算出

#### I. PURPOSE & SCOPE

The Environmental Protection Agency's (EPA) Office of Pesticide Programs (OPP) is a licensing program regulating pesticides in the U.S under the Federal Insecticide, Fungicide, and Rodenticide Act (FIFRA) and the Federal Food, Drug, and Cosmetic Act (FFDCA). As part of this program, OPP evaluates a substantial body of toxicology and exposure data to assess the effects of pesticides on human health and the environment. In evaluating human health, EPA looks first for information directly evaluating the potential for effects to people, including epidemiological data. Historically, however, few epidemiology studies have been available to inform the potential toxicity of pesticide chemicals. As such, OPP has in the past primarily relied on toxicology studies in laboratory animals to assess the hazard potential and to estimate human health risk. With the publication of numerous papers from the Agricultural Health Study<sup>1</sup> and from the National Institute of Environmental Health Sciences (NIEHS)/EPA Children's Centers<sup>2</sup>, among others, the availability of epidemiology studies conducted on U.S.-relevant exposures to pesticides is increasing. Nevertheless, since the number of pesticides for which quality epidemiology data either exist or are being developed remains relatively low in the near term, experimental laboratory data will likely continue to be the primary source of data for use in quantitative risk assessment for most pesticides.

OPP's goal is to use such information -- when available -- in a scientifically robust and transparent way. To accomplish this, OPP has developed a general epidemiologic framework, as described in this document, that outlines the scientific considerations that OPP will weigh in evaluating how such studies and scientific information can be more fully integrated into risk assessments of pesticide chemicals. The current document is neither a binding regulation nor is it intended to be or serve as a reviewer's guide or manual or as a Standard Operating Procedure for assessing or using epidemiology data. Nor is it intended to be a full treatise on more modern or advanced epidemiological methods or to adequately convey the nuances and complexity that is important for interpreting these types of studies. As such, it does not discuss (or does not discuss in any detail) such important epidemiological topics as causal inference and causal diagrams (Rothman et al., 2012a; Glymor and Greenland, 2012); more recent approaches to confounder identification, assessment, and control; meta-analysis and heterogeneity and its assessment/evaluation (Borenstein et al., 2009; Greenland and O'Rourke, 2012); or sensitivity/quantitative bias analysis for epidemiologic data (Lash et al., 2009; Lash et al, 2014; Ioannidis, 2008; Greenland and Lash, 2012; Jurek et al., 2007). All these topics, concepts, and issues can and do apply to epidemiology studies concerning pesticides, but are not covered in this OPP framework document. Instead, this document provides overall conceptual considerations concerning the evaluation and use of epidemiology studies on pesticides in

<sup>&</sup>lt;sup>1</sup> https://aghealth.nih.gov/

 $<sup>^{2}\</sup> https://www.epa.gov/research-grants/niehsepa-childrens-environmental-health-and-disease-prevention-research-centers$ 

the context of human health risk assessments to support OPP's FIFRA and FFDCA activities. An earlier version of this document was reviewed favorably by the FIFRA Scientific Advisory Panel (SAP) in February, 2010 (USEPA, 2010; FIFRA SAP, 2010). This document incorporates improvements recommended by the SAP, public comments, and the experience gained since 2010 conducting assessments on several pesticides for which epidemiological data were available, and should be considered a document that will be updated from time-to-time as we progress and on as-needed basis

#### II. INTRODUCTION

Two reports by the National Research Council (NRC) of the National Academy of Science (NAS), "Toxicity Testing in the 21st Century: A Vision and A Strategy (2007)" and "Science and Decisions (2009)," together provide new directions in toxicology and risk assessment. These two NRC reports advocate far reaching changes in how toxicity testing is performed, how such data are interpreted, and ultimately how regulatory decisions are made. Specifically, the 2007 report on 21<sup>st</sup> century toxicity testing advocates a shift away from the current focus of using apical toxicity endpoints to using toxicity pathways<sup>3</sup> to inform toxicity testing, risk assessment, and ultimately decision making. This approach is based on the rapidly evolving scientific understanding of how genes, proteins, and small molecules interact to form molecular pathways that maintain cell function in human cells. The goal for the new toxicity testing paradigm is to determine how exposure to environmental agents can perturb these pathways, thereby causing a cascade of subsequent key events leading to adverse health effects. Human information like that found in epidemiology studies, human incident databases, and biomonitoring studies, along with experimental toxicological information are expected to play a significant role in this new approach. Specifically, these types of human information provide insight into the effects caused by actual chemical exposures in humans and thus can contribute to problem formulation and hazard/risk characterization. In addition, epidemiologic and human incident data can guide additional analyses or data generations (e.g., dose and endpoint selection for use in *in vitro* and targeted *in vivo* experimental studies), identify potentially susceptible populations, identify new health effects, or confirm the existing toxicological observations.

This new vision of toxicity testing and risk assessment will involve data from multiple levels of biological organization ranging from the molecular level up to population-based surveillance with a goal of considering chemical effects from their source to the ultimate health outcome and effects on populations. Such data will come from *in vitro* and *in vivo* experimental studies along with *in silico* and modeled data. OPP's framework for incorporating epidemiology and incident data is conceptually consistent with the 2007 NRC report on 21<sup>st</sup> century toxicity testing in that both emphasize the use of the best available information from multiple data sources are compiled in a weight of the evidence (WOE) analysis.

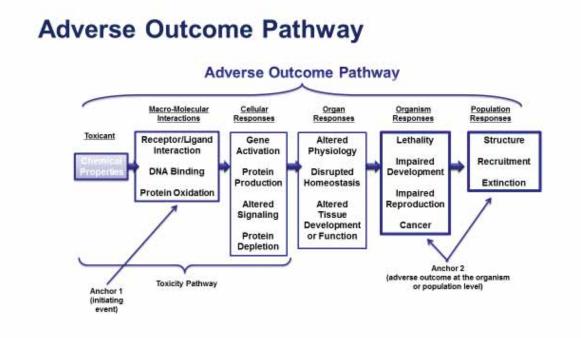

<sup>&</sup>lt;sup>3</sup> Toxicity pathways are cellular response pathways that, when sufficiently perturbed, are expected to result in adverse health effects.

As a general principle, occupational and environmental epidemiology studies are conducted only on widely used pesticides; these pesticides also tend to have to be wellstudied in the scientific literature. Thus, OPP expects in many cases where epidemiologic data are available, a significant body of literature data on toxicology, exposure, pharmacokinetics (PK), and mode of action/adverse outcome pathway information (MOA/AOP) may also be available. Human incident data are available on a broader range of chemicals, some of which have robust databases and others which do not. In those situations, where there are significant human incident cases and little is known about the MOA/AOP or PK of a particular pesticide, the WOE analysis can be used to identify areas of new research.

OPP's approach in this framework for incorporating epidemiology and human incident data is not a new or novel approach. Instead, this approach is a reasonable, logical extension of existing tools and methods. This document relies on existing guidance documents and frameworks (Table 1) as the starting point for reviewing and evaluating epidemiology and human incident data for use in pesticide risk assessment. This framework on using epidemiology and incident data in human health risk assessment is consistent with the recommendations of the NRC in its 2009 report on *Science and Decisions*, and with the agency's recent Human Health Risk Assessment Framework (USEPA, 2014a) with respect to emphasizing the use of problem formulation as a tool for scoping, planning, and reviewing available, particularly in the context of risk management needs.

Similarly, OPP's framework is consistent with updates to the World Health Organization/International Programme on Chemical Safety MOA/human relevance framework, which highlights the importance of problem formulation and the need to integrate information at different levels of biological organization (Meek et al., 2014). The MOA/HR framework begins with identifying the series of key events that are along the causal path, that are established on weight of evidence, using principles like those described by Bradford Hill, taking into account factors such as dose-response and temporal concordance, biological plausibility, coherence and consistency (Hill, 1965). Using this analytic approach, epidemiologic findings can be evaluated in the context of other human information (including human incident findings) and experimental studies and for identifying areas of uncertainty and future research. However, it is noteworthy that the availability of a fully elucidated MOA/AOP is a not requirement for using epidemiology studies in human health risk assessment. As the agency continues to move forward in implementing the transformative approach in the 2007 and 2009 NRC reports and as OPP gains experience in integration of epidemiology and human incident information, OPP will re-evaluate and update this framework as appropriate.

### Table 1. Key guidance documents and frameworks used by OPP

	1983: Risk Assessment in the Federal Government: Managing the Process	
	1994: Science and Judgment	
NAS	2007: Toxicity Testing in the 21st Century	
	2009: Science and Decisions: Advancing Risk Assessment	
	2011: NAS report on Formaldehyde	
	2014: Review of EPA's Integrated Risk Information System (IRIS) Process	
	2001-2007: Mode of Action/Human Relevance Framework	
WHO/IPCS	2005: Chemical Specific Adjustment Factors (CSAF)	
	2014: New developments in the evolution and application of the WHO/IPCS framework on mode of action/species concordance analysis.	

	1991-2005: Risk Assessment Forum Guidances for Risk Assessment (e.g., guidelines for carcinogen, reproductive, developmental, neurotoxicity, ecological, and exposure assessment, guidance for benchmark dose modeling, review of reference dose and reference concentration processes) <sup>4</sup>	
EPA	2000: Science Policy Handbook on Risk Characterization	
	2006b. Approaches for the Application of Physiologically Based Pharmacokinetic (PBPK) Models and Supporting Data in Risk Assessment	
	2014a. Framework for Human Health Risk Assessment to Inform Decision Making.	
	2014b. Guidance for Applying Quantitative Data to Develop Data-Derived	
	Extrapolation Factors for Interspecies and Intraspecies Extrapolation	
	2001: Aggregate risk assessment	
OPP	2001 and 2002: Cumulative risk assessment	
OECD	2013: Organisation for Economic Co-operation and Development Guidance Document On Developing And Assessing Adverse Outcome Pathways	

Although there are other sources of human information, the focus of this framework is on interpreting and using *epidemiology* and *human incident data* in human risk assessment; other sources of human information are not addressed in this document in any depth. Specifically, this document does not extensively discuss research with pesticides involving intentional exposure of human subjects<sup>5</sup> or on studies done to measure dermal or inhalation exposures in agricultural workers as they perform their activities<sup>6,7</sup>.

<sup>&</sup>lt;sup>4</sup> https://www.epa.gov/osa/products-and-publications-relating-risk-assessment-produced-office-science-advisor

<sup>&</sup>lt;sup>5</sup> Both the conduct of such research and OPP's reliance on data from such research are governed by EPA's Rule for the Protection of Human Subjects of Research (40 CFR Part 26.) Among other things, these rules forbid research involving intentional exposure of pregnant or nursing women or of children, require prior review of proposals for new research by EPA-OPP and by the Human Studies Review Board (HSRB), and require further review by EPA-OPP and the HSRB of reports of completed research.

<sup>&</sup>lt;sup>6</sup> In the last several years, OPP has extensively evaluated existing observational studies with agricultural workers in efforts to improve the data and approaches used in worker exposure assessment; those evaluations can be found elsewhere (http://www.epa.gov/scipoly/sap/meetings/2007/010907\_mtg.htm)

<sup>&</sup>lt;sup>7</sup> For additional information on how such worker exposure studies are conducted and used by OPP, see PPP-48 "Pesticides and human Health Risk Assessment: Policies, Processes, and Procedures "available at <u>https://www.extension.purdue.edu/extmedia/PPP/PPP-48.pdf</u>.

#### III. SYSTEMATIC REVIEW IN PESTICIDE RISK ASSESSMENT: EPIDEMIOLOGY

In recent years, the NRC has encouraged the agency to move towards systematic review processes to enhance the transparency of scientific literature reviews that support chemical-specific risk assessments to inform regulatory decision making (NRC 2011, 2014). The NRC defines systematic review as "a scientific investigation that focuses on a specific question and uses explicit, pre-specified scientific methods to identify, select, assess, and summarize the findings of similar but separate studies" (NRC, 2014). Consistent with NRC's recommendations, the Office of Chemical Safety and Pollution Prevention (OCSPP) employs fit-for-purpose systematic reviews that rely on standard methods for collecting, evaluating and integrating the scientific data supporting our decisions.

According to the NRC, systematic reviews "have several common elements: transparent and explicitly documented methods, consistent and critical evaluation of all relevant literature, application of a standardized approach for grading the strength of evidence, and clear and consistent summative language (NRC, 2014)." In recent years, several groups (Rooney et al., 2014; Woodruff and Sutton, 2014; Hartung, 2010) have published systematic review approaches for use in environmental health sciences. The OCSPP approach to systematic review is consistent with the principles articulated in the Cochrane Handbook for Systematic Reviews of Interventions for evidence-based medicine and with the principles of the Grading of Recommendations Assessment, Development and Evaluation (GRADE). GRADE guidelines used by systematic review approaches for environmental health sciences developed by the National Institute of Environmental Health Sciences (NIEHS) Office of Health Assessment and Translation (OHAT) (Rooney et al., 2014) and University of California, San Diego (Woodruff and Sutton, 2014). According to the *Cochrane Handbook*, the key characteristics of a systematic review are:

- a clearly stated set of objectives with pre-defined eligibility criteria for studies;
- an explicit, reproducible methodology;
- a systematic search that attempts to identify all studies that would meet the eligibility criteria;
- an assessment of the validity of the findings from the identified studies;
- a systematic presentation and synthesis of the characteristics and findings of the included studies.

Each approach mentioned above share common themes and workflow starting with a statement of scientific context (e.g., problem formulation or protocol) followed by literature review with explicit search strategy methods, analysis of study quality (often called risk of bias), evaluation of the quality of the totality of the evidence (e.g., integration) and ultimately leading to a conclusion(s). Each approach recommends transparent and pre-determined criteria for inclusion/exclusion of scientific literature, evaluation of study quality, and reporting of study quality (e.g., high, medium, low). Each approach recommends a pre-stated tool for data integration that provides the foundation for the conclusion(s).

So far, no single nomenclature has been agreed upon by the risk assessment community for systematic review and OCSPP expects terminology to evolve over time as more broad experience is gained. OCSPP considers its systematic review process and workflow as starting with problem formulation followed by data collection, data evaluation, data integration, and summary findings with critical data gaps identified. Scientific analysis is often iterative in nature as new knowledge is obtained.

### A. Problem Formulation

In the NRC report *Science and Decisions-Advancing Risk Assessment*, the National Academy of Sciences (NAS) recommended to EPA that risk assessments and associated scientific analyses be developed to be useful to policy makers; in order to attain this goal, the NRC recommended that the agency more broadly use problem formulation in developing its risk assessments. In response to the NRC, the agency published the Human Health Risk Assessment Framework (USEPA, 2014) which highlights the importance of problem formulation. Problem formulation entails an initial dialogue between scientists and risk managers and provides the regulatory context for the scientific analysis and helps define the scope of an analysis. Problem formulation draws from regulatory, decision-making and policy context of the assessment, informs the technical approach to the assessment and systematically identifies the major factors to be considered. As such, the complexity and scope of each systematic review will vary among the different risk assessment contexts. In other words, an OCSPP systematic review is conducted as "fit-for-purpose" (NRC, 2009) based on the pre-determined scope and purpose determined from problem formulation.

The problem formulation involves consideration of the available information along with key gaps in data or scientific information. OPP uses problem formulation as a tool to identify exposure pathways and potential health outcomes along with the appropriate methods, data sources, and approaches for the scientific analysis. If missing data are critical to the assessment, options are discussed as to how best to obtain that information (e.g., required testing, research). The peer review process is identified and the timeline for completing the assessment is defined.

Systematic review provides a transparent tool for organizing available information and identifying gaps in information for the regulatory purpose for the analysis. As such, in problem formulation, the regulatory context of a scientific analysis is described which in turn defines the scope of and purpose for collection and evaluation of scientific literature. Some considerations in problem formulation may be related to population or life-stage, exposure pathways (e.g., route, duration, frequency), and/or health outcomes of interest identified from *in vitro* or *in vivo* laboratory studies along with epidemiology or human incident studies along with resources available and regulatory timeframe. In the context of considering epidemiology and human incident information, an initial evaluation of the study quality, study design, and uncertainties are considered. Key scientific issues related to hazard assessment considered in problem formulation include: What are the effects associated with exposure? What are the MOA/AOPs associated with these effects? What are the temporal aspects of the effects? Are there susceptible populations and if so, who are they and what factors contribute to susceptibility? Are there differences in PK or pharmacodynamics (PD) between laboratory animals and humans? Exposure information is also evaluated in problem formulation. Key scientific issues related to exposure assessment considered in problem formulation include: How is the pesticide used? What are all of the relevant use sites of exposure? To what chemical substances will people be exposed? What are the routes, durations, and frequencies of exposures? Who may be exposed? Does the exposure pose different risks to different groups (e.g., due age or activity patterns?) In the specific case of epidemiology data, this review considers a variety of factors including, but not limited to, research hypothesis, study design (i.e., sample size, sufficient controls, quality of measurements, etc.), exposure dose/concentration, statistical analysis, and conclusions.

# B. Data Collection

The data collection phase of systematic review is the collection of available information from various published and unpublished sources, such as the open scientific literature and submitted studies for pesticide registration. OPP reviews data collected under the Organisation for Economic Cooperation and Development (OECD) test guidelines, OCSPP harmonized test guidelines, and other pesticide (OPP guidelines). These guideline studies are collected primarily from in-house databases of submitted studies and are found through searches of such internal databases.

In the case of epidemiology, most studies are expected to be found in the open scientific literature. Although in some cases supplemental analyses or information may be available, dialogue with the researchers may provide additional, important information not published in the original paper in understanding and interpreting epidemiology studies. The sources of human incident information are summarized in Section IV.

Open literature search strategies use specified criteria to retrieve health effects information from the open scientific literature and unpublished sources. After identifying and selecting the most appropriate sources/databases and determining the most resource effective strategy utilizing classification codes, medical subject headings, and/or keywords, a search is conducted of the literature. Depending on the complexity of the scientific evaluation, support from a reference librarian may or may not be needed. The goal of a human health literature search is to perform a reliable and reproducible literature search by providing proper documentation of the literature search process. The following steps are conducted to retrieve relevant studies:

- The purpose of the scientific analysis and inclusion criteria are established.
- Combinations of terms/key words and/or MeSH (Medical Subject Heading) terms and their Boolean combinations (AND; OR; NOT) are used and documented.

Advanced Search and Field Search by author, title, keywords or subject heading may also be performed as needed. Knowledge of database structure, and using a separate search strategy for a specific database is helpful in retrieving relevant studies. In addition to an initial comprehensive search, periodic searches may be conducted to update the literature list.

- The search strategy is documented, including the date(s) of the search(es) to ensure that all the searches of all the databases are reproducible.
- Reference lists of retrieved articles are examined<sup>2</sup> for additional background and to look for articles that were not discovered in the initial search.
- After combining the retrieved articles from different databases and removing duplicates, the available titles and abstracts are screened. For some of the articles where relevance could not be determined from the title and the abstract, the article is retrieved for further review.
- Following the initial screening, articles that were not relevant (exclusion criteria) such as opinion articles, studies not in English, and those consisting only of abstracts are excluded. Additional exclusion criteria can be identified on a case by case basis. All exclusion criteria are documented. The rest of the articles, even those that found no adverse health effects, are included for review and evaluation.

# C. Data Evaluation

In the data evaluation phase, data quality is reviewed and conclusions are made about the utility of such data. Study quality reflects the overall confidence that reports findings are correct (Balshem et al., 2011). As such, study quality can include:

- reporting quality (how well or completely a study is reported);
- how credible the findings are based on the design and conduct of the study;
- and how well the study addresses the topic under review (Rooney et al., 2014).

Study quality is first considered on an individual study basis, and the quality is judged. For example, one may have stronger confidence in a well conducted case control study than a poorly conducted cohort study. Credibility of the scientific findings, often called risk of bias, is evaluated using pre-determined criteria for specific domains related to study design and conduct (See Table 2).

OPP initially developed a guidance on using the open scientific literature considerations called the "Guidance for Considering and Using Open Literature Toxicity Studies to Support Human Health Risk Assessment" (USEPA, 2012) and generally continues to follow this guidance. However, with the acceleration of systematic review in risk assessment, some aspects of the literature guidance may need updating in the future. Conclusions about the quality of the data are made and can be described in conclusion statements or categories (e.g., acceptable/not acceptable; low, medium, high).

Specific considerations used in evaluating epidemiology studies on pesticide chemicals are provided in Section III.C below. As part of the data review, a concise written review of the study is developed. This written review describes the study design, results, conclusions, and the strengths and weaknesses of the study. The quality of the epidemiologic exposure assessment is an important factor in determining what role epidemiologic data will play in the risk assessment. As such, it is important to fully characterize the assumptions used in the epidemiologic exposure assessment and the degree to which these assumptions affect the interpretation and generalizability of the epidemiologic findings. The evaluation of the epidemiologic exposure assessment may include a consideration of past and present exposure patterns (e.g., exposed populations, pathways, routes, and levels of exposure) and may include significant changes in use patterns (e.g., risk mitigation actions or new use patterns). With regard to evaluating meta-analyses, reporting guidelines for Meta-analysis Of Observational Studies in Epidemiology (MOOSE) have been developed by Stroup et al., (2000) that are useful in evaluating the quality and interpreting meta-analysis.

# D. Data Integration: Weight of Evidence (WOE)

OPP's human health characterizations involve the consideration of all available and relevant data, including but not limited to human studies/epidemiology, biomonitoring data, *in vitro* and *in vivo* experimental laboratory toxicological studies, MOA/AOP information, pharmacokinetic studies, and structure-activity relationships (SAR). Once the different types of hazard data are collected and a full evaluation of each relevant study is conducted and documented, the next step is to integrate multiple lines of evidence.

Data integration is based on the principle of reaching a judgment of the totality of the available negative and positive data for relevant hazards. OPP uses a WOE analysis for evaluating epidemiology and human incident data, such conclusions are made on the preponderance of the information rather than relying on any one study. OPP uses the modified Bradford Hill criteria like those in the MOA/human relevance framework as a tool for organizing and integrating information from different sources (Hill, 1965; U.S. EPA, 1999, 2005; Sonich-Mullin et al., 2001; Meek et al., 2003; Seed et al., 2005; OECD AOP Wiki Users Handbook<sup>8</sup>). It is important to note that the Hill Criteria are not intended as a check box approach but instead are points to consider when evaluating the totality of evidence. In addition, the availability of a fully elucidated MOA/AOP is a not requirement for using epidemiology studies in human health risk assessment. However, even in the absence of a fully developed MOA/AOP, collection and evaluation of mechanistic data may provide support for biological plausibility and help explain differences in tissue sensitivity, species, gender, life-stage, or other factor. The MOA/human relevance framework is a flexible tool which provides a foundation for organizing information without rigidity. It is this

<sup>&</sup>lt;sup>8</sup> https://aopwiki.org/wiki/index.php/Main\_Page#OECD\_User\_Handbook

flexibility that makes it a useful tool for a variety of purposes such as evaluating causality, integrating information across multiple lines of scientific evidence, and identifying data gaps and areas of future research. In this analysis, epidemiologic findings and human incident data can be evaluated in the context of other human information and experimental studies to evaluate biological plausibility, to identify areas of uncertainty and areas of further research. To describe how Bradford Hill aspects are considered in the WOE evaluations, OPP has used some definitions of terms as outlined in EPA's Preamble to the Integrated Science Assessments (ISAs) which serve as a scientific foundation for the review of EPA's National Ambient Air Quality Standards (NAAQS). (USEPA, 2015).

- **Key events.** In cases where the MOA/AOP are established for a particular health outcome, a clear description of each of the key events (i.e., measurable parameters) that underlie the MOA/AOP are given. Data to inform the key events may come from a combination of *in vitro* or *in vivo* data sources (human or animal). These key events can be a combination of PK and PD events. However, it noteworthy that the availability of a fully elucidated MOA/AOP is a not requirement for using epidemiology studies in human health risk assessment.
- Biological Gradient/Exposure-Response/Dose-Response Concordance & Relationships. The Preamble to the ISAs notes that "In the context of epidemiology, a well-characterized exposure-response relationship (e.g., increasing effects associated with greater exposure) strongly suggests cause and effect, especially when such relationships are also observed for duration of exposure (e.g., increasing effects observed following longer exposure times) (USEPA, 2015)." When the MOA/AOP is known, dose-response relationships are identified for each key event. Dose-response relationships are compared among key events. In some cases, the earlier key events may be more sensitive than later key events. In other cases, key events may share similar dose-response curves.
- **Temporal association**. Evidence of a temporal sequence between the introduction of an agent and appearance of the effect constitutes another argument in favor of causality (USEPA, 2015). The Preamble to the ISAs notes that "Strong evidence for causality can be provided through 'natural experiments' when a change in exposure is found to result in a change in occurrence or frequency of health."

This analysis considers key events which occur rapidly (e.g., metabolism to an active metabolite which could occur within minutes of exposure) and those which occur after longer durations (e.g., development of a tumor) to ensure coherence of the effects. Specific to considering epidemiology data, the temporal relationship between the exposure and health outcome may be considered.

# • Strength, consistency, and specificity.

*Consistency:* An inference of causality is strengthened when a pattern of elevated risks is observed across several independent studies. The reproducibility of findings constitutes one of the strongest arguments for causality. Statistical significance is not the sole criterion by which the presence or absence of an effect is determined. If there are discordant results among investigations, possible reasons such as differences in exposure, confounding factors, and the power of the study are considered (USEPA, 2015).

Consistency of findings across studies is informed by the repeated observation of effects or associations across multiple independent studies. Further support is provided by reproducibility of findings in different populations under different circumstances. However, discordant results among independent investigations may be explained by differences in study methods, random errors, exposure, confounding factors, or study power, and thus may not be used to rule out a causal connection (USEPA, 2015).

*Strength of the observed association:* The finding of large, precise risks increases confidence that the association is not likely due to chance, bias, or other factors. However, it is noted that a small magnitude in an effect estimate may or may not represent a substantial effect in a population (USEPA, 2015).

*Specificity of the observed association:* Evidence linking a specific outcome to an exposure can provide a strong argument for causation. However, it must be recognized that rarely, if ever, do environmental exposures invariably predict the occurrence of an outcome, and that a given outcome may have multiple causes (USEPA, 2015).

# • Biological plausibility and coherence.

*Coherence:* An inference of causality from one line of evidence (e.g., epidemiologiccontrolled human exposure, animal, or ecological studies) may be strengthened by other lines of evidence that support a cause-and-effect interpretation of the association. There may be coherence in demonstrating effects from evidence across various fields and/or across multiple study designs or related health endpoints within one scientific line of evidence (USEPA, 2015).

When animal and human data show a similar toxic profile, both quantitatively and qualitatively, there is high confidence in the human health risk assessment. Whereas in other cases, animal and human data may show a qualitatively similar toxic profile but quantitative differences are observed. For example, a particular chemical exhibits the same MOA/AOP in animals and humans but there may be species differences in dose-response characteristics. These dose-response differences could be due to tissue dosimetry (i.e., PK) or from different response characteristics (i.e., PD). In contrast, animal and human data can, in some instances, show qualitatively dissimilar outcomes. This situation highlights the need to fully and objectively evaluate all available information in a

transparent and comprehensive manner to consider factors such as species, gender, and life-stage differences and potential susceptibilities along with study design considers and exposure potential.

*Biological plausibility:* An inference of causality is strengthened by results from experimental studies or other sources demonstrating biologically plausible mechanisms. A proposed mechanism, which is based on experimental evidence and which links exposure to an agent to a given effect, is an important source of support for causality (USEPA, 2015).

Similarly, information on MOA/AOP for a chemical, as one of many structural analogs, can inform decisions regarding likely causality. Structure activity relationships and information on the agent's structural analogs can provide insight into whether an association is causal (USEPA, 2015).

EPA's Cancer Guidelines (2005) indicate:

"evaluation of the biological plausibility of the associations observed in epidemiologic studies reflects consideration of both exposure-related factors and toxicological evidence relevant to identification of potential modes of action (MOAs). Similarly, consideration of the coherence of health effects associations reported in the epidemiologic literature reflects broad consideration of information pertaining to the nature of the biological markers evaluated in toxicologic and epidemiologic studies. [p. 39]."

However, The Cancer Guidelines further state that *"lack of mechanistic data, however, is not a reason to reject causality* [p. 41]." As such, lack of established MOA/AOP is not necessary knowledge when using epidemiology data and epidemiology associations may still be valid even in the absence of an established MOA/AOP and may also provide insight into potential MOA/AOP.

• **Uncertainties**. Uncertainties are discussed in the WOE transparently and objectively.

# E. Overall conclusions, recommendations for risk assessment, statement of areas of confidence and uncertainty

It is important to document a summary of the evidence, the procedures or methods used to weigh the evidence, the basis for the WOE conclusion or recommendation, any uncertainties and areas for further research. Recommendations are made on the role of the epidemiologic or human incident data in the risk assessment. Generally, OPP does not use human incident information for quantitative risk assessment but instead to inform risk assessment/risk management activities such as indicating a potential need for a new risk assessment or new risk management measures, evaluating the success of risk mitigation actions after they are implemented, and targeting possible enforcement activities. In contrast to more limited role of human incident data, epidemiology studies have the potential to help inform multiple components of the risk assessment in a variety of ways. High quality studies with robust exposure assessment may be used to estimate a risk metric quantitatively. Alternatively, outcomes reported in epidemiologic studies may be compared qualitatively with those seen in *in vitro* and animal studies to evaluate the human relevance of animal findings (Hertz-Picciotto, 1995) and may be useful in assessing the biological plausibility of epidemiologic outcomes. In the final portion of the proposed WOE analysis, the overall conclusions along with statement of areas of confidence and uncertainty. This section also identifies areas of additional research. This section recommends the source of data for regulatory values and the appropriate approach for extrapolating between species (if necessary) and among humans.

### IV. REVIEWING EPIDEMIOLOGY STUDIES FOR USE IN PESTICIDE RISK ASSESSMENT

### A. Introduction

Epidemiology is a science that seeks to identify and evaluate relationships between exposure to chemical, physical or biological agents, and the health status of populations (Boyes et al., 2007). It has been defined as the "study of how disease is distributed in populations and the factors that influence or determine this distribution" (Gordis, 2009). More broadly, it is considered as "the study of the occurrence and distribution of healthrelated events, states, and processes in specified populations, including the study of the determinants influencing such processes and the application of this knowledge to control of relevant health problems" (Porta, 2014). The objective of much epidemiologic research is to obtain a valid and precise estimate of the effect of a potential cause on the occurrence of disease. A key objective of epidemiology, like other sciences, is determining cause and effect or - said differently - of identifying the etiology of a disease or health outcome and the risk factors with which it might be associated. Calderon (2000) described four major uses of such studies: 1) describe the health status of a population and discover important time trends in disease and exposure frequency; 2) explain the occurrence of diseases by identifying factors that are associated with specific diseases or trends; 3) predict the number of disease occurrences and the distribution of health states in specific populations; and 4) improving the health status of the population by identifying factors that affect environmental or human health. In the case of pesticides, epidemiology focuses on the relation between exposure and adverse health effects in the general population and in specific sub-populations, such as occupationally exposed workers or applicators.

Epidemiology studies have the potential to help inform multiple components of the risk assessment in a variety of ways. High quality studies with robust exposure assessment may be used to quantitatively estimate risk or an appropriate risk surrogate such as an odds ratio or risk ratio. However, many epidemiology studies that deal with pesticides and pesticide exposure suffer some limitations in size, scope, exposure assessment, or data analysis which prevent or otherwise impede their full use in quantitative risk assessment

(Ntzani et al., 2013). Pesticide use in the US has changed significantly over the last few decades. As the use changes, so does the exposure to workers. Changes in pesticide use have occurred due to risk mitigation actions by EPA, resistance management activities, introduction of new chemistries, and increased use of genetically modified crops. These significant changes in exposure have to be taken into account when interpreting epidemiology studies and, ultimately, the decision to use such studies in quantitative risk assessment. Even so, epidemiology studies may be used to compare with evidence from experimental animal studies to characterize assumptions used in deriving such values. In other cases, outcomes reported in epidemiologic studies may be compared qualitatively with those seen in *in vitro* and laboratory animal studies to evaluate biological plausibility or human relevance of animal findings (Hertz-Picciotto, 1995). Human information like that found in epidemiology studies are expected to potentially play a significant role in the new vision of toxicity testing recommended by the NRC (2007). Specifically, epidemiology studies can provide insight on health outcomes that may arise from real-world chemical exposures in humans and thus can contribute to problem formulation and hazard/risk characterization. Human information may guide additional studies (e.g., dose and endpoint selection for use in *in vitro* and targeted *in vivo* experimental studies); and identify novel health effects or host susceptibilities which can be investigated with future research.

When laboratory data from animal studies provide the primary source of information for hazard characterization, one potential source of uncertainty is the relevance of animal models to humans. In the absence of data to support the contrary, animal findings are assumed to be relevant to humans. Furthermore, EPA assumes that humans are more sensitive than laboratory animals in the absence of data to support the contrary. In actuality, humans may be more or less sensitive to pesticides than other animal species. Epidemiology and human incident data can provide scientific information and support to inform uncertainties associated with species extrapolation. With respect to population variability, epidemiology studies better characterize potential variability than do animal studies. Specifically, epidemiologic data include the genetic diversity, and variability inherent in human populations and thus can better account for and represent actual population response to environmental chemicals than laboratory animals (Calderon, 2000).

With respect to dose-response characterization, animal toxicology studies have the benefit that studies can be designed to cover a broad range of exposure levels. However, animal toxicology studies generally use exposures which are much larger (sometimes orders of magnitude) than those that occur in the environment. These high exposure levels in animal studies dictate the need for extrapolation from high to low doses. This extrapolation introduces added uncertainty into the risk assessment. Epidemiology studies and human incident data involve actual real-world exposures and thus high dose extrapolation may in many cases not be needed. Epidemiology studies conducted over a range of exposures (from low to high) are most useful.

Animal studies do not replicate the length, magnitude, duration, routes of exposure and variability in exposure experienced by humans (Calderon, 2000). Human exposure often occurs through multimedia exposure pathways, including food, water, air, and indoor and outdoor environments. In contrast, controlled laboratory studies typically use a single

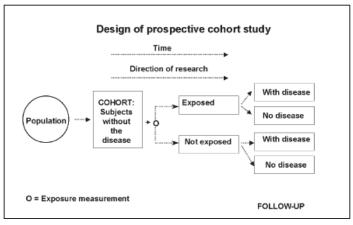

route of exposure. In addition, humans may experience exposure to multiple chemicals and/or non-chemical stressors simultaneously, whereas most animal studies involve a single chemical stressor. On one hand, this multi-chemical exposure in epidemiology studies can provide a challenge when attempting to attribute epidemiologic outcomes to a single pesticide chemical. On the other hand, epidemiologic research considers real-world exposures and may help, when considered along with experimental approaches, address questions associated with multiple chemical exposures which can be difficult to evaluate in an experimental setting.

# B. Types of Epidemiology Studies

The major types of observational epidemiologic studies are described briefly below with consideration of their strengths and weaknesses (Lilienfeld and Lilienfeld, 1979; Mausner and Kramer, 1985; Kelsey et al., 1996; Rothman and Greenland, 2012; Paddle and Harrington, 2000; USEPA, 2005; Purdue Pesticide Programs, PPP-43).

**Cohort studies** begin with a group of people that share common characteristics—the cohort—and evaluate their health over an extended follow-up time period during which the occurrence of disease is recorded (see figure box from van den Brandt et al. (2002)). The common characteristic is often the presence vs. absence of "risk factors" (such as

exposures)<sup>9</sup>. In such studies, differences in disease occurrence between the "exposed" and "nonexposed" individuals are identified and studied over time to determine differences in the rate of disease<sup>10</sup>. This difference in the rate of disease occurrence is then investigated to determine if the rate of disease differs between the exposed and non-exposed groups. Cohort studies have the ability to simultaneously evaluate multiple disease outcomes

under study (which is not true for case-control studies, which are generally limited to evaluating only a single (pre-specified) disease outcome, discussed below). Cohort studies can also be performed either prospectively, like the Agricultural Health Study (AHS, <u>http://aghealth.nci.nih.gov/</u>), or retrospectively from historical records. A prospective cohort design focuses on a group of people from a current point in time through a future point in time. A retrospective cohort design focuses on a group exposed at some point in the past, and compares disease rates after exposure occurred (generally through existing

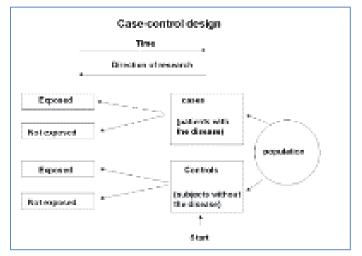

<sup>&</sup>lt;sup>9</sup> While exposure is often dichotomized on an exposed vs. non-exposed basis in cohort studies, exposure can also be measured on a quantitative scale (e.g., by a continuous measure or by quantiles)

<sup>&</sup>lt;sup>10</sup> Cohort studies commonly study differences in rates of disease, but these can also include other focal outcomes of interest such as birth weight, mental abilities, blood pressure, etc.

available exposure databases (or records) available on a person-by-person (individual) basis). Prospective cohort studies can be relatively lengthy and expensive to conduct, particularly for rare diseases, and require a large number of subjects to be under study. Importantly, significant resources and professional staff are required for a long period of time to collect high quality data.

**Case-control studies** are studies in which groups of individuals with (cases) and generally without (controls) a given disease are identified and compared with respect to (generally past<sup>11</sup>) exposure to determine whether those with the disease of interest are

more likely or no more likely to have been exposed to the agent(s) or factor(s) of interest. That is, the analysis of case-control studies contrasts the frequency of exposure of the agent or factor in the cases with those in the controls to determine if these differ and, thus, whether there is a differential association. In case-control studies, determination of the disease status (i.e., cases with the disease; controls without) generally precedes determination of the exposure status (see figure box from van den Brandt et

al. (2002)) Because disease has already occurred at the time of selection into the casecontrol study, this study design is particularly useful in studying uncommon diseases or diseases with long latency and can be utilized to evaluate the relation between many different exposures and a specific (pre-specified) disease outcome of interest. And because case-control studies begin with individuals who have the disease, the studies can involve fewer subjects than cohort studies and can be completed in a comparatively shorter time frame. Challenges in case-control investigations include the selection of an appropriate control group and the assessment of exposures which may have occurred long before the disease was diagnosed (Rothman, 2012; Wacholder et al. 1992a; Wacholder et al. 1992b; Wacholder et al. 1992c; Shultz and Grimes, 2002; Grimes and Schultz, 2005). Case-control studies can be particularly susceptible to "recall bias" in which diseased individuals may remember exposures or events differently (generally better) than those who serve as the controls and are healthy.

**Nested case-control studies** are an example of a hybrid design and contain the elements of a cohort and a case-control study. These designs can be useful when the analytical costs for determining pesticide exposure are too high for the entire cohort to be studies. For example, a cases that that have developed the disease or health outcome in an

<sup>&</sup>lt;sup>11</sup> It is possible for case-control studies to be done prospectively in which the cases have not yet developed the disease until after the study begins under which circumstance the cases are enrolled in the study over time.

ongoing cohort study can be matched with appropriate controls from the study that have not yet developed the disease or outcome of interest at the time of the analysis. One recognized advantage of the nested case-control study (as opposed to a more standard case-control study) is that the issues of selection bias and recall bias are minimized.

Cross-sectional studies focus on the prevalence of disease (e.g., birth defects, smallfor-gestational age or SGA), symptoms, biological/physical and physiologic response measurements (e.g., pulmonary function tests, blood pressure, chest X-ray, clinical examinations, liver and kidney biomarkers). A key feature of such studies is that they are observational studies which focuses on the *prevalence* as a frequency measure, with the presence or absence of disease determined at the time of sampling or over a sampling period. Prevalence is the proportion of individuals in a population that has the disease and can either be determined as a "point prevalence" or as a "period prevalence".<sup>12</sup> A prevalence is a proportion not a rate and thus the cross sectional studies do not involve a follow up period. Typically, the exposure status (e.g., exposed or unexposed), disease status/outcome, and demographic characteristics are determined at a point in (or over) time. The major comparison in this study design is a comparison of the prevalence of the outcome in the exposed population vs. the prevalence of that outcome in the non-exposed population, with the risk measure being the prevalence risk ratio or odds ratio. Crosssectional studies are generally used to identify patterns or trends in disease occurrence over time or in different geographical locations, and can be conducted guickly and relatively inexpensively. However, they measure the prevalence of a disease outcome which is affected by both incidence – the rate of occurrence of new cases – and duration of the disease, and it can be difficult in any analysis to sufficiently separate these factors. Thus, they involve "survivor populations" and do not measure, evaluate, or consider those that have left the population of interest because they became ill. Another important limitation of cross-sectional studies is they do not allow one to determine whether exposure precedes the disease. As such, cross-sectional studies are unable to establish temporal relationships between disease and exposure and typically require additional studies to confirm a hypothesized causal association suggested by a cross-sectional study.

**Ecologic studies** examine exposure and disease patterns using information reflecting group or population-level data. In an ecologic study, the unit of analysis is a group and not an individual<sup>13</sup>. Here, groups of subjects are sampled, with the exposure, disease, and potential confounding factors measured at this group (or cluster) level. Groups are generally defined on a geographic, administrative, or organizations unit basis (e.g., districts, towns, counties, schools, workplaces, etc.) with all exposure, disease, or confounder measurements made or summarized at the group level rather than at the level of the individual. An ecological (group-based) study contrasts with an individual-level study in that in the former there is no information on whether the cases are the actual individuals

<sup>&</sup>lt;sup>12</sup> The former involve measurements at a particular place and/or a particular time while the latter involves determinations of the proportion of cases over a given time period.

<sup>&</sup>lt;sup>13</sup> Some studies can be "partially ecologic" in design in which either the exposure or the disease outcome is measured on a group level but the other variable is measures at an individual level with the researcher making inferences to the individual level.

with the exposure whereas in the latter exposure information is tied to the individual. As an example, a study of disease rates by contaminant levels in water can be ecologic with respect to evaluation of the exposure, but the health outcome or disease status may have determined on an individual basis. In these instances, the term "semi-ecological" can sometimes be used when exposure is determined at the group level but outcome is determined at the level of the individual.

Using this design, it is not possible to know whether all members of the exposed group are individually exposed (or the individual exposure levels) nor is it possible to infer individual-level effects from the group level effects that result. If the intent of the study is to direct inferences to the *group* (rather than the individual), then this is <u>not</u> a concern and these studies can be appropriate, particularly if measurements are constrained or difficult to perform at the individual level and exposures within the group are generally homogenous. If the intent of the study is instead to direct inferences to the individual, then this study design suffers from what is termed the ecological fallacy: the assumption that an observed relationship in an aggregated or grouped data set will reflect what would have been observed had the sampling occurred at the individual level. In addition to this ecological fallacy issue, an additional bias arises a result of the inability to appropriately control for confounding variables at the level of the individual as opposed to the group when information on confounding factors is only available at the group level.

In most cases, ecologic studies are considered as hypothesis-generating studies and best used for suggesting research hypotheses for future studies and may contribute to problem formulation. Nevertheless, it is important to assess ecological studies on the basis of the quality of their design, and useful information can be gleaned from an ecologic study if it is well-designed (FIFRA SAP, 2010). Ecologic studies alone generally do not have the ability to establish a causal association. When taken with other these studies can be useful under certain circumstances and should be noted in the hazard characterization. In particular, stable populations, clear exposure contrasts, and large differences in risk can be important factors that might increase the utility of these studies.

### C. Evaluating epidemiology studies for use in pesticide risk assessment

OPP searches the peer reviewed literature for observational epidemiology studies of potential adverse acute and chronic health effects linked to chemical use. Details regarding literature search protocols and strategies are provided elsewhere. Epidemiologic research utilizing cohort, case-control, or cross-sectional study designs may provide information to OPP to strengthen OPP's understanding of the potential hazards, exposure-response characterization, exposure scenarios. or assessment methods, and – ultimately -- risk characterization (van den Brandt, 2002). In addition, compelling case reports or case series analysis may illumine a health effect or mechanism of action previously unidentified.

Generally speaking, the quality of epidemiologic research, sufficiency of documentation of the study (study design and results), and relevance to risk assessment is considered when evaluating epidemiology studies from the open literature for use in OPP's

risk assessments. It is important that these criteria are endpoint-specific as various methodological details become more or less important given the endpoint of concern. For example, it is important to understand relevant factors that influence outcome ascertainment (*e.g.*, is there a test or a biomarker available to indicate presence of an effect, or are symptoms gradual and non-specific initially leading to physician diagnosis upon advanced disease state). In addition, for environmental and occupational epidemiology studies, the quality of the exposure assessment is vitally important. Prior consideration must be given to aspects of exposure and confounder measurement to the question under consideration.

When considering individual study quality, various aspects of the design, conduct, analysis and interpretation of the epidemiology studies are important. These include:

- 1. Clear articulation of the hypothesis, even if the study is hypothesis-generating in nature;
- 2. Adequate assessment of exposure for the relevant critical windows of the health effects, the range of exposure of interest for the risk assessment target population, and the availability of a dose/exposure-response trend from the study, among other qualities of exposure assessment,
- 3. Reasonably valid and reliable outcome ascertainment (the correct identification of those with and without the health effect in the study population),
- 4. Appropriate inclusion and exclusion criteria that result in a sample population representative of the target population, and absent systematic bias,
- 5. Adequate measurement and analysis of potentially confounding variables, including measurement or discussion of the role of multiple pesticide exposure, or mixtures exposure in the risk estimates observed,
- 6. Overall characterization of potential systematic biases in the study including errors in the selection of participation and in the collection of information; this can include performing sensitivity analysis to determine the potential influence of systematic error on the risk estimates presented (*e.g.*, Greenland's formula)
- 7. Evaluation of the statistical power of the study to observe health effects with appropriate discussion and/or presentation of power estimates,
- 8. Use of appropriate statistical modeling techniques, given the study design and the nature of the outcomes under study

Other Federal and non-Federal entities have offered such guides (*e.g.*, OHAT, Navigation Guide, National Toxicology Program [NTP] Report on Carcinogens [ROC<sup>14</sup>], IRIS, Cochrane ACROBAT-Non-Randomized Studies of Interventions) (Sterne et al., 2015 as well as the STROBE (Strengthening the Reporting of Observational Studies in Epidemiology) statement for observational epidemiological studies (see <u>www.strobe-statement.org</u> and Vandenbroucke et al., 2007; Von Elm, 2014) As OPP gains experience with integrating epidemiology studies into human health risk assessment, relevant adjustments to its evaluation approach will be made.

<sup>&</sup>lt;sup>14</sup> http://ntp.niehs.nih.gov/pubhealth/roc/index.html

Independent study evaluation is performed and documented prior to the development of evidence- tables of detailed summary tables which are informative to hazard identification and exposure response assessment. Table 2 provides a structure to the major considerations evaluated and the associated weight (low, medium, high) for each consideration. Table 2 provides a generic set of considerations and should not be considered a checklist. The specific scientific considerations appropriate for particular science analysis are adjusted on a case by case basis.

The culmination of the study evaluation process would be to provide professional/expert opinion as to the nature of the potential bias that may result from systematic errors in each specific study identified through study specific evaluations, and an assessment of overall confidence in the epidemiological database. In this way, data integration (animal, human, mechanistic, other) would be informed by level of confidence in the human epidemiological studies that inform human health effects of environmental and occupational exposures.

	aKind et al., 2014)					
Parameter	High	Moderate	Low			
Exposure assessment	Accurate and precise quantitative relationship with external exposure, internal dose, or target dose, possibly associated with an MOA/AOP. If questionnaire utilized, questionnaire and/or interview answered by subjects for chemical-specific exposure	Evidence exists for a relationship between biomarker in a specified matrix and external exposure, internal dose, or target dose. Questionnaire and/or interview for chemical- specific exposure answered by subjects or proxy individuals	Poor surrogate Low-quality questionnaire and/or interview; information collected for groups of chemicals rather than chemical-specific; no chemical-specific exposure information collected; ever/never use of pesticides in general evaluated			
Outcome Assessment	Standardized tool, validated in study population; medical record review/diagnosis confirmation by trained staff; appropriate consideration of prevalence/incidence of cases	Standardized tool, not validated in population, or screening tool; or, medical record review, methods unstated	Selected sections of test, or maternal report, other; or, maternal/paternal self-report; unclear/no consideration for whether prevalent or incident cases are appropriate			
Confounder control	Good control for important confounders relevant to scientific question, and standard confounders	Moderately good control confounders, standard variables, not all variables relevant for scientific question	Multi-variable analysis not performed no adjustments; no stratification, restriction, or matching			
Statistical Analysis	Appropriate to study question and design, supported by adequate sample size, maximizing use of data, reported well (not selective)	Acceptable methods, questionable study power (especially sub-analyses), analytic choices that lose information, not reported clearly	Minimal attention to statistical analyses, comparisons not performed or described clearly			
Risk of (other) bias (selection, differential misclassification, effect size magnification, other)	Major sources of other potential biases not likely present, present but analyzed, unlikely to influence magnitude and direction of the risk estimate	Other sources of bias present, acknowledged but not addressed in study, may influence magnitude but not direction of estimate	Major study biases present, unacknowledged or unaddressed in study, cannot exclude other explanations for study finding

<sup>a</sup> Overall study quality ranking based on comprehensive assessment across the parameters.

# 1. Exposure Assessment

Exposure assessment can be defined as the "process of estimating or measuring the magnitude, frequency and duration of exposure to an agent, along with the number and characteristics of the population exposed. Ideally, it describes the sources, pathways, routes, and the uncertainties in the assessment. (Zartarian et al., 2005)." In environmental epidemiology, exposure assessment poses a unique challenge, particularly for toxicants that are found in low concentrations in environmental media (NRC, 1991; NRC, 1997). Given the complexity of exposure pathways, researchers have developed a number of different approaches to assess exposure, which vary in accuracy, precision, and resource requirements (Niewenhuijsen, 2003). Some of these approaches are not specific to epidemiologic research but may be used to inform exposure assessment in a variety of scientific analyses. These approaches include indirect methods, based on historical records, questionnaires, and environmental monitoring, and direct methods, based on personal monitoring and biomonitoring. A brief description of each method and its strengths and limitations is summarized below.

Table 5. Summary of multi-ect and un ect exposure assessment methods.			
Approach	Method/Tools	Example	Exposure Estimation
Indirect	Historical Records	Estimating proximity to agricultural crops using address information	Dichotomous or ordinal exposure
	Questionnaires	Determine potential for exposure based on pesticide-use responses	Dichotomous or ordinal exposure
	Environmental Monitoring	Measuring pesticide levels in community water drinking system	Dichotomous or ordinal exposure, although exposure can be estimated using modeling
Direct	Personal Monitoring	Measuring pesticide inhalation and dermal contact	Quantified exposure
	Biomonitoring	Measuring pesticide levels in blood and urine	Quantified internal dose

Table 3. Summary	of indirect and direct ex	posure assessment methods.
------------------	---------------------------	----------------------------

Historical records and questionnaires are used to characterize key characteristics which may be associated with chemical exposure. When used in epidemiologic studies, historical records and questionnaires are not typically used to predict quantitative levels of exposure. Rather, historical record information or questionnaire responses are used to assign categorical levels of exposure. Examples of historical record information that can be used to assign exposure levels includes address in proximity to an agricultural crop and employment history information on job title and history. Similarly, questionnaires can be used to determine if individuals recall using pesticides or identify individuals that perform specific job functions that increase their potential for exposure. While historical records and questionnaires can be cost-effective sources of data on potential exposure, they do have limitations. Data collected from historical records and questionnaires is only a surrogate of exposure. As a result, these data sources may be an oversimplification of exposure and not accurately rank individual's exposure potential.

**Environmental monitoring** is used to characterize the levels of contaminants in environmental media, including air, water, soil, food, and home and work environments. Many state and Federal programs collect environmental monitoring data that may be useful in epidemiologic studies. Environmental monitoring is particularly useful for exposure that can be defined by geographic boundaries, such as air pollution and drinking water. As such, many epidemiologic studies have utilized ambient air monitoring data and community drinking water system data to characterize exposure to air pollution and drinking water contamination, respectively. While environmental monitoring data is useful for estimating exposures defined by geographic boundaries, it can be less reliable for the purposes of assigning individual-levels exposures, particularly when individuals live, work, and spend time in many different locations.

**Personal monitoring** is used to characterize exposure at the point of contact of a body boundary. Examples of personal monitoring include the use of dosimeters to assess dermal contact with pesticides, personal air sampling devices to assess inhalation exposure, and collection of duplicate diet samples to determine pesticide levels in food. The advantage of personal monitoring is that it is likely to provide more accurate estimates of individual-level exposure than indirect methods. Personal monitoring also makes it possible to guantify exposure levels that can be useful for prioritizing the relevance of different routes of exposure. Additionally, personal monitoring can also be used to assess longitudinal exposure when repeated measurements are taken over time. While personal monitoring offers many advantages over indirect approaches, it also tends to be labor and resource intensive (Niewenhuijsen, 2003). As a result, it is not typically feasible to conduct large-scale epidemiologic studies that assess exposure using personal monitoring. Furthermore, personal monitoring is highly dependent on the measurement techniques and analytic tools used to obtain samples and it is less likely that information that characterizes exposures during the relevant time period (usually in the past) will be available. In addition, it is unlikely that the full range of exposures over the time period of interest will be captured, and sampling may not be over a sufficient time period to capture peaks and fluctuations As such, it is extremely important to consider the scientific rigor and reliability of personal monitoring methodologies that are used in epidemiologic studies, and such monitoring may need to be supplemented by other monitoring (e.g., environmental, biological, and/or interview/questionnaire data).

**Biomonitoring** is used to characterize exposure by measuring a chemical, its metabolite(s), or reactive product(s) in biological samples, such as blood, urine, saliva, milk, adipose, and other body tissues (Needham et al., 2007). Zartarian et al. (2005) state that "a biomarker/biological marker has been defined as an "indicator of changes or events in biological systems. Biological markers of exposure refer to cellular, biochemical, analytical, or molecular measures that are obtained from biological media such as tissues, cells, or fluids and are indicators of health effects (LaKind et al., 2014). Table 4 provides scientific considerations for evaluating the quality and relevance of biomonitoring data

collected from epidemiology studies. Assessing exposure using biomonitoring has expanded rapidly as analytical tools have become more cost-effective and more biomarkers are identified. Compared with self-reported questionnaire or interview data, biomonitoring may reduce exposure misclassification and enhance the precision of the risk estimates. Similarly, biomonitoring integrates exposures from different routes and can be used to determine the amount of exposure that is absorbed into the body (Checkoway et al., 2004). Furthermore, knowledge as to the role of the biomarker in the natural history of disease is known in certain instances, such that biomarkers may help resolve temporality of exposure issues.

While biomonitoring has many advantages over others exposure assessment methods, it also has its own limitations. In many studies, biological sample are only taken from a single point in time and may not reflect accurately reflect longitudinal patterns, particularly if exposures are highly variable. Furthermore, evaluation of biomarkers also requires an understanding of degradation and metabolism of chemicals in both the environment and human body. As such, biomarkers of exposure may differ between individuals for reasons other than exposure level. Differences in metabolism, comorbidities such as kidney disease in relation to urinary measurements, uncertainty as to whether the biomarker measures exposure to the active ingredient or the environmental degradates may all account for apparent differences in biomarkers of exposure among individuals, and possibly between comparison groups. Table 4. Considerations of biomonitoring data from environmental epidemiology research (Adapted from LaKind et al. (2014).

Biomarker Consideration	Tier 1	Tier 2	Tier 3
Exposure biomarker	Biomarker has accurate and precise quantitative relationship with external exposure, internal dose, or target dose.	Biomarker has an unknown quantitative relationship with external exposure, internal dose, or target dose or is poor surrogate (low accuracy and precision) for exposure/dose.	NA
Effect biomarker	Bioindicator of a key event in a MOA/AOP.	Biomarkers of effect for which the relationship to health outcome is understood	Biomarker has undetermined consequences (e.g., biomarker is not specific to a health outcome).
Specificity	Biomarker is derived from exposure to one parent chemical.	Biomarker is derived from multiple parent chemicals with similar toxicities.	Biomarker is derived from multiple parent chemicals with varying types of adverse endpoints.
Method sensitivity	Limits of detection are low enough to detect chemicals in a sufficient percentage of the samples to address the research question.	Frequency of detection too low to address the research hypothesis.	NA
Biomarker stability	Samples with a known history and documented stability data.	Samples have known losses during storage but the difference between low and high exposures can be qualitatively assessed.	Samples with either unknown history and/or no stability data for analytes of interest.
Sample contamination	Samples are contamination-free from time of collection to time of measurement (e.g., by use of	Study not using/documenting these procedures.	There are known contamination issues and no documentation that the issues were addressed

Biomarker Consideration	Tier 1	Tier 2	Tier 3
	certified analyte-free collection supplies and reference materials, and appropriate use of blanks both in the field and lab). Research includes documentation of the steps taken to provide the necessary assurance that the study data are reliable.		
Method requirements	Instrumentation that provides unambiguous identification and quantitation of the biomarker at the required sensitivity (e.g., GC- HRMS, GC-MS/MS, LC-MS/MS)	Instrumentation that allows for identification of the biomarker with a high degree of confidence and the required sensitivity (e.g., GC-MS, GC- ECD).	Instrumentation that only allows for possible quantification of the biomarker but the method has known interferants (e.g., GC-FID, spectroscopy)
Matrix adjustment	Study includes results for adjusted and non-adjusted concentrations	Study only provides results using one method (matrix-adjusted or not).	NA

FP = false positive; FN = false negative; GC-HRMS = gas chromatography/high-resolution mass spectrometry; GC-MS = gas chromatography/mass spectrometry; GC-ECD = gas chromatography-electron capture detector; GC-FID = gas chromatography-flame ionization detector], ICC = intra-class correlation coefficient; NA = not applicable; PFP = probability of false positive

Indirect exposure assessment methods are common in retrospective studies and based on factors that are surrogates of chemical exposure. As described above, indirect exposure data cannot generally be used to estimate quantitative exposure levels without additional modeling. For example, a questionnaire can be used to determine if an individual has ever used a pesticide, but can less reliably collect data on all the environmental and behavioral factors that are needed to calculate that individual's exposure. As such, indirect exposure data are often used to classify exposure using a dichotomous exposure variable (i.e. exposed/unexposed) or ordinal exposure scale. In contrast, direct exposure assessment methods are based on data on actual individual-level exposure through personal monitoring and biomonitoring. Thus, direct methods are more common in prospective studies, but are also used in retrospective studies when existing biological samples are available from well-defined population groups.

<u>**Ouantified personal measurements**</u>, such as personal monitoring and biomonitoring, are generally considered the best source of data for estimating actual exposure levels (NRC, 1991; NRC, 1997). While this is the case, accurate qualitative measures of exposure (e.g. dichotomous and ordinal exposure metrics) from indirect methods can be just as accurate for the purpose of epidemiology. Moreover, indirect methods are often easier to interpret and may require less additional research and development to demonstrate their utility in exposure assessment.

Regardless of the approach, exposure assessment methods should be able to provide exposure estimates that are reliable and valid. In the context of epidemiology, *reliability* general refers to the ability to reproduce results and *validity* generally refers to the extent that exposure estimates reflect true exposure levels (Checkoway et al., 2004). When evaluating a particular exposure assessment's reliability and validity, it is important to consider the exposure assessment's strengths and weaknesses in the context of the study's research objectives. Less refined exposure assessment may be suitable for exploratory studies. This is because exploratory studies help raise awareness about potential hazards that can encourage investment in more focused research. Conversely, studies with more focused hypotheses can be greatly strengthened through the use of more refined exposure assessment methods. Therefore, indirect and direct exposure assessment methods represent a spectrum of tools that are complimentary and can be used at different stages of research when exploring exposure-disease relationships.

# 2. Confounding Factors

Confounding occurs when the relationship between the exposure and disease is to some extent attributable to the effect of a second (confounding) risk factor. This can happen when this second (i.e., confounding) risk factor is an independent, causally-associated risk factor for the disease but is also associated -- causally or non-causally -- with the exposure under analysis and does not also serve as an intermediate variable in the causal pathway between the exposure and the outcome of interest. If not properly measured and accounted

for, confounders have the ability to change the magnitude (and potentially the direction) of the estimated association between an exposure and health outcome. This can result in an over- or under-estimation of the relationship between exposure and disease because the effects of the two risk factors have not been appropriately separated, or "disentangled". As an example: a given pesticide may be associated with lung cancer in a given study, but this may be due to a confounding effect of farm tractor diesel fumes: here, this second factor farm tractor diesel fumes - would be a confounder if it was causally associated with the disease outcome (here, lung cancer) but also associated with pesticide exposure. Confounding factors may include less intuitive lifestyle exposures such as cigarette smoking, dietary factors (e.g., high energy/calorie laden diet), and physical activity (e.g., lack of physical activity) genetics, comorbidity, medication use, alcohol consumption, etc., all of which may adversely affect health and may be statistically associated with pesticide use. In epidemiological analyses, confounding factors are measured in the study sample and typically "adjusted for" in the final risk estimate in either the design phase of the study or the analysis phase. With respect to the former, the epidemiological researcher can "restrict" the study population to individuals that share a characteristic which the researcher wishes to control; this has the result of removing the potential effect of confounding caused by that (now controlled) characteristic. A second available method – also applicable to the design phase of the study -- is for the researcher to control confounding by "matching" individuals based on the confounding variable. This ensures that the confounding variable is evenly distributed between the two comparison groups and effectively controls for this. It is important to note that the relationship between the confounder and the exposure or outcome does not need to be found to be statistically significant in order for it to have an impact on the risk estimate for the main effect<sup>15</sup>.

At the analysis stage, one method by which confounding can be controlled is by stratification. Under this means of control, the association is measured separately under each of the (potentially) confounding variables; the separate estimates are "brought together" statistically -- if determined to be appropriate -- to produce a common odds ratio or other effect size measure by using Mantel-Haenszel approaches which weight the estimates measured in each stratum. Stratification can be difficult if there are multiple potential confounders that need to be controlled simultaneously. In such cases, confounding is typically dealt with by means of statistical modelling. (e.g., logistic regression).

It is important that careful consideration be given to confounders prior to any epidemiological studies being initiated in the field and it is important that any study adequately describe how this was done: epidemiological studies are frequently critiqued for ignoring or paying insufficient attention to potential confounders. For this reason, a sensitivity analysis can be helpful to demonstrate the potential effects that a missing or unaccounted for confounder may have on the observed effect sizes (see Gustafson and

<sup>&</sup>lt;sup>15</sup> This is why it is generally considered inappropriate to "statistically test" for a confounder to determine whether the confounder needs to be adjusted for. Instead, some consider a change in the effect size of 10% or more after adjustment for (inclusion of) a potential confounder to be sufficient evidence for the confounder to be incorporated into the analysis.

McCandless, 2010). If unmeasured confounders are thought to affect the results, researchers should conduct sensitivity analyses to estimate the range of impacts and the resulting range of adjusted effect measures. Such sensitivity analyses -- generally not uniformly conducted in most published epidemiological studies – can be used when available to estimate the impact of biases and potential confounding by known but unmeasured risk factors.

Depending upon the specific exposure-disease association under study, a factor may or may not be a confounding factor that is necessary to control: in order for a substantial distortion in the effect size estimate to occur due to confounding, the confounder must be not only a relatively strong risk factor for the disease of interest<sup>16</sup>, but also be strongly associated with the exposure of interest. Assessment of potential confounding is made on a study specific basis and - if unmeasured confounders are thought to affect the results -researchers should conduct a sensitivity analysis to estimate the range of impacts and resulting range of adjusted effect measures. When evaluating the guality of observational epidemiology studies, OPP will consider whether relevant confounding factors are properly identified, described, measured and analyzed such that an unbiased estimate of the specific association under study can be made, and, when possible, may consider sensitivity analysis as a potential tool to assist in determining the degree to which such confounding might potentially affect the estimate of the effect size. It should be emphasized that a confounder must be a relatively strong risk factor for the disease to be strongly associated with the exposure of interest to create a substantial distortion in the risk estimate. In such cases, it is not sufficient to simply raise the possibility of confounding; one should make a persuasive argument explaining why a risk factor is likely to be a confounder, what its impact might be, and how important that impact might be to the interpretation of findings. (p. 23-25, FIFRA SAP Report, 22 April 2010)

Finally, it is important to distinguish between confounding, effect modification, synergy, and other mediating effects of covariates. Confounding is a bias that results from not controlling for a variable that is associated causally with the disease and associated – causally or non-causally -- with the exposure of interest. Epidemiologic researchers seek to minimize this bias. Effect modifiers -- on the other hand -- are variables that differentially affect the magnitude of the effect size, by strata (e.g., age, race/ethnicity, SES status, genetic polymorphisms). Effect modifiers may or may not also be confounders. Typically, they are modelled by either introducing interaction terms in multivariable models or by evaluating effect sizes by strata after stratifying the data by levels of the effect modifier. A study frequently needs to be specifically designed to evaluate effect modifiers in order to have a sufficient sample size in each population strata of interest. Epidemiologic researchers seek to understand effect modifiers (not minimize them, as they do with confounders) because they can be important in evaluating risk differences across population strata, in evaluating the association between exposure and the effect of interest, and in identifying susceptible

<sup>&</sup>lt;sup>16</sup> Consideration needs to be given not only to ensuring that the confounding factor is indeed a risk factor on its own but also to ensuring not only related to the exposure of interest. Adjusting for a factor that has an association with the disease of interest wholly or partly because of its association with the exposure of interest will lead to attenuation of the exposure-disease relationship if it truly exists.

subpopulations. Effect modifiers may or may not also be confounders. For example, smoking may be a confounder in a study associating lung cancer with a pesticide often used on tobacco, but it may also be an effect modifier if the risk of exposure to this pesticide is higher among smokers than non-smokers. Synergy is often introduced as a biological or pharmacological/toxicological concept rather than an epidemiological one and relates to the ability of two chemicals, together and acting jointly, to magnify or exaggerate the effect beyond that which would be seen considering the (mathematical) sum of each chemical's effects alone. In epidemiological and statistical terms, this is often expressed as effect modification or interaction.

### 3. Statistical Analysis

Epidemiologic studies are designed to measure an association between a specific exposure and a disease. When evaluating the quality of pesticide epidemiology studies, OPP will also consider the statistical methods used. Specifically, OPP will consider the extent to which the analytic methods described in the study are appropriate to the research question; the completeness of the description of the statistical methods utilized; the appropriateness of the methods for identification, assessment and adjustment of potentially confounding variables in the exposure-disease relation; and, the description, extent of, and presentation of any sub-group analyses which may have been performed (including whether statistical corrections for multiple comparisons have been made).

Epidemiologic investigations typically utilize statistical modeling to estimate risk (e.g. generalized linear models such as logistic (for odds ratios) or Poisson (for count data) regression. To do so, researchers must consider not only the relevant main exposure and outcome variables, but also consider relevant confounding factors, and whether the association under investigation may differ by level of these factors, i.e., effect modification or interaction (Szklo et al., 2004). Upon identification of a potentially confounding variable -- one that substantively changes the magnitude and/or direction of the association under study -- adjustment through regression modeling can help to isolate the risk estimate of interest, i.e., the association under study. In addition, OPP will evaluate the stratification of statistical interaction. If the magnitude and direction of the association of interest differs greatly by level of a third variable, then the stratified results should be considered primary.

When performing statistical modeling when the outcome is rare or the sample size is relatively small, it is important to be cautious about including too many covariates in the model. Any resulting effect size estimate may be too high or too low and is unlikely to reflect the true estimate of effect. Such issues due to rare events or low sample sizes are also possible when conditional methods are used (e.g., conditional logistic regression when the design includes matching of the comparison group under study): if too few discordant pairs (or discordant sets) are observed, the estimated effect size may also be unreliable. Thus: while controlling for confounders and other covariates is important, the assessor must take care not to over-control or end up with too few degrees of freedom to produce a

reliable test. In these cases, it may be more important to seek parsimonious models that adjust for only a smaller number of the most influential confounders and other covariates so that the effective sample size remains adequate.

Finally, it is important in any statistical modeling exercise to consider statistical significance in the context of clinical/biological/scientific significance of the result. It may be that some results are statistically significant but unimportant in a clinical/biological/ scientific context. The reverse can be true: it may be that results are not statistically significant but may be important in a clinical/biological/scientific context. The former may suggest a sample size that is larger than necessary while the latter may suggest one than is smaller than needed. The latter case may be important from a public health perspective and warrant further exploration, especially when the association is strong (despite it being imprecise)

### 4. Potential Bias in Observational Research

Bias is a systematic error in the design or conduct of a study that gives rise to study results that are systematically different from the (unobserved) true situation. This contrasts with random errors which relate to sampling variability and precision (or, equivalently, confidence bounds) around the effect size measure, but which do not "drive" or "push" the result in one particular direction (e.g., either toward or away from the null).

Bias is a reflection of methodological imperfections in the design or conduct of the study and should be addressed or discussed by researchers as part of their analysis. There are a number of ways that bias can be introduced into a study: studies may be biased in the way in which participants are selected into the study (selection bias), or the way in which information about exposure and disease status is collected (information bias, including recall bias discussed earlier for case-control studies). One example of a common occupational selection bias is the "healthy worker effect" which can create an important bias in occupational epidemiology studies, leading to bias toward the null, and even below (creating the interpretation that the exposure is "protective") No study is totally devoid of bias and one should consider the extent to which authors of published studies described potential bias in the study, and how (if at all) they attempted to address it and characterize it in the study. Bias can result from differential or non-differential misclassification (Greenland, 1998). Differential misclassification (bias) means that misclassification has occurred in a way that depends on the values of other variables, while non-differential misclassification (bias) refers to misclassifications that do not depend on the value of other variables. Misclassification biases – either differential or non-differential – depend on the sensitivity and specificity of the study's methods used to categorize such exposures and can have a predictable effect on the direction of bias under certain (limited) conditions: this ability to characterize the direction of the bias based on knowledge of the study methods and analyses can be useful to the regulatory decision-maker since it may allow the decision maker to determine the extent to which, if any, the epidemiological effect sizes being considered (e.g., OR, RR) are likely underestimates or overestimates of the true effect

size<sup>17</sup>. It is not atypical to find degrees of misclassification in the range of 10 to 20 percent and it can be helpful in reviewing epidemiological studies to consider a form of sensitivity (or "what if") analysis which evaluates such a degree of misclassification -- and whether it is differential or non-differential – and the degree to which such misclassification might impact the odds ratio or relative risk with respect to both magnitude and direction<sup>18</sup>. (p.25, FIFRA EPA SAP report, 22 April, 2010). As mentioned earlier with respect to confounding, such quantitative sensitivity analysis is only rarely performed or practiced in published epidemiology studies, with bias instead more typically evaluated in a narrative manner without any quantitative assessment of its potential magnitude and the effect it may have on the epidemiological effect size estimates (Jurek at al., 2006). This may be due – in part -- to a general lack of availability of computational tools for such analysis by epidemiologists or their unfamiliarity with them. Such tools are becoming increasingly available and may be valuable in developing more rigorous quantitative methods for evaluation of potential biases.

# 5. Interpretation of Null studies

"Null" studies -- or well-conducted studies which report no association between exposure to the pesticide and an adverse health outcome -- will be evaluated carefully for their potential usefulness in human health risk assessment. The study may report a null result either because the investigated association indeed does not in reality exist, or because the study was conducted failed to detect an association at a given predetermined level of significance. This latter result – the failure to detect an association -- should not necessarily be interpreted to mean that no association exists, but rather as simply one was not found in the particular study<sup>19,20</sup>. To evaluate which of these two conditions may be correct when reviewing "null" studies, one should consider other research reported concerning the same or similar research question, the manner in which exposure and outcome were assessed, the extent to which exposure misclassification may have biased the study to the null, the statistical methods used including the identification and analysis of confounding variables in the association, the extent to which the exposure is below a threshold at which an effect would occur or be detected, as well as the power of the study and its ability to detect an effect size of substantive interest. Statistical power refers to the probability that researchers may correctly identify that there is a difference between the two comparison groups, i.e., there is an association between exposure and disease, when in

<sup>&</sup>lt;sup>17</sup> The direction of bias that results from the degree of non-differential misclassification will also depend on the categorization of exposure (either dichotomous or polytomous).

<sup>&</sup>lt;sup>18</sup> Such sensitivity analyses might be especially recommended for exposure misclassification biases which in many cases are expected to result in more substantive effects on the effect size estimate than those from confounding.

<sup>&</sup>lt;sup>19</sup> The old adage that "the absence of evidence does should not be interpreted as the evidence of absence" is true here.

<sup>&</sup>lt;sup>20</sup> See also the American Statistical Association's Statement on Statistical Significance and P-values at <u>https://www.amstat.org/asa/files/pdfs/P-ValueStatement.pdf</u>

fact there is in fact a true difference (or association). Studies that are "low powered" may falsely conclude there is no association, when an association actually exists<sup>21</sup>.

Finally, it is important to consider the effects of publication bias in any systematic review of the literature with respect to interpretation of null studies. The term publication bias refers to the tendency for the available published literature to disproportionately exclude such null studies. Studies that demonstrate such a "null" association between a disease or health outcome can be as equally informative as those that do provided that the study in question meets the quality criteria established as part of the epidemiological review process. These may include such factors as study design; the existence of an *a priori* hypothesis vs. an exploratory analysis; sample size and statistical power to detect an effect size of interest; proper ascertainment of outcome *vis-à-vis* sensitivity and specificity; the quality of the exposure assessment and the potential for differential and non-differential misclassification; adequacy of the measurement of key potential confounders and other forms of bias (information, selection, etc.); and evaluation of effect modifiers; appropriate statistical analyses, including consideration of and possible correction for multiple comparisons that a unsupported by a priori hypotheses, biological plausibility, or other supporting information.

# 6. External Validity (Generalizability)

As noted above, *validity* generally refers to the extent that exposure estimates reflect true exposure levels (Checkoway et al., 2004). *External validity*, or *generalizability*, refers to the ability to extend the epidemiologic study results derived from a sample of the population (e.g., pesticide applicators) to other populations (e.g., all agricultural workers). To assess external validity, comparison of characteristics in the sample to the larger population (if known) can be made. Such evaluation should include not only demographic factors, but also whether exposures (e.g., dose, timing, duration) are similar and whether important effect modifiers (e.g., sensitivity of vulnerable populations) were considered. Generalizability is of particular importance because it is important to understand whether and how individual study results may be applied to the larger group or targeted sub-groups in regulatory risk assessment. For example, the AHS has reported statistical associations between some cancer and non-cancer health outcomes for some pesticide chemicals. OPP has an interest in evaluating the extent to which the reported findings may apply to pesticide applicators in states other than North Carolina and lowa or to farm workers who primarily do post-application activities.

<sup>&</sup>lt;sup>21</sup> Studies that are low-powered but find statistically significant effects may also be subject to the phenomenon of effect size magnification and this can be important to investigate as well. (loannidis, 2008).

## V. HUMAN INCIDENT SURVEILLANCE DATA

Generally speaking, epidemiology studies on pesticides such as those described above focus on lower exposures (over a longer time period) that are less likely to result in acute clinical symptoms. OPP is also interested in exposures that are higher and occur over shorter-intervals (often on an acute "one-time" basis). This "human incident," or poisoning data can be useful for evaluating short term, high exposure scenarios that can be readily attributed to the pesticide in question.

OPP uses such "human incident information" for several purposes. Most broadly, the program uses incident data to inform risk assessment/risk management activities; this forms an integral part of our registration review activities under our Pesticide Registration Improvement Act (PRIA) responsibilities. To this end, OPP evaluates human incident data for trends over time and examines patterns in the severity and frequency of different pesticide exposures. In some cases, incident information can indicate need for additional information or additional risk management measures. Incident information can also help assess the success of risk mitigation actions after they are implemented, and incident information is an important part of OPP's performance accountability system to ensure the effectiveness of risk management actions that OPP has taken to protect human health and the environment. Lastly, incident information can be useful in providing real world use information with respect to usage practices and also in potentially targeting enforcement or educational activities, where appropriate.

OPP obtains this information from a variety of sources. Sources of human incident data include both (human) **medical case reports** appearing in the medical and toxicological literature as well as information from a variety of national **toxico-surveillance activities** for acute pesticide poisonings which are considered jointly to aid acute and chronic hazard identification and as an integral part of the risk assessment process.<sup>22</sup>

**Medical case reports** (first-hand accounts written by physicians) or medical case series (a compendium of medical case reports across individuals that share common source or symptomology) are valuable tools for analyzing all available evidence of health effects, and to complement the findings of animal studies and epidemiological studies. In addition, they can identify unusual or novel occurrences of an adverse health effects plausibly associated with use of a specific pesticide providing "advance notice" to the agency for toxico-vigilance purposes. Published case reports for pesticides typically describe the effects from an atypical (high exposure/dose, illegal, off-label) acute or short-term exposure. The reports are often anecdotal and can be highly selective in nature. They can, however, can be particularly valuable in identifying previously unidentified toxic effects in humans and in learning about the effects, health outcomes, and medical sequelae following high exposures. They frequently have more detailed medical information (including sequelae), detailed follow-up, and generally higher quality and/or quantitative

<sup>&</sup>lt;sup>22</sup> OPP is aware of efforts by IPSC to consider human incident data in risk assessment. <u>http://www.who.int/ipcs/publications/methods/human\_data/en/index.html</u>

information about dose. If similarities are seen across multiple medical case studies or patterns emerge – in symptoms, exposure scenarios or usage practices -- these can provide valuable information for the risk assessment process and strengthen any findings. Medical case studies and series that include quantitative exposure information can be compared to exposure estimates in the risk assessment (which are based on labeled application rates and surrogate exposure information) to characterize margins of exposure expected from typical use, when appropriate.

The following considerations are evaluated in assessing medical case reports and medical case series:

- A detailed history of exposure (when, how, how much); time of onset of adverse effects; and signs and symptoms of the patient, are reported.
- Information on the product/chemical/pesticide, such as name, pesticide label, registration number, etc.
- Patient information (e.g. age, race, sex); underlying health conditions and use of any medications that can produce similar signs and symptoms; relevant medical history; and the presence of any risk factors.
- Description of events and how the diagnosis was made.
- Management and treatment of the patient, and laboratory data (before, during and after the therapy), including blood levels of pesticides and chemicals.
- Whether the medical report is reliable, reasonable and whether it is consistent with current knowledge, including other research, reviews and guidelines.
- Clinical course of the event and patient outcome (e.g. patient recovered and discharged from hospital; condition of patient after the discharge, any chronic health effects or premature death related to the pesticide or chemical exposure).

In addition to using medical case reports/series as a source of real-world exposure and toxicological information, OPP also engages in toxico-surveillance activities using a variety of pesticide poisoning incident databases are also available. Specifically, OPP has access to the following five human incident data sources: the *OPP Incident Data System* (IDS); the American Association of Poison Control Centers (PCC) summary reports from their *National Poison Data System* (NPDS); data from the EPA-funded *National Pesticide Information Center* (NPIC), currently at Oregon State University; the Centers for Disease Control and Prevention/National Institute for Occupational Safety and Health *Sentinel Event Notification System for Occupational Risk-Pesticides* (NIOSH SENSOR-Pesticides) and the *California Pesticide Illness Surveillance Program* (PISP). Each of these are described, in turn below:

□ <u>OPP Incident Data System (IDS)</u> is maintained by OPP and incorporates data submitted by registrants under FIFRA section 6(a)(2)<sup>23</sup>, as well as other incidents reported directly to EPA. OPP has compiled the pesticide related

<sup>&</sup>lt;sup>23</sup> Under FIFRA 6(a) (2), pesticide registrants are required to notify EPA if and when they become aware of "factual information regarding unreasonable adverse effects on the environment of the pesticide."

incident reports in the IDS since 1992. The IDS includes reports of alleged human health incidents from various sources, including mandatory FIFRA Section 6 (a) (2) reports from registrants, other federal and state health and environmental agencies and individual consumers. IDS include information on incidents involving humans, plants, wild and domestic animals where there is a claim of an adverse effect. The vast majority of IDS reports are received by the agency in paper format. IDS entries act as a "pointers" to copies of original reports retained on microfilm and scanned images in OPP's Information Service Center.

While IDS includes both occupational and non-occupational incidents, the majority of incidents reported relate to non-occupational/residential scenarios The reports are obtained from across the U.S. and most incidents have all relevant product information (such as the EPA Registration Number) recorded. As IDS is populated mostly by information provided by pesticide registrants under their FIFRA 6(a)(2) reporting requirements, the agency has relatively high confidence in the identification of the specific product which is involved. Severity rankings are included for each incident (as specified by CFR §159.184). Symptom information is sometimes included in the narrative portion of the incident, but this information is usually not validated/confirmed by a healthcare professional. IDS also includes narrative information on exposure scenario and hazard information. Many companies use standardized, industry-developed Voluntary Incident Reporting Forms.

OPP collects and evaluates the data from the IDS and identifies potential patterns with respect to the extent and severity of the health effects due to pesticides exposure. While IDS reports are broad in scope and can in some cases contain detailed information, the system does not necessarily consistently capture detailed information about incident events, such as occupational exposure circumstances or medical outcome.

In addition, most cases data going into IDS is not validated or verified, though some reports are collected from calls to contract poison control centers. Nevertheless, incident information can provide an important post-marketing feedback loop to the agency following initial registration of the product: IDS incidents of a severe nature, or a suggested pattern or trend among less severe incidents can signal the agency to further investigate a particular chemical or product. Because IDS has such extensive coverage, it can assist in providing temporal trend information and determining whether risk mitigation has helped reduce potential pesticide exposure and decreased the number of potential incidents reported to IDS. Overall, IDS provides good information about national trends and frequency of incidents for pesticides and can provide valuable insights into the hazard and/or exposure potential of a pesticide. □ The National Poison Data System (NPDS) -- formerly called the Toxic Effects Surveillance System (TESS) -- is maintained by the American Association of Poison Control Centers (AAPCC) and is supported with funding from several federal agencies. NPDS is a computerized information system with geographically specific and near real-time reporting. Although the main mission of Poison Control Centers is in helping callers respond to emergencies, NPDS data can help identify emerging problems in chemical product safety. Hotlines at 61 PCC's nationwide are open 24/7, 365 days a year and are staffed by specially trained nurses, pharmacists, and other clinical health care specialists to provide poisoning information. Using computer assisted data entry, standardized protocols, and strict data entry criteria, local callers report incidents. These reported incidents are retained locally and are updated in summary form to the national database maintained by AAPCC. Information calls are tallied separately and not counted as incidents. The PCC system covers nearly all the US and its territories and has undergone major computer enhancements since 2001.

NPDS includes mainly non-occupational incidents. NPDS does not include narrative information and the product information may not be complete. NPDS provides severity rankings and symptom information that are designated/recorded by trained specialists, and the agency has relatively high confidence in this information. NPDS also provides some information on the likelihood of the adverse effect being a result of the reported exposure. Overall, NPDS provides good information about national trends, frequency of incidents for pesticides, as well as the hazard potential for particular pesticides. However, resource limitations permit the agency to only access AAPCC summary reports published each year (e.g., see <u>http://www.aapcc.org/annual-reports/</u>) and these serve as a supplement to other data sources for which the agency has more complete access.

### The National Pesticide Information Center (NPIC)

(http://npic.orst.edu/index.html) is funded by EPA to serve as a source of objective, science-based pesticide information in response to inquiries and to respond to incidents. NPIC functions nationally during weekday business hours and is a cooperative effort between Oregon State University (currently) and EPA; it is intended to serve as a source of objective, science-based pesticide information and to respond to inquiries from the public and to incidents. Similar to Poison Control Centers, NPIC's primary purpose is not to collect incident data (about 10% of NPIC's annual calls are considered "incident" related), but rather to provide information to inquirers on a wide range of pesticide topics, and direct them to other sources for pesticide incident investigation and emergency treatment. Nevertheless, NPIC does collect information about incidents (approximately 4000 incidents per year) from inquirers and records that information in a database. NPIC is a source of national incident information, but generally receives fewer reports than IDS. Regardless, if a high frequency is observed in IDS for a given pesticide or

product, NPIC provides a source of information that can prove valuable in determining consistency across national data sets.

As with IDS and PCC, the incidents in NPIC are mainly non-occupational. NPIC incidents include narratives and product information when the caller provides the information. Although the scope is national, there are significantly fewer incidents reported to NPIC than to NPDS or IDS but considerably more information is provided and the agency can request custom reports on an as-needed basis. Hazard information includes severity rankings, route of exposure and symptoms – which are recorded by trained personnel. NPIC also provides information on how likely the link between exposure and adverse effect is (which they call a certainty index). NPIC also publishes annual reports and analyses in the open literature which are valuable resources.

The Center for Disease Control and Prevention National Institute for Occupational Health (CDC/NIOSH) manages a pesticide surveillance program and database entitled the Sentinel Event Notification System for Occupational Risk (SENSOR)-Pesticides.<sup>24</sup> This database includes pesticide illness case reports in 12 states from 1998-2013. Participating states are: California, Florida, Iowa, Louisiana, Michigan, Nebraska, New Mexico, New York, North Carolina, Oregon, Texas and Washington. The participating states for a given year vary depending on state and federal funding for pesticide surveillance.

Cases of pesticide-related illnesses in the SENSOR-Pesticides database are ascertained from a variety of sources, including: reports from local Poison Control Centers, state Department of Labor workers' compensation claims when reported by physicians, reports from state Departments of Agriculture, and physician reports to state Departments of Health. Although both occupational and non-occupational incidents are included in the database, the SENSOR coordinators primarily focus their follow-up case investigation efforts on the occupational pesticide incidents. The SENSOR coordinator at the state Department of Health will follow-up with cases and work to obtain medical records in order to verify exposure scenario, symptoms, severity, and health outcome. Using standardized protocol and case definitions, SENSOR coordinators at state Departments of Health enter the incident interview description provided by the case, medical report, physician and patient into the SENSOR data system.

All SENSOR-Pesticides cases must report a minimum of two health effects in order to be included in the aggregate database that EPA uses for incident

<sup>&</sup>lt;sup>24</sup> SENSOR-Pesticides webpage: <u>http://www.cdc.gov/niosh/topics/pesticides/overview.html</u>

analyses. Evidence for each case is evaluated, based on the NIOSH case classification matrix, for its causal relationship between exposure and illness. 98% of SENSOR-Pesticides cases are classified as definite, probable, or possible, and 2% of the cases are classified as suspicious. Unlikely, asymptomatic, and unrelated cases, as well as those with insufficient information, are not included in the SENSOR-Pesticides database.

Overall, SENSOR-Pesticides provides very useful information on both occupational and non-occupational incidents, and sometimes valuable insights into the hazard and/or exposure potential of a pesticide. SENSOR-Pesticides also conducts analyses of its own data and publishes these in the Morbidity and Mortality Weekly. Unlike the aforementioned databases and although it contains both non-occupational/residential and occupational incidents, SENSOR's has traditionally focused on occupational pesticide incidents, and is of particular value in providing that information. SENSOR-Pesticides data from 1998-2011 is available online at: <u>http://wwwn.cdc.gov/Niosh-whc/Home/Pesticides</u>.

The California Pesticide Illness Surveillance Program (PISP) is maintained by the State of California. This database documents pesticide-related illnesses and injuries. Case reports are received from physicians and via workers' compensation records. The local County Agricultural Commissioner investigates the circumstances of the exposure. Medical records and investigative findings are then evaluated by California's Department of Pesticide Regulation (DPR) technical experts and entered into an illness registry. All reported pesticide illnesses in the California PISP program are investigated by the county agricultural commissioners, and the DPR evaluates the reports and compiles them into a database, which is used to improve the state's program to protect workers and others from the adverse effects of pesticide exposure (http://apps.cdpr.ca.gov/calpiq/).

Currently, OPP evaluates human incident data on a chemical-specific basis. Incidents from each database are analyzed for hazard potential (deaths, frequency of more severe incidents, and patterns/trends of reported symptoms) and exposure potential (frequency of incidents/ trends over time, patterns/trends of exposure scenarios, of factors affecting exposure or of products). When evaluating human incident data from the above databases, OPP considers several general criteria. OPP considers the relative severity and frequency of symptoms. Additionally, OPP generally has greater confidence in reports in which temporal association can be verified or are at least plausible. Lastly, other factors that are used to evaluate human incident data include evidence of an exposure response association, consistency in reported health effects, biological plausibility of reported health effects, elimination of alternative causes of health effects. Additionally, narratives of more severe incidents are often evaluated for any temporal association between time-of-exposure and effects reported to determine whether an association is supported by the circumstances. For example, a heart attack in an elderly individual that occurs three

months following an indoor pesticide application may be determined not to be a likely causal association. On the other hand, a severe incident occurring at or shortly after the time of exposure with symptoms consistent with known symptomology for the pesticide class and that occurs without prior medical history may suggest that causal inference is more justified.

In sum, then, incident data -- consisting of both medical case reports/case series appearing the medical and human toxicological literature and toxico-surveillance data derived from the databases that EPA either maintains, funds, or accesses -- can provide useful, complementary information that assists OPP in evaluating the real-world risks of pesticides.

## **VI. SUMMARY & CONCLUSIONS**

This framework describes important factors in reviewing epidemiology and human incident data and describes a proposed WOE analysis for incorporating such data in pesticide human health risk assessment. OPP uses the best available data across multiple lines of evidence and from *in vitro*, *in vivo*, and *in silico* data sources. OPP uses a WOE approach when integrating data from multiple sources to take into account for quality, consistency, relevancy, coherence and biological plausibility using modified Bradford Hill criteria as an organizational tool. Application of WOE analysis is an integrative and interpretive process routinely used by EPA according to in scientific analysis outlined in its risk assessment guidelines. The WOE analysis also evaluates the quality of the combined data set and is consistent with the level of effort and complexity that is appropriate for a particular scientific assessment (U.S. EPA, 2002). OPP acknowledges that toxicology and risk assessment are currently undergoing transformational changes towards implementing the new vision of 21<sup>st</sup> century toxicity testing. As these transformation changes occur, OPP will update this approach as appropriate.

#### I. 目的と範囲

米国環境保護庁(EPA)の農薬プログラム(OPP)は、連邦殺虫剤・殺菌剤・殺鼠剤法 (FIFRA)及び連邦食品・医薬品・化粧品法(FFDCA)に基づき、米国内の農薬を規制する認 可プログラムである。このプログラムの一環として、OPPは毒性とばく露の多くの主要データ を評価し、農薬がヒトの健康及び環境に及ぼす影響を評価している。ヒト健康影響を評価する際、 EPAは、まず疫学データを含めたヒトへの影響の可能性を直接評価する情報に注目する。しかし、 これまでは農薬の潜在的な毒性を報告した疫学研究はほとんどない。したがって、OPPはハザ ードの可能性を評価し、ヒトの健康リスクを推定するため、これまでは実験動物を用いた毒性試 験に主に依存してきた。Agricultural Health Study<sup>1</sup>や National Institute of Environmental Health Sciences (NIEHS) / EPA Children's Centers<sup>2</sup>などから数多くの論文が発表されたこ とで、米国で実施された農薬へのばく露に関する疫学研究の有用性が高まっている。とはいえ、 質の高い疫学データが存在する、あるいは充実しつつある農薬の数は、今後短期的には比較的少 ないので、ほとんどの農薬の定量的リスク評価に用いるためのデータの主な情報源は試験データ であることがおそらく継続するだろう。

OPP の目標は、そのような情報が入手可能な場合には、科学的に正確で明白な方法で利用す ることである。これを達成するために OPP は、この文書に記載されているように総合的な疫学 的フレームワークを開発した。このフレームワークでは、そのような研究や科学的情報を農薬の リスク評価にどのようにして一層完全に統合することができるかを評価する際に OPP が検討す る科学的に考慮すべき要点を述べている。現在の文書は、拘束力のある規則ではなく、疫学デー タを評価または使用するためのレビュアー向けのガイドやマニュアル、標準作業手順書であるこ とを意図したものでも、その役割を果たすことを意図したものでもない。また、より最新で進歩 した疫学的方法の完全な専門書となることも、この種の研究を解釈するために重要なニュアンス や複雑さを適切に伝えることも意図していない。したがって、因果推論及び因果関係図 (Rothman ら、2009年; Greenland and O'Rourke、2012年)、交絡因子の特定・評価・制御 に対する最新の研究法、メタ分析と異質性の評価(Borenstein ら、2009 年; Greenland and O'Rourke、2012 年)、または疫学データの感度/定量的バイアス解析(Lash ら、2009 年; Lash ら、2014年; Joannidis、2008年; Greenland and Lash、2012年; Jurek ら、2007年)と いった重要な疫学の話題は(詳細に)論じていない。これらの話題、概念及び問題点のすべては、 農薬に関する疫学研究に応用できるが、この OPP フレームワーク文書では取り上げていない。 代わりに、この文書では、OPP の FIFRA 及び FFDCA の機能支援のためのヒト健康リスク評価 の文脈において農薬の疫学研究の評価と使用に関する全体的な概念を提供している。

<sup>&</sup>lt;sup>1</sup> <u>https://aghealth.nih.gov/</u>

<sup>&</sup>lt;sup>2</sup> https://www.epa.gov/research-grants/niehsepa-childrens-environmental-health-and-diseaseprevention-research-centers

本文書の以前のバージョンは、2010年2月にFIFRA科学諮問パネル(SAP)によって好意的に レビューされた(USEPA、2010年、FIFRA SAP、2010年)。この文書は、SAPが推奨する改 善点、パブリックコメント及び2010年以降に疫学データが利用可能であった農薬の評価から得 られた知識が盛り込まれており、進捗及び必要に応じて随時更新される文書と考えるべきである。

#### II. 序章

全米科学アカデミー(NAS)の米国研究評議会(NRC)による2つの報告書、「21世紀の毒 性試験:ビジョンと戦略(2007年)」と「科学と政策調査(2009年)」は、共に毒性学とリス ク評価の新たな方向性を示している。これら 2 つの NRC 報告書は、毒性試験の実施方法、デー タの解釈方法、そして最終的に規制上の政策調査の方法に大きな変更を提唱している。具体的に は、21世紀の毒性試験に関する 2007年の報告書では、毒性試験、リスク評価、そして最終的な 政策調査に情報を提供するために、現在の先端毒性エンドポイントの使用に焦点を当てたものか ら、毒性発現経路3を使用するようにシフトすることを提唱している。このアプローチは、遺伝 子、タンパク質、低分子がどのように相互作用してヒト細胞の機能を維持する分子経路を形成し ているかという急速に進化する科学的理解に基づいている。新しい毒性試験のパラダイムの目標 は、環境因子へのばく露がこれらの経路をどのように乱すかを明らかにし、それによって有害な 健康影響につながる重要な事象を連鎖的に引き起こす原因を明らかにすることである。この新し いアプローチでは、疫学研究、ヒトでの事例データベース、バイオモニタリング研究に見られる ようなヒトの情報と実験毒性学的情報が重要な役割を果たすことが期待されている。具体的には、 このようなヒト情報は、実際の化学物質ばく露による影響についての見識を提供し、問題の定式 化やハザード/リスクの特性評価に貢献することができる。さらに、疫学データやヒトでの事例 データは、追加の解析やデータ生成(例えば、in vitro試験や目標とする in vivo試験で使用する ための用量やエンドポイントの選択)の指針となり、影響を受けやすい集団を特定したり、新た な健康影響を特定したり、既存の毒性学的結果を確認したりすることができる。

この毒性試験とリスク評価の新しいビジョンには、生物学的体系の多種多様なレベル(分子レ ベルから化学物質の影響をその発生源から最終的な健康影響や集団への影響まで考慮することを 目的とした集団を基にした調査レベルまで)のデータが含まれる。このようなデータには、 *in vitro*試験や *in vivo*試験から得られるデータのほかに、*in silico*モデルデータがある。疫学デ ータと事例データを取り入れる OPP のフレームワークは、21 世紀の毒性試験に関する 2007 年 の NRC の報告書と概念的に一致しており、どちらも多種多様なデータソースから得られる最良 の情報の用途はエビデンスの重み付け(WOE)解析にまとめて使用することを強調している。

<sup>&</sup>lt;sup>3</sup>毒性発現経路とは、十分に撹乱された場合に有害な健康影響を及ぼすことが予想される細胞応 答経路のことである。

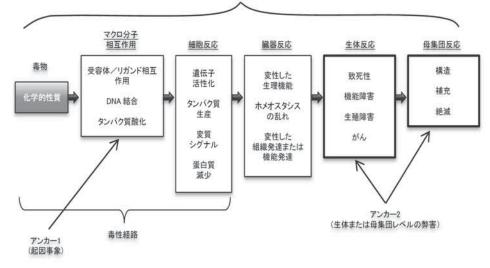

一般的な原則として、産業環境疫学研究は広く使用されている農薬のみを対象に実施されてお り、これらの農薬も科学的文献で十分に研究されている必要がある。したがって、疫学データが 利用可能な多くの場合、毒性、ばく露、薬物動態(PK)、作用機序/有害性発現経路(MOA/ AOP)の情報に関する主要な文献データも利用可能であると OPP は予想している。ヒトでの事 例データは、より広範囲の化学物質について入手可能であるが、中には正確なデータベースを持 つものと持たないものがある。ヒトでの重大な事例があり、特定の農薬の MOA/AOP や PK に ついてほとんど知られていない場合には、WOE 解析を用いて新たな研究分野を特定することが できる。

疫学データとヒトでの事例データを組み込むための当該フレームワークにおける OPP のアプ ローチは、初めてのものもしくは新しいものではない。むしろ、このアプローチは、既存のツー ルや方法を合理的かつ論理的に拡張したものである。当該文書は、農薬リスク評価に使用する疫 学データ及びヒトでの事例データを検討するための出発点として、既存のガイダンス文書及びフ レームワーク(表 1)に依存している。ヒトの健康リスク評価における疫学データ及びヒトでの 事例データの使用に関する当該フレームワークは、2009 年の「*科学と政策調査*」に関する報告 書での NRC の提言や、特にリスク管理の必要性の文脈で、利用可能なものを調査、企画、検討 するためのツールとして問題の定式化の使用を強調する点に関して、政府機関の最新のヒト健康 リスク評価フレームワーク(USEPA、2014 年 a) と一致している。

同様に、OPP のフレームワークは、問題の定式化の重要性と生物学的体系の多種多様なレベルでの情報統合の必要性を強調した「世界保健機関/化学物質の安全性に関する国際プログラムMOA/ヒト関連(MOA/HR)フレームワーク」の最新版と一致している(Meek 6、2014 年)。 MOA/HRフレームワークは、用量反応や時間的一致、ならびに生物学的な妥当性、整合性及び 一致性などの要素を考慮に入れて、Bradford Hill によって記述されたような原則を使用して、 エビデンスの重み付けに基づいて確立された因果経路に沿った一連の重要な事象を特定すること から始まる(Hill、1965年)。この解析アプローチを用いることで、疫学的知見は、他のヒト情 報(ヒトでの事例所見を含む)や実験的研究の文脈で評価することができ、不確実分野や今後の 研究分野を特定することができる。しかし、完全に解明された MOA/AOP があることが、ヒト 健康リスク評価に疫学研究を利用するための要件ではないことは注目に値する。政府機関が 2007 年及び 2009 年の NRC 報告書にある変化するアプローチの実施を引き続き進め、OPP が疫 学情報とヒトでの事例情報の統合の経験を積む中で、OPP は当該フレームワークを適切に再評 価し、更新していく予定である。

ヒトの情報源は他にもあるが、このフレームワークの意図は、ヒトのリスク評価における *学データととトでの事例データ*の解釈と利用にあり、他にもあるヒトの情報源については当該 文書で深く触れていない。特に、当該文書では、意図的なヒトを対象としたばく露に関する農 薬の研究<sup>5</sup>や、農業従事者の活動に伴う経皮や吸入によるばく露量を測定するために行われた 研究<sup>6,7</sup>については、広く論じていない。

 $<sup>^4\</sup>$  https://www.epa.gov/osa/products-and-publications-relating-risk-assessment-produced-office-science-advisor

<sup>&</sup>lt;sup>5</sup> このような研究の実施及び OPP がこのような研究から得られたデータに依存することは、 EPA の研究対象者保護規則(40 CFR Part 26)によって管理されている。その他に、この規 則は妊婦、授乳婦、子供への意図的なばく露に関する研究を禁じ、EPA-OPP やヒト研究評価 委員会(HSRB)による新規研究計画の事前評価、ならびに研究成果報告の評価を求めてい る。

<sup>&</sup>lt;sup>6</sup> 過去数年間に OPP は、農業従事者のばく露評価に使用されるデータとアプローチを改善する ために、農業従事者を対象とした既存の観察研究を広範囲に評価してきた。それらの評価は (http://www.epa.gov/scipoly/sap/meetings/2007/010907\_mtg.htm) で閲覧できる。

<sup>7</sup> OPP が農業従事者ばく露研究をどのように実施し、成果を利用するかについての追加情報は、 PPP-48「農薬とヒト健康リスク評価: Policy, Processes, and Procedures」 (<u>https://www.extension.purdue.edu/extmedia/PPP/PPP-48.pdf</u>で入手可能)を参照のこと。

#### III. 農薬のリスク評価におけるシステマティックレビュー: 疫学

近年、NRC は、規制上の政策調査に情報を提供するための化学物質固有のリスク評価をサポ ートする科学的文献レビューの明白性を高めるために、システマティックレビュープロセスに移 行するよう政府機関に奨励している(NRC、2011 年、2014 年)。NRC はシステマティックレ ビューを「特定の疑問に焦点を当て、明確で事前に指定された科学的方法を用いて、類似してい るが別個の研究の結果を特定、選択、評価、要約する科学的調査」と定義している(NRC、 2014 年)。NRC の勧告に沿って、化学物質安全・公害防止局(OCSPP)は、政策調査を支え る科学的データの収集、評価、統合のための標準的な方法に依存する、目的にかなったシステマ ティックレビューを採用している。

NRC によると、システマティックレビューには、"明白性があり明確に文書化された方法、関連するすべての文献の一貫した厳しい評価、エビデンスの強さを評価するための標準化されたアプローチの適用、明白で一貫性のある総括的用語(NRC、2014年)"といういくつかの共通要素がある。近年、いくつかの集団(Rooney ら、2014年; Woodruff and Sutton、2014年; Hartung、2010年)が、環境保健科学で使用するためのシステマティックレビューのアプローチを発表している。システマティックレビューでの OCSPP のアプローチは、Cochrane Handbook for Systematic Reviews of Interventions for evidence-based medicine に明記されている原則と、Grading of Recommendations Assessment, Development and Evaluation (GRADE)の原則と一致している。GRADE ガイドラインは、国立環境保健科学研究所(NIEHS)健康評価・翻訳局(OHAT) (Rooney ら、2014年)とカリフォルニア大学サンディエゴ校(Woodruff and Sutton、2014年)が開発した環境保健科学のためのシステマティックレビューアプローチで使用されているものである。コクラン・ハンドブックによると、システマティックレビューの主な特性は以下の通りである。

- ・目的が明確に示されており、研究の適格性基準があらかじめ定義されていること。
- ・明示的で再現性のある方法論。
- ・適格性基準を満たすすべての研究を特定するための系統的検索。
- ・特定された研究から得られた知見の妥当性の評価。
- ・収録された研究の特性と知見を体系的に提示し、総合的にまとめたもの。

上記の各アプローチは共通のテーマとワークフローを共有しており、科学的な文脈(例えば、 問題の定式化やプロトコル)の記述から始まり、明確な検索戦略の方法を用いた文献レビュー、 研究の質の解析(しばしばバイアスのリスクと呼ばれる)、エビデンス全体の質の評価(例えば、 統合)、そして最終的に結論に至るまでの流れを示している。それぞれのアプローチでは、科学 文献の包含/除外、研究の質の評価、研究の質(例:高、中、低)の報告のための透明性のある 事前に設定された基準を推奨している。各アプローチでは、結論の基礎となるデータ統合のため の事前に定められたツールを推奨している。

これまでのところ、リスクアセスメントに関係する人々の間では、システマティックレビュー のための単一の命名法は合意されておらず、OCSPP は、より広範な経験が積まれるにつれて用 語が進化していくことを期待している。OCSPP は、システマティックレビューのプロセスとワ ークフローを、問題の定式化から始まり、データ収集、データ評価、 データ統合、そして重要 なデータギャップを特定した結果の要約と考えている。

科学的な解析は、新しい知識が得られるたびに、繰り返し行われることが多い。

#### A. 問題の定式化

NRCの報告書「Science and Decisions-Advancing Risk Assessment (科学と意思決定・リス ク評価の促進)」において、全米科学アカデミー(NAS)は EPA に対して、政策立案者に有用 なリスク評価と関連する科学的解析を開発するよう勧告した。この目標達成のために NRC は、 政府機関に対してリスク評価の開発において一層幅広く問題の定式化を用いるよう勧告した。 NRCの勧告を受けて、USEPA は「ヒト健康リスク評価フレームワーク」(USEPA、2014年) を公表し、問題の定式化の重要性を強調している。問題の定式化は、科学者とリスク管理者の間 の初期対話を伴うものであり、科学的解析のための規制上の背景を提供し、解析の範囲を定義す るのに役立つ。問題の定式化は、評価の規制、政策調査及び政策の背景から導き出され、評価の 技術的なアプローチの情報を提供し、考慮すべき主要な要因を体系的に特定するものである。こ のように、各システマティックレビューの複雑さと範囲は、異なるリスク評価の文脈によってさ まざまである。言い換えれば、OCSPP のシステマティックレビューは、問題設定から事前に設 定された範囲と目的に基づいた「目的にかなったもの」(NRC、2009年)として実施される。

問題の定式化には、利用可能な情報とともにデータや科学的情報の主要なギャップを考慮する ことが含まれる。OPP は、ばく露経路と潜在的な健康影響を特定するためのツールとして問題 の定式化を用いており、適切な方法、情報源及び科学的解析のアプローチとともに使用している。 欠損データが評価において重要な場合、情報(例えば、必要とされる試験)を得るための最良の 選択肢が議論される。ピアレビュープロセスが特定され、評価を完了するためのタイムラインが 定義される。

システマティックレビューは、利用可能な情報を整理し、解析に対する規制目的に関する情報 のギャップを特定するための明白なツールを提供する。このように、問題の設定では、科学的解 析の規制上の文脈が説明され、それによって科学的文献の収集と評価の範囲と目的が定義される。 問題の設定における考慮すべき事項は、集団またはライフステージ、ばく露経路(例:経路、期 間、頻度)及び/または in vitro または in vivo の実験室での研究、疫学またはヒトの事故によ る研究から特定された目的の健康結果、ならびに利用可能な資源及び規制の時間枠に関すること であろう。疫学情報及びヒトでの事例情報を考慮する文脈では、試験の質、試験デザイン及び不 確実性の初期評価が考慮される。

問題の設定で考慮されるハザード評価に関連する主な科学的課題は以下の通りである。ばく露 に関連する影響とは何か?これらの影響に関連する MOA/AOPs はどのようなものか?影響の 時間的側面は?影響を受けやすい集団があるのか、あるとすれば、その集団は誰であり、どのよ うな要因によって影響を受けやすいのか。実験動物とヒトの間で PK や薬力学 (PD) に違いは あるか?また、ばく露情報は問題の設定においても評価される。問題の設定で考慮されるばく露 評価に関連する主な科学的課題は以下の通りである。農薬はどのように使用されるのか?ばく露 の関連する使用場所のすべてはどのようなものか?ヒトはどのような化学物質にばく露されるの か?ばく露の方法、期間、頻度はどのようなものか?きがばく露される可能性があるか?ばく露 は異なる集団 (例えば、年齢や行動パターンのため)に異なるリスクをもたらすのか?疫学デー タの具体的なケースでは、このレビューでは、研究仮説、研究デザイン(すなわち、サンプルサ イズ、十分な対照、測定方法の質など)、ばく露量/ばく露濃度、統計解析及び結論を含むが、 これらに限定されない様々な要因を考慮して検討する。

#### B. データ収集

システマティックレビューのデータ収集段階では、公開科学文献や農薬登録のために提出され た研究論文など、様々な公開・未公開の情報源から利用可能な情報を収集する。OPP では、経 済協力開発機構(OECD)試験ガイドライン、OCSPP 調和試験ガイドライン及び農薬ガイドラ イン(OPP ガイドライン)に基づいて収集されたデータをレビューしている。これらのガイド ライン研究論文は、主に提出された研究の社内データベースから収集され、そのような社内デー タベースの検索によって発見される。

疫学の場合、ほとんどの研究は公開されている科学文献に掲載されていることが予想される。 場合によっては補足的な解析や情報が得られることもあるが、研究者との対話によって、疫学研 究を理解し解釈する上で、原著論文には掲載されていない追加の重要な情報が得られることもあ る。ヒトでの事例の情報源はセクション IV にまとめられている。

公開文献検索戦略では、特定の基準を用いて、公開されている科学文献や未発表の情報源から 健康影響情報を検索する。最も適切な情報源/データベースを特定して選択し、分類コード、医 学的主題の見出し及び/またはキーワードを利用した最もリソース効率の良い戦略を調査した後、 文献の検索が行われる。科学的評価の複雑さに応じて、文献管理責任者のサポートが必要な場合 もあれば、必要でない場合もある。ヒトの健康に関する文献検索の目標は、文献検索プロセスの 適切な文書を提供することにより、信頼性が高く再現性のある文献検索を行うことである。有用 な研究を検索するには、以下の手順で行う。

- 科学的解析の目的と包括基準が確立されている。
- 用語/キーワードや MeSH (Medical Subject Heading) 用語の組み合わせと、それらの ブール考案の組み合わせ(AND; OR; NOT)を使用し、文書化する。

必要に応じて、著者名、タイトル、キーワード、主題見出しによる高度な検索やフィー ルド検索を行うこともできる。データベースの構造を知り、特定のデータベースに対し て別の検索戦略を使用することは、有用な研究論文を検索する際に役立つ。最初の包括 的な検索に加えて、文献リストを更新するために定期的な検索を行うこともある。

- すべてのデータベースのすべての検索が再現可能であることを保証するために、検索戦略は検索の日付を含めて文書化されている。
- 検索された論文のリファレンスリスト<sup>2</sup>は、追加の文脈を調べたり、最初の検索では発見 されなかった論文を探したりするために調査されている。
- 異なるデータベースから検索された論文を組み合わせて重複を除去した後、利用可能な タイトルと要約を選別する。タイトルと要約から関連性が判断できなかった論文につい ては、その論文を検索し、さらなる再検討を行う。
- 最初の選別の後、有用性のない論文(除外基準)一例えば、持論の論文、英語で記述されていない研究論文、要約のみで構成された論文は、除外される。追加の除外基準は個別的に特定される。すべての除外基準は文書化されている。残りの論文は、有害な健康影響が認められなかったものであっても、検討と評価のために含まれる。

## C. データ評価

データ評価段階では、データの質が検討され、そのようなデータの有用性について結論が出される。研究の質は、報告された結果が正しいという全体的な信頼性を反映する(Balshem ら、2011年)。このように、研究の質には以下のようなものがある。

- 報告の質(研究の報告がどの程度に十分であるか、または完全であるか)。
- 試験のデザインと実施に基づいて、試験結果がどの程度に信頼性のあるものか。
- さらに、その研究が評価下の主題にどの程度に十分な対応しているか(Rooney ら、 2014 年)。

研究の質は、まず個々の研究基盤で検討され、その質が判断される。例えば、不完全に実施さ れたコホート研究よりも、適切に実施された症例対照研究の方が信頼性は高い場合がある。科学 的知見の信頼性は、しばしばバイアスのリスクと呼ばれ、試験のデザインと実施に関連する特定 の分野について、あらかじめ定められた基準を用いて評価される(表2参照)。

OPP は当初、「ヒトの健康リスク評価を支援するための公表されている科学文献の毒性研究 の検討と使用に関するガイダンス」(Guidance for Considering and Using Open Literature Toxicity Studies to Support Human Health Risk Assessment)(USEPA、2012年)と呼ばれ る公表されている科学文献の考えの使用に関するガイダンスを作成し、一般的にはこのガイダン スに従っている。しかし、リスク評価におけるシステマティックレビューの促進に伴い、この文 献ガイダンスの一部の側面は将来的に更新が必要になる可能性がある。 データの質についての結論が出され、結論の記述またはカテゴリー(例えば、許容可/許容不 可;低、中、高)で記述される。

農薬に関する疫学研究の評価に用いられる具体的な考えは、以下のセクション III.C に記載されている。データレビューの一環として、研究の簡潔なレビュー文書を作成する。このレビュー 文書には、研究のデザイン、結果、結論と、研究の長所と短所が記載されている。疫学的ばく露 評価の質は、疫学的データがリスク評価においてどのような役割を果たすかを調査する上で重要 な要素である。そのため、疫学的ばく露評価で使用された仮定と、その仮定が疫学的知見の解釈 と一般化の可能性にどの程度影響を与えるかを十分に特性評価することが重要である。疫学的ば く露評価には、過去及び現在のばく露パターン(例えば、ばく露集団、ばく露経路、ばく露方法 及びばく露レベル)の検討が含まれ、また、使用パターンの大幅な変化(例えば、リスク軽減措 置や新たな使用パターン)が含まれている場合がある。メタ分析の評価に関しては、Stroup ら (2000 年)によって報告された「疫学における観察研究のメタアナリシス」Meta-analysis Of Observational Studies in Epidemiology (MOOSE)のガイドラインが、メタ分析の質の評価や 解釈に有用である。

# D. データ統合:エビデンスの重み付け(WOE)

OPP のヒト健康影響評価では、ヒトでの調査/疫学、バイオモニタリングデータ、in vitro の 毒性試験及び in vivo の毒性試験、MOA/AOP 情報、薬物動態試験、構造活性関係(SAR) な どを含む(但し、これらに限定されない)利用可能なすべての関連データを考慮する必要がある。 さまざまな種類のハザードデータを収集し、関連する各試験の完全な評価を実施して記録した後、 次のステップは複数のエビデンスを統合することである。

データ統合は、関連するハザードについて利用可能なネガティブデータとポジティブデータを 総合的に判断するという原則に基づいている。OPP は、疫学データ及びヒトでの事例データの 評価に WOE 解析を使用しているが、結論は、特定の研究に依拠するのではなく、情報の優越性 に基づいて出される。OPP は、異なる情報源からの情報を整理して統合するためのツールとし て、MOA/HR のような修正された Bradford Hill 基準を使用している(Hill、1965 年; U.S. EPA、1999 年、2005 年; Sonich-Mullin ら、2001 年; Meek ら、2003 年; Seed ら、2005 年; OECD AOP Wiki Users Handbook<sup>8</sup>)。Hill 基準は、チェックボックス方式ではなくて、エビデ ンスの総合的評価の検討を示唆していることに注目することが重要である。また、MOA/AOP が完全に解明されていることは、ヒト健康リスク評価に疫学研究を利用するための必須条件では ない。しかし、完全に解明された MOA/AOP がない場合でも、メカニズムデータの収集と評価 は、生物学的な妥当性の裏付けとなり、生体組織の感受性、生物種、性別、ライフステージ、ま たはその他の要因での違いを説明するのに役立つ可能性がある。MOA/HR は、厳密ではない情 報を整理するための基盤を提供する柔軟なツールである。

<sup>&</sup>lt;sup>8</sup> https://aopwiki.org/wiki/index.php/Main\_Page#OECD\_User\_Handbook

これは因果関係の評価、複数の科学的根拠に基づく情報の統合、データのギャップや今後の研究 分野の特定などの様々な目的に有用なツールとなる柔軟性を備えている。この解析では、疫学的 知見やヒトでの事例データは、生物学的な妥当性を評価するために、他のヒト情報や試験の文脈 で評価され、不確実分野や今後の研究分野を特定することができる。Bradford Hill の側面が WOE 評価でどのように考慮されるかを説明するために、OPP は、EPA の全米環境大気質基準 (NAAQS)のレビューのための科学的基盤となる統合科学評価(ISA)の EPA 前文に記載され ている用語の定義を使用している(USEPA、2015 年)。

- 重要事象。特定の健康影響について MOA/AOP が確立されている場合には、MOA/AOP の基礎となる重要事象(すなわち、測定可能なパラメータ)をそれぞれ明確に記述する。重要事象を示すデータは、*in vitro*または *in vivo*のデータソース(ヒトまたは動物)の組み合わせから得られる可能性がある。これらの重要事象は、PK 事象と PD 事象の組み合わせである。しかし、完全に解明された MOA/AOP を利用できることは、ヒト健康リスク評価に 疫学研究を利用するための必須条件ではないことは注目に値する。
- 生物学的勾配/ばく露-反応/用量-反応の一致と関係。ISAs の前文では、「疫学の文脈では、よく特徴づけられたばく露-反応関係(例:ばく露量が多いほど影響が増加する)は、特にばく露期間(例:ばく露時間が長くなると影響が増加する)についても因果関係を強く示唆する」(USEPA, 2015)と指摘している。MOA/AOPが明らかである場合、各重要事象について用量反応関係が特定される。用量反応関係は、重要事象間で比較される。場合によっては、初期の重要事象の方が後期の重要事象よりも感度が高い場合がある。他の場合では、重要事象は類似した量反応曲線を共有しているかもしれない。
- 時間的関連付け。薬剤の投与と影響の出現との間に時間的な順序があるというエビデンスは、
   因果関係を支持するもう1つの根拠となる(USEPA、2015年)。ISAsの前文では、「ばく露の変化が健康影響の発現または発生頻度の変化をもたらすことが判明した場合には、
   『自然実験』を通じて因果関係を示す強固なエビデンスを提供することができる」と指摘している。

この解析では、影響の整合性を確保するために急速に発現する重要事象(例えば、ばく露後数 分以内に発現する活性代謝物への代謝)と長い継続期間の後に発現する重要事象(例えば、腫瘍 の発生)を考慮している。疫学データを検討する際には、ばく露と健康影響の間の時間的関係が 考慮される。

#### 強固性、一致性、特異度。

一致性。複数の独立した研究でリスクの上昇が観察された場合に、因果関係の推測は強固になる。結果の再現性は因果関係を示す最も強力な根拠の一つである。統計的な有意性は、効果の有無を判断する唯一の基準ではない。研究間で不一致な結果がある場合は、ばく露の違い、交絡因子、研究の検出力などの理由が考えられる(USEPA、2015年)。

複数の研究における結果の一貫性は、複数の独立した研究における効果または関連付けの繰り 返しの観察から得られる。さらに、異なる状況下での異なる母集団における結果の再現性によっ ても支持される。しかし、独立した調査の間での結果の不一致は、調査方法の違い、ランダムエ ラー、ばく露、交絡因子、または研究の検出力の違いによって説明される可能性があり、因果関 係を否定するために使用することはできない(USEPA、2015年)。

**観察された関連付けの強固性。**大規模で正確なリスクの発見は、関連付けが偶然、偏りまたは その他の要因によるものではない可能性が高いという確信を得られる。しかし、影響の推定が小 さい場合は、母集団における実質的な影響を表す場合もあれば、そうでない場合もあることに注 意が必要である(USEPA、2015 年)。

**観察された関連付けの特異度。**特定の結果をばく露に結びつけるエビデンスは、因果関係を示 す強い根拠となる。しかし、環境ばく露が結果の発生を必ず予測できることは稀であり、結果に は複数の原因がある可能性を認識しなければならない(USEPA、2015 年)。

### 生物学的な妥当性と整合性。

**整合性。**1 つのエビデンス(例えば、疫学的に管理されたヒトのばく露研究、毒性試験、または生態毒性試験)からの因果関係の推測は、関連付けの因果関係の解釈を支持する他のエビデンスによって強化されることがある。1 つの科学的エビデンスグループの中で、さまざまな分野にわたるエビデンス、複数の試験デザインにわたるエビデンス、または健康影響に関連するエビデンスから、効果を示す一貫性があるかもしれない(USEPA、2015年)。

動物でのデータとヒトでのデータが、定量的にも定性的にも同様の毒性プロファイルを示してい る場合、ヒト健康リスク評価の信頼性は高い。一方、動物でのデータとヒトでのデータが定性的 には類似した毒性プロファイルを示していても、定量的な相違が観察される場合もある。例えば、 ある化学物質が動物とヒトでは同じMOA/AOPを示していても、用量反応特性に種差がある場 合がある。このような用量反応性の相違は、生体組織薬量測定(すなわちPK)に起因するか、 または異なる反応特性(すなわちPD)に起因する可能性がある。一方、動物でのデータとヒト でのデータは、場合によっては質的に異なる結果を示すことがある。このような状況から、種、 性別及びライフステージの違いや潜在的な感受性などの要因を考慮するために、入手可能なすべ ての情報を透明性のある包括的な方法で十分かつ客観的に評価する必要性が明らかになった。

**生物学的妥当性。**因果関係の推測は、生物学的に妥当なメカニズムを示す試験またはその他の 情報源からの結果によって強化される。提案されたメカニズムは、実験的エビデンスに基づいて おり、ある物質へのばく露を所定の効果に結びつけるもので、因果関係を支持する重要な情報源 である(USEPA、2015 年)。

同様に、多くの構造的類似物の1つとしての化学物質のMOA/AOPに関する情報は、因果関係の可能性が高いかどうかの判断に役立てることができる。構造活性相関及び薬剤の構造的類似物に関する情報は、関連性が因果関係にあるかどうかについての洞察が提供される(USEPA、2015年)。

EPA のがんガイドライン(2005年)は以下の通りに指摘している。

「疫学研究で観察された関連付けの生物学的妥当性の評価は、潜在的作用機序(MOA)の 特定に関連する毒性学的エビデンスとばく露関連因子の両方を考慮したものである。同様に、 疫学的文献で報告された健康影響の関連付けの整合性を考慮することは、毒性試験や疫学研 究で評価された生物学的マーカーの特性に関する情報を幅広く考慮することを示している [p.39]。」

しかし、このガイドラインはさらに、「しかしながら、メカニズムデータの欠如は因果関係を 否定する理由にはならない [p.41]」と述べている。このように、確立された MOA/AOP の欠 如は、疫学データを使用する際に必要な知識ではなく、確立された MOA/AOP がなくても疫学 的関連付けは有効である可能性があり、また、潜在的な MOA/AOP について洞察も得られる可 能性がある。

・不確実性。不確実性は WOE で明白かつ客観的に述べられている。

## E. 全体的な結論、リスク評価の推奨事項、信頼性と不確実性の分野の陳述

エビデンスの要約、エビデンスの重み付けに使用した手順または方法、WOE の結論または勧 告の根拠、不確実性及び更なる研究分野を文書化することが重要である。また、リスク評価にお ける疫学的データまたはヒト由来のデータの役割についても推奨されている。一般的に、OPP はヒトでの事例情報を定量的リスク評価には使用しないが、その代わりに、新たなリスク評価や 新たなリスク管理措置の必要性を示すこと、リスク軽減措置が実施された後の成功度を評価する こと及び可能性のある施行活動を対象とすることなど、リスク評価/リスク管理の活動を対象と する。

ヒトでの事例データの役割がより限定的であるのとは対照的に、疫学研究は様々な方法でリス ク評価の複数の構成要素に情報を提供するのに役立つ可能性を持っている。正確なばく露評価を 行った質の高い研究は、リスク指標を定量的に推定するために使用することができる。

また、疫学的研究で報告された結果は、*in vitro* 試験や動物試験で見られた結果と定性的に比較して動物試験の結果のヒトへの関連性を評価することもでき(Hertz-Picciotto、1995年)、 疫学的結果の生物学的妥当性を評価することにも有用である。提案されている WOE 解析の最後 の部分では、全体的な結論と信頼性と不確実性の分野の記述が行われる。このセクションでは、 追加研究の分野も特定している。本セクションでは、規制値の情報源及び(必要に応じて)種間 及びヒトの間での外挿法での推定のための適切なアプローチを推奨している。

# IV. 農薬のリスク評価に用いるための疫学研究のレビュー A. 緒言

疫学は、化学的、物理的、または生物学的要因へのばく露と集団の健康状態との関係を特定し、 評価することを目指す科学である(Boves ら、2007 年)。疫学とは、「集団における疾病の分 布と、その分布に影響を与えたり、調査したりする要因の研究」と定義されている(Gordis、 2009年)。より広義には、「特定の集団における健康に関連する事象、状態、プロセスの発生 と分布の研究であり、そのようなプロセスに影響を与える調査要因の研究と、この知識を関連す る健康問題の制御に応用することを含む」(Porta、2014 年)と考えられている。多くの疫学研 究の目的は、病気の発生に対する潜在的な原因の影響を有効かつ正確に推定することである。疫 学の主な目的は、他の科学と同様に、原因と結果を明らかにすることであり、別の言い方をすれ ば、病気や健康影響の病因とそれに関連する可能性のあるリスク因子を特定することである。 Calderon(2000年)は、このような研究の4つの主要な用途を説明している。1)集団の健康状 態を記述し、疾病やばく露頻度の重要な時間的傾向を発見すること、2)特定の疾病や傾向に関 連する因子を特定することで疾病の発生を説明すること、3)特定の集団における疾病の発生数 や健康状態の分布を予測すること、4)環境やヒト健康に悪影響を及ぼす因子を特定することで 集団の健康状態を改善すること、である。農薬の場合、疫学は、一般集団と、職業上ばく露され る農業従事者や農薬散布者などの特定の小集団におけるばく露と健康への悪影響との関係に焦点 を当てている。

疫学研究は、様々な方法でリスク評価の複数の要素に情報を提供するのに役立つ可能性がある。 正確なばく露評価を行った質の高い研究は、リスクを定量的に推定するために、あるいはオッズ 比やリスク比のような適切なリスク・サロゲート(代理)を用いることができる。しかし、農薬 や農薬ばく露を扱う疫学研究の多くは、規模、範囲、ばく露評価、またはデータ解析になんらか の制限があり、それが定量的リスク評価への十分な利用を妨げている(Ntzani ら、2013 年)。

米国での農薬使用は、ここ数十年で大きく変化した。使用が変化すると、農業従事者へのばく 露も変化する。農薬使用の変化は、EPA によるリスク軽減措置、抵抗性管理活動、新しい化学 物質の導入、遺伝子組換え作物の使用量の増加によって生じている。疫学研究を解釈し、最終的 には定量的リスク評価にそのような研究を使用するかどうかを調査する際には、ばく露における これらの大きな変化を考慮しなければならない。そうであっても、疫学研究は、実験的動物研究 から得られたエビデンスと比較して、そのような値を導き出す際の仮定を特徴づけるために使用 することが可能である。また、疫学研究で報告された結果を *in vitro* 試験や動物試験で得られた 結果と定性的に比較して、動物実験で得られた結果の生物学的妥当性や人間との関連性を評価す る場合もある(Hertz-Picciotto、1995 年)。疫学研究で得られたようなヒトでの情報は、NRC (2007 年)が推奨する毒性試験の新しいビジョンにおいて重要な役割を果たす可能性があると 期待されている。具体的には、疫学研究は、ヒトの実社会での化学物質ばく露から生じる可能性 のある健康影響についての知見を提供し、その結果、問題の設定やハザード/リスクの特性評価 に貢献することができる。ヒトでの情報は、追加的な研究(例えば、*in vitro* 試験や目標とする *in vivo*試験で使用するための用量やエンドポイントの選択)の指針となり、今後の研究で調査さ れる新たな健康影響や感受性を特定することができる。

動物実験から得られた実験データがハザードの特性評価のための主要な情報源となる場合、潜 在的な不確実性の原因の一つとして、動物モデルのヒトへの関連性が挙げられる。これに反する データがない場合には、動物の結果はヒトとの関連性があると想定される。さらに EPA はヒト は実験動物よりも感受性が高いと仮定しているが、それを裏付けるデータがない。実際には、ヒ トは他の動物種よりも農薬に対して感受性が高い場合も低い場合もある。疫学データ及びヒトで の事例データは、科学的な情報を提供し、外挿法での推定に関連する不確実性を伝えるための裏 付けとなり得る。母集団の変動性に関しては、動物試験よりも疫学研究の方が潜在的な変動性を の特徴をよく表している。具体的には、疫学データは、ヒトの集団に固有の遺伝的多様性と変動 性を含むため、実験動物よりも環境化学物質に対する実際の集団での反応をよりよく説明し、代 表することができる(Calderon、2000 年)。

用量反応の特性評価に関して、動物の毒性試験には、広範囲のばく露レベルをカバーするよう に試験デザインできるという利点がある。しかし、動物の毒性試験では、一般的に環境中でのば く露レベルよりもはるかに高い(時には桁違いの)ばく露レベルが用いられている。動物試験で は、このような高いばく露レベルがあるため、高用量から低用量の外挿法での推定が必要である。 この外挿法での推定はリスク評価に不確実性をもたらす。疫学研究データやヒトでの事例データ は、ヒトの実社会でのばく露を含んでいるため、多くの場合、高用量の外挿法での推定は必要な いと考えられる。疫学研究は低用量から高用量までの広い範囲のばく露が最も有用である。

動物試験では、ヒトが経験するばく露の時間、程度、期間、ばく露経路及びばく露の変動性を 再現するものではない(Calderon、2000年)。ヒトでのばく露は、食品、水、空気、屋内外の 環境を含む多岐のばく露経路を介して行われることが多い。対照的に、制御された実験室での研 究では、通常、単一のばく露経路である。

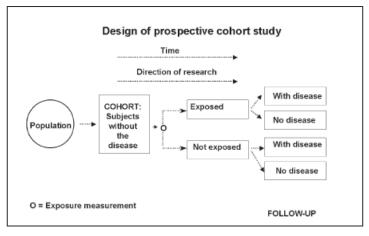

さらに、ほとんどの動物試験では単一の化学的ストレス因子を用いているのに対し、ヒトでは複数の化学物質及び/または非化学的ストレス因子へのばく露を同時に受けている可能性がある。 一方で、疫学研究における複数の化学物質へのばく露は、疫学研究の結果が単一の農薬に帰属させようとする場合に問題となり得る。一方で、疫学研究は実社会のばく露を考慮しており、実験的アプローチと併せて考慮することで、実験環境では評価が困難な複数の化学物質ばく露に関連した問題に対処するのに役立つ可能性がある。

#### B. 疫学研究の種類

観察疫学研究の主なタイプを、その長所と短所を考慮しながら以下に簡単に説明する (Lilienfeld and Lilienfeld、1979年; Mausner and Kramer、1985年; Kelsey ら、1996年; Rothman and Greenland、2012年; Paddle and Harrington、2000年; USEPA、2005年; Purdue Pesticide Programs, PPP-43)。

**コホート研究**では、共通の特性を共有する人々の集団(コホート)から始まり、病気の発生が記録されている長期の追跡期間にわたって健康状態を評価を行う(van den Brandtら(2002年)

から引用の図を参照)。共通の特性 は、しばしば「リスク因子」(ばく露 など)<sup>9</sup>の有無である。このような研 究では疾病発生率の違いを調べるため に、「ばく露者」と「非ばく露者」の 間の疾病発生率の違いを特定し、時間 をかけて調査する<sup>10</sup>。次に、この疾病 発生率の差を調査して、「ばく露群」 と「非ばく露群」の間で疾病発生率が 異なるかどうかを判断する。コホート 研究は、複数の疾病発生を同時に評価 対照研究では当てはまらない。症例対照

研究では、一般的には後述するように単一の(事前に指定された)疾病発生のみを評価すること に限定される)。

コホート研究は、Agricultural Health Study (AHS\_http://aghealth.nci.nih.gov/) のように前 向きで実施することもできるし、過去の記録から後ろ向きに実施することもできる。前向きコホ ート研究は、現在の時点から将来の時点までの人々の集団に焦点を当てている。後ろ向きコホー ト研究は、過去のある時点でばく露された集団に焦点を当て、ばく露が発生した後の疾病率を比 較するものである(一般的には、一人(個人)単位で利用できる既存のばく露データベース(ま たは記録)を利用)。

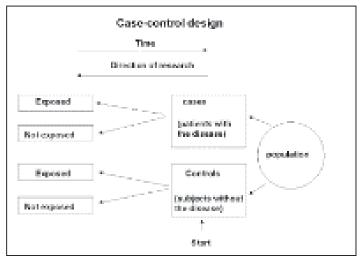

<sup>9</sup> コホート研究では、ばく露はしばしばばく露者と非ばく露者に二分されるが、ばく露は定量的 尺度(例えば、連続的尺度または定量値)で測定することも可能である。

<sup>&</sup>lt;sup>10</sup> コホート研究では、一般的に疾病発生率の違いを研究しているが、これらの研究には、出生時の体重、知能、血圧など、関係のある他の限局的な結果も含まれる。

前向きコホート研究は、特に希少疾病の場合、実施に比較的時間がかかり、費用がかかることが あり、研究対象となる被験者の数が多いことが必要である。重要なことは、質の高いデータを収 集するためには、長期間にわたって多大な資源と専門スタッフが必要であるということである。

**症例対照研究**は、特定の疾病を持つ(症例)個人と、そうでない(対照)個人の集団を特定し、 ばく露(一般的には過去<sup>11</sup>のばく露)に関して比較することで、関係ある疾病を持つ人が、関係 ある薬剤あるいは要因にばく露されていたか否かを判断する研究である。すなわち、症例対照研

究の解析では、症例において関係ある薬剤 または要因のばく露頻度と、対照群におけ るばく露頻度を対比させて、これらが異な るかどうか、要するに関連があるかどうか を判断する。症例対照研究では、一般的 に、疾病状態(すなわち、疾病を持つ症例 と疾病を持たない対照群)を決定すること が、通常、ばく露状態の調査に先立って行 われる(van den Brandt ら、(2002年)か ら引用の図を参照)。この研究デザインは 症例対照研究に選択された時点ですでに疾 病が発生しているので、希な疾病や潜伏期 間の長い疾病の研究で特に有用であり、多 くのばく露と関係ある特定の(事前に指定 された)疾病発生との関連性を評価するた

めに利用することができる。また、症例対照研究は、その疾病に罹患している個人を対象として いるので、コホート研究に比べて被験者数が少なく、比較的短い期間で終了することができる。 症例対照研究の問題は、適切な対照群の選択と、疾病が診断されるずっと前に発生した可能性の あるばく露の評価である(Rothman, 2012 年; Wacholder ら、1992 年 a; Wacholder ら、1992 年 b; Wacholder ら、1992 年 c; Shultz and Grimes、2002 年; Grimes and Schultz、2005 年)。症 例対照研究は、特に"想起バイアス"の影響を受けやすい。これは、罹患した人は、対照あるいは 健康人と比べてばく露や出来事を違った形で(一般的にはよく)覚えている可能性がある。

**コホート内症例対照研究**は、ハイブリッドデザインの一例であり、コホート研究と症例対照研究の要素を含んでいる。この研究デザインは、農薬ばく露を調査するための解析コストが、高すぎて、コホート全体を調査することができない場合に有用である。

<sup>&</sup>lt;sup>11</sup>時間をかけて症例を研究に登録した状況下では研究開始後まで発症していない症例で前向きに 症例対照研究を実施することは可能である。

例えば、現在進行中のコホート研究で疾病または健康影響を生じた症例は、解析時に関係ある疾 病や影響を生じていない研究からの適切な対照群と組み合わせることが可能である。コホート内 症例対照研究(標準的な症例対照研究とは対照的に)の利点として認識されているのは、選択バ イアスと想起バイアスの問題が最小限に抑えられることである。

横断研究では、疾病(例えば、先天性異常、胎児発育遅延(SGA))、症状、生物学的/身体 的及び生理学的反応の測定値(例えば、肺機能検査、血圧、胸部X線、臨床検査、肝臓及び腎臓 のバイオマーカー)の有病率に焦点を当てている。このような研究の主な特徴は、サンプリング 時またはサンプリング期間中に疾病の有無を判定し、有病率を頻度の尺度として重視した観察研 究であるということである。有病率とは、ある集団の中で罹患している人の割合であり、「点有 病率」または「期間有病率」として調査される12。有病率は比率ではなく、割合であるため、横 断研究では追跡調査期間を必要としない。一般的に、ばく露状態(例えば、ばく露または非ばく 露)、疾病の状態/発生、人口統計学的特性は、ある時点(またはその時点以後)で調査される。 この研究デザインにおける主な比較は、ばく露集団における疾病発生の有病率と非ばく露集団に おける疾病発生の有病率の比較であり、リスク尺度は有病率リスク比またはオッズ比である。横 断研究は、一般的に、長年にわたる疾病発生または地理的に異なる場所のパターンや傾向を明ら かにするために使用され、迅速かつ比較的安価に実施することができる。しかし、これらの調査 では、疾病の発生率(新規症例の発生率)と疾病の持続期間の両方に影響される疾病発生の有病 率を測定しているため、これらの要因を十分に分離することは、どのような解析においても困難 な場合がある。したがって、これらの研究は「生存者集団」を対象としており、病気になったた めに関係ある集団から離れてしまった人を測定、評価、考慮することはない。横断研究のもう一 つの重要な限界は、ばく露が疾病に先行しているかどうかを判断できないことである。そのため、 横断研究では疾病とばく露の時間的関係を確立することができず、横断研究で示唆された仮説に 基づく因果関係を確認するために、追加の研究を必要とするのが一般的である。

**生態学的研究**では、グループまたは集団のレベルでのデータを反映した情報を用いてばく露や 疾病のパターンを調べる。生態学的研究では、解析の単位は個人ではなく集団である<sup>13</sup>。ここで は、被験者の集団がサンプリングされ、ばく露、疾病及び潜在的な交絡因子を、この集団(また はクラスター)レベルで測定される。集団は一般的に地理的、行政的、組織的な単位(例えば、 地区、町、郡、学校、職場など)で定義され、すべてのばく露、疾病、交絡因子の測定は、個人 のレベルではなく、集団のレベルで行われたり、まとめられたりする。生態学的(集団ベース) 研究は、個人レベルの研究とは対照的であり、前者では症例がばく露された実際の個人であるか どうかの情報がないのに対し、後者ではばく露情報が個人に結びついている。

<sup>&</sup>lt;sup>12</sup>前者は特定の場所及び/または特定の時間での測定であるのに対し、後者は特定の期間における症例の割合の調査である。

<sup>&</sup>lt;sup>13</sup> 一部の研究では、ばく露または疾病発生のいずれかが集団のレベルで測定されるが、他の変数 は個人のレベルで測定され、研究者は個人のレベルで推測を行うという「部分的に生態学的」 研究もある。

例えば、水中の汚染物質レベルによる疾病率の研究は、ばく露の評価に関しては生態学的である が、健康影響や疾病状態は個人で調査されている場合がある。このような場合、ばく露は集団レ ベルで決定されるが、結果は個人レベルで調査される場合に「半生態学的」という用語が使用さ れることがある。

この研究デザインでは、ばく露集団のすべてのメンバーが個別にばく露されているかどうか (または個人のばく露レベル)を知ることはできないし、グループレベルの影響から個人レベル の影響を推測することもできない。研究の目的が(個人ではなく)*集団*への直接的な推測を目的 としている場合には、これは問題では<u>なく</u>、特に個人レベルでの測定が制約されていたり、困難 であったり、集団内のばく露が一般的に均質であったりする場合には、このような研究が適切で あると考えられる。研究の意図が個人への直接的な推測である場合、この研究デザインは生態学 的誤謬と呼ばれる問題を抱えていることになる。集合またはグループ化されたデータセットで観 察された関係が、個人レベルでサンプリングが行われていたら観察されていたであろうことを反 映するという仮定である。この生態学的誤謬の問題に加えて、交絡因子に関する情報が集団レベ ルでしか得られない場合、集団とは対照的に個人レベルで交絡変数を適切にコントロールできな い結果、追加のバイアスが発生する。

ほとんどの場合、生態学的研究は仮説を生み出す研究と考えられており、今後の研究のための 研究仮説を提案するのに最適であり、問題の提起に貢献する可能性がある。とはいえ、生態学的 研究をデザインの質に基づいて評価することは重要であり、デザインが優れていれば、生態学的 研究から有用な情報を得ることができる(FIFRA SAP、2010 年)。一般的に、生態学的研究だ けでは、因果関係を立証する能力はない。これらの研究を他の研究と併用した場合、特定の状況 下では有用となる可能性があり、ハザード特性評価の際に留意すべきである。特に、安定した母 集団、明確なばく露の対比、リスクの大きな差は、これらの研究の有用性を高める重要な要因と なり得る。

#### C. 農薬のリスク評価に用いるための疫学研究の評価

OPP は、化学物質の使用に関連した潜在的な急性及び慢性の健康影響に関する観察疫学研究 を査読済み文献で検索する。文献検索の手順と戦略に関する詳細は、別の場所で提供されている。 コホート研究、症例対照研究、または横断研究のデザインを利用した疫学研究は、潜在的なハザ ード、ばく露反応の特性、ばく露シナリオ、または評価方法、そして最終的にはリスクの特性評 価に関する OPP の理解を深めるための情報を提供することができる(van den Brandt、2002 年)。さらに、説得力のある症例報告や症例集積解析は、これまで明らかにされていなかった健 康影響や作用機序を明らかにする可能性がある。

一般的には、OPP のリスク評価で用いられる公開文献からの疫学研究を評価する際には、疫 学研究の質、研究の文書化の十分さ(研究デザインと結果)、リスク評価との関連性が考慮され る。

これらの基準は、懸念されるエンドポイントに応じて様々な方法論の詳細が重要になったり、な らなかったりするため、エンドポイントを特定することが重要である。疾病発生の確認に影響を 与える関連因子を理解することが重要である(*例えば、*影響の有無を示す検査やバイオマーカー が利用できるか、あるいは初期段階では非特異的な症状であり、進行した病状では医師の診断に つながるかなど)。さらに、環境及び職域疫学研究では、ばく露評価の質が極めて重要である。 検討中の問題に対して、ばく露と交絡要因の評価の側面を事前に考慮しなければならない。

個々の研究の質を考える際には、疫学研究のデザイン、実施、解析、解釈の様々な側面が重要 である。これらには以下が含まれる。

- 1. 仮説を明確に明示することで、たとえその研究が本質的に仮説生成的なものであったとしても、その仮説を明確に示されていること。
- 健康影響の関連する重大な時期、リスク評価対象集団の関係あるばく露範囲、試験から 得られる用量/ばく露反応の傾向の入手可能性など、ばく露評価の資質の中で、適切な ばく露評価が十分であること。
- 3. 合理的に有効で信頼性の高い結果の確認(研究集団における健康影響の有無を正しく識 別されていること)。
- 4. 対象集団を代表するサンプル集団となり、系統的な偏りがない適切な組み入れ基準と除 外基準。
- 5. 観察されたリスク推定値における複数の農薬ばく露、または混合物ばく露の役割の評価 または考察を含む、潜在的な交絡変数の適切な評価及び解析。
- 6. 参加者の選択や情報収集における誤りを含む、研究における潜在的な系統的な偏りの全体的な特性。これには、提示されたリスク推定値に対する系統的誤差の潜在的な影響を調査するための感度分析の実施を含む(例:Greenland's 公式)。
- 7. 健康影響を観察するための研究の統計的検出力の評価と適切な考察及び/または説明。
- 8. 研究デザインと対象となる結果の性質を考慮した適切な統計的モデル化技術の使用。

他の連邦及び非連邦の機関が次のようなガイドを提供している(*例えば、*OHAT、ナビゲーシ ョンガイド、National Toxicology Program [NTP] Report on Carcinogens [ROC<sup>14</sup>]、IRIS、 Cochrane ACROBAT-Non-Randomized Studies of Interventions)(Sterne ら、2015 年)、及 び観察疫学研究に関する STROBE(Strengthening the Reporting of Observational Studies in Epidemiology)声明(<u>www.strobe-statement.org</u>, Vandenbroucke ら、2007 年; Von Elm、 2014 年)を参照)。OPP が疫学研究をヒトの健康リスク評価に統合する経験を積むにつれ、評 価アプローチに関連する調整が行われることになる。

<sup>&</sup>lt;sup>14</sup> http://ntp.niehs.nih.gov/pubhealth/roc/index.html

独立した研究評価は、ハザードの特定及びばく露反応評価に有益である詳細な要約表を作成す る前に実施され、文書化されている。表2は、評価された主な考慮事項と、各考慮事項に関連す る重み(低、中、高)の構造を示している。表2は考慮事項の一般的な検討事項を示したもので あり、チェックリストと考えるべきではない。特定の科学的解析に適した特定の科学的考慮事項 は、ケース・バイ・ケースで調整される。

研究評価プロセスの最終段階では、研究固有の評価を通じて特定された各研究における系統的 な誤りから生じる可能性のあるバイアスの性質についての専門家/エキスパートの意見を提供し、 疫学データベースに対する全体的な信頼性の評価を行うことである。このようにして、データ統 合(動物、ヒト、メカニズム、その他)は、環境ばく露や職業上ばく露のヒト健康影響を伝える ヒト疫学研究の信頼度に基づいて行われることになる。

# 1. ばく露評価

ばく露評価は、「ある物質へのばく露の規模、頻度及び期間を、ばく露された集団の数と特性 とともに推定または評価するプロセス」と定義することができる。理想的には、評価において原 因、経路、方法及び不確実性を記述すると記載(Zartarian ら、2005年)されている。環境疫学 において、ばく露評価は、特に環境媒体中に低濃度で存在する毒性物質については、独特の課題 となっている(NRC、1991年; NRC、1997年)。ばく露経路の複雑さを考慮して、研究者はば く露を評価するための多くの異なるアプローチを開発してきたが、その正確さ、精度及び必要な 資源は様々である(Niewenhuijsen、2003年)。これらのアプローチのいくつかは、疫学研究 に特化したものではないが、様々な科学的解析におけるばく露評価の情報を提供するために使用 される可能性がある。これらのアプローチには、過去の記録、アンケート、環境モニタリングに 基づく間接的な方法と、個人モニタリングやバイオモニタリングに基づく直接的な方法がある。 それぞれの方法の簡単な説明とその長所と限界を以下に要約する。

アプローチ	方法/ツール	例	ばく露の推定
間接的	過去の記録	住所情報を利用した農地 への近接推定	二分法または順序のばく露
	アンケート	農薬使用の回答に基づく ばく露の可能性の調査	二分法または順序のばく露
	環境モニタリング	地域の水道における農薬 レベルの測定	モデル化を用いてばく露を 推定することができるが、 二分法または順序のばく露
直接的	個人モニタリング	吸入と経皮でばく露され た農薬の測定	定量化されたばく露
	バイオモニタリング	血中・尿中の農薬の測定	定量化された内部ばく露量

表 3. 間接的ばく露評価方法と直接的ばく露評価方法のまとめ

過去の記録やアンケートは、化学物質へのばく露に関連する可能性のある主要な特性を評価す るために使用される。疫学研究で使用される場合、過去の記録やアンケートは通常、定量的なば く露レベルを予測するためには使用されない。むしろ、過去の記録情報やアンケートの回答は、 ばく露のカテゴリーレベルを調査するために使用される。ばく露レベルを調査するために使用で きる過去の記録情報の例としては、農地に近接した住所や、職位や職歴に関する雇用履歴情報な どが挙げられる。同様に、アンケートは、個人が農薬を使用したことを思い出すかどうかを調査 するために、またはばく露の可能性を高める特定の職務を行っている個人を特定するために使用 される。過去の記録やアンケートは、潜在的なばく露に関するデータの費用対効果の高い情報源 になり得るが、限界がある。過去の記録やアンケートから収集されたデータは、ばく露のサロゲ ート(代理)に過ぎない。

その結果、これらの情報源はばく露の単純化しすぎているため、個人のばく露の可能性を正確 に並べていない可能性がある。

**環境モニタリング**は、大気、水、土壌、食品、家庭環境や職場環境などの環境媒体中の汚染物 質のレベルを特性評価するために使用される。多くの州及び連邦政府のプログラムでは、疫学研 究に有用な環境モニタリングデータを収集している。環境モニタリングは、大気汚染や飲料水な ど、地理的な境界によって定義されるばく露に対して特に有用である。そのため、多くの疫学研 究では、大気汚染と飲料水汚染へのばく露を特性評価するために、大気モニタリングデータと地 域の水道のデータをそれぞれ利用している。環境モニタリングデータは、地理的境界によって定 義されるばく露量を推定するのに有用であるが、個人レベルのばく露量を調査する目的では、特 に個人が多くの異なる場所で生活し、仕事をし、時間を過ごす場合には、信頼性が低くなる可能 性がある。

個人モニタリングは、体の境界の接触点でのばく露を特性評価するために使用される。個人モ ニタリングの例としては、農薬との経皮接触を評価するための線量計の使用、吸入ばく露を評価 するための個人用空気サンプリング装置、食品中の農薬レベルを調査するための対の食品サンプ ルの収集などがある。個人モニタリングの利点は、間接的な方法よりも個人レベルのばく露量を より正確に推定できる可能性が高いことである。また、個人モニタリングは、異なる経路でのば く露の関連性の優先順位付けに有用なばく露レベルの定量化を可能にする。さらに、個人モニタ リングは、時間をかけて測定を繰り返すことで、縦断的なばく露量を評価するためにも使用され る。個人的なモニタリングは間接的なアプローチに比べて多くの利点があるが、労力と資源が必 要とする傾向がある(Niewenhuijsen、2003 年)。その結果、個人モニタリングを用いてばく 露を評価する大規模な疫学研究を実施することは一般的には不可能である。さらに、個人的なモ ニタリングは、サンプルを取得するために使用される測定技術や解析ツールに大きく依存してお り、関連する期間(通常は過去)のばく露を特性評価する情報が利用可能になる可能性は低い。 さらに、対象となる期間のばく露の全容が捕捉される可能性は低く、ピークと変動を捕捉するの に十分な期間でのサンプリングがではないかもしれない。そのため、疫学研究で使用される個人 モニタリング手法の科学的厳密さと信頼性を考慮することが非常に重要であり、そのようなモニ タリングは他のモニタリング(例えば、環境データ、生物学的データ及び/またはインタビュー /アンケートのデータ)で補完する必要があるかもしれない。

バイオモニタリングは、血液、尿、唾液、乳、脂肪、その他の生体組織などの生物学的試料中の化学物質、その代謝物、または反応生成物を測定することであり、ばく露の特性を明らかにするために使用される(Needham ら、2007年)。Zartarian ら(2005年)は、「バイオマーカー/生物学的マーカーは、「生物学的システムにおける変化や事象の指標」として定義されてきた」と述べている。「ばく露の生物学的マーカーとは、組織、細胞、体液などの生物学的媒体から得られる細胞や生化学的、分析的、または分子的な測定値を指し、ある物質へのばく露指標である」と述べている。したがって、バイオマーカーは、ばく露を評価に用いられ、また健康影響の指標として使用される(LaKind ら、2014年)。表4は、疫学研究から収集されたバイオモニタリングデータの質と関連性を評価するための科学的考察を示している。

解析ツールがより費用対効果の高いものになり、より多くのバイオマーカーが同定されるよう になったため、バイオモニタリングを用いたばく露評価は急速に拡大してきた。自己申告のアン ケートやインタビューデータと比較して、バイオモニタリングはばく露の誤分類を減らし、リス ク推定の精度を高めることができるかもしれない。同様に、バイオモニタリングは、異なる経路 からのばく露を統合し、体内に吸収されるばく露量を調査するために使用されている (Checkoway ら、2004 年)。さらに、疾病の履歴におけるバイオマーカーの役割が知られるよ うになってきている場合もあり、バイオマーカーはばく露の時間的な問題を解決するのに役立つ かもしれない。

バイオモニタリングは他のばく露評価方法に比べて多くの利点があるが、それ自体にも限界が ある。多くの研究では、生物学的サンプルはある時点での一点からしか採取されず、特にばく露 が大きく変動する場合には、経時的なパターンを正確に反映していない可能性がある。さらに、 バイオマーカーの評価には、環境とヒトの両方での化学物質の分解と代謝についての理解も必要 である。そのため、ばく露のバイオマーカーはばく露以外の理由で個人間で異なる場合がある。 代謝の違い、尿の測定値に関連した腎臓病などの併発疾患やバイオマーカーが有効成分のばく露 を測定しているのか、環境中分解物のばく露を測定しているのかといった不確実性が、個人間や 想定される比較集団間におけるばく露のバイオマーカーの見かけ上の違いの原因となっているか もしれない。

表 4. 環境疫学研究におけるバイオモニタリングデータの考察(LaKind ら、2014年より引用)

バイオマーカーの考察	ティア1	ティア2	ティア 3
ばく露バイオマーカー	バイオマーカーは、外部ばく露、 内部ばく露量、目標ばく露量と正 確かつ精密な定量的関係にある。	バイオマーカーは、外部ばく露、 内部ばく露量、目標ばく露量との 定量的関係が不明であるか、ばく 露/用量に関してわずかなサロゲ ート[代理](正確さ・精度が低い)である。	
効果バイオマーカー	MOA/AOP では key events のバ イオインジケーター。	健康影響との関係に対する効果の バイオマーカーは明らかである。	バイオマーカーは結論をもたらさ ない(例えば、バイオマーカーは 健康影響を明確にしない)。
特異度	バイオマーカーは、1 つの親化合 物へのばく露に由来する。	バイオマーカーは、類似の毒性を 持つ複数の親化合物に由来する。	バイオマーカーは、様々な有害エ ンドポイントがある複数の親化合 物に由来する。
手法の感度	検出限界は、研究課題に取り組む のに十分な割合のサンプルから化 学物質を検出するのに十分に低 い。	研究仮説に取り組むには、検出頻 度が低すぎる。	NA

バイオマーカーの考察	ティア1	ティア2	ティア 3
サンプルの汚染	サンプルは、収集時から測定時ま で汚染されていない(例えば、分 析物の無いことが保証された収集 用品及び参照物質の使用及びフィ ールドとラボの両方でのブランク の適切な使用による)。研究に は、研究データの信頼性を保証す るために必要な手順の文書化が含 まれる。		汚染の問題が知られているが、問 題を取り上げた文書はない。
手法の要件		マーカーの同定を可能にする装置	<ul> <li>バイオマーカーの定量のみが可能</li> <li>であるが、その方法には既知の干</li> <li>渉物質がある装置(例:GC-</li> <li>FID、分光法)</li> </ul>
マトリックス調整	研究には、調整濃度と非調整濃度 の結果が含まれている。	研究では、1 つの方法(マトリッ クス調整済みかどうか)を用いた 結果のみを提供している。	

FP=偽陽性、FN=偽陰性、GC-HRMS=ガスクロマトグラフィー/高分解能質量分析、GC-MS=ガスクロマトグラフィー/質量分析、 GC-ECD=ガスクロマトグラフィー-電子補足検出器;GC-FID=ガスクロマトグラフィー-水素炎イオン化型検出器]、 ICC=クラス内相関係数;NA=該当しない;PFP=偽陽性の確率 **間接的ばく露評価**方法は、後ろ向き研究では一般的であり、化学物質のばく露のサロゲート (代理)となる因子に基づいている。上述したように、間接的なばく露データは、追加のモデル 化を行わない限り、一般的には定量的なばく露レベルを推定するためには使用できない。例えば、 ある個人が農薬を使用したことがあるかどうかを調査するためにアンケートを使用することはで きるが、その個人のばく露量を計算するために必要なすべての環境的・行動的な要因に関するデ ータを確実に集めることは困難である。そのため、間接的ばく露データは、二分法のばく露変数 (すなわち、ばく露/非ばく露)または順序ばく露尺度を用いてばく露を分類するために使用さ れることが多い。一方、直接的ばく露評価方法は、個人のモニタリングやバイオモニタリングに よる実際の個人レベルのばく露に関するデータに基づいている。したがって、直接法は、個人の ばく露または内部ばく露量レベルを推定するために使用することができる。直接法は前向き研究 で用いられることが多いが、十分に定義された母集団から既存の生物学的サンプルが入手可能な 場合には、後ろ向き研究でも使用される。

定量化された個人評価には、個人モニタリングやバイオモニタリングがあり、一般的に実際の ばく露レベルを推定するための最良のデータソースと考えられている(NRC、1991年; NRC、 1997年)。その一方で、間接的な方法による正確なばく露の質的測定(例えば、二分式や順序 式のばく露測定)も、疫学の目的では同じように正確であると考えられる。さらに、間接法は解 釈が容易であることが多く、ばく露評価における有用性を示すための追加の研究開発が少なくて 済む可能性がある。

どのようなアプローチであっても、ばく露評価方法は信頼性と妥当性のあるばく露推定値を提 供できなければならない。疫学の文脈では、一般的に*信頼性とは*結果を再現する能力を意味し、 *妥当性とは、一*般的にばく露推定値が真のばく露レベルを反映しているかどうかを意味している (Checkoway ら、2004 年)。特定のばく露評価の信頼性と妥当性を評価する際には、研究目的 の文脈でばく露評価の長所と短所を考慮することが重要である。あまり洗練されていないばく露 評価は、探索的研究に適しているかもしれない。これは、探索的研究は潜在的なハザードについ ての認識を高めるのに役立つため、より焦点を絞った研究への専心を促すことができるからであ る。逆に、より焦点を絞った仮説を持つ研究は、より洗練されたばく露評価法を用いることで大 幅に強固となる。したがって、間接的ばく露評価法と直接ばく露評価法は補完的なツールであり、 ばく露と疾病の関係を調査する際に研究の様々な段階で使用することができる。

## 2. 交絡因子

交絡因子は、ばく露と疾病との関係がある程度で第二のリスク因子(交絡因子)の影響に起因 している場合に発生する。これは、この第二のリスク因子(すなわち、交絡因子)が、疾病の独 立した因果関係のあるリスク因子でありながら、解析対象のばく露と因果関係(因果関係または 非因果関係)があり、ばく露と関係のある疾病との間の因果経路の中間変数としての役割を果た していない場合に起こりうる。交絡因子は、適切に測定され、考慮されなければ、ばく露と健康 影響との間の推定された関連性の大きさ(そして場合によっては方向性)を変化させる可能があ る。

これは、2 つのリスク因子の影響が適切に分離、あるいは「区別」されていないため、ばく露と 疾病の関係が過大または過小に評価される結果となりうる。例えば、ある研究では、ある農薬が 肺がんと関連しているかもしれないが、これは農場のトラクターのディーゼル排気ガスの交絡効 果によるものかもしれない。このように疾病発生(ここでは肺がん)との因果関係が農薬ばく露 とも関連する場合、第二の因子の「農場のトラクターのディーゼル排気ガス」は交絡因子である。 交絡因子には、喫煙、食事因子(例えば、高エネルギー/高カロリーの食事)、身体活動(例え ば、身体活動の欠如)、遺伝子、併存症、薬物使用、アルコール摂取などのあまり直感的でない ライフスタイルでのばく露が含まれることがあり、これらはすべて健康に悪影響を及ぼし、農薬 使用と統計的に関連している可能性がある。疫学的解析では、交絡因子は研究サンプルで測定さ れ、通常、研究のデザイン段階または解析段階のいずれかで最終的なリスク推定値に「調整」さ れる。前者に関しては、疫学研究者は、研究者がコントロールしたい特性を共有する個人に研究 集団を「限定」することができる。これにより、その特性(現在はコントロールされている)に 起因する交絡の潜在的な影響を取り除くことがでる。2番目に利用可能な方法は、研究のデザイ ン段階にも適用可能な方法で、研究者が交絡変数に基づいて個人を「マッチング」することで交 絡をコントロールすることである。これにより、交絡変数が2つの比較群の間で均等に分布し、 交絡変数を効果的にコントロールすることができる。主効果のリスク推定値に影響を与えるため には、交絡因子とばく露または疾病との関係が統計的に有意である必要はないことに注目するこ とが重要である15。

解析の段階で、交絡因子をコントロールできる方法の1つは、層化がある。この方法では、交 絡変数(の可能性がある)ごとに関連性を測定し、適切であると判断された場合には、個別の推 定値を統計的に「まとめる」ことで、各層で評価された推定値に重みをつける Mantel-Haenszel アプローチを使用して共通のオッズ比または他の効果を算出する。層化は同時にコントロールす る必要のある潜在的な交絡因子が複数存在する場合には困難である。このような場合、交絡因子 は通常、統計的モデル化によって対処される。(例:ロジスティック回帰)。

疫学研究が現場で開始される前に交絡因子を慎重に考慮することが重要であり、どのような研 究でも交絡因子をどのようにして考慮したかを適切に記述することが重要である。疫学研究は、 潜在的交絡因子を無視したり、あるいは十分な注意を払っていないと批評されることか多い。こ のため、感度分析は、欠落している交絡因子や考慮されていない交絡因子が観察された効果量に 与える潜在的な影響を示すのに役立つ(Gustafson and McCandless, 2010年を参照)。

<sup>&</sup>lt;sup>15</sup>これが、一般的に、交絡因子を調整する必要があるかどうかを判断するために交絡因子を「統計的に検定」することが不適切であると考えられている理由である。その代わりに、潜在的な交絡因子を調整した(交絡因子を含む)後の効果量の変化が10%以上であれば、交絡因子を分析に組み込むのに十分なエビデンスであると考える人もいる。

測定されていない交絡因子が結果に悪影響を及ぼすと考えられる場合、研究者は感度分析を実施 して、影響の範囲とその結果として得られる調整後の効果測定値の範囲を推定すべきである。こ のような感度分析は、一般的にほとんどの公表されている疫学研究では一様には行われていない が、既知ではあるが評価されていないリスク因子によるバイアスや潜在的な交絡因子の影響を推 定するために、利用可能な場合には使用することができる。

特定のばく露・疾病関連付けに応じて、ある因子はコントロールするために必要な交絡因子で ある場合とそうでない場合がある。交絡因子によって推定された効果量に大きな歪みが生じるた めには、交絡因子は、関係ある疾病が比較的強いリスク因子でなければならない<sup>16</sup>し、関係ある ばく露とも強固に関連付けられていなければならない。潜在的な交絡因子の評価は研究ごとに行 われ、測定されていない交絡因子が結果に悪影響を与えると考えられる場合には、研究者は感度 分析を行い、影響の範囲とその結果として得られる調整された効果評価の範囲を推定すべきであ る。観察疫学研究の質を評価する際、OPP は、関連する交絡因子が適切に同定、記述、評価、 解析されているかどうかを検討し、研究対象となっている特定の関連性を偏りのない推定が可能 であるかどうかを検討し、研究対象となっている特定の関連性を偏りのない推定が可能 であるかどうかを検討する。可能な場合は、交絡因子が推定された効果量の推定値に影響を及ぼ す範囲の判断を助けるツールとして感度分析を考慮する。交絡因子は、疾患の比較的強いリスク 因子でなければならず、リスク推定値に大きな歪みをもたらすためには、対象となるばく露と強 く関連していなければならないということを強調すべきである。このような場合には、交絡因子 の可能性を提起するだけでは十分ではなく、なぜリスク因子が交絡因子となりうるのか、その影 響がどのようなものなのか、そしてその影響が結果の解釈にとってどの程度重要なものなのかに ついて、説得力のある議論が必要である。(p.23・25、FIFRA SAP レポート、2010 年 4 月 22 日)

最後に、共変量の交絡、効果修正、相乗効果、その他の媒介効果を区別することが重要である。 交絡因子とは、疾病と因果関係のある変数及び対象となるばく露と因果関係があるか、否かにか かわらず、関連する変数をコントロールしないことによって生じるバイアスである。疫学研究者 はこのバイアスを最小化しようと努める。一方、効果修飾因子とは、層化(例えば、年齢、人種 /民族、SESの状態、遺伝的多型)によって、効果量に異なる影響を与える変数である。効果修 飾因子は、交絡因子である場合もあればそうでない場合もある。一般的に、効果修飾因子は多変 量モデルに交互作用項を導入するか、効果修飾因子のレベルによってデータを層化した後、層化 に効果量を評価することによってモデル化される。対象となる各集団層において十分なサンプル サイズを確保するためには、効果修飾因子を評価するための特別な研究デザインが必要となるこ とが多い。疫学研究者は、母集団の層化にわたるリスクの違いの評価、ばく露と関係のある効果 の関連付けの評価、影響を受けやすい亜集団の特定が重要であることから、効果修飾因子を理解 することを目指す(交絡因子のように最小化するのではなく、効果修飾因子の理解に努めてい る)。

<sup>&</sup>lt;sup>16</sup>交絡因子がそれ自体が本当にリスク因子であることを確認するだけでなく、関係のあるばく露との関連性だけではないことを確認することも考慮する必要がある。関係のある疾病との関連性を持つ因子の全部または一部を、関係のあるばく露との関連性のために調整することは、ばく露と疾病の関係が本当に存在する場合には、ばく露と疾病の関係を減衰させることにつながる。

効果修飾因子は交絡因子である場合もあればそうでない場合もある。例えば、タバコによく使用 される殺虫剤と肺がんを関連付ける研究では、喫煙は交絡因子になるかもしれないが、この殺虫 剤へのばく露のリスクが非喫煙者よりも喫煙者の方が高い場合には、効果修飾因子になるかもし れない。相乗効果は、疫学的な概念ではなく、生物学的または薬理学的/毒物学的な概念として 紹介されることが多く、2 つの化学物質が一緒になって共同で作用することで、各化学物質の効 果の(数学的な)合計を考慮した場合の効果を超えて、効果を拡大したり、増強したりする能力 に関係している。疫学や統計学の用語では、これは効果の修飾や相互作用として表現されること が多い。

#### 3. 統計解析

疫学研究は、特定のばく露と疾病との関連付けを評価することを目的としている。農薬疫学研究の質を評価する際、OPP は使用された統計的手法も考慮する。具体的には、研究に記載されている分析方法が研究課題に適切であるかどうか、使用された統計的方法の記述の完全性、ばく露と疾病の関係における潜在的な交絡変数の特定、評価、調整のための方法の適切性、実施された可能性のある小集団解析の説明、範囲、提示(多重比較のための統計的補正が行われているかどうかを含む)が考慮される。

疫学研究では通常、リスクを推定するために統計的モデル(例えば、ロジスティック回帰(オ ッズ比)やポアソン回帰(カウントデータ)のような一般化された線形モデル)を利用する。そ のためには、研究者は関連する主要なばく露変数と転帰変数だけでなく、関連する交絡因子を考 慮しなければならず、また、研究における関連付けがこれらの因子、すなわち、効果の修飾や相 互作用のレベルによって異なるかどうかを考慮しなければならない(Szklo ら、2004 年)。交絡 の可能性のある変数(調査対象となる関連性の大きさや方向性を実質的に変化させる変数)が同 定された場合、回帰モデルによる調整を行うことで、目的のリスク推定値、すなわち調査対象と なる関連性を分離することができる。さらに、OPP は、研究における潜在的な効果修飾因子の レベルまたは統計的相互作用の評価による関連付けの層化を評価する。関係のある関連付けの規 模と方向性が第三の変数のレベルによって大きく異なる場合、層化された結果は一次的なものと みなされるべきである。

発現事象がまれな場合やサンプル規模が比較的小さい場合に統計的モデリングを行う場合、モ デルにおける共変量が多すぎないように注意することが重要である。結果として得られる効果量 の推定が高すぎたり、低すぎたりすることがあり、効果の真の推定を反映しているとは考えにく い。稀な事象やサンプル規模が小さいことによるこのような問題は、条件付き手法(例えば、デ ザインに研究における比較群の組み合わせを含む場合の条件付きロジスティック回帰)を使用す る場合にも起こり得る。すなわち不一致ペア(または不一致セット)の観察数が少なすぎると、 推定された効果量もまた信頼性が低くなる可能性がある。このように、交絡因子及びその他の共 変量をコントロールすることは重要であるが、信頼性の高い検定を行うために過度にコントロー ルしたり、自由度が少なくしすぎたりしないように評価者は注意しなければならない。

このような場合には、有効なサンプルサイズを十分に確保するため、最も影響力のある交絡因子 や他の共変量をより少ない数だけ調整して、より解析的なモデルを求めることがより重要である。

最後に、どのような統計モデリング演習においても、結果の臨床的/生物学的/科学的な意義 の文脈で統計的有意性を考慮することが重要である。統計的には有意だが、臨床/生物学的/科 学的な文脈では重要ではないということもある。逆に、統計的には有意ではないが、臨床的/生 物学的/科学的な文脈では重要な結果である場合もある。前者の場合はサンプルサイズが必要以 上に大きいことを示唆し、後者の場合は必要以上に小さなサンプル規模を示唆しているかもしれ ない。後者の場合は、公衆衛生の観点から重要であり、(不正確であるにもかかわらず)特に関 連付けが強固である場合には、さらなる調査が必要である。

#### 4. 観察研究における潜在的なバイアス

バイアスとは、(観察されていない)真の状況とは系統的に異なる研究結果をもたらす研究の デザインまたは実施における系統的な誤差のことである。これは、効果量の評価におけるサンプ リングの変動や精度(または同義で信頼限界)に関係するランダム誤差とは対照的であるが、結 果をある特定の方向(例えば、帰無仮説に向かって、または帰無仮説から離れて)に「追い込む (drive)」または「押し込む(push)」ようなことはない。

バイアスとは、研究のデザインや実施における方法論的な不完全性の反映であり、研究者は解 析の一部として、それに対処したり、議論したりすべきである。研究にバイアスが導入される方 法はいくつかある。研究は、参加者を研究に選択する方法(選択バイアス)や、ばく露や疾病に 関する情報を収集する方法(情報バイアス、先に説明した症例対照研究の想起バイアスを含む) にバイアスがかかっている可能性がある。一般的な職業選択バイアスの例としては、「健康な労 働者効果」があり、職域疫学研究において重要なバイアスを生じさせ、帰無値に向かってバイア スを生じさせ、さらにはそれ以下のバイアス(ばく露が「保護的」であるという解釈を生じさせ る)につながる。バイアスの全くない研究はなく、公表した研究の著者は研究における潜在的バ イアスどの程度説明したか、研究におけるバイアスを(もしあれば)どのように対処し、研究の 特徴を明らかにしたかを検討すべきである。バイアスは、差異的(differential)または非差異 的(non-differential) な誤分類から生じる可能性がある(Greenland、1998 年)。差異的誤 分類(バイアス)とは、他の変数の値に依存する方法で誤分類が発生したことを意味し、非差異 的誤分類(バイアス)とは、他の変数の値に依存しない誤分類を意味する。誤分類バイアス(差 異的または非差異的のいずれか)は、そのようなばく露を分類するために使用される試験方法の 感度と特異度に依存し、特定の(限定された)条件の下でバイアスの方向性を予測可能な影響を 及ぼすことがある。研究の方法と解析の知識に基づいてバイアスの方向を特定できるということ は、規制当局の意思決定者にとって有用である。なぜなら、意思決定者は、検討されている疫学 的効果の大きさ(例:OR、RR)が、真の効果の大きさの過小評価または過大評価である可能性 がどの程度あるかを判断することができるからである 17。

誤分類の程度が 10~20%の範囲にあることは異例ではなく、このような誤分類の程度(それが 差異的か非差異的か)と、そのような誤分類の大きさと方向性の両方に関してオッズ比または相 対リスクに影響を与える可能性の程度を評価する感度(または「もしも」)解析の形態を検討す ることは、疫学研究をレビューする際に有用であると考えられる<sup>17</sup>。(p.25、FIFRA EPA SAP 報告書、2010年4月22日)。交絡因子に関して前述したように、このような定量的感度分析は、 公表されている疫学研究ではほとんど実施されておらず、バイアスの潜在的な規模や疫学的効果 量推定への影響の定量的な評価は行われずに、むしろ一般的には解説文で評価されている (Jurek at al., 2006)。これは次のような理由によるものである。その理由の一部は、疫学者が このような解析のための計算ツールを一般的に利用できないことや、そのようなツールに慣れて いないことにある。このようなツールは次第に利用可能になりつつあり、潜在的なバイアスを評 価するためのより厳密な定量的手法を開発する上で有用であると考えられる。

# 5. 帰無研究の解釈

「帰無」研究、すなわち、農薬へのばく露と有害な健康影響との間に関連付けがないと報告す るよく行われている研究は、ヒト健康リスク評価に有用な可能性があるかどうか慎重に評価され る。研究が無効という結果になるのは、調査された関連付けが実際には存在しないか、あるいは、 実施された研究が所定の有意水準で関連付けを検出することができなかったためである。後者の 結果(関連性を検出できなかった)は、必ずしも関連付けが存在しないことを意味するものでは なく、特定の研究で関連付けが検出されなかったと解釈すべきである<sup>18,19</sup>。「帰無」研究をレビ ューする際に、これら2つの条件のどちらが正しいかを評価するためには、同一または類似の研 究課題について報告された他の研究、ばく露と発現事象の評価方法、ばく露の誤分類が研究を帰 無に偏らせた可能性の程度、関連付けの交絡変数の同定と分析を含む使用された統計的方法、影 響が発生する、あるいは影響が検出される閾値を下回っているばく露の程度、研究の検出力と実 質的な関係のある効果量を検出する能力を考慮する必要がある。統計的検出力とは、実際に真の 違い(または関連付け)がある場な、研究者が2つの比較群間に差があること、すなわち、ばく 露と疾病の間に関連付けがあることを正しく識別できる確率を意味する。

<sup>&</sup>lt;sup>17</sup>このような感度分析は、多くの場合、交絡因子よりも効果量推定に実質的な影響を及ぼすと予想されるばく露の誤分類バイアスに対して特に推奨されるかもしれない。

<sup>&</sup>lt;sup>18</sup>「エビデンスがないからといって、エビデンスがないと解釈すべきではない→エビデンスがないことを、ないことのエビデンスと解釈してはならない」という古い格言は、ここでは真実である。

<sup>&</sup>lt;sup>19</sup>米国統計協会の統計的意義と P 値に関する声明 <u>https://www.amstat.org/asa/files/pdfs/P-</u> <u>ValueStatement.pdf も</u>参照のこと。

「低検出力」の研究は、関連付けが実際に存在しているのに、関連付けがないと誤って結論を下 すことがある<sup>20</sup>。

最後に、帰無研究の解釈に関しては、文献のシステマティックレビューにおける出版バイアス の影響を考慮することが重要である。出版バイアスとは、利用可能な公表文献が、そのような帰 無研究を不釣り合いに除外する傾向のことである。疾病または健康影響の間にこのような「帰無」 関連付けを示す研究は、研究課題が疫学的レビュープロセスの一部として確立された質の基準を 満たしていれば、その研究と同様に有益な情報を得ることができる。これらには、研究デザイン、 *優先*的仮説と探索的解析の比較、関係のある効果量を検出するためのサンプルサイズと統計的検 出力、感度と特異度*に対する*影響の適切な確認、ばく露評価の質と差異的・非差異的な誤分類の 可能性、主要な潜在的交絡因子とその他のバイアス(情報、選択等)の評価の適切性、効果修飾 因子の評価(優先的仮説による裏付けがない仮設、生物学的妥当性、またはその他の裏付け情報 についての多重比較の検討とその補正を含む適切な統計解析)などの要因が含まれる。

# 6. 外的妥当性(一般化可能性)

上述したように、妥当性とは、一般的にはばく露推定が真のばく露レベルを反映している程度 を指す(Checkoway ら)。外的妥当性または一般化可能性とは、母集団のサンプル(例:農薬 散布者)から得られた疫学的研究結果を他の母集団(例:すべての農業従事者)に拡張する能力 のことである。外的妥当性を評価するために、サンプルの特性とより大きな集団(既知の場合) との比較を行うことができる。このような評価には、人口統計学的要因だけでなく、ばく露(例 えば、用量、時期、期間)が類似しているかどうか及び重要な影響修飾因子(例えば、脆弱者集 団の感受性)が考慮されているかどうかも含まれるべきである。一般化可能性は特に重要であり、 個々の研究結果が、規制当局のリスク評価において、より大きな集団または対象となる亜集団に 適用できるかどうか、またどのように適用できるかを理解することが重要である。例えば、AHS は、いくつかの農薬について、いくつかのがんとがん以外の健康影響との間に統計的な関連付け があることを報告している。OPP は、報告された知見が、ノースカロライナ州とアイオワ州以 外の州の農薬散布者や、主に散布後の作業を行う農業従事者にどの程度適用できるかを評価する

<sup>&</sup>lt;sup>20</sup> 検出力は低くても統計的に有意な効果が見られる研究は、効果量の拡大という現象である可能 性があり、これを調査することが重要である(Ioannidis、2008年)。

## V. ヒトでの事例調査データ

一般的に言えば、上記のような農薬に関する疫学研究は、急性の臨床症状をもたらす可能性が 小さい低量ばく露(より長い期間にわたって)に焦点を当てている。OPP はまた、より高く、 より短い間隔(多くの場合、急性の"一回限り"で)のばく露に関心を持っている。この「ヒトで の事例」または中毒データは、問題となっているに起因すると考えられる短期的で高濃度の高量 ばく露シナリオを評価するのに有用である。

OPP はこのような「ヒトでの事例情報」をいくつかの目的で使用している。最も広い意味で は、OPP はリスク評価/リスク管理の活動に情報を提供するためにヒトでの事例データを使用 している。これは、農薬登録改善法(PRIA)の責任のもと、登録審査活動の重要な一部となっ ている。この目的のために、OPP は人の事例データを評価して経時的な傾向を調べ、さまざま な農薬ばく露の重大さの程度と頻度のパターンを調べている。場合によっては、事例情報は、追 加の情報や追加のリスク管理措置の必要性を示すことができる。また、事例情報は、リスク軽減 措置が実施された後の達成の評価にも役立ち、事例情報は、OPP がヒト健康と環境を保護する ために行ってきたリスク管理措置の有効性を保証するための OPP のパフォーマンス・アカウン タビリティ・システムの重要な部分である。最後に、事例情報は、使用方法に関する実際の使用 情報を提供する上で有用であり、また、必要に応じて、施行や教育の活動の対象となる可能性が ある。

**OPP** はこの情報を様々な情報源から入手している。ヒトでの事例データの情報源には、医学的及び毒物学的文献に掲載されている(ヒトの)**医学的症例報告**や急性及び慢性のハザードの特定を促進し、リスク評価プロセスに不可欠な共同で検討されている急性農薬中毒の様々な国の中 **毒サーベイランス活動**からの情報が含まれている<sup>21</sup>。

**医学的症例報告**(医師によって書かれた直接の証言)や医学的症例集積(共通の原因や症状を 持つ個人の症例報告をまとめたもの)は、健康影響に関する利用可能なすべてのエビデンスを解 析するための貴重なツールであり、動物試験や疫学研究の知見を補完するものでもある。さらに、 特定の農薬の使用に関連すると思われる有害な健康影響の稀な発生や新規の発生を特定すること ができ、中毒警戒の行政機関に「事前通知」を提供できる。公表されている農薬の症例報告は、 通常、非定型的な(高量ばく露/大量投与、違法、適用外)急性または短期のばく露による影響 を記述している。報告書はしばしば個々の事例に基づいており、その性質上、選択性が高い。し かし、これらの報告書は、ヒトにおいてこれまでに確認されていなかった毒性影響を特定し、高 量ばく露後の影響、健康影響及び医学的後遺症を知る上で、特に有用である。これらの研究には、 より詳細な医学的情報(後遺症を含む)や詳細な追跡調査が行われていることが多く、一般的に 用量に関する高い質及び/または定量的な情報が得られている。

<sup>21</sup> OPP は、IPSC がリスク評価においてヒトでの事例データを考慮する成果を認識している。 http://www.who.int/ipcs/publications/methods/human data/en/index.html

複数の医療事例研究で類似点が見られたり、症状、ばく露シナリオ、使用方法などにパターン が見られた場合には、リスク評価プロセスと結果の裏付けに有用な情報を提供することができる。 医学的症例研究や定量的なばく露情報集積は、必要に応じて、典型的な使用から予想されるばく 露マージンを特性評価することで(ラベルに明示された適用率や代替ばく露情報に基づく)リス ク評価のばく露推定値と比較できる。

医学的症例報告や医学的症例集積を評価する際には、以下の点を考慮する。

ばく露の詳細な履歴(いつ、どのように、どのくらい)、健康影響の発現時期、患者の 徴候や症状が報告されている。

商品名、農薬表示、登録番号など、商品・化学品・農薬に関する情報。

患者情報(例:年齢、人種、性別);基本的な健康状態及び同様の徴候や症状をもたら す可能性のある医薬品の使用;関連する病歴及びリスク因子の有無。

疾病の説明と診断に至った経緯。

患者の管理・治療、農薬や化学物質の血中濃度などの検査データ(治療前、治療中、治療後)。

医学的報告は信頼性があるか、妥当であるか。他の研究、レビュー、ガイドラインを含む最新の知見と一致しているかどうか。

疾病の臨床経過及び患者の転帰(例:患者の回復及び退院;退院後の患者の状態、農薬 または化学物質へのばく露に関連した慢性的な健康影響または早期死亡)。

実際のばく露情報及び毒物学的情報の情報源として医学的症例の報告/集積を利用することに 加えて、OPP は様々な農薬中毒事例データベースを利用した中毒サーベイランス活動も行って いる。具体的には、OPP は以下の 5 つのヒトでの事例データソースにアクセスできる。OPP Incident Data System (IDS) 、American Association of Poison Control Centers (PCC) の National Poison Data System (NPDS) からの要約報告書、現在オレゴン州立大学にある EPA が資金提供している National Pesticide Information Center (NPIC) からのデータ、疾病管理 予防センター (Centers for Disease Control and Prevention) /National Institute for Occupational Safety and Health for Occupational Risk - Pesticides (NIOSH SENSOR-Pesticides) 及び California Pesticide Illness Surveillance Program (PISP) のデータ。以下、 それぞれについて順番に説明していく。

> □ <u>OPP Incident Data System (IDS)</u>は OPP が管理しており、FIFRA 第 6 条 (a)(2)<sup>22</sup>項に基づき登録者が提出したデータ及び EPA に直接報告されたその他の 事例を含んでいる。

<sup>&</sup>lt;sup>22</sup> FIFRA 6(a)(2)に基づき、農薬登録者は、「農薬の環境への不適切な悪影響に関する事実情報」を知った場合には、EPA に通知するよう求められている。

OPPは1992年以来、IDSに農薬関連の事例報告をまとめている。IDSには、登録者、他の連邦・州の保健・環境機関及び個人消費者からの強制的な FIFRA 第6章(a)(2)報告を含む、様々な情報源から主張されたヒトでの健康影響事例の報告が含まれている。IDS には、ヒト、植物、野生動物、家畜への悪影響を主張している事例に関する情報が含まれている。IDS 報告の大部分は、政府機関が紙形式で受け取っている。IDSの項目は、OPPの情報サービスセンターにあるマイクロフィルムやスキャンした画像に保存されているオリジナルの報告書のコピーへの「ポインタ」として機能する。

IDS には職業上及び非職業上の両方の事例が含まれているが、報告された事例の 大部分は非職業/住居のシナリオに関するものである。全米から報告された事例 のほとんどは製品情報(EPA登録番号など)の記載に関連している。IDS はほと んどが FIFRA 6(a)(2)報告要件に基づき農薬登録者から提供された情報で構成さ れているため、政府機関は特定の製品を識別することに対して比較的高い信頼性 を持っている。重大さの程度の順位付けは、各事例について(CFR §159.184 で 規定されている)記載されている。症状情報は、事例の解説部分に含まれること があるが、この情報は通常、医療専門家による検証/確認を受けていない。IDS には、ばく露シナリオやハザード情報の解説情報も含まれている。多くの企業は、 標準化された、業界で開発された自主的な事例報告フォームを使用している。

OPP は IDS からデータを収集・評価し、農薬ばく露による健康影響の程度や重 大さの程度に関して潜在的なパターンを識別している。IDS の報告書は範囲が広 く、場合によっては詳細な情報を含むが、システムは必ずしも職業上ばく露状況 や医学的転帰などの発現事象に関する詳細な情報を一貫して把握しているわけで はない。

また、IDS に入る症例データのほとんどは、中毒管理センターへの電話からの収 集もあるが、確認・照合されない。とはいえ、事例情報は、製品の初期登録後、 製造販売後の重要なフィードバックループを政府機関に提供できる。重大な性質 の IDS 事例や、それほど重大ではない事例の間で示唆されたパターンや傾向は、 特定の化学物質や製品をさらに調査するように政府機関に求めることができる。 IDS はこのように広範囲をカバーしているため、一時的な傾向情報を提供し、リ スク軽減によって潜在的な農薬ばく露が減少し、IDS に報告された潜在的な事例 の数が減少したかどうかを判断するのに役立つ可能性がある。全体的に見ると、 IDS は農薬の全国的な傾向と事例の頻度に関する良好な情報を提供し、農薬のハ ザード及び/またはばく露の可能性について有用な予測を提供することができる。

全米中毒データシステム(NPDS)(以前は毒性影響監視システム(TESS)と 呼ばれていた)は、米国中毒管理センター協会(AAPCC)によって維持されて おり、いくつかの連邦政府機関からの資金援助を受けている。NPDSはコンピュ ータ化された情報システムで、地理的に特定されたほぼリアルタイムの報告が可 能である。中毒管理センターの主な任務は、緊急事態に対応する通報者を支援す ることであるが、NPDSのデータは、化学製品の安全性に関する新たな問題を特 定するのに役立つ。全国にある 61 の PCCのホットラインは、365 日 24 時間年 中無休で開設されており、特別な訓練を受けた看護師、薬剤師及びその他の臨床 医療専門家が中毒情報を提供している。コンピュータによるデータ入力、標準化 されたプロトコル、厳格なデータ入力基準を使用して、現地の通報者が事例を報 告する。これらの報告された事例は現地で保存され、AAPCCによって維持され ている全国データベースに要約された形で更新される。情報通報は個別に集計さ れ、事例としてはカウントされない。PCCシステムは、ほぼすべての米国とそ の領土をカバーしており、2001年以来、コンピュータの大幅な強化が行われて きた。

NPDSには主に非職業上の事例が含まれている。NPDSには解説情報は含まれて おらず、製品情報は完全ではない。NPDSは、訓練を受けた専門家が指定/記録 した重大さの程度の順位と症状情報を提供しており、政府機関はこれらの情報に 対して比較的高い信頼性を持っている。NPDSはまた、報告されたばく露による 健康影響の可能性に関する情報も提供している。全体として、NPDSは全国的な 傾向、農薬の事例発生頻度、特定の農薬の潜在的ハザードについての良好な情報 を提供している。しかし、情報源の制限により、毎年発行される AAPCCのサマ リーレポート(例:http://www.aapcc.org/annual-reports/を参照)にしかアク セスできず、これらのレポートは他の情報源を補完する役割を果たしているため、 NPDSはより完全なアクセスが可能となっている。

## □ National Pesticide Information Center (NPIC)

(http://npic.orst.edu/index.html)は、EPA の資金提供を受けており、客観的で科 学的根拠に基づいた農薬情報を提供し、問い合わせに対応したり、事例に対応し たりすることを目的としている。NPIC は平日の営業時間内に全国的に機能して おり、オレゴン州立大学(現在)と EPA との間で協力している。中毒管理セン ターと同様に、NPIC の主な目的は事例データの収集ではなく(NPIC の年間の 問い合わせの約 10%は「事例」に関連していると考えられている)、むしろ幅 広い農薬に関する情報を問い合わせ者に提供し、農薬での事例の調査や緊急処置 のための他の情報源に誘導することである。とはいえ、NPIC では問い合わせ者 からの事例情報(年間約 4000 件)を収集し、データベースに記録している。 NPIC は全国の事例の情報源であるが、一般的に IDS に比べて報告件数は少ない。

特定の農薬や製品が IDS で高頻度に観察された場合でも、NPIC は全国のデータ セット間の整合性を判断する上で有用な情報源を提供している。

IDSやPCCと同様に、NPICの事例は主に非職業上のものである。NPICの事例 には、通報者が情報を提供する際に解説情報や製品情報が含まれている。対象範 囲は全国であるが、NPIC に報告される事例の数は NPDS や IDS に比べてかな り少ない。一方、提供される情報量はかなり多く、必要に応じて政府機関がカス タムレポートを要求することも可能である。ハザード情報には、重大さの程度の 順位付け、ばく露経路、症状などが含まれており、これらは訓練を受けた担当者 によって記録される。また、ばく露と有害影響の関連性がどの程度であるかにつ いての情報も提供している(これを確実性指数と呼んでいる)。また、NPIC は 年次報告や解析結果を公開しており、有用な情報源となっている。

□ 疾病管理予防国立産業衛生研究所(CDC/NIOSH)は、SENSOR(Sentinel Event Notification System for Occupational Risk) - Pesticides と題した農薬監 視プログラムとデータベースを管理している<sup>23</sup>。このデータベースには、1998年 から 2013 年までの 12 の州における農薬による疾病症例報告が含まれている。参 加している州は、カリフォルニア州、フロリダ州、アイオワ州、ルイジアナ州、 ミシガン州、ネブラスカ州、ニューメキシコ州、ニューヨーク州、ノースカロラ イナ州、オレゴン州、テキサス州、ワシントン州である。ある年の参加州は、州 と連邦政府が農薬監視のために資金を提供しているかどうかによって異なる。

SENSOR-農薬データベース内の農薬関連の疾病症例は、様々な情報源(現地の 中毒管理センターからの報告、医師によって報告された際に農業従事者の補償請 求の州労働局からの報告、州農業局からの報告及び州保健局への医師の報告)か ら把握されている。職業上及び非職業上の事例の両方がデータベースに含まれて いるが、SENSOR 責任者は、主に職業上の農業従事者事例に関する追跡症例調 査の成果に焦点を当てている。州保健局の SENSOR 責任者は、症例を追跡し、 ばく露シナリオ、症状、重大さの程度、健康影響を確認するために、カルテを取 得する。標準化されたプロトコルと症例の定義を使用して、州保健局の SENSOR 責任者は、症例、カルテ、医師と患者によって提供された事例インタ ビュー解説を SENSOR データシステムに入力する。

すべての SENSOR-Pesticides の症例は、EPA が事例の解析に使用する集合デー タベースに含まれるために、最低2つの健康影響を報告しなければならない。

<sup>&</sup>lt;sup>23</sup> SENSOR-Pesticidesのホームページ: http://www.cdc.gov/niosh/topics/pesticides/overview.html

各症例のエビデンスは、NIOSH の症例分類マトリックスに基づいて、ばく露と 疾病との因果関係について評価される。SENSOR-Pesticides の症例の 98%は、 確定、可能性高い、または可能性ありに分類され、2%は疑わしい症例に分類さ れている。可能性の低い症例、無症候性の症例、無関係の症例及び情報が不十分 な症例は、SENSOR-Pesticides のデータベースには含まれ いない。

全体的には、職業上及び非職業上の事例について非常に有用な情報を提供してお り、時には農薬のハザードやばく露の可能性についての有用な予想を提供してい る。また、SENSOR-Pesticides は独自のデータの解析を行い、Morbidity and Mortality Weekly に公表している。前述のデータベースとは異なり、非職業上/ 住居上と職業上の両方の事例が含まれているが、SENSOR'S は伝統的に農業従 事者での事例に焦点を当てており、その情報を提供する上で特に価値のあるもの となっている。1998 年から 2011 年までの SENSOR-Pesticides のデータはオン ラインで入手可能である: http://wwwn.cdc.gov/Niosh-whc/Home/Pesticides。

□ カリフォルニア州農薬疾病サーベイランスプログラム (PISP) は、カリフォル ニア州によって管理されている。このデータベースは、農薬に関連した疾病や傷害を記録している。症例報告は、医師からの報告と農業従事者補償記録を介して行われる。現地の郡農業委員会がばく露の状況を調査する。カルテと調査結果は、カリフォルニア州農薬規制局 (DPR)の技術専門家によって評価され、疾病の登録簿に登録される。カリフォルニア州の PISP プログラムで報告されたすべての農薬による疾病は、郡の農業委員会によって調査され、DPR は報告書を評価してデータベースにまとめ、農業従事者やその他の人々を農薬ばく露の悪影響から保護するための州のプログラムを改善するために使用される(http://apps.cdpr.ca.gov/calpig/)。

現在、OPP は化学物質別にヒトの事例データを評価している。各データベースからの事例は、 ハザードポテンシャル(死亡者数、より重大な事例の頻度、報告された症状のパターン/傾向) とばく露ポテンシャル(事例の頻度/経時的傾向、ばく露シナリオのパターン/傾向、ばく露に 影響を与える要因のパターン/傾向、または製品のパターン/傾向)について解析されている。 上記のデータベースからのヒトでの事例データを評価する際、OPP はいくつかの一般的な基準 を考慮している。OPP は症状の相対的な重大さの程度と頻度を考慮している。さらに、OPP は 一般的に、時間的な関連付けが確認できる報告を、あるいは少なくとも妥当と思われる報告を、 より信頼性の高いものとしている。最後に、ヒトの事例データを評価するために使用される他の 要因には、ばく露反応の関連付けのエビデンス、報告された健康影響の一貫性、報告された健康 影響の生物学的妥当性、医薬品の使用などの健康影響の代替原因の排除及び観察された症状や健 康影響の特異度が含まれる。さらに、より重大な事例の解説は、ばく露の時間と報告された影響 の間に時間的な関連付けがあるかどうかを評価し、関連付けが状況によって裏付けられているか どうかを判断することが多い。

例えば、屋内での農薬散布後3か月に発生した高齢者の心臓発作は、因果関係があるとは判断されない。一方で、農薬種類に応じた既知の症状と一致する症状を伴うばく露時またはばく露後間 もなく発生した重大な事例は、事前の病歴がなく発生した場合、因果関係の推測がより正当化されることを示唆している。

以上のことから、医学的文献やヒトの毒性学的文献に掲載されている医学的症例報告/症例シ リーズと、EPA が維持、資金提供またはアクセスしているデータベースから得られる中毒サー ベイランスデータの両方からなる事例データは、実社会での農薬のリスクを評価する際に OPP を支援する有用で補完的な情報を提供することが可能である。

#### VI. 要約と結論

このフレームワークでは、疫学とヒトでの事例データをレビューする際の重要な要素を説明し、 そのようなデータを農薬のヒト健康リスク評価に組み込むために提案されている WOE 解析につ いて説明している。OPP では、複数のエビデンスと、*in vitro、in vivo*及び *in silico*の情報源か ら得られた入手可能な最善のデータを使用する。OPP では、複数の情報源からのデータを統合 する際に、系統化されたツールとして修正された Bradford Hill 基準を用いて、品質、一貫性、 関連性、整合性、生物学的妥当性を考慮するため、WOE アプローチを使用している。WOE 解 析の適用は、リスク評価ガイドラインに概説されている科学的解析に従って EPA が日常的に使 用している統合的かつ解釈的なプロセスである。WOE 解析はまた、結合されたデータセットの 質も評価し、特定の科学的評価に適切である成果と複雑性のレベルと一致している(U.S.EPA、 2002 年)。OPP は、21 世紀の毒性試験の新たなビジョンの実施に向けて、現在、毒性学とリス ク評価が変革期にあることを認識している。これらの変革に伴い、OPP はこのアプローチを適 宜更新して行くであろう。

目次

## I. PURPOSE & SCOPE

The Environmental Protection Agency's (EPA) Office of Pesticide Programs (OPP) is a licensing program regulating pesticides in the U.S under the Federal Insecticide, Fungicide, and Rodenticide Act (FIFRA) and the Federal Food, Drug, and Cosmetic Act (FFDCA). As part of this program, OPP evaluates a substantial body of toxicology and exposure data to assess the effects of pesticides on human health and the environment. In evaluating human health, EPA looks first for information directly evaluating the potential for effects to people, including epidemiological data. Historically, however, few epidemiology studies have been available to inform the potential toxicity of pesticide chemicals. As such, OPP has in the past primarily relied on toxicology studies in laboratory animals to assess the hazard potential and to estimate human health risk. With the publication of numerous papers from the Agricultural Health Study<sup>1</sup> and from the National Institute of Environmental Health Sciences (NIEHS)/EPA Children's Centers<sup>2</sup>, among others, the availability of epidemiology studies conducted on U.S.-relevant exposures to pesticides is increasing. Nevertheless, since the number of pesticides for which quality epidemiology data either exist or are being developed remains relatively low in the near term, experimental laboratory data will likely continue to be the primary source of data for use in quantitative risk assessment for most pesticides.

OPP's goal is to use such information -- when available -- in a scientifically robust and transparent way. To accomplish this, OPP has developed a general epidemiologic framework, as described in this document, that outlines the scientific considerations that OPP will weigh in evaluating how such studies and scientific information can be more fully integrated into risk assessments of pesticide chemicals. The current document is neither a binding regulation nor is it intended to be or serve as a reviewer's guide or manual or as a Standard Operating Procedure for assessing or using epidemiology data. Nor is it intended to be a full treatise on more modern or advanced epidemiological methods or to adequately convey the nuances and complexity that is important for interpreting these types of studies. As such, it does not discuss (or does not discuss in any detail) such important epidemiological topics as causal inference and causal diagrams (Rothman et al., 2012a; Glymor and Greenland, 2012); more recent approaches to confounder identification, assessment, and control; meta-analysis and heterogeneity and its assessment/evaluation (Borenstein et al., 2009: Greenland and O'Rourke, 2012): or sensitivity/quantitative bias analysis for epidemiologic data (Lash et al., 2009; Lash et al., 2014; Ioannidis, 2008; Greenland and Lash, 2012; Jurek et al., 2007). All these topics, concepts, and issues can and do apply to epidemiology studies concerning pesticides, but are not covered in this OPP framework document. Instead, this document provides overall conceptual considerations concerning the evaluation and use of epidemiology studies on pesticides in

#### I.目的と範囲

米国環境保護庁(EPA)の農薬プログラム(OPP)は、連邦殺虫剤・殺菌剤・殺鼠剤法 (FIFRA)及び連邦食品・医薬品・化粧品法(FFDCA)に基づき、米国内の農薬を規制する認 可プログラムである。このプログラムの一環として、OPPは毒性とばく露の多くの主要データ を評価し、農薬がヒトの健康及び環境に及ぼす影響を評価している。ヒト健康影響を評価する際、 EPAは、まず疫学データを含めたヒトへの影響の可能性を直接評価する情報に注目する。しかし、 これまでは農薬の潜在的な毒性を報告した疫学研究はほとんどない。したがって、OPPはハザ ードの可能性を評価し、ヒトの健康リスクを推定するため、これまでは実験動物を用いた毒性試 験に主に依存してきた。Agricultural Health Study<sup>1</sup>や National Institute of Environmental Health Sciences (NIEHS) / EPA Children's Centers<sup>2</sup> などから数多くの論文が発表されたこ とで、米国で実施された農薬へのばく露に関する疫学研究の有用性が高まっている。とはいえ、 質の高い疫学データが存在する、あるいは充実しつつある農薬の数は、今後短期的には比較的少 ないので、ほとんどの農薬の定量的リスク評価に用いるためのデータの主な情報源は試験データ であることがおそらく継続するだろう。

OPP の目標は、そのような情報が入手可能な場合には、科学的に正確で明白な方法で利用す ることである。これを達成するために OPP は、この文書に記載されているように総合的な疫学 的フレームワークを開発した。このフレームワークでは、そのような研究や科学的情報を農薬の リスク評価にどのようにして一層完全に統合することができるかを評価する際に OPP が検討す る科学的に考慮すべき要点を述べている。現在の文書は、拘束力のある規則ではなく、疫学デー タを評価または使用するためのレビュアー向けのガイドやマニュアル、標準作業手順書であるこ とを意図したものでも、その役割を果たすことを意図したものでもない。また、より最新で進歩 した疫学的方法の完全な専門書となることも、この種の研究を解釈するために重要なニュアンス や複雑さを適切に伝えることも意図していない。したがって、因果推論及び因果関係図 (Rothman ら、2009 年; Greenland and O'Rourke、2012 年)、交絡因子の特定・評価・制御 に対する最新の研究法、メタ分析と異質性の評価 (Borenstein ら、2009 年; Greenland and O'Rourke、2012 年)、または疫学データの感度/定量的バイアス解析(Lash ら、2009 年; Lash ら、2014年; Joannidis、2008年; Greenland and Lash、2012年; Jurek ら、2007年)と いった重要な疫学の話題は(詳細に)論じていない。これらの話題、概念及び問題点のすべては、 農薬に関する疫学研究に応用できるが、この OPP フレームワーク文書では取り上げていない。 代わりに、この文書では、OPP の FIFRA 及び FFDCA の機能支援のためのヒト健康リスク評価 の文脈において農薬の疫学研究の評価と使用に関する全体的な概念を提供している。

<sup>&</sup>lt;sup>1</sup> https://aghealth.nih.gov/

the context of human health risk assessments to support OPP's FIFRA and FFDCA activities. An earlier version of this document was reviewed favorably by the FIFRA Scientific Advisory Panel (SAP) in February, 2010 (USEPA, 2010; FIFRA SAP, 2010). This document incorporates improvements recommended by the SAP, public comments, and the experience gained since 2010 conducting assessments on several pesticides for which epidemiological data were available, and should be considered a document that will be updated from time-to-time as we progress and on as-needed basis

#### II. INTRODUCTION

Two reports by the National Research Council (NRC) of the National Academy of Science (NAS), "Toxicity Testing in the 21st Century: A Vision and A Strategy (2007)" and "Science and Decisions (2009)," together provide new directions in toxicology and risk assessment. These two NRC reports advocate far reaching changes in how toxicity testing is performed, how such data are interpreted, and ultimately how regulatory decisions are made. Specifically, the 2007 report on 21st century toxicity testing advocates a shift away from the current focus of using apical toxicity endpoints to using toxicity pathways<sup>3</sup> to inform toxicity testing, risk assessment, and ultimately decision making. This approach is based on the rapidly evolving scientific understanding of how genes, proteins, and small molecules interact to form molecular pathways that maintain cell function in human cells. The goal for the new toxicity testing paradigm is to determine how exposure to environmental agents can perturb these pathways, thereby causing a cascade of subsequent key events leading to adverse health effects. Human information like that found in epidemiology studies, human incident databases, and biomonitoring studies, along with experimental toxicological information are expected to play a significant role in this new approach. Specifically, these types of human information provide insight into the effects caused by actual chemical exposures in humans and thus can contribute to problem formulation and hazard/risk characterization. In addition, epidemiologic and human incident data can guide additional analyses or data generations (e.g., dose and endpoint selection for use in *in vitro* and targeted *in vivo* experimental studies), identify potentially susceptible populations, identify new health effects, or confirm the existing toxicological observations.

This new vision of toxicity testing and risk assessment will involve data from multiple levels of biological organization ranging from the molecular level up to population-based surveillance with a goal of considering chemical effects from their source to the ultimate health outcome and effects on populations. Such data will come from *in vitro* and *in vivo* experimental studies along with *in silico* and modeled data. OPP's framework for incorporating epidemiology and incident data is conceptually consistent with the 2007 NRC report on 21st century toxicity testing in that both emphasize the use of the best available information from multiple data sources are compiled in a weight of the evidence (WOE) analysis.

本文書の以前のバージョンは、2010年2月にFIFRA科学諮問パネル(SAP)によって好意的に レビューされた(USEPA、2010年、FIFRA SAP、2010年)。この文書は、SAPが推奨する改 善点、パブリックコメント及び2010年以降に疫学データが利用可能であった農薬の評価から得 られた知識が盛り込まれており、進捗及び必要に応じて随時更新される文書と考えるべきである。

#### II. 序章

全米科学アカデミー (NAS) の米国研究評議会 (NRC) による 2 つの報告書、「21 世紀の毒 性試験:ビジョンと戦略(2007年)」と「科学と政策調査(2009年)」は、共に毒性学とリス ク評価の新たな方向性を示している。これら 2 つの NRC 報告書は、毒性試験の実施方法、デー タの解釈方法、そして最終的に規制上の政策調査の方法に大きな変更を提唱している。具体的に は、21世紀の毒性試験に関する 2007年の報告書では、毒性試験、リスク評価、そして最終的な 政策調査に情報を提供するために、現在の先端毒性エンドポイントの使用に焦点を当てたものか ら、毒性発現経路3を使用するようにシフトすることを提唱している。このアプローチは、遺伝 子、タンパク質、低分子がどのように相互作用してヒト細胞の機能を維持する分子経路を形成し ているかという急速に進化する科学的理解に基づいている。新しい毒性試験のパラダイムの目標 は、環境因子へのばく露がこれらの経路をどのように乱すかを明らかにし、それによって有害な 健康影響につながる重要な事象を連鎖的に引き起こす原因を明らかにすることである。この新し いアプローチでは、疫学研究、ヒトでの事例データベース、バイオモニタリング研究に見られる ようなヒトの情報と実験毒性学的情報が重要な役割を果たすことが期待されている。具体的には、 このようなヒト情報は、実際の化学物質ばく露による影響についての見識を提供し、問題の定式 化やハザード/リスクの特性評価に貢献することができる。さらに、疫学データやヒトでの事例 データは、追加の解析やデータ生成(例えば、in vitro試験や目標とする in vivo試験で使用する ための用量やエンドポイントの選択)の指針となり、影響を受けやすい集団を特定したり、新た な健康影響を特定したり、既存の毒性学的結果を確認したりすることができる。

この毒性試験とリスク評価の新しいビジョンには、生物学的体系の多種多様なレベル(分子レベルから化学物質の影響をその発生源から最終的な健康影響や集団への影響まで考慮することを 目的とした集団を基にした調査レベルまで)のデータが含まれる。このようなデータには、 *in vitro*試験や *in vivo*試験から得られるデータのほかに、*in silico*モデルデータがある。疫学デ ータと事例データを取り入れる OPP のフレームワークは、21 世紀の毒性試験に関する 2007 年 の NRC の報告書と概念的に一致しており、どちらも多種多様なデータソースから得られる最良 の情報の用途はエビデンスの重み付け (WOE) 解析にまとめて使用することを強調している。

<sup>&</sup>lt;sup>3</sup> Toxicity pathways are cellular response pathways that, when sufficiently perturbed, are expected to result in adverse health effects.

<sup>3</sup> 毒性発現経路とは、十分に撹乱された場合に有害な健康影響を及ぼすことが予想される細胞応 答経路のことである。

As a general principle, occupational and environmental epidemiology studies are conducted only on widely used pesticides; these pesticides also tend to have to be wellstudied in the scientific literature. Thus, OPP expects in many cases where epidemiologic data are available, a significant body of literature data on toxicology, exposure, pharmacokinetics (PK), and mode of action/adverse outcome pathway information (MOA/AOP) may also be available. Human incident data are available on a broader range of chemicals, some of which have robust databases and others which do not. In those situations, where there are significant human incident cases and little is known about the MOA/AOP or PK of a particular pesticide, the WOE analysis can be used to identify areas of new research.

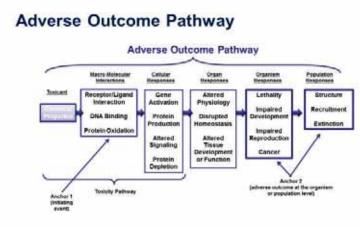

OPP's approach in this framework for incorporating epidemiology and human incident data is not a new or novel approach. Instead, this approach is a reasonable, logical extension of existing tools and methods. This document relies on existing guidance documents and frameworks (Table 1) as the starting point for reviewing and evaluating epidemiology and human incident data for use in pesticide risk assessment. This framework on using epidemiology and incident data in human health risk assessment is consistent with the recommendations of the NRC in its 2009 report on *Science and Decisions*, and with the agency's recent Human Health Risk Assessment Framework (USEPA, 2014a) with respect to emphasizing the use of problem formulation as a tool for scoping, planning, and reviewing available, particularly in the context of risk management needs.

Similarly, OPP's framework is consistent with updates to the World Health Organization/International Programme on Chemical Safety MOA/human relevance framework, which highlights the importance of problem formulation and the need to integrate information at different levels of biological organization (Meek et al., 2014). The MOA/HR framework begins with identifying the series of key events that are along the causal path, that are established on weight of evidence, using principles like those described by Bradford Hill, taking into account factors such as dose-response and temporal concordance, biological plausibility, coherence and consistency (Hill, 1965). Using this analytic approach, epidemiologic findings can be evaluated in the context of other human information (including human incident findings) and experimental studies and for identifying areas of uncertainty and future research. However, it is noteworthy that the availability of a fully elucidated MOA/AOP is a not requirement for using epidemiology studies in human health risk assessment. As the agency continues to move forward in implementing the transformative approach in the 2007 and 2009 NRC reports and as OPP gains experience in integration of epidemiology and human incident information. OPP will re-evaluate and update this framework as appropriate.

一般的な原則として、産業環境疫学研究は広く使用されている農薬のみを対象に実施されてお り、これらの農薬も科学的文献で十分に研究されている必要がある。したがって、疫学データが 利用可能な多くの場合、毒性、ばく露、薬物動態(PK)、作用機序/有害性発現経路(MOA/ AOP)の情報に関する主要な文献データも利用可能であるとOPP は予想している。ヒトでの事 例データは、より広範囲の化学物質について入手可能であるが、中には正確なデータベースを持 つものと持たないものがある。ヒトでの重大な事例があり、特定の農薬の MOA/AOP や PK に ついてほとんど知られていない場合には、WOE 解析を用いて新たな研究分野を特定することが できる。

疫学データとヒトでの事例データを組み込むための当該フレームワークにおける OPP のアプ ローチは、初めてのものもしくは新しいものではない。むしろ、このアプローチは、既存のツー ルや方法を合理的かつ論理的に拡張したものである。当該文書は、農薬リスク評価に使用する疫 学データ及びヒトでの事例データを検討するための出発点として、既存のガイダンス文書及びフ レームワーク(表 1)に依存している。ヒトの健康リスク評価における疫学データ及びヒトでの 事例データの使用に関する当該フレームワークは、2009 年の「科学と政策調査」に関する報告 書での NRC の提言や、特にリスク管理の必要性の文脈で、利用可能なものを調査、企画、検討 するためのツールとして問題の定式化の使用を強調する点に関して、政府機関の最新のヒト健康 リスク評価フレームワーク(USEPA、2014 年 a) と一致している。

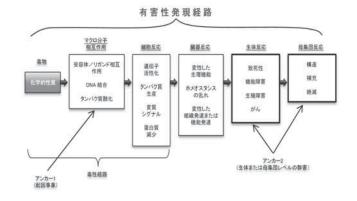

同様に、OPP のフレームワークは、問題の定式化の重要性と生物学的体系の多種多様なレベルでの情報統合の必要性を強調した「世界保健機関/化学物質の安全性に関する国際プログラムMOA/ヒト関連(MOA/HR)フレームワーク」の最新版と一致している(Meek 6、2014 年)。 MOA/HRフレームワークは、用量反応や時間的一致、ならびに生物学的な妥当性、整合性及び 一致性などの要素を考慮に入れて、Bradford Hill によって記述されたような原則を使用して、 エビデンスの重み付けに基づいて確立された因果経路に沿った一連の重要な事象を特定すること から始まる(Hill、1965年)。この解析アプローチを用いることで、疫学的知見は、他のヒト情 報(ヒトでの事例所見を含む)や実験的研究の文脈で評価することができ、不確実分野や今後の 研究分野を特定することができる。しかし、完全に解明された MOA/AOP があることが、ヒト 健康リスク評価に疫学研究を利用するための要件ではないことは注目に値する。政府機関が 2007 年及び 2009 年の NRC 報告書にある変化するアプローチの実施を引き続き進め、OPP が疫 学情報とヒトでの事例情報の統合の経験を積む中で、OPP は当該フレームワークを適切に再評 価し、更新していく予定である。 Figure 1. #### III. SYSTEMATIC REVIEW IN PESTICIDE RISK ASSESSMENT: EPIDEMIOLOGY

In recent years, the NRC has encouraged the agency to move towards systematic review processes to enhance the transparency of scientific literature reviews that support chemical-specific risk assessments to inform regulatory decision making (NRC 2011, 2014). The NRC defines systematic review as "a scientific investigation that focuses on a specific question and uses explicit, pre-specified scientific methods to identify, select, assess, and summarize the findings of similar but separate studies" (NRC, 2014). Consistent with NRC's recommendations, the Office of Chemical Safety and Pollution Prevention (OCSPP) employs fit-for-purpose systematic reviews that rely on standard methods for collecting, evaluating and integrating the scientific data supporting our decisions.

According to the NRC, systematic reviews "have several common elements: transparent and explicitly documented methods, consistent and critical evaluation of all relevant literature, application of a standardized approach for grading the strength of evidence, and clear and consistent summative language (NRC, 2014)." In recent years, several groups (Rooney et al., 2014; Woodruff and Sutton, 2014; Hartung, 2010) have published systematic review approaches for use in environmental health sciences. The OCSPP approach to systematic review is consistent with the principles articulated in the Cochrane Handbook for Systematic Reviews of Interventions for evidence-based medicine and with the principles of the Grading of Recommendations Assessment, Development and Evaluation (GRADE). GRADE guidelines used by systematic review approaches for environmental health sciences developed by the National Institute of Environmental Health Sciences (NIEHS) Office of Health Assessment and Translation (OHAT) (Rooney et al., 2014) and University of California, San Diego (Woodruff and Sutton, 2014). According to the *Cochrane Handbook*, the key characteristics of a systematic review are:

- a clearly stated set of objectives with pre-defined eligibility criteria for studies;
- an explicit, reproducible methodology;
- a systematic search that attempts to identify all studies that would meet the eligibility criteria;
- an assessment of the validity of the findings from the identified studies;
- a systematic presentation and synthesis of the characteristics and findings of the included studies.

Each approach mentioned above share common themes and workflow starting with a statement of scientific context (e.g., problem formulation or protocol) followed by literature review with explicit search strategy methods, analysis of study quality (often called risk of bias), evaluation of the quality of the totality of the evidence (e.g., integration) and ultimately leading to a conclusion(s). Each approach recommends transparent and pre-determined criteria for inclusion/exclusion of scientific literature, evaluation of study quality (e.g., high, medium, low). Each approach recommends a pre-stated tool for data integration that provides the foundation for the conclusion(s).

#### III. 農薬のリスク評価におけるシステマティックレビュー: 疫学

近年、NRC は、規制上の政策調査に情報を提供するための化学物質固有のリスク評価をサポ ートする科学的文献レビューの明白性を高めるために、システマティックレビュープロセスに移 行するよう政府機関に奨励している (NRC、2011 年、2014 年)。NRC はシステマティックレ ビューを「特定の疑問に焦点を当て、明確で事前に指定された科学的方法を用いて、類似してい るが別個の研究の結果を特定、選択、評価、要約する科学的調査」と定義している (NRC、 2014 年)。NRC の勧告に沿って、化学物質安全・公害防止局 (OCSPP) は、政策調査を支え る科学的データの収集、評価、統合のための標準的な方法に依存する、目的にかなったシステマ ティックレビューを採用している。

NRC によると、システマティックレビューには、"明白性があり明確に文書化された方法、関 連するすべての文献の一貫した厳しい評価、エビデンスの強さを評価するための標準化されたア プローチの適用、明白で一貫性のある総括的用語 (NRC、2014 年) "といういくつかの共通要素 がある。近年、いくつかの集団 (Rooney 6、2014 年; Woodruff and Sutton、2014 年; Hartung、2010 年) が、環境保健科学で使用するためのシステマティックレビューのアプロー チを発表している。システマティックレビューでの OCSPP のアプローチは、Cochrane Handbook for Systematic Reviews of Interventions for evidence-based medicine に明記されて いる原則と、Grading of Recommendations Assessment, Development and Evaluation (GRADE) の原則と一致している。GRADE ガイドラインは、国立環境保健科学研究所 (NIEHS) 健康評価・翻訳局 (OHAT) (Rooney 6、2014 年) とカリフォルニア大学サンデ ィエゴ校 (Woodruff and Sutton、2014 年) が開発した環境保健科学のためのシステマティック レビューアプローチで使用されているものである。*コクラン・ハンドブックに*よると、システマテ ィックレビューの主な特性は以下の通りである。

・目的が明確に示されており、研究の適格性基準があらかじめ定義されていること。

- ・明示的で再現性のある方法論。
- ・適格性基準を満たすすべての研究を特定するための系統的検索。
- 特定された研究から得られた知見の妥当性の評価。
- ・収録された研究の特性と知見を体系的に提示し、総合的にまとめたもの。

上記の各アプローチは共通のテーマとワークフローを共有しており、科学的な文脈(例えば、 問題の定式化やプロトコル)の記述から始まり、明確な検索戦略の方法を用いた文献レビュー、 研究の質の解析(しばしばバイアスのリスクと呼ばれる)、エビデンス全体の質の評価(例えば、 統合)、そして最終的に結論に至るまでの流れを示している。それぞれのアプローチでは、科学 文献の包含/除外、研究の質の評価、研究の質(例:高、中、低)の報告のための透明性のある 事前に設定された基準を推奨している。各アプローチでは、結論の基礎となるデータ統合のため の事前に定められたツールを推奨している。 So far, no single nomenclature has been agreed upon by the risk assessment community for systematic review and OCSPP expects terminology to evolve over time as more broad experience is gained. OCSPP considers its systematic review process and workflow as starting with problem formulation followed by data collection, data evaluation, data integration, and summary findings with critical data gaps identified. Scientific analysis is often iterative in nature as new knowledge is obtained.

#### A. Problem Formulation

In the NRC report *Science and Decisions-Advancing Risk Assessment*, the National Academy of Sciences (NAS) recommended to EPA that risk assessments and associated scientific analyses be developed to be useful to policy makers; in order to attain this goal, the NRC recommended that the agency more broadly use problem formulation in developing its risk assessments. In response to the NRC, the agency published the Human Health Risk Assessment Framework (USEPA, 2014) which highlights the importance of problem formulation. Problem formulation entails an initial dialogue between scientists and risk managers and provides the regulatory context for the scientific analysis and helps define the scope of an analysis. Problem formulation draws from regulatory, decision-making and policy context of the assessment, informs the technical approach to the complexity and scope of each systematic review will vary among the different risk assessment contexts. In other words, an OCSPP systematic review is conducted as "fit-for-purpose" (NRC, 2009) based on the pre-determined scope and purpose determined from problem formulation.

The problem formulation involves consideration of the available information along with key gaps in data or scientific information. OPP uses problem formulation as a tool to identify exposure pathways and potential health outcomes along with the appropriate methods, data sources, and approaches for the scientific analysis. If missing data are critical to the assessment, options are discussed as to how best to obtain that information (e.g., required testing, research). The peer review process is identified and the timeline for completing the assessment is defined.

Systematic review provides a transparent tool for organizing available information and identifying gaps in information for the regulatory purpose for the analysis. As such, in problem formulation, the regulatory context of a scientific analysis is described which in turn defines the scope of and purpose for collection and evaluation of scientific literature. Some considerations in problem formulation may be related to population or life-stage, exposure pathways (e.g., route, duration, frequency), and/or health outcomes of interest identified from *in vitro* or *in vivo* laboratory studies along with epidemiology or human incident studies along with resources available and regulatory timeframe. In the context of considering epidemiology and human incident information, an initial evaluation of the study quality, study design, and uncertainties are considered. これまでのところ、リスクアセスメントに関係する人々の間では、システマティックレビュー のための単一の命名法は合意されておらず、OCSPP は、より広範な経験が積まれるにつれて用 語が進化していくことを期待している。OCSPP は、システマティックレビューのプロセスとワ ークフローを、問題の定式化から始まり、データ収集、データ評価、データ統合、そして重要 なデータギャップを特定した結果の要約と考えている。

科学的な解析は、新しい知識が得られるたびに、繰り返し行われることが多い。

#### A. 問題の定式化

NRCの報告書「Science and Decisions Advancing Risk Assessment (科学と意思決定・リス ク評価の促進)」において、全米科学アカデミー(NAS)は EPA に対して、政策立案者に有用 なリスク評価と関連する科学的解析を開発するよう勧告した。この目標達成のために NRC は、 政府機関に対してリスク評価の開発において一層幅広く問題の定式化を用いるよう勧告した。 NRCの勧告を受けて、USEPAは「ヒト健康リスク評価フレームワーク」(USEPA、2014年) を公表し、問題の定式化の重要性を強調している。問題の定式化は、科学者とリスク管理者の間 の初期対話を伴うものであり、科学的解析のための規制上の背景を提供し、解析の範囲を定義す るのに役立つ。問題の定式化は、評価の規制、政策調査及び政策の背景から導き出され、評価の 技術的なアプローチの情報を提供し、考慮すべき主要な要因を体系的に特定するものである。こ のように、各システマティックレビューの複雑さと範囲は、異なるリスク評価の文脈によってさ まざまである。言い換えれば、OCSPPのシステマディックレビューは、問題設定から事前に設 定された範囲と目的に基づいた「目的にかなったもの」(NRC、2009年)として実施される。

問題の定式化には、利用可能な情報とともにデータや科学的情報の主要なギャップを考慮する ことが含まれる。OPP は、ばく露経路と潜在的な健康影響を特定するためのツールとして問題 の定式化を用いており、適切な方法、情報源及び科学的解析のアプローチとともに使用している。 欠損データが評価において重要な場合、情報(例えば、必要とされる試験)を得るための最良の 選択肢が議論される。ピアレビュープロセスが特定され、評価を完了するためのタイムラインが 定義される。

システマティックレビューは、利用可能な情報を整理し、解析に対する規制目的に関する情報 のギャップを特定するための明白なツールを提供する。このように、問題の設定では、科学的解 析の規制上の文脈が説明され、それによって科学的文献の収集と評価の範囲と目的が定義される。 問題の設定における考慮すべき事項は、集団またはライフステージ、ばく露経路(例:経路、期 間、頻度)及び/または in vitro または in vivo の実験室での研究、疫学またはヒトの事故によ る研究から特定された目的の健康結果、ならびに利用可能な資源及び規制の時間枠に関すること であろう。疫学情報及びヒトでの事例情報を考慮する文脈では、試験の質、試験デザイン及び不 確実性の初期評価が考慮される。 Key scientific issues related to hazard assessment considered in problem formulation include: What are the effects associated with exposure? What are the MOA/AOPs associated with these effects? What are the temporal aspects of the effects? Are there susceptible populations and if so, who are they and what factors contribute to susceptibility? Are there differences in PK or pharmacodynamics (PD) between laboratory animals and humans? Exposure information is also evaluated in problem formulation. Key scientific issues related to exposure assessment considered in problem formulation include: How is the pesticide used? What are all of the relevant use sites of exposure? To what chemical substances will people be exposed? What are the routes, durations, and frequencies of exposures? Who may be exposed? Does the exposure pose different risks to different groups (e.g., due age or activity patterns?) In the specific case of epidemiology data, this review considers a variety of factors including, but not limited to, research hypothesis, study design (i.e., sample size, sufficient controls, quality of measurements, etc.), exposure dose/concentration, statistical analysis, and conclusions.

#### B. Data Collection

The data collection phase of systematic review is the collection of available information from various published and unpublished sources, such as the open scientific literature and submitted studies for pesticide registration. OPP reviews data collected under the Organisation for Economic Cooperation and Development (OECD) test guidelines, OCSPP harmonized test guidelines, and other pesticide (OPP guidelines). These guideline studies are collected primarily from in-house databases of submitted studies and are found through searches of such internal databases.

In the case of epidemiology, most studies are expected to be found in the open scientific literature. Although in some cases supplemental analyses or information may be available, dialogue with the researchers may provide additional, important information not published in the original paper in understanding and interpreting epidemiology studies. The sources of human incident information are summarized in Section IV.

Open literature search strategies use specified criteria to retrieve health effects information from the open scientific literature and unpublished sources. After identifying and selecting the most appropriate sources/databases and determining the most resource effective strategy utilizing classification codes, medical subject headings, and/or keywords, a search is conducted of the literature. Depending on the complexity of the scientific evaluation, support from a reference librarian may or may not be needed. The goal of a human health literature search is to perform a reliable and reproducible literature search by providing proper documentation of the literature search process. The following steps are conducted to retrieve relevant studies:

- The purpose of the scientific analysis and inclusion criteria are established.
- Combinations of terms/key words and/or MeSH (Medical Subject Heading) terms and their Boolean combinations (AND; OR; NOT) are used and documented.

問題の設定で考慮されるハザード評価に関連する主な科学的課題は以下の通りである。ばく露 に関連する影響とは何か?これらの影響に関連する MOA/AOPs はどのようなものか?影響の 時間的側面は?影響を受けやすい集団があるのか、あるとすれば、その集団は誰であり、どのよ うな要因によって影響を受けやすいのか。実験動物とヒトの間で PK や薬力学 (PD) に違いは あるか?また、ばく露情報は問題の設定においても評価される。問題の設定で考慮されるばく露 評価に関連する主な科学的課題は以下の通りである。農薬はどのように使用されるのか?ばく露 の関連する使用場所のすべてはどのようなものか?ヒトはどのような化学物質にばく露されるの か?ばく露の方法、期間、頻度はどのようなものか?とトはどのような化学物質にばく露されるの か?ばく露の方法、期間、頻度はどのようなものか?ほどのようれる可能性があるか?ばく露 は異なる集団 (例えば、年齢や行動パターンのため)に異なるリスクをもたらすのか?疫学デー タの具体的なケースでは、このレビューでは、研究仮説、研究デザイン(すなわち、サンブルサ イズ、十分な対照、測定方法の質など)、ばく露量/ばく露濃度、統計解析及び結論を含むが、 これらに限定されない様々な要因を考慮して検討する。

# B. データ収集

システマティックレビューのデータ収集段階では、公開科学文献や農薬登録のために提出され た研究論文など、様々な公開・未公開の情報源から利用可能な情報を収集する。OPP では、経 済協力開発機構(OECD)試験ガイドライン、OCSPP 調和試験ガイドライン及び農薬ガイドラ イン(OPP ガイドライン)に基づいて収集されたデータをレビューしている。これらのガイド ライン研究論文は、主に提出された研究の社内データベースから収集され、そのような社内デー タベースの検索によって発見される。

疫学の場合、ほとんどの研究は公開されている科学文献に掲載されていることが予想される。 場合によっては補足的な解析や情報が得られることもあるが、研究者との対話によって、疫学研 究を理解し解釈する上で、原著論文には掲載されていない追加の重要な情報が得られることもあ る。ヒトでの事例の情報源はセクション IV にまとめられている。

公開文献検索戦略では、特定の基準を用いて、公開されている科学文献や未発表の情報源から 健康影響情報を検索する。最も適切な情報源/データベースを特定して選択し、分類コード、医 学的主題の見出し及び/またはキーワードを利用した最もリソース効率の良い戦略を調査した後、 文献の検索が行われる。科学的評価の複雑さに応じて、文献管理責任者のサポートが必要な場合 もあれば、必要でない場合もある。ヒトの健康に関する文献検索の目標は、文献検索プロセスの 適切な文書を提供することにより、信頼性が高く再現性のある文献検索を行うことである。有用 な研究を検索するには、以下の手順で行う。

- 科学的解析の目的と包括基準が確立されている。
- 用語/キーワードや MeSH (Medical Subject Heading) 用語の組み合わせと、それらの ブール考案の組み合わせ(AND; OR; NOT)を使用し、文書化する。

Advanced Search and Field Search by author, title, keywords or subject heading may also be performed as needed. Knowledge of database structure, and using a separate search strategy for a specific database is helpful in retrieving relevant studies. In addition to an initial comprehensive search, periodic searches may be conducted to update the literature list.

- The search strategy is documented, including the date(s) of the search(es) to ensure that all the searches of all the databases are reproducible.
- Reference lists of retrieved articles are examined<sup>2</sup> for additional background and to look for articles that were not discovered in the initial search.
- After combining the retrieved articles from different databases and removing duplicates, the available titles and abstracts are screened. For some of the articles where relevance could not be determined from the title and the abstract, the article is retrieved for further review.
- Following the initial screening, articles that were not relevant (exclusion criteria) such as opinion articles, studies not in English, and those consisting only of abstracts are excluded. Additional exclusion criteria can be identified on a case by case basis. All exclusion criteria are documented. The rest of the articles, even those that found no adverse health effects, are included for review and evaluation.

## C. Data Evaluation

In the data evaluation phase, data quality is reviewed and conclusions are made about the utility of such data. Study quality reflects the overall confidence that reports findings are correct (Balshem et al., 2011). As such, study quality can include:

- reporting quality (how well or completely a study is reported);
- how credible the findings are based on the design and conduct of the study;
- and how well the study addresses the topic under review (Rooney et al., 2014).

Study quality is first considered on an individual study basis, and the quality is judged. For example, one may have stronger confidence in a well conducted case control study than a poorly conducted cohort study. Credibility of the scientific findings, often called risk of bias, is evaluated using pre-determined criteria for specific domains related to study design and conduct (See Table 2).

OPP initially developed a guidance on using the open scientific literature considerations called the "Guidance for Considering and Using Open Literature Toxicity Studies to Support Human Health Risk Assessment" (USEPA, 2012) and generally continues to follow this guidance. However, with the acceleration of systematic review in risk assessment, some aspects of the literature guidance may need updating in the future.

必要に応じて、著者名、タイトル、キーワード、主題見出しによる高度な検索やフィー ルド検索を行うこともできる。データベースの構造を知り、特定のデータベースに対し て別の検索戦略を使用することは、有用な研究論文を検索する際に役立つ。最初の包括 的な検索に加えて、文献リストを更新するために定期的な検索を行うこともある。

- すべてのデータベースのすべての検索が再現可能であることを保証するために、検索戦略は検索の日付を含めて文書化されている。
- 検索された論文のリファレンスリスト<sup>2</sup>は、追加の文脈を調べたり、最初の検索では発見 されなかった論文を探したりするために調査されている。
- 異なるデータベースから検索された論文を組み合わせて重複を除去した後、利用可能な タイトルと要約を選別する。タイトルと要約から関連性が判断できなかった論文につい ては、その論文を検索し、さらなる再検討を行う。
- 最初の選別の後、有用性のない論文(除外基準)・例えば、持論の論文、英語で記述されていない研究論文、要約のみで構成された論文は、除外される。追加の除外基準は個別的に特定される。すべての除外基準は文書化されている。残りの論文は、有害な健康影響が認められなかったものであっても、検討と評価のために含まれる。

#### C. データ評価

データ評価段階では、データの質が検討され、そのようなデータの有用性について結論が出さ れる。研究の質は、報告された結果が正しいという全体的な信頼性を反映する(Balshem ら、 2011 年)。このように、研究の質には以下のようなものがある。

- 報告の質(研究の報告がどの程度に十分であるか、または完全であるか)。
- 試験のデザインと実施に基づいて、試験結果がどの程度に信頼性のあるものか。
- さらに、その研究が評価下の主題にどの程度に十分な対応しているか(Rooney ら、2014 年)。

研究の質は、まず個々の研究基盤で検討され、その質が判断される。例えば、不完全に実施さ れたコホート研究よりも、適切に実施された症例対照研究の方が信頼性は高い場合がある。科学 的知見の信頼性は、しばしばバイアスのリスクと呼ばれ、試験のデザインと実施に関連する特定 の分野について、あらかじめ定められた基準を用いて評価される(表2参照)。

OPP は当初、「ヒトの健康リスク評価を支援するための公表されている科学文献の毒性研究 の検討と使用に関するガイダンス」(Guidance for Considering and Using Open Literature Toxicity Studies to Support Human Health Risk Assessment) (USEPA、2012 年)と呼ばれ る公表されている科学文献の考えの使用に関するガイダンスを作成し、一般的にはこのガイダン スに従っている。しかし、リスク評価におけるシステマティックレビューの促進に伴い、この文 献ガイダンスの一部の側面は将来的に更新が必要になる可能性がある。 Conclusions about the quality of the data are made and can be described in conclusion statements or categories (e.g., acceptable/not acceptable; low, medium, high).

Specific considerations used in evaluating epidemiology studies on pesticide chemicals are provided in Section III.C below. As part of the data review, a concise written review of the study is developed. This written review describes the study design, results, conclusions, and the strengths and weaknesses of the study. The quality of the epidemiologic exposure assessment is an important factor in determining what role epidemiologic data will play in the risk assessment. As such, it is important to fully characterize the assumptions used in the epidemiologic exposure assessment and the degree to which these assumptions affect the interpretation and generalizability of the epidemiologic findings. The evaluation of the epidemiologic exposure assessment may include a consideration of past and present exposure patterns (e.g., exposed populations, pathways, routes, and levels of exposure) and may include significant changes in use patterns (e.g., risk mitigation actions or new use patterns). With regard to evaluating meta-analyses, reporting guidelines for Meta-analysis Of Observational Studies in Epidemiology (MOOSE) have been developed by Stroup et al., (2000) that are useful in evaluating the quality and interpreting meta-analysis.

# D. Data Integration: Weight of Evidence (WOE)

OPP's human health characterizations involve the consideration of all available and relevant data, including but not limited to human studies/epidemiology, biomonitoring data, *in vitro* and *in vivo* experimental laboratory toxicological studies, MOA/AOP information, pharmacokinetic studies, and structure-activity relationships (SAR). Once the different types of hazard data are collected and a full evaluation of each relevant study is conducted and documented, the next step is to integrate multiple lines of evidence.

Data integration is based on the principle of reaching a judgment of the totality of the available negative and positive data for relevant hazards. OPP uses a WOE analysis for evaluating epidemiology and human incident data, such conclusions are made on the preponderance of the information rather than relying on any one study. OPP uses the modified Bradford Hill criteria like those in the MOA/human relevance framework as a tool for organizing and integrating information from different sources (Hill, 1965; U.S. EPA, 1999, 2005; Sonich-Mullin et al., 2001; Meek et al., 2003; Seed et al., 2005; OECD AOP Wiki Users Handbook<sup>8</sup>). It is important to note that the Hill Criteria are not intended as a check box approach but instead are points to consider when evaluating the totality of evidence. In addition, the availability of a fully elucidated MOA/AOP is a not requirement for using epidemiology studies in human health risk assessment. However, even in the absence of a fully developed MOA/AOP, collection and evaluation of mechanistic data may provide support for biological plausibility and help explain differences in tissue sensitivity, species, gender, life-stage, or other factor. The MOA/human relevance framework is a flexible tool which provides a foundation for organizing information without rigidity. It is this

データの質についての結論が出され、結論の記述またはカテゴリー(例えば、許容可/許容不 可;低、中、高)で記述される。

農薬に関する疫学研究の評価に用いられる具体的な考えは、以下のセクション III.C に記載さ れている。データレビューの一環として、研究の簡潔なレビュー文書を作成する。このレビュー 文書には、研究のデザイン、結果、結論と、研究の長所と短所が記載されている。疫学的ばく露 評価の質は、疫学的データがリスク評価においてどのような役割を果たすかを調査する上で重要 な要素である。そのため、疫学的ばく露評価で使用された仮定と、その仮定が疫学的知見の解釈 と一般化の可能性にどの程度影響を与えるかを十分に特性評価することが重要である。疫学的ば く露評価には、過去及び現在のばく露パターン(例えば、ばく露集団、ばく露経路、ばく露方法 及びばく露レベル)の検討が含まれ、また、使用パターンの大幅な変化(例えば、リスク軽減措 置や新たな使用パターン)が含まれている場合がある。メタ分析の評価に関しては、Stroup ら (2000 年)によって報告された「疫学における観察研究のメタアナリシス」Meta-analysis Of Observational Studies in Epidemiology (MOOSE)のガイドラインが、メタ分析の質の評価や 解釈に有用である。

# D. データ統合:エビデンスの重み付け(WOE)

OPPのヒト健康影響評価では、ヒトでの調査/疫学、バイオモニタリングデータ、in vitroの 毒性試験及び in vivoの毒性試験、MOA/AOP 情報、薬物動態試験、構造活性関係(SAR) な どを含む(但し、これらに限定されない)利用可能なすべての関連データを考慮する必要がある。 さまざまな種類のハザードデータを収集し、関連する各試験の完全な評価を実施して記録した後、 次のステップは複数のエビデンスを統合することである。

データ統合は、関連するハザードについて利用可能なネガティブデータとポジティブデータを 総合的に判断するという原則に基づいている。OPP は、疫学データ及びヒトでの事例データの 評価に WOE 解析を使用しているが、結論は、特定の研究に依拠するのではなく、情報の優越性 に基づいて出される。OPP は、異なる情報源からの情報を整理して統合するためのツールとし て、MOA/HR のような修正された Bradford Hill 基準を使用している (Hill、1965 年; U.S. EPA、1999 年、2005 年; Sonich-Mullin ら、2001 年; Meek ら、2003 年; Seed ら、2005 年; OECD AOP Wiki Users Handbook<sup>8</sup>)。 Hill 基準は、チェックボックス方式ではなくて、エビデ ンスの総合的評価の検討を示唆していることに注目することが重要である。また、MOA/AOP が完全に解明されていることは、ヒト健康リスク評価に疫学研究を利用するための必須条件では ない。しかし、完全に解明された MOA/AOP がない場合でも、メカニズムデータの収集と評価 は、生物学的な妥当性の裏付けとなり、生体組織の感受性、生物種、性別、ライフステージ、ま たはその他の要因での違いを説明するのに役立つ可能性がある。MOA/HR は、厳密ではない情 報を整理するための基盤を提供する柔軟なツールである。

<sup>&</sup>lt;sup>8</sup> https://aopwiki.org/wiki/index.php/Main\_Page#OECD\_User\_Handbook

<sup>&</sup>lt;sup>8</sup> https://aopwiki.org/wiki/index.php/Main\_Page#OECD\_User\_Handbook

flexibility that makes it a useful tool for a variety of purposes such as evaluating causality, integrating information across multiple lines of scientific evidence, and identifying data gaps and areas of future research. In this analysis, epidemiologic findings and human incident data can be evaluated in the context of other human information and experimental studies to evaluate biological plausibility, to identify areas of uncertainty and areas of further research. To describe how Bradford Hill aspects are considered in the WOE evaluations, OPP has used some definitions of terms as outlined in EPA's Preamble to the Integrated Science Assessments (ISAs) which serve as a scientific foundation for the review of EPA's National Ambient Air Quality Standards (NAAQS). (USEPA, 2015).

- Key events. In cases where the MOA/AOP are established for a particular health outcome, a clear description of each of the key events (i.e., measurable parameters) that underlie the MOA/AOP are given. Data to inform the key events may come from a combination of *in vitro* or *in vivo* data sources (human or animal). These key events can be a combination of PK and PD events. However, it noteworthy that the availability of a fully elucidated MOA/AOP is a not requirement for using epidemiology studies in human health risk assessment.
- Biological Gradient/Exposure-Response/Dose-Response Concordance & Relationships. The Preamble to the ISAs notes that "In the context of epidemiology, a well-characterized exposure-response relationship (e.g., increasing effects associated with greater exposure) strongly suggests cause and effect, especially when such relationships are also observed for duration of exposure (e.g., increasing effects observed following longer exposure times) (USEPA, 2015)." When the MOA/AOP is known, dose-response relationships are identified for each key event. Dose-response relationships are compared among key events. In some cases, the earlier key events may be more sensitive than later key events. In other cases, key events may share similar dose-response curves.
- Temporal association. Evidence of a temporal sequence between the introduction of an agent and appearance of the effect constitutes another argument in favor of causality (USEPA, 2015). The Preamble to the ISAs notes that "Strong evidence for causality can be provided through 'natural experiments' when a change in exposure is found to result in a change in occurrence or frequency of health."

This analysis considers key events which occur rapidly (e.g., metabolism to an active metabolite which could occur within minutes of exposure) and those which occur after longer durations (e.g., development of a tumor) to ensure coherence of the effects. Specific to considering epidemiology data, the temporal relationship between the exposure and health outcome may be considered.

これは因果関係の評価、複数の科学的根拠に基づく情報の統合、データのギャップや今後の研究 分野の特定などの様々な目的に有用なツールとなる柔軟性を備えている。この解析では、疫学的 知見やヒトでの事例データは、生物学的な妥当性を評価するために、他のヒト情報や試験の文脈 で評価され、不確実分野や今後の研究分野を特定することができる。Bradford Hill の側面が WOE 評価でどのように考慮されるかを説明するために、OPP は、EPA の全米環境大気質基準 (NAAQS)のレビューのための科学的基盤となる統合科学評価(ISA)の EPA 前文に記載され ている用語の定義を使用している(USEPA、2015年)。

- 重要事象。特定の健康影響について MOA/AOP が確立されている場合には、MOA/AOP の基礎となる重要事象(すなわち、測定可能なパラメータ)をそれぞれ明確に記述する。重要事象を示すデータは、*in vitro*または *in vivo*のデータソース(ヒトまたは動物)の組み合わせから得られる可能性がある。これらの重要事象は、PK 事象と PD 事象の組み合わせである。しかし、完全に解明された MOA/AOP を利用できることは、ヒト健康リスク評価に 疫学研究を利用するための必須条件ではないことは注目に値する。
- 生物学的勾配/ばく露・反応/用量・反応の一致と関係。ISAsの前文では、「疫学の文脈では、よく特徴づけられたばく露・反応関係(例:ばく露量が多いほど影響が増加する)は、特にばく露期間(例:ばく露時間が長くなると影響が増加する)についても因果関係を強く示唆する」(USEPA, 2015)と指摘している。MOA/AOPが明らかである場合、各重要事象について用量反応関係が特定される。用量反応関係は、重要事象間で比較される。場合によっては、初期の重要事象の方が後期の重要事象よりも感度が高い場合がある。他の場合では、重要事象は類似した量反応曲線を共有しているかもしれない。
- ・時間的関連付け。薬剤の投与と影響の出現との間に時間的な順序があるというエビデンスは、 因果関係を支持するもう1つの根拠となる(USEPA、2015年)。ISAsの前文では、「ば く露の変化が健康影響の発現または発生頻度の変化をもたらすことが判明した場合には、 『自然実験』を通じて因果関係を示す強固なエビデンスを提供することができる」と指摘し ている。

この解析では、影響の整合性を確保するために急速に発現する重要事象(例えば、ばく露後数 分以内に発現する活性代謝物への代謝)と長い継続期間の後に発現する重要事象(例えば、腫瘍 の発生)を考慮している。疫学データを検討する際には、ばく露と健康影響の間の時間的関係が 考慮される。

## • Strength, consistency, and specificity.

**Consistency:** An inference of causality is strengthened when a pattern of elevated risks is observed across several independent studies. The reproducibility of findings constitutes one of the strongest arguments for causality. Statistical significance is not the sole criterion by which the presence or absence of an effect is determined. If there are discordant results among investigations, possible reasons such as differences in exposure, confounding factors, and the power of the study are considered (USEPA, 2015).

Consistency of findings across studies is informed by the repeated observation of effects or associations across multiple independent studies. Further support is provided by reproducibility of findings in different populations under different circumstances. However, discordant results among independent investigations may be explained by differences in study methods, random errors, exposure, confounding factors, or study power, and thus may not be used to rule out a causal connection (USEPA, 2015).

*Strength of the observed association:* The finding of large, precise risks increases confidence that the association is not likely due to chance, bias, or other factors. However, it is noted that a small magnitude in an effect estimate may or may not represent a substantial effect in a population (USEPA, 2015).

*Specificity of the observed association:* Evidence linking a specific outcome to an exposure can provide a strong argument for causation. However, it must be recognized that rarely, if ever, do environmental exposures invariably predict the occurrence of an outcome, and that a given outcome may have multiple causes (USEPA, 2015).

### Biological plausibility and coherence.

*Coherence:* An inference of causality from one line of evidence (e.g., epidemiologiccontrolled human exposure, animal, or ecological studies) may be strengthened by other lines of evidence that support a cause-and-effect interpretation of the association. There may be coherence in demonstrating effects from evidence across various fields and/or across multiple study designs or related health endpoints within one scientific line of evidence (USEPA, 2015).

When animal and human data show a similar toxic profile, both quantitatively and qualitatively, there is high confidence in the human health risk assessment. Whereas in other cases, animal and human data may show a qualitatively similar toxic profile but quantitative differences are observed. For example, a particular chemical exhibits the same MOA/AOP in animals and humans but there may be species differences in dose-response characteristics. These dose-response differences could be due to tissue dosimetry (i.e., PK) or from different response characteristics (i.e., PD). In contrast, animal and human data can, in some instances, show qualitatively dissimilar outcomes. This situation highlights the need to fully and objectively evaluate all available information in a

# • 強固性、一致性、特異度。

- **致性。**複数の独立した研究でリスクの上昇が観察された場合に、因果関係の推測は強固になる。結果の再現性は因果関係を示す最も強力な根拠の一つである。統計的な有意性は、効果の有無を判断する唯一の基準ではない。研究間で不一致な結果がある場合は、ばく露の違い、交絡因子、研究の検出力などの理由が考えられる(USEPA、2015年)。

複数の研究における結果の一貫性は、複数の独立した研究における効果または関連付けの繰り 返しの観察から得られる。さらに、異なる状況下での異なる母集団における結果の再現性によっ ても支持される。しかし、独立した調査の間での結果の不一致は、調査方法の違い、ランダムエ ラー、ばく露、交絡因子、または研究の検出力の違いによって説明される可能性があり、因果関 係を否定するために使用することはできない(USEPA、2015年)。

**観察された関連付けの強固性。**大規模で正確なリスクの発見は、関連付けが偶然、偏りまたは その他の要因によるものではない可能性が高いという確信を得られる。しかし、影響の推定が小 さい場合は、母集団における実質的な影響を表す場合もあれば、そうでない場合もあることに注 意が必要である(USEPA、2015 年)。

*観察された関連付けの特異度。*特定の結果をばく露に結びつけるエビデンスは、因果関係を示 す強い根拠となる。しかし、環境ばく露が結果の発生を必ず予測できることは稀であり、結果に は複数の原因がある可能性を認識しなければならない(USEPA、2015年)。

# 生物学的な妥当性と整合性。

**整合性。**1 つのエビデンス(例えば、疫学的に管理されたヒトのばく露研究、毒性試験、また は生態毒性試験)からの因果関係の推測は、関連付けの因果関係の解釈を支持する他のエビデン スによって強化されることがある。1 つの科学的エビデンスグループの中で、さまざまな分野に わたるエビデンス、複数の試験デザインにわたるエビデンス、または健康影響に関連するエビデ ンスから、効果を示す一貫性があるかもしれない(USEPA、2015年)。

動物でのデータとヒトでのデータが、定量的にも定性的にも同様の毒性プロファイルを示してい る場合、ヒト健康リスク評価の信頼性は高い。一方、動物でのデータとヒトでのデータが定性的 には類似した毒性プロファイルを示していても、定量的な相違が観察される場合もある。例えば、 ある化学物質が動物とヒトでは同じMOA/AOPを示していても、用量反応特性に種差がある場 合がある。このような用量反応性の相違は、生体組織薬量測定(すなわちPK)に起因するか、 または異なる反応特性(すなわちPD)に起因する可能性がある。一方、動物でのデータとヒト でのデータは、場合によっては質的に異なる結果を示すことがある。このような状況から、種、 性別及びライフステージの違いや潜在的な感受性などの要因を考慮するために、入手可能なすべ ての情報を透明性のある包括的な方法で十分かつ客観的に評価する必要性が明らかになった。

transparent and comprehensive manner to consider factors such as species, gender, and life-stage differences and potential susceptibilities along with study design considers and exposure potential.

**Biological plausibility:** An inference of causality is strengthened by results from experimental studies or other sources demonstrating biologically plausible mechanisms. A proposed mechanism, which is based on experimental evidence and which links exposure to an agent to a given effect, is an important source of support for causality (USEPA, 2015).

Similarly, information on MOA/AOP for a chemical, as one of many structural analogs, can inform decisions regarding likely causality. Structure activity relationships and information on the agent's structural analogs can provide insight into whether an association is causal (USEPA, 2015).

EPA's Cancer Guidelines (2005) indicate:

" evaluation of the biological plausibility of the associations observed in epidemiologic studies reflects consideration of both exposure-related factors and toxicological evidence relevant to identification of potential modes of action (MOAs). Similarly, consideration of the coherence of health effects associations reported in the epidemiologic literature reflects broad consideration of information pertaining to the nature of the biological markers evaluated in toxicologic and epidemiologic studies. [p. 39]."

However, The Cancer Guidelines further state that *"lack of mechanistic data, however, is not a reason to reject causality* [p. 41]." As such, lack of established MOA/AOP is not necessary knowledge when using epidemiology data and epidemiology associations may still be valid even in the absence of an established MOA/AOP and may also provide insight into potential MOA/AOP.

Uncertainties. Uncertainties are discussed in the WOE transparently and objectively.

# E. Overall conclusions, recommendations for risk assessment, statement of areas of confidence and uncertainty

It is important to document a summary of the evidence, the procedures or methods used to weigh the evidence, the basis for the WOE conclusion or recommendation, any uncertainties and areas for further research. Recommendations are made on the role of the epidemiologic or human incident data in the risk assessment. Generally, OPP does not use human incident information for quantitative risk assessment but instead to inform risk assessment/risk management activities such as indicating a potential need for a new risk assessment or new risk management measures, evaluating the success of risk mitigation actions after they are implemented, and targeting possible enforcement activities. In **生物学的妥当性。**因果関係の推測は、生物学的に妥当なメカニズムを示す試験またはその他の 情報源からの結果によって強化される。提案されたメカニズムは、実験的エビデンスに基づいて おり、ある物質へのばく露を所定の効果に結びつけるもので、因果関係を支持する重要な情報源 である(USEPA、2015 年)。

同様に、多くの構造的類似物の1つとしての化学物質の MOA/AOP に関する情報は、因果関係の可能性が高いかどうかの判断に役立てることができる。構造活性相関及び薬剤の構造的類似物に関する情報は、関連性が因果関係にあるかどうかについての洞察が提供される(USEPA、2015年)。

EPA のがんガイドライン(2005年)は以下の通りに指摘している。

「疫学研究で観察された関連付けの生物学的妥当性の評価は、潜在的作用機序(MOA)の 特定に関連する毒性学的エビデンスとばく露関連因子の両方を考慮したものである。同様に、 疫学的文献で報告された健康影響の関連付けの整合性を考慮することは、毒性試験や疫学研 究で評価された生物学的マーカーの特性に関する情報を幅広く考慮することを示している [p.39]。」

しかし、このガイドラインはさらに、「しかしながら、メカニズムデータの欠如は因果関係を 否定する理由にはならない[p.41]」と述べている。このように、確立された MOA/AOP の欠 如は、疫学データを使用する際に必要な知識ではなく、確立された MOA/AOP がなくても疫学 的関連付けは有効である可能性があり、また、潜在的な MOA/AOP について洞察も得られる可 能性がある。

• 不確実性。不確実性は WOE で明白かつ客観的に述べられている。

# E. 全体的な結論、リスク評価の推奨事項、信頼性と不確実性の分野の陳述

エビデンスの要約、エビデンスの重み付けに使用した手順または方法、WOE の結論または勧 告の根拠、不確実性及び更なる研究分野を文書化することが重要である。また、リスク評価にお ける疫学的データまたはヒト由来のデータの役割についても推奨されている。一般的に、OPP はヒトでの事例情報を定量的リスク評価には使用しないが、その代わりに、新たなリスク評価や 新たなリスク管理措置の必要性を示すこと、リスク軽減措置が実施された後の成功度を評価する こと及び可能性のある施行活動を対象とすることなど、リスク評価/リスク管理の活動を対象と する。 contrast to more limited role of human incident data, epidemiology studies have the potential to help inform multiple components of the risk assessment in a variety of ways. High quality studies with robust exposure assessment may be used to estimate a risk metric quantitatively. Alternatively, outcomes reported in epidemiologic studies may be compared qualitatively with those seen in *in vitro* and animal studies to evaluate the human relevance of animal findings (Hertz-Picciotto, 1995) and may be useful in assessing the biological plausibility of epidemiologic outcomes. In the final portion of the proposed WOE analysis, the overall conclusions along with statement of areas of confidence and uncertainty. This section also identifies areas of additional research. This section recommends the source of data for regulatory values and the appropriate approach for extrapolating between species (if necessary) and among humans.

# IV. REVIEWING EPIDEMIOLOGY STUDIES FOR USE IN PESTICIDE RISK ASSESSMENT

#### A. Introduction

Epidemiology is a science that seeks to identify and evaluate relationships between exposure to chemical, physical or biological agents, and the health status of populations (Boyes et al., 2007). It has been defined as the "study of how disease is distributed in populations and the factors that influence or determine this distribution" (Gordis, 2009). More broadly, it is considered as "the study of the occurrence and distribution of healthrelated events, states, and processes in specified populations, including the study of the determinants influencing such processes and the application of this knowledge to control of relevant health problems" (Porta, 2014). The objective of much epidemiologic research is to obtain a valid and precise estimate of the effect of a potential cause on the occurrence of disease. A key objective of epidemiology, like other sciences, is determining cause and effect or - said differently - of identifying the etiology of a disease or health outcome and the risk factors with which it might be associated. Calderon (2000) described four major uses of such studies: 1) describe the health status of a population and discover important time trends in disease and exposure frequency: 2) explain the occurrence of diseases by identifying factors that are associated with specific diseases or trends; 3) predict the number of disease occurrences and the distribution of health states in specific populations; and 4) improving the health status of the population by identifying factors that affect environmental or human health. In the case of pesticides, epidemiology focuses on the relation between exposure and adverse health effects in the general population and in specific sub-populations, such as occupationally exposed workers or applicators.

Epidemiology studies have the potential to help inform multiple components of the risk assessment in a variety of ways. High quality studies with robust exposure assessment may be used to quantitatively estimate risk or an appropriate risk surrogate such as an odds ratio or risk ratio. However, many epidemiology studies that deal with pesticides and pesticide exposure suffer some limitations in size, scope, exposure assessment, or data analysis which prevent or otherwise impede their full use in quantitative risk assessment

ヒトでの事例データの役割がより限定的であるのとは対照的に、疫学研究は様々な方法でリス ク評価の複数の構成要素に情報を提供するのに役立つ可能性を持っている。正確なばく露評価を 行った質の高い研究は、リスク指標を定量的に推定するために使用することができる。

また、疫学的研究で報告された結果は、*in vitro* 試験や動物試験で見られた結果と定性的に比較して動物試験の結果のヒトへの関連性を評価することもでき(Hertz-Picciotto、1995年)、 疫学的結果の生物学的妥当性を評価することにも有用である。提案されている WOE 解析の最後 の部分では、全体的な結論と信頼性と不確実性の分野の記述が行われる。このセクションでは、 追加研究の分野も特定している。本セクションでは、規制値の情報源及び(必要に応じて)種間 及びヒトの間での外挿法での推定のための適切なアプローチを推奨している。

# IV. 農薬のリスク評価に用いるための疫学研究のレビュー A. 緒言

疫学は、化学的、物理的、または生物学的要因へのばく露と集団の健康状態との関係を特定し、 評価することを目指す科学である(Boyes ら、2007 年)。疫学とは、「集団における疾病の分 布と、その分布に影響を与えたり、調査したりする要因の研究」と定義されている(Gordis、 2009年)。より広義には、「特定の集団における健康に関連する事象、状態、プロセスの発生 と分布の研究であり、そのようなプロセスに影響を与える調査要因の研究と、この知識を関連す る健康問題の制御に応用することを含む」(Porta、2014 年)と考えられている。多くの疫学研 究の目的は、病気の発生に対する潜在的な原因の影響を有効かつ正確に推定することである。疫 学の主な目的は、他の科学と同様に、原因と結果を明らかにすることであり、別の言い方をすれ ば、病気や健康影響の病因とそれに関連する可能性のあるリスク因子を特定することである。 Calderon(2000年)は、このような研究の4つの主要な用途を説明している。1)集団の健康状 態を記述し、疾病やばく露頻度の重要な時間的傾向を発見すること、2)特定の疾病や傾向に関 i車する因子を特定することで疾病の発生を説明すること、3)特定の集団における疾病の発生数 や健康状態の分布を予測すること、4)環境やヒト健康に悪影響を及ぼす因子を特定することで 集団の健康状態を改善すること、である。農薬の場合、疫学は、一般集団と、職業上ばく露され る農業従事者や農薬散布者などの特定の小集団におけるばく露と健康への悪影響との関係に焦点 を当てている。

疫学研究は、様々な方法でリスク評価の複数の要素に情報を提供するのに役立つ可能性がある。 正確なばく露評価を行った質の高い研究は、リスクを定量的に推定するために、あるいはオッズ 比やリスク比のような適切なリスク・サロゲート(代理)を用いることができる。しかし、農薬 や農薬ばく露を扱う疫学研究の多くは、規模、範囲、ばく露評価、またはデータ解析になんらか の制限があり、それが定量的リスク評価への十分な利用を妨げている(Ntzani ら、2013 年)。

(Ntzani et al., 2013). Pesticide use in the US has changed significantly over the last few decades. As the use changes, so does the exposure to workers. Changes in pesticide use have occurred due to risk mitigation actions by EPA, resistance management activities, introduction of new chemistries, and increased use of genetically modified crops. These significant changes in exposure have to be taken into account when interpreting epidemiology studies and, ultimately, the decision to use such studies in quantitative risk assessment. Even so, epidemiology studies may be used to compare with evidence from experimental animal studies to characterize assumptions used in deriving such values. In other cases, outcomes reported in epidemiologic studies may be compared qualitatively with those seen in *in vitro* and laboratory animal studies to evaluate biological plausibility or human relevance of animal findings (Hertz-Picciotto, 1995). Human information like that found in epidemiology studies are expected to potentially play a significant role in the new vision of toxicity testing recommended by the NRC (2007). Specifically, epidemiology studies can provide insight on health outcomes that may arise from real-world chemical exposures in humans and thus can contribute to problem formulation and hazard/risk characterization. Human information may guide additional studies (e.g., dose and endpoint selection for use in *in vitro* and targeted *in vivo* experimental studies); and identify novel health effects or host susceptibilities which can be investigated with future research.

When laboratory data from animal studies provide the primary source of information for hazard characterization, one potential source of uncertainty is the relevance of animal models to humans. In the absence of data to support the contrary, animal findings are assumed to be relevant to humans. Furthermore, EPA assumes that humans are more sensitive than laboratory animals in the absence of data to support the contrary. In actuality, humans may be more or less sensitive to pesticides than other animal species. Epidemiology and human incident data can provide scientific information and support to inform uncertainties associated with species extrapolation. With respect to population variability, epidemiology studies better characterize potential variability than do animal studies. Specifically, epidemiologic data include the genetic diversity, and variability inherent in human populations and thus can better account for and represent actual population response to environmental chemicals than laboratory animals (Calderon, 2000).

With respect to dose-response characterization, animal toxicology studies have the benefit that studies can be designed to cover a broad range of exposure levels. However, animal toxicology studies generally use exposures which are much larger (sometimes orders of magnitude) than those that occur in the environment. These high exposure levels in animal studies dictate the need for extrapolation from high to low doses. This extrapolation introduces added uncertainty into the risk assessment. Epidemiology studies and human incident data involve actual real-world exposures and thus high dose extrapolation may in many cases not be needed. Epidemiology studies conducted over a range of exposures (from low to high) are most useful.

Animal studies do not replicate the length, magnitude, duration, routes of exposure and variability in exposure experienced by humans (Calderon, 2000). Human exposure often occurs through multimedia exposure pathways, including food, water, air, and indoor and outdoor environments. In contrast, controlled laboratory studies typically use a single

米国での農薬使用は、ここ数十年で大きく変化した。使用が変化すると、農業従事者へのばく 露も変化する。農薬使用の変化は、EPA によるリスク軽減措置、抵抗性管理活動、新しい化学 物質の導入、遺伝子組換え作物の使用量の増加によって生じている。疫学研究を解釈し、最終的 には定量的リスク評価にそのような研究を使用するかどうかを調査する際には、ばく露における これらの大きな変化を考慮しなければならない。そうであっても、疫学研究は、実験的動物研究 から得られたエビデンスと比較して、そのような値を導き出す際の仮定を特徴づけるために使用 することが可能である。また、疫学研究で報告された結果を *in vito* 試験や動物試験で得られた 結果と定性的に比較して、動物実験で得られた結果の生物学的妥当性や人間との関連性を評価す る場合もある(Hertz-Picciotto、1995年)。疫学研究で得られたようなヒトでの情報は、NRC (2007年)が推奨する毒性試験の新しいビジョンにおいて重要な役割を果たす可能性があると 期待されている。具体的には、疫学研究は、ヒトの実社会での化学物質ばく露から生じる可能性 のある健康影響についての知見を提供し、その結果、問題の設定やハザード/リスクの特性評価 に貢献することができる。ヒトでの情報は、追加的な研究(例えば、*in vitro* 試験や目標とする *in vivo*試験で使用するための用量やエンドボイントの選択)の指針となり、今後の研究で調査さ れる新たな健康影響や感受性を特定することができる。

動物実験から得られた実験データがハザードの特性評価のための主要な情報源となる場合、潜 在的な不確実性の原因の一つとして、動物モデルのヒトへの関連性が挙げられる。これに反する データがない場合には、動物の結果はヒトとの関連性があると想定される。さらに EPA はヒト は実験動物よりも感受性が高いと仮定しているが、それを裏付けるデータがない。実際には、ヒ トは他の動物種よりも農薬に対して感受性が高い場合も低い場合もある。夜学データ及びヒトで の事例データは、科学的な情報を提供し、外挿法での推定に関連する不確実性を伝えるための裏 付けとなり得る。母集団の変動性に関しては、動物試験よりも疫学研究の方が潜在的な変動性を の特徴をよく表している。具体的には、疫学データは、ヒトの集団に固有の遺伝的多様性と変動 性を含むため、実験動物よりも環境化学物質に対する実際の集団での反応をよりよく説明し、代 表することができる(Calderon、2000年)。

用量反応の特性評価に関して、動物の毒性試験には、広範囲のばく露レベルをカバーするよう に試験デザインできるという利点がある。しかし、動物の毒性試験では、一般的に環境中でのば く露レベルよりもはるかに高い(時には桁違いの)ばく露レベルが用いられている。動物試験で は、このような高いばく露レベルがあるため、高用量から低用量の外挿法での推定が必要である。 この外挿法での推定はリスク評価に不確実性をもたらす。疫学研究データやヒトでの事例データ は、ヒトの実社会でのばく露を含んでいるため、多くの場合、高用量の外挿法での推定は必要な いと考えられる。疫学研究は低用量から高用量までの広い範囲のばく露が最も有用である。

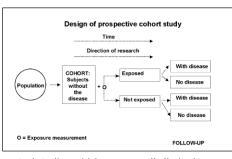

動物試験では、ヒトが経験するばく露の時間、程度、期間、ばく露経路及びばく露の変動性を 再現するものではない(Calderon、2000年)。ヒトでのばく露は、食品、水、空気、屋内外の 環境を含む多岐のばく露経路を介して行われることが多い。対照的に、制御された実験室での研 究では、通常、単一のばく露経路である。 route of exposure. In addition, humans may experience exposure to multiple chemicals and/or non-chemical stressors simultaneously, whereas most animal studies involve a single chemical stressor. On one hand, this multi-chemical exposure in epidemiology studies can provide a challenge when attempting to attribute epidemiologic outcomes to a single pesticide chemical. On the other hand, epidemiologic research considers real-world exposures and may help, when considered along with experimental approaches, address questions associated with multiple chemical exposures which can be difficult to evaluate in an experimental setting.

## B. Types of Epidemiology Studies

The major types of observational epidemiologic studies are described briefly below with consideration of their strengths and weaknesses (Lilienfeld and Lilienfeld, 1979; Mausner and Kramer, 1985; Kelsey et al., 1996; Rothman and Greenland, 2012; Paddle and Harrington, 2000; USEPA, 2005; Purdue Pesticide Programs, PPP-43).

**Cohort studies** begin with a group of people that share common characteristics—the cohort—and evaluate their health over an extended follow-up time period during which the occurrence of disease is recorded (see figure box from van den Brandt et al. (2002)). The common characteristic is often the presence vs. absence of "risk factors" (such as

exposures)<sup>9</sup>. In such studies, differences in disease occurrence between the "exposed" and "nonexposed" individuals are identified and studied over time to determine differences in the rate of disease<sup>10</sup>. This difference in the rate of disease occurrence is then investigated to determine if the rate of disease differs between the exposed and non-exposed groups. Cohort studies have the ability to simultaneously evaluate multiple disease outcomes

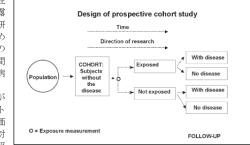

under study (which is not true for case-control studies, which are generally limited to evaluating only a single (pre-specified) disease outcome, discussed below). Cohort studies can also be performed either prospectively, like the Agricultural Health Study (AHS, <u>http://aghealth.nci.nih.gov/</u>), or retrospectively from historical records. A prospective cohort design focuses on a group of people from a current point in time through a future point in time. A retrospective cohort design focuses on a group exposed at some point in the past, and compares disease rates after exposure occurred (generally through existing さらに、ほとんどの動物試験では単一の化学的ストレス因子を用いているのに対し、ヒトでは複 数の化学物質及び/または非化学的ストレス因子へのばく露を同時に受けている可能性がある。 一方で、疫学研究における複数の化学物質へのばく露は、疫学研究の結果が単一の農薬に帰属さ せようとする場合に問題となり得る。一方で、疫学研究は実社会のばく露を考慮しており、実験 的アプローチと併せて考慮することで、実験環境では評価が困難な複数の化学物質ばく露に関連 した問題に対処するのに役立つ可能性がある。

#### B. 疫学研究の種類

観察疫学研究の主なタイプを、その長所と短所を考慮しながら以下に簡単に説明する (Lilienfeld and Lilienfeld、1979 年; Mausner and Kramer、1985 年; Kelsey ら、1996 年; Rothman and Greenland、2012 年; Paddle and Harrington、2000 年; USEPA、2005 年; Purdue Pesticide Programs, PPP-43)。

**コホート研究**では、共通の特性を共有する人々の集団(コホート)から始まり、病気の発生が記録されている長期の追跡期間にわたって健康状態を評価を行う(van den Brandt ら (2002 年)

から引用の図を参照)。共通の特性 は、しばしば「リスク因子」(ばく露 など)<sup>9</sup>の有無である。このような研 究では疾病発生率の違いを調べるため に、「ばく露者」と「非ばく露者」の 間の疾病発生率の違いを特定し、時間 をかけて調査する<sup>10</sup>。次に、この疾病 発生率の差を調査して、「ばく露群」 と「非ばく露群」の間で疾病発生率が 異なるかどうかを判断する。コホート 研究は、複数の疾病発生を同時に評価 する能力を持っている(これは症例対 照研究では当てはまらない。症例対照

研究では、一般的には後述するように単一の(事前に指定された)疾病発生のみを評価すること に限定される)。

コホート研究は、Agricultural Health Study (AHS\_http://aghealth.nci.nih.gov/) のように前 向きで実施することもできるし、過去の記録から後ろ向きに実施することもできる。前向きコホ ート研究は、現在の時点から将来の時点までの人々の集団に焦点を当てている。後ろ向きコホー ト研究は、過去のある時点でばく露された集団に焦点を当て、ばく露が発生した後の疾病率を比 較するものである(一般的には、一人(個人)単位で利用できる既存のばく露データベース(ま たは記録)を利用)。

9コホート研究では、ばく露はしばしばばく露者と非ばく露者に二分されるが、ばく露は定量的 尺度(例えば、連続的尺度または定量値)で測定することも可能である。

10 コホート研究では、一般的に疾病発生率の違いを研究しているが、これらの研究には、出生時の体重、知能、血圧など、関係のある他の限局的な結果も含まれる。

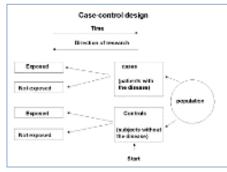

<sup>&</sup>lt;sup>9</sup> While exposure is often dichotomized on an exposed vs. non-exposed basis in cohort studies, exposure can also be measured on a quantitative scale (e.g., by a continuous measure or by quantiles)
<sup>10</sup> Cohort studies commonly study differences in rates of disease, but these can also include other focal

outcomes of interest such as birth weight, mental abilities, blood pressure, etc.

available exposure databases (or records) available on a person-by-person (individual) basis). Prospective cohort studies can be relatively lengthy and expensive to conduct, particularly for rare diseases, and require a large number of subjects to be under study. Importantly, significant resources and professional staff are required for a long period of time to collect high quality data.

**Case-control studies** are studies in which groups of individuals with (cases) and generally without (controls) a given disease are identified and compared with respect to (generally past<sup>11</sup>) exposure to determine whether those with the disease of interest are

more likely or no more likely to have been exposed to the agent(s) or factor(s) of interest. That is, the analysis of case-control studies contrasts the frequency of exposure of the agent or factor in the cases with those in the controls to determine if these differ and, thus, whether there is a differential association. In case-control studies, determination of the disease status (i.e., cases with the disease; controls without) generally precedes determination of the exposure status (see figure box from van den Brandt et

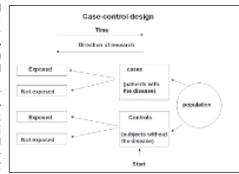

al. (2002)) Because disease has already occurred at the time of selection into the casecontrol study, this study design is particularly useful in studying uncommon diseases or diseases with long latency and can be utilized to evaluate the relation between many different exposures and a specific (pre-specified) disease outcome of interest. And because case-control studies begin with individuals who have the disease, the studies can involve fewer subjects than cohort studies and can be completed in a comparatively shorter time frame. Challenges in case-control investigations include the selection of an appropriate control group and the assessment of exposures which may have occurred long before the disease was diagnosed (Rothman, 2012; Wacholder et al. 1992a; Wacholder et al. 1992b; Wacholder et al. 1992c; Shultz and Grimes, 2002; Grimes and Schultz, 2005). Case-control studies can be particularly susceptible to "recall bias" in which diseased individuals may remember exposures or events differently (generally better) than those who serve as the controls and are healthy.

**Nested case-control studies** are an example of a hybrid design and contain the elements of a cohort and a case-control study. These designs can be useful when the analytical costs for determining pesticide exposure are too high for the entire cohort to be studies. For example, a cases that that have developed the disease or health outcome in an

前向きコホート研究は、特に希少疾病の場合、実施に比較的時間がかかり、費用がかかることが あり、研究対象となる被験者の数が多いことが必要である。重要なことは、質の高いデータを収 集するためには、長期間にわたって多大な資源と専門スタッフが必要であるということである。

**症例対照研究**は、特定の疾病を持つ(症例)個人と、そうでない(対照)個人の集団を特定し、 ばく露(一般的には過去<sup>11</sup>のばく露)に関して比較することで、関係ある疾病を持つ人が、関係 ある薬剤あるいは要因にばく露されていたか否かを判断する研究である。すなわち、症例対照研

究の解析では、症例において関係ある薬剤 または要因のばく露頻度と、対照群におけ るばく露頻度を対比させて、これらが異な るかどうか、要するに関連があるかどうか を判断する。症例対照研究では、一般的 に、疾病状態(すなわち、疾病を持つ症例 と疾病を持たない対照群)を決定すること が、通常、ばく露状態の調査に先立って行 われる(van den Brandt ら、(2002年)か ら引用の図を参照)。この研究デザインは 症例対照研究に選択された時点ですでに疾 病が発生しているので、希な疾病や潜伏期 間の長い疾病の研究で特に有用であり、多 くのばく露と関係ある特定の(事前に指定 された)疾病発生との関連性を評価するた

めに利用することができる。また、症例対照研究は、その疾病に罹患している個人を対象として いるので、コホート研究に比べて被験者数が少なく、比較的短い期間で終了することができる。 症例対照研究の問題は、適切な対照群の選択と、疾病が診断されるずっと前に発生した可能性の あるばく露の評価である(Rothman, 2012 年; Wacholder ら、1992 年 a; Wacholder ら、1992 年 b; Wacholder ら、1992 年 c; Shultz and Grimes、2002 年; Grimes and Schultz、2005 年)。症 例対照研究は、特に"想起バイアス"の影響を受けやすい。これは、罹患した人は、対照あるいは 健康人と比べてばく露や出来事を違った形で(一般的にはよく)覚えている可能性がある。

**コホート内症例対照研究**は、ハイブリッドデザインの一例であり、コホート研究と症例対照研 究の要素を含んでいる。この研究デザインは、農薬ばく露を調査するための解析コストが、高す ぎて、コホート全体を調査することができない場合に有用である。

<sup>11</sup>時間をかけて症例を研究に登録した状況下では研究開始後まで発症していない症例で前向きに 症例対照研究を実施することは可能である。

Page 19

<sup>&</sup>lt;sup>11</sup> It is possible for case-control studies to be done prospectively in which the cases have not yet developed the disease until after the study begins under which circumstance the cases are enrolled in the study over time.

ongoing cohort study can be matched with appropriate controls from the study that have not yet developed the disease or outcome of interest at the time of the analysis. One recognized advantage of the nested case-control study (as opposed to a more standard case-control study) is that the issues of selection bias and recall bias are minimized.

**Cross-sectional studies** focus on the prevalence of disease (e.g., birth defects, smallfor-gestational age or SGA), symptoms, biological/physical and physiologic response measurements (e.g., pulmonary function tests, blood pressure, chest X-ray, clinical examinations, liver and kidney biomarkers). A key feature of such studies is that they are observational studies which focuses on the *prevalence* as a frequency measure, with the presence or absence of disease determined at the time of sampling or over a sampling period. Prevalence is the proportion of individuals in a population that has the disease and can either be determined as a "point prevalence" or as a "period prevalence".12 A prevalence is a proportion not a rate and thus the cross sectional studies do not involve a follow up period. Typically, the exposure status (e.g., exposed or unexposed), disease status/outcome, and demographic characteristics are determined at a point in (or over) time. The major comparison in this study design is a comparison of the prevalence of the outcome in the exposed population vs. the prevalence of that outcome in the non-exposed population, with the risk measure being the prevalence risk ratio or odds ratio. Crosssectional studies are generally used to identify patterns or trends in disease occurrence over time or in different geographical locations, and can be conducted guickly and relatively inexpensively. However, they measure the prevalence of a disease outcome which is affected by both incidence - the rate of occurrence of new cases - and duration of the disease, and it can be difficult in any analysis to sufficiently separate these factors. Thus, they involve "survivor populations" and do not measure, evaluate, or consider those that have left the population of interest because they became ill. Another important limitation of cross-sectional studies is they do not allow one to determine whether exposure precedes the disease. As such cross-sectional studies are unable to establish temporal relationships between disease and exposure and typically require additional studies to confirm a hypothesized causal association suggested by a cross-sectional study.

Ecologic studies examine exposure and disease patterns using information reflecting group or population-level data. In an ecologic study, the unit of analysis is a group and not an individual<sup>13</sup>. Here, groups of subjects are sampled, with the exposure, disease, and potential confounding factors measured at this group (or cluster) level. Groups are generally defined on a geographic, administrative, or organizations unit basis (e.g., districts, towns, counties, schools, workplaces, etc.) with all exposure, disease, or confounder measurements made or summarized at the group level rather than at the level of the individual. An ecological (group-based) study contrasts with an individual-level study in that in the former there is no information on whether the cases are the actual individuals

例えば、現在進行中のコホート研究で疾病または健康影響を生じた症例は、解析時に関係ある疾 病や影響を生じていない研究からの適切な対照群と組み合わせることが可能である。コホート内 症例対照研究(標準的な症例対照研究とは対照的に)の利点として認識されているのは、選択バ イアスと想起バイアスの問題が最小限に抑えられることである。

構断研究では、疾病(例えば、先天性異常、胎児発育遅延(SGA))、症状、生物学的/身体 的及び生理学的反応の測定値(例えば、肺機能検査、血圧、胸部X線、臨床検査、肝臓及び腎臓 のバイオマーカー)の有病率に焦点を当てている。このような研究の主な特徴は、サンプリング 時またはサンプリング期間中に疾病の有無を判定し、有病率を頻度の尺度として重視した観察研 究であるということである。有病率とは、ある集団の中で罹患している人の割合であり、「点有 病率|または「期間有病率|として調査される12。有病率は比率ではなく、割合であるため、横 断研究では追跡調査期間を必要としない。一般的に、ばく露状態(例えば、ばく露または非ばく 露)、疾病の状態/発生、人口統計学的特性は、ある時点(またはその時点以後)で調査される。 この研究デザインにおける主な比較は、ばく露集団における疾病発生の有病率と非ばく露集団に おける疾病発生の有病率の比較であり、リスク尺度は有病率リスク比またはオッズ比である。横 断研究は、一般的に、長年にわたる疾病発生または地理的に異なる場所のパターンや傾向を明ら かにするために使用され、迅速かつ比較的安価に実施することができる。しかし、これらの調査 では、疾病の発生率(新規症例の発生率)と疾病の持続期間の両方に影響される疾病発生の有病 率を測定しているため、これらの要因を十分に分離することは、どのような解析においても困難 な場合がある。したがって、これらの研究は「生存者集団」を対象としており、病気になったた めに関係ある集団から離れてしまった人を測定、評価、考慮することはない。横断研究のもう一 つの重要な限界は、ばく露が疾病に先行しているかどうかを判断できないことである。そのため、 横断研究では疾病とばく露の時間的関係を確立することができず、横断研究で示唆された仮説に 基づく因果関係を確認するために、追加の研究を必要とするのが一般的である。

**生態学的研究**では、グループまたは集団のレベルでのデータを反映した情報を用いてばく露や 疾病のパターンを調べる。生態学的研究では、解析の単位は個人ではなく集団である<sup>13</sup>。ここで は、被験者の集団がサンプリングされ、ばく露、疾病及び潜在的な交絡因子を、この集団(また はクラスター)レベルで測定される。集団は一般的に地理的、行政的、組織的な単位(例えば、 地区、町、郡、学校、職場など)で定義され、すべてのばく露、疾病、交絡因子の測定は、個人 のレベルではなく、集団のレベルで行われたり、まとめられたりする。生態学的(集団ペース) 研究は、個人レベルの研究とは対照的であり、前者では症例がばく露された実際の個人であるか どうかの情報がないのに対し、後者ではばく露情報が個人に結びついている。

<sup>&</sup>lt;sup>12</sup> The former involve measurements at a particular place and/or a particular time while the latter involves determinations of the proportion of cases over a given time period.

<sup>&</sup>lt;sup>13</sup> Some studies can be "partially ecologic" in design in which either the exposure or the disease outcome is measured on a group level but the other variable is measures at an individual level with the researcher making inferences to the individual level.

<sup>&</sup>lt;sup>12</sup>前者は特定の場所及び/または特定の時間での測定であるのに対し、後者は特定の期間における症例の割合の調査である。

<sup>&</sup>lt;sup>13</sup>一部の研究では、ばく露または疾病発生のいずれかが集団のレベルで測定されるが、他の変数 は個人のレベルで測定され、研究者は個人のレベルで推測を行うという「部分的に生態学的」 研究もある。

with the exposure whereas in the latter exposure information is tied to the individual. As an example, a study of disease rates by contaminant levels in water can be ecologic with respect to evaluation of the exposure, but the health outcome or disease status may have determined on an individual basis. In these instances, the term "semi-ecological" can sometimes be used when exposure is determined at the group level but outcome is determined at the level of the individual.

Using this design, it is not possible to know whether all members of the exposed group are individually exposed (or the individual exposure levels) nor is it possible to infer individual-level effects from the group level effects that result. If the intent of the study is to direct inferences to the *group* (rather than the individual), then this is <u>not</u> a concern and these studies can be appropriate, particularly if measurements are constrained or difficult to perform at the individual level and exposures within the group are generally homogenous. If the intent of the study is instead to direct inferences to the individual, then this study design suffers from what is termed the ecological fallacy: the assumption that an observed relationship in an aggregated or grouped data set will reflect what would have been observed had the sampling occurred at the individual level. In addition to this control for confounding variables at the level of the individual as opposed to the group when information on confounding factors is only available at the group level.

In most cases, ecologic studies are considered as hypothesis-generating studies and best used for suggesting research hypotheses for future studies and may contribute to problem formulation. Nevertheless, it is important to assess ecological studies on the basis of the quality of their design, and useful information can be gleaned from an ecologic study if it is well-designed (FIFRA SAP, 2010). Ecologic studies alone generally do not have the ability to establish a causal association. When taken with other these studies can be useful under certain circumstances and should be noted in the hazard characterization. In particular, stable populations, clear exposure contrasts, and large differences in risk can be important factors that might increase the utility of these studies.

#### C. Evaluating epidemiology studies for use in pesticide risk assessment

OPP searches the peer reviewed literature for observational epidemiology studies of potential adverse acute and chronic health effects linked to chemical use. Details regarding literature search protocols and strategies are provided elsewhere. Epidemiologic research utilizing cohort, case-control, or cross-sectional study designs may provide information to OPP to strengthen OPP's understanding of the potential hazards, exposure-response characterization, exposure scenarios. or assessment methods, and – ultimately -- risk characterization (van den Brandt, 2002). In addition, compelling case reports or case series analysis may illumine a health effect or mechanism of action previously unidentified.

Generally speaking, the quality of epidemiologic research, sufficiency of documentation of the study (study design and results), and relevance to risk assessment is considered when evaluating epidemiology studies from the open literature for use in OPP's

例えば、水中の汚染物質レベルによる疾病率の研究は、ばく露の評価に関しては生態学的である が、健康影響や疾病状態は個人で調査されている場合がある。このような場合、ばく露は集団レ ベルで決定されるが、結果は個人レベルで調査される場合に「半生態学的」という用語が使用さ れることがある。

この研究デザインでは、ばく露集団のすべてのメンバーが個別にばく露されているかどうか (または個人のばく露レベル)を知ることはできないし、グループレベルの影響から個人レベル の影響を推測することもできない。研究の目的が(個人ではなく)集団への直接的な推測を目的 としている場合には、これは問題では<u>なく</u>、特に個人レベルでの測定が制約されていたり、困難 であったり、集団内のばく露が一般的に均質であったりする場合には、このような研究が適切で あると考えられる。研究の意図が個人への直接的な推測である場合、この研究デザインは生態学 的誤謬と呼ばれる問題を抱えていることになる。集合またはグループ化されたデータセットで観 察された関係が、個人レベルでサンプリングが行われていたら観察されていたであろうことを反 映するという仮定である。この生態学的誤謬の問題に加えて、交絡因子に関する情報が集団レベ ルでしか得られない場合、集団とは対照的に個人レベルで交絡変数を適切にコントロールできな い結果、追加のバイアスが発生する。

ほとんどの場合、生態学的研究は仮説を生み出す研究と考えられており、今後の研究のための 研究仮説を提案するのに最適であり、問題の提起に貢献する可能性がある。とはいえ、生態学的 研究をデザインの質に基づいて評価することは重要であり、デザインが優れていれば、生態学的 研究から有用な情報を得ることができる(FIFRA SAP、2010 年)。一般的に、生態学的研究だ けでは、因果関係を立証する能力はない。これらの研究を他の研究と併用した場合、特定の状況 下では有用となる可能性があり、ハザード特性評価の際に留意すべきである。特に、安定した母 集団、明確なばく露の対比、リスクの大きな差は、これらの研究の有用性を高める重要な要因と なり得る。

#### C. 農薬のリスク評価に用いるための疫学研究の評価

OPP は、化学物質の使用に関連した潜在的な急性及び慢性の健康影響に関する観察疫学研究 を査読済み文献で検索する。文献検索の手順と戦略に関する詳細は、別の場所で提供されている。 コホート研究、症例対照研究、または横断研究のデザインを利用した疫学研究は、潜在的なハザ ード、ばく露反応の特性、ばく露シナリオ、または評価方法、そして最終的にはリスクの特性評 価に関する OPP の理解を深めるための情報を提供することができる(van den Brandt、2002 年)。さらに、説得力のある症例報告や症例集積解析は、これまで明らかにされていなかった健 康影響や作用機序を明らかにする可能性がある。

一般的には、OPP のリスク評価で用いられる公開文献からの疫学研究を評価する際には、疫 学研究の質、研究の文書化の十分さ(研究デザインと結果)、リスク評価との関連性が考慮され る。 risk assessments. It is important that these criteria are endpoint-specific as various methodological details become more or less important given the endpoint of concern. For example, it is important to understand relevant factors that influence outcome ascertainment (*e.g.*, is there a test or a biomarker available to indicate presence of an effect, or are symptoms gradual and non-specific initially leading to physician diagnosis upon advanced disease state). In addition, for environmental and occupational epidemiology studies, the quality of the exposure assessment is vitally important. Prior consideration must be given to aspects of exposure and confounder measurement to the question under consideration.

When considering individual study quality, various aspects of the design, conduct, analysis and interpretation of the epidemiology studies are important. These include:

- 1. Clear articulation of the hypothesis, even if the study is hypothesis-generating in nature;
- Adequate assessment of exposure for the relevant critical windows of the health effects, the range of exposure of interest for the risk assessment target population, and the availability of a dose/exposure-response trend from the study, among other qualities of exposure assessment,
- 3. Reasonably valid and reliable outcome ascertainment (the correct identification of those with and without the health effect in the study population),
- 4. Appropriate inclusion and exclusion criteria that result in a sample population representative of the target population, and absent systematic bias,
- Adequate measurement and analysis of potentially confounding variables, including measurement or discussion of the role of multiple pesticide exposure, or mixtures exposure in the risk estimates observed,
- 6. Overall characterization of potential systematic biases in the study including errors in the selection of participation and in the collection of information; this can include performing sensitivity analysis to determine the potential influence of systematic error on the risk estimates presented (*e.g.*, Greenland's formula)
- 7. Evaluation of the statistical power of the study to observe health effects with appropriate discussion and/or presentation of power estimates,
- 8. Use of appropriate statistical modeling techniques, given the study design and the nature of the outcomes under study

Other Federal and non-Federal entities have offered such guides (*e.g.*, OHAT, Navigation Guide, National Toxicology Program [NTP] Report on Carcinogens [ROC<sup>14</sup>], IRIS, Cochrane ACROBAT-Non-Randomized Studies of Interventions) (Sterne et al., 2015 as well as the STROBE (Strengthening the Reporting of Observational Studies in Epidemiology) statement for observational epidemiological studies (see <u>www.strobe-statement.org</u> and Vandenbroucke et al., 2007; Von Elm, 2014) As OPP gains experience with integrating epidemiology studies into human health risk assessment, relevant adjustments to its evaluation approach will be made.

これらの基準は、懸念されるエンドポイントに応じて様々な方法論の詳細が重要になったり、な らなかったりするため、エンドポイントを特定することが重要である。疾病発生の確認に影響を 与える関連因子を理解することが重要である(*例えば、*影響の有無を示す検査やバイオマーカー が利用できるか、あるいは初期段階では非特異的な症状であり、進行した病状では医師の診断に つながるかなど)。さらに、環境及び職域疫学研究では、ばく露評価の質が極めて重要である。 検討中の問題に対して、ばく露と交絡要因の評価の側面を事前に考慮しなければならない。

個々の研究の質を考える際には、疫学研究のデザイン、実施、解析、解釈の様々な側面が重要 である。これらには以下が含まれる。

- 1. 仮説を明確に明示することで、たとえその研究が本質的に仮説生成的なものであったとしても、その仮説を明確に示されていること。
- 2. 健康影響の関連する重大な時期、リスク評価対象集団の関係あるばく露範囲、試験から 得られる用量/ばく露反応の傾向の入手可能性など、ばく露評価の資質の中で、適切な ばく露評価が十分であること。
- 3. 合理的に有効で信頼性の高い結果の確認(研究集団における健康影響の有無を正しく識別されていること)。
- 対象集団を代表するサンプル集団となり、系統的な偏りがない適切な組み入れ基準と除 外基準。
- 5. 観察されたリスク推定値における複数の農薬ばく露、または混合物ばく露の役割の評価 または考察を含む、潜在的な交絡変数の適切な評価及び解析。
- 6. 参加者の選択や情報収集における誤りを含む、研究における潜在的な系統的な偏りの全体的な特性。これには、提示されたリスク推定値に対する系統的誤差の潜在的な影響を調査するための感度分析の実施を含む(例:Greenland's 公式)。

<sup>14</sup> http://ntp.niehs.nih.gov/pubhealth/roc/index.html

Independent study evaluation is performed and documented prior to the development of evidence- tables of detailed summary tables which are informative to hazard identification and exposure response assessment. Table 2 provides a structure to the major considerations evaluated and the associated weight (low, medium, high) for each consideration. Table 2 provides a generic set of considerations and should not be considered a checklist. The specific scientific considerations appropriate for particular science analysis are adjusted on a case by case basis.

The culmination of the study evaluation process would be to provide professional/expert opinion as to the nature of the potential bias that may result from systematic errors in each specific study identified through study specific evaluations, and an assessment of overall confidence in the epidemiological database. In this way, data integration (animal, human, mechanistic, other) would be informed by level of confidence in the human epidemiological studies that inform human health effects of environmental and occupational exposures. 独立した研究評価は、ハザードの特定及びばく露反応評価に有益である詳細な要約表を作成す る前に実施され、文書化されている。表2は、評価された主な考慮事項と、各考慮事項に関連す る重み(低、中、高)の構造を示している。表2は考慮事項の一般的な検討事項を示したもので あり、チェックリストと考えるべきではない。特定の科学的解析に適した特定の科学的考慮事項 は、ケース・バイ・ケースで調整される。

研究評価プロセスの最終段階では、研究固有の評価を通じて特定された各研究における系統的 な誤りから生じる可能性のあるバイアスの性質についての専門家/エキスパートの意見を提供し、 疫学データベースに対する全体的な信頼性の評価を行うことである。このようにして、データ統 合(動物、ヒト、メカニズム、その他)は、環境ばく露や職業上ばく露のヒト健康影響を伝える ヒト疫学研究の信頼度に基づいて行われることになる。

#### 1. Exposure Assessment

Exposure assessment can be defined as the "process of estimating or measuring the magnitude, frequency and duration of exposure to an agent, along with the number and characteristics of the population exposed. Ideally, it describes the sources, pathways, routes, and the uncertainties in the assessment. (Zartarian et al., 2005)." In environmental epidemiology, exposure assessment poses a unique challenge, particularly for toxicants that are found in low concentrations in environmental media (NRC, 1991; NRC, 1997). Given the complexity of exposure pathways, researchers have developed a number of different approaches to assess exposure, which vary in accuracy, precision, and resource requirements (Niewenhuijsen, 2003). Some of these approaches are not specific to epidemiologic research but may be used to inform exposure assessment in a variety of scientific analyses. These approaches include indirect methods, based on historical records, questionnaires, and environmental monitoring, and direct methods, based on personal monitoring and biomonitoring. A brief description of each method and its strengths and limitations is summarized below.

Approach	Method/Tools	Example	Exposure Estimation
	Historical Records	Estimating proximity to agricultural crops using address information	Dichotomous or ordinal exposure
Indirect	Questionnaires	Determine potential for exposure based on pesticide-use responses	Dichotomous or ordinal exposure
	Environmental Monitoring	Measuring pesticide levels in community water drinking system	Dichotomous or ordinal exposure, although exposure can be estimated using modeling
Direct	Personal Monitoring	Measuring pesticide inhalation and dermal contact	Quantified exposure
	Biomonitoring	Measuring pesticide levels in blood and urine	Quantified internal dose

Table 3. Summary of indirect and direct exposure assessment methods.
--

Historical records and questionnaires are used to characterize key characteristics which may be associated with chemical exposure. When used in epidemiologic studies, historical records and questionnaires are not typically used to predict quantitative levels of exposure. Rather, historical record information or questionnaire responses are used to assign categorical levels of exposure. Examples of historical record information that can be used to assign exposure levels includes address in proximity to an agricultural crop and employment history information on job title and history. Similarly, questionnaires can be used to determine if individuals recall using pesticides or identify individuals that perform specific job functions that increase their potential for exposure. While historical records and questionnaires can be cost-effective sources of data on potential exposure, they do have limitations. Data collected from historical records and questionnaires is only a surrogate of exposure. As a result, these

#### 1. ばく露評価

ばく露評価は、「ある物質へのばく露の規模、頻度及び期間を、ばく露された集団の数と特性 とともに推定または評価するプロセス」と定義することができる。理想的には、評価において原 因、経路、方法及び不確実性を記述すると記載(Zartarian 6、2005 年)されている。環境疫学 において、ばく露評価は、特に環境媒体中に低濃度で存在する毒性物質については、独特の課題 となっている(NRC、1991 年; NRC、1997 年)。ばく露経路の複雑さを考慮して、研究者はば く露を評価するための多くの異なるアプローチを開発してきたが、その正確さ、精度及び必要な 資源は様々である(Niewenhuijsen、2003 年)。これらのアプローチのいくつかは、疫学研究 に特化したものではないが、様々な科学的解析におけるばく露評価の情報を提供するために使用 される可能性がある。これらのアプローチには、過去の記録、アンケート、環境モニタリングに 基づく間接的な方法と、個人モニタリングやバイオモニタリングに基づく直接的な方法がある。 それぞれの方法の簡単な説明とその長所と限界を以下に要約する。

#### 表 3. 間接的ばく露評価方法と直接的ばく露評価方法のまとめ

アプローチ	方法/ツール	例	ばく露の推定
	過去の記録	住所情報を利用した農地 への近接推定	二分法または順序のばく露
間接的	アンケート	農薬使用の回答に基づく ばく露の可能性の調査	二分法または順序のばく露
	環境モニタリング	地域の水道における農薬 レベルの測定	モデル化を用いてばく露を 推定することができるが、 二分法または順序のばく露
直接的	個人モニタリング	吸入と経皮でばく露され た農薬の測定	定量化されたばく露
	バイオモニタリング	血中・尿中の農薬の測定	定量化された内部ばく露量

**過去の記録やアンケート**は、化学物質へのばく露に関連する可能性のある主要な特性を評価す るために使用される。疫学研究で使用される場合、過去の記録やアンケートは通常、定量的なば く露レベルを予測するためには使用されない。むしろ、過去の記録情報やアンケートの回答は、 ばく露のカテゴリーレベルを調査するために使用される。ばく露レベルを調査するために使用で きる過去の記録情報の例としては、農地に近接した住所や、職位や職歴に関する雇用履歴情報な どが挙げられる。同様に、アンケートは、個人が農薬を使用したことを思い出すかどうかを調査 するために、またはばく露の可能性を高める特定の職務を行っている個人を特定するために使用 される。過去の記録やアンケートは、潜在的なばく露に関するデータの費用対効果の高い情報源 になり得るが、限界がある。過去の記録やアンケートから収集されたデータは、ばく露のサロゲ ート(代理)に過ぎない。

data sources may be an oversimplification of exposure and not accurately rank individual's exposure potential.

**Environmental monitoring** is used to characterize the levels of contaminants in environmental media, including air, water, soil, food, and home and work environments. Many state and Federal programs collect environmental monitoring data that may be useful in epidemiologic studies. Environmental monitoring is particularly useful for exposure that can be defined by geographic boundaries, such as air pollution and drinking water. As such, many epidemiologic studies have utilized ambient air monitoring data and community drinking water system data to characterize exposure to air pollution and drinking water contamination, respectively. While environmental monitoring data is useful for estimating exposures defined by geographic boundaries, it can be less reliable for the purposes of assigning individual-levels exposures, particularly when individuals live, work, and spend time in many different locations.

**Personal monitoring** is used to characterize exposure at the point of contact of a body boundary. Examples of personal monitoring include the use of dosimeters to assess dermal contact with pesticides, personal air sampling devices to assess inhalation exposure, and collection of duplicate diet samples to determine pesticide levels in food. The advantage of personal monitoring is that it is likely to provide more accurate estimates of individual-level exposure than indirect methods. Personal monitoring also makes it possible to quantify exposure levels that can be useful for prioritizing the relevance of different routes of exposure. Additionally, personal monitoring can also be used to assess longitudinal exposure when repeated measurements are taken over time. While personal monitoring offers many advantages over indirect approaches, it also tends to be labor and resource intensive (Niewenhuijsen, 2003). As a result, it is not typically feasible to conduct large-scale epidemiologic studies that assess exposure using personal monitoring. Furthermore, personal monitoring is highly dependent on the measurement techniques and analytic tools used to obtain samples and it is less likely that information that characterizes exposures during the relevant time period (usually in the past) will be available. In addition, it is unlikely that the full range of exposures over the time period of interest will be captured, and sampling may not be over a sufficient time period to capture peaks and fluctuations As such, it is extremely important to consider the scientific rigor and reliability of personal monitoring methodologies that are used in epidemiologic studies, and such monitoring may need to be supplemented by other monitoring (e.g., environmental, biological, and/or interview/questionnaire data).

**Biomonitoring** is used to characterize exposure by measuring a chemical, its metabolite(s), or reactive product(s) in biological samples, such as blood, urine, saliva, milk, adipose, and other body tissues (Needham et al., 2007). Zartarian et al. (2005) state that "a biomarker/biological marker has been defined as an "indicator of changes or events in biological systems. Biological markers of exposure refer to cellular, biochemical, analytical, or molecular measures that are obtained from biological media such as tissues, cells, or fluids and are indicative of exposure to an agent". Thus, biomarkers can be used to assess exposure or as indicators of health effects (LaKind et al., 2014). Table 4 provides scientific considerations for evaluating the quality and relevance of biomonitoring data

その結果、これらの情報源はばく露の単純化しすぎているため、個人のばく露の可能性を正確 に並べていない可能性がある。

**環境モニタリング**は、大気、水、土壌、食品、家庭環境や職場環境などの環境媒体中の汚染物 質のレベルを特性評価するために使用される。多くの州及び連邦政府のプログラムでは、疫学研 究に有用な環境モニタリングデータを収集している。環境モニタリングは、大気汚染や飲料水な ど、地理的な境界によって定義されるばく露に対して特に有用である。そのため、多くの疫学研 究では、大気汚染と飲料水汚染へのばく露を特性評価するために、大気モニタリングデータと地 域の水道のデータをそれぞれ利用している。環境モニタリングデータは、地理的境界によって定 義されるばく露量を推定するのに有用であるが、個人レベルのばく露量を調査する目的では、特 に個人が多くの異なる場所で生活し、仕事をし、時間を過ごす場合には、信頼性が低くなる可能 性がある。

個人モニタリングは、体の境界の接触点でのばく露を特性評価するために使用される。個人モ ニタリングの例としては、農薬との経皮接触を評価するための線量計の使用、吸入ばく露を評価 するための個人用空気サンプリング装置、食品中の農薬レベルを調査するための対の食品サンプ ルの収集などがある。個人モニタリングの利点は、間接的な方法よりも個人レベルのばく露量を より正確に推定できる可能性が高いことである。また、個人モニタリングは、異なる経路でのば く露の関連性の優先順位付けに有用なばく露レベルの定量化を可能にする。さらに、個人モニタ リングは、時間をかけて測定を繰り返すことで、縦断的なばく露量を評価するためにも使用され る。個人的なモニタリングは間接的なアプローチに比べて多くの利点があるが、労力と資源が必 要とする傾向がある(Niewenhuijsen、2003年)。その結果、個人モニタリングを用いてばく 露を評価する大規模な疫学研究を実施することは一般的には不可能である。さらに、個人的なモ ニタリングは、サンプルを取得するために使用される測定技術や解析ツールに大きく依存してお り、関連する期間(通常は過去)のばく露を特性評価する情報が利用可能になる可能性は低い。 さらに、対象となる期間のばく露の全容が捕捉される可能性は低く、ピークと変動を捕捉するの に十分な期間でのサンプリングがではないかもしれない。そのため、疫学研究で使用される個人 モニタリング手法の科学的厳密さと信頼性を考慮することが非常に重要であり、そのようなモニ タリングは他のモニタリング(例えば、環境データ、牛物学的データ及び/またはインタビュー /アンケートのデータ)で補完する必要があるかもしれない。

**バイオモニタリング**は、血液、尿、唾液、乳、脂肪、その他の生体組織などの生物学的試料中 の化学物質、その代謝物、または反応生成物を測定することであり、ばく露の特性を明らかにす るために使用される(Needham 6、2007年)。Zartarian 6 (2005年)は、「バイオマーカー /生物学的マーカーは、「生物学的システムにおける変化や事象の指標」として定義されてきた」 と述べている。「ばく露の生物学的マーカーとは、組織、細胞、体液などの生物学的媒体から得 られる細胞や生化学的、分析的、または分子的な測定値を指し、ある物質へのばく露指標である」 と述べている。したがって、バイオマーカーは、ばく露を評価に用いられ、また健康影響の指標 として使用される(LaKind 6、2014年)。表4は、疫学研究から収集されたバイオモニタリン グデータの質と関連性を評価するための科学的考察を示している。 collected from epidemiology studies. Assessing exposure using biomonitoring has expanded rapidly as analytical tools have become more cost-effective and more biomarkers are identified. Compared with self-reported questionnaire or interview data, biomonitoring may reduce exposure misclassification and enhance the precision of the risk estimates. Similarly, biomonitoring integrates exposures from different routes and can be used to determine the amount of exposure that is absorbed into the body (Checkoway et al., 2004). Furthermore, knowledge as to the role of the biomarker in the natural history of disease is known in certain instances, such that biomarkers may help resolve temporality of exposure issues.

While biomonitoring has many advantages over others exposure assessment methods, it also has its own limitations. In many studies, biological sample are only taken from a single point in time and may not reflect accurately reflect longitudinal patterns, particularly if exposures are highly variable. Furthermore, evaluation of biomarkers also requires an understanding of degradation and metabolism of chemicals in both the environment and human body. As such, biomarkers of exposure may differ between individuals for reasons other than exposure level. Differences in metabolism, comorbidities such as kidney disease in relation to urinary measurements, uncertainty as to whether the biomarker measures exposure to the active ingredient or the environmental degradates may all account for apparent differences in biomarkers of exposure among individuals, and possibly between comparison groups. 解析ツールがより費用対効果の高いものになり、より多くのバイオマーカーが同定されるよう になったため、バイオモニタリングを用いたばく露評価は急速に拡大してきた。自己申告のアン ケートやインタビューデータと比較して、バイオモニタリングはばく露の誤分類を減らし、リス ク推定の精度を高めることができるかもしれない。同様に、バイオモニタリングは、異なる経路 からのばく露を統合し、体内に吸収されるばく露量を調査するために使用されている (Checkoway 6、2004 年)。さらに、疾病の履歴におけるバイオマーカーの役割が知られるよ うになってきている場合もあり、バイオマーカーはばく露の時間的な問題を解決するのに役立つ かもしれない。

バイオモニタリングは他のばく露評価方法に比べて多くの利点があるが、それ自体にも限界が ある。多くの研究では、生物学的サンプルはある時点での一点からしか採取されず、特にばく露 が大きく変動する場合には、経時的なパターンを正確に反映していない可能性がある。さらに、 バイオマーカーの評価には、環境ととトの両方での化学物質の分解と代謝についての理解も必要 である。そのため、ばく露のバイオマーカーはばく露以外の理由で個人間で異なる場合がある。 代謝の違い、尿の測定値に関連した腎臓病などの併発疾患やバイオマーカーが有効成分のばく露 を測定しているのか、環境中分解物のばく露を測定しているのかといった不確実性が、個人間や 想定される比較集団間におけるばく露のバイオマーカーの見かけ上の違いの原因となっているか もしれない。 Table 4. Considerations of biomonitoring data from environmental epidemiology research (Adapted from LaKind et al. (2014).

Biomarker Consideration	Tier 1	Tier 2	Tier 3
Exposure biomarker with external exposure, internal dose, or target dose.		Biomarker has an unknown quantitative relationship with external exposure, internal dose, or target dose or is poor surrogate (low accuracy and precision) for exposure/dose.	NA
Effect biomarker	Bioindicator of a key event in a MOA/AOP.	Biomarkers of effect for which the relationship to health outcome is understood	Biomarker has undetermined consequences (e.g., biomarker is not specific to a health outcome).
Specificity	Biomarker is derived from exposure to one parent chemical.	Biomarker is derived from multiple parent chemicals with similar toxicities.	Biomarker is derived from multiple parent chemicals with varying types of adverse endpoints.
Limits of detection are low enough to detect chemicals in a sufficient percentage of the samples to address the research ouestion.		Frequency of detection too low to address the research hypothesis.	NA
Biomarker stability	Samples with a known history and documented stability data.	Samples have known losses during storage but the difference between low and high exposures can be qualitatively assessed.	Samples with either unknown history and/or no stability data for analytes of interest.
Sample contamination	Samples are contamination-free from time of collection to time of measurement (e.g., by use of	Study not using/documenting these procedures.	There are known contamination issues and no documentation that the issues were addressed

Page 29

Indirect exposure assessment methods are common in retrospective studies and based on factors that are surrogates of chemical exposure. As described above, indirect exposure data cannot generally be used to estimate quantitative exposure levels without additional modeling. For example, a questionnaire can be used to determine if an individual has ever used a pesticide, but can less reliably collect data on all the environmental and behavioral factors that are needed to calculate that individual's exposure. As such, indirect exposure data are often used to classify exposure using a dichotomous exposure variable (i.e. exposed/unexposed) or ordinal exposure scale. In contrast, direct exposure assessment methods are based on data on actual individual-level exposure through personal monitoring and biomonitoring. Thus, direct methods can be used to estimate individual exposure or internal dose levels. Direct methods are more common in prospective studies, but are also used in retrospective studies when existing biological samples are available from well-defined population groups.

<u>Quantified personal measurements</u>, such as personal monitoring and biomonitoring, are generally considered the best source of data for estimating actual exposure levels (NRC, 1991; NRC, 1997). While this is the case, accurate qualitative measures of exposure (e.g. dichotomous and ordinal exposure metrics) from indirect methods can be just as accurate for the purpose of epidemiology. Moreover, indirect methods are often easier to interpret and may require less additional research and development to demonstrate their utility in exposure assessment.

Regardless of the approach, exposure assessment methods should be able to provide exposure estimates that are reliable and valid. In the context of epidemiology, *reliability* general refers to the ability to reproduce results and *validity* generally refers to the extent that exposure estimates reflect true exposure levels (Checkoway et al., 2004). When evaluating a particular exposure assessment's reliability and validity, it is important to consider the exposure assessment's strengths and weaknesses in the context of the study's research objectives. Less refined exposure assessment may be suitable for exploratory studies. This is because exploratory studies help raise awareness about potential hazards that can encourage investment in more focused research. Conversely, studies with more focused hypotheses can be greatly strengthened through the use of more refined exposure assessment methods. Therefore, indirect and direct exposure assessment stages of research when exploring exposure-disease relationships.

#### 2. Confounding Factors

Confounding occurs when the relationship between the exposure and disease is to some extent attributable to the effect of a second (confounding) risk factor. This can happen when this second (i.e., confounding) risk factor is an independent, causally-associated risk factor for the disease but is also associated -- causally or non-causally -- with the exposure under analysis and does not also serve as an intermediate variable in the causal pathway between the exposure and the outcome of interest. If not properly measured and accounted

**間接的はく露評価**方法は、後ろ向き研究では一般的であり、化学物質のばく露のサロゲート (代理)となる因子に基づいている。上述したように、間接的なばく露データは、追加のモデル 化を行わない限り、一般的には定量的なばく露レベルを推定するためには使用できない。例えば、 ある個人が農薬を使用したことがあるかどうかを調査するためにアンケートを使用することはで きるが、その個人のばく露量を計算するために必要なすべての環境的・行動的な要因に関するデ ータを確実に集めることは困難である。そのため、間接的ばく露データは、二分法のばく露変数 (すなわち、ばく露/非ばく露)または順序ばく露尺度を用いてばく露を効するために使用さ れることが多い。一方、直接的ばく露評価方法は、個人のモニタリングやバイオモニタリングに よる実際の個人レベルのばく露に関するデータに基づいている。したがって、直接法は前向き研究 で用いられることが多いが、十分に定義された母集団から既存の生物学的サンプルが入手可能な 場合には、後ろ向き研究でも使用される。

定量化された個人評価には、個人モニタリングやバイオモニタリングがあり、一般的に実際の ばく露レベルを推定するための最良のデータソースと考えられている(NRC、1991年;NRC、 1997年)。その一方で、間接的な方法による正確なばく露の質的測定(例えば、二分式や順序 式のばく露測定)も、疫学の目的では同じように正確であると考えられる。さらに、間接法は解 釈が容易であることが多く、ばく露評価における有用性を示すための追加の研究開発が少なくて 済む可能性がある。

どのようなアプローチであっても、ばく露評価方法は信頼性と妥当性のあるばく露推定値を提 供できなければならない。疫学の文脈では、一般的に*信頼性とは*結果を再現する能力を意味し、 *妥当性とは、一*般的にばく露推定値が真のばく露レベルを反映しているかどうかを意味している (Checkoway 6、2004 年)。特定のばく露評価の信頼性と妥当性を評価する際には、研究目的 の文脈でばく露評価の長所と短所を考慮することが重要である。あまり洗練されていないばく露 評価は、探索的研究に適しているかもしれない。これは、探索的研究は潜在的なハザードについ ての認識を高めるのに役立つため、より焦点を絞った研究への専心を促すことができるからであ る。逆に、より焦点を絞った仮説を持つ研究は、より洗練されたばく露評価法は相完的なツールであり、 ばく露と疾病の関係を調査する際に研究の様々な段階で使用することができる。

#### **2. 交絡因**子

交絡因子は、ばく露と疾病との関係がある程度で第二のリスク因子(交絡因子)の影響に起因 している場合に発生する。これは、この第二のリスク因子(すなわち、交絡因子)が、疾病の独 立した因果関係のあるリスク因子でありながら、解析対象のばく露と因果関係(因果関係または 非因果関係)があり、ばく露と関係のある疾病との間の因果経路の中間変数としての役割を果た していない場合に起こりうる。交絡因子は、適切に測定され、考慮されなければ、ばく露と健康 影響との間の推定された関連性の大きさ(そして場合によっては方向性)を変化させる可能があ る。

for, confounders have the ability to change the magnitude (and potentially the direction) of the estimated association between an exposure and health outcome. This can result in an over- or under-estimation of the relationship between exposure and disease because the effects of the two risk factors have not been appropriately separated, or "disentangled". As an example: a given pesticide may be associated with lung cancer in a given study, but this may be due to a confounding effect of farm tractor diesel fumes; here, this second factor farm tractor diesel fumes - would be a confounder if it was causally associated with the disease outcome (here, lung cancer) but also associated with pesticide exposure. Confounding factors may include less intuitive lifestyle exposures such as cigarette smoking, dietary factors (e.g., high energy/calorie laden diet), and physical activity (e.g., lack of physical activity) genetics, comorbidity, medication use, alcohol consumption, etc., all of which may adversely affect health and may be statistically associated with pesticide use. In epidemiological analyses, confounding factors are measured in the study sample and typically "adjusted for" in the final risk estimate in either the design phase of the study or the analysis phase. With respect to the former, the epidemiological researcher can "restrict" the study population to individuals that share a characteristic which the researcher wishes to control; this has the result of removing the potential effect of confounding caused by that (now controlled) characteristic. A second available method also applicable to the design phase of the study -- is for the researcher to control confounding by "matching" individuals based on the confounding variable. This ensures that the confounding variable is evenly distributed between the two comparison groups and effectively controls for this. It is important to note that the relationship between the confounder and the exposure or outcome does not need to be found to be statistically significant in order for it to have an impact on the risk estimate for the main effect<sup>15</sup>.

At the analysis stage, one method by which confounding can be controlled is by stratification. Under this means of control, the association is measured separately under each of the (potentially) confounding variables; the separate estimates are "brought together" statistically -- if determined to be appropriate -- to produce a common odds ratio or other effect size measure by using Mantel-Haenszel approaches which weight the estimates measured in each stratum. Stratification can be difficult if there are multiple potential confounders that need to be controlled simultaneously. In such cases, confounding is typically dealt with by means of statistical modelling. (e.g., logistic regression).

It is important that careful consideration be given to confounders prior to any epidemiological studies being initiated in the field and it is important that any study adequately describe how this was done: epidemiological studies are frequently critiqued for ignoring or paying insufficient attention to potential confounders. For this reason, a sensitivity analysis can be helpful to demonstrate the potential effects that a missing or unaccounted for confounder may have on the observed effect sizes (see Gustafson and

これは、2 つのリスク因子の影響が適切に分離、あるいは「区別」されていないため、ばく露と 疾病の関係が過大または過小に評価される結果となりうる。例えば、ある研究では、ある農薬が 肺がんと関連しているかもしれないが、これは農場のトラクターのディーゼル排気ガスの交絡効 果によるものかもしれない。このように疾病発生(ここでは肺がん)との因果関係が農薬ばく露 とも関連する場合、第二の因子の「農場のトラクターのディーゼル排気ガス」は交絡因子である。 交絡因子には、喫煙、食事因子(例えば、高エネルギー/高カロリーの食事)、身体活動(例え ば、身体活動の欠如)、遺伝子、併存症、薬物使用、アルコール摂取などのあまり直感的でない ライフスタイルでのばく露が含まれることがあり、これらはすべて健康に悪影響を及ぼし、農薬 使用と統計的に関連している可能性がある。疫学的解析では、交絡因子は研究サンプルで測定さ れ、通常、研究のデザイン段階または解析段階のいずれかで最終的なリスク推定値に「調整」さ れる。前者に関しては、疫学研究者は、研究者がコントロールしたい特性を共有する個人に研究 集団を「限定」することができる。これにより、その特性(現在はコントロールされている)に 起因する交絡の潜在的な影響を取り除くことがでる。2 番目に利用可能な方法は、研究のデザイ ン段階にも適用可能な方法で、研究者が交絡変数に基づいて個人を「マッチング」することで交 絡をコントロールすることである。これにより、交絡変数が2つの比較群の間で均等に分布し、 交絡変数を効果的にコントロールすることができる。主効果のリスク推定値に影響を与えるため には、交絡因子とばく露または疾病との関係が統計的に有意である必要はないことに注目するこ とが重要である15。

解析の段階で、交絡因子をコントロールできる方法の1つは、層化がある。この方法では、交 絡変数(の可能性がある)ごとに関連性を測定し、適切であると判断された場合には、個別の推 定値を統計的に「まとめる」ことで、各層で評価された推定値に重みをつける Mantel-Haenszel アプローチを使用して共通のオッズ比または他の効果を算出する。層化は同時にコントロールす る必要のある潜在的な交絡因子が複数存在する場合には困難である。このような場合、交絡因子 は通常、統計的モデル化によって対処される。(例:ロジスティック回帰)。

疫学研究が現場で開始される前に交絡因子を慎重に考慮することが重要であり、どのような研 究でも交絡因子をどのようにして考慮したかを適切に記述することが重要である。疫学研究は、 潜在的交絡因子を無視したり、あるいは十分な注意を払っていないと批評されることか多い。こ のため、感度分析は、欠落している交絡因子や考慮されていない交絡因子が観察された効果量に 与える潜在的な影響を示すのに役立つ(Gustafson and McCandless, 2010 年を参照)。

<sup>&</sup>lt;sup>15</sup> This is why it is generally considered inappropriate to "statistically test" for a confounder to determine whether the confounder needs to be adjusted for. Instead, some consider a change in the effect size of 10% or more after adjustment for (inclusion of) a potential confounder to be sufficient evidence for the confounder to be incorporated into the analysis.

<sup>&</sup>lt;sup>15</sup>これが、一般的に、交絡因子を調整する必要があるかどうかを判断するために交絡因子を「統計的に検定」することが不適切であると考えられている理由である。その代わりに、潜在的な交絡因子を調整した(交絡因子を含む)後の効果量の変化が10%以上であれば、交絡因子を分析に組み込むのに十分なエビデンスであると考える人もいる。

McCandless, 2010). If unmeasured confounders are thought to affect the results, researchers should conduct sensitivity analyses to estimate the range of impacts and the resulting range of adjusted effect measures. Such sensitivity analyses -- generally not uniformly conducted in most published epidemiological studies – can be used when available to estimate the impact of biases and potential confounding by known but unmeasured risk factors.

Depending upon the specific exposure-disease association under study, a factor may or may not be a confounding factor that is necessary to control: in order for a substantial distortion in the effect size estimate to occur due to confounding, the confounder must be not only a relatively strong risk factor for the disease of interest<sup>16</sup>, but also be strongly associated with the exposure of interest. Assessment of potential confounding is made on a study specific basis and - if unmeasured confounders are thought to affect the results -researchers should conduct a sensitivity analysis to estimate the range of impacts and resulting range of adjusted effect measures. When evaluating the guality of observational epidemiology studies, OPP will consider whether relevant confounding factors are properly identified, described, measured and analyzed such that an unbiased estimate of the specific association under study can be made, and, when possible, may consider sensitivity analysis as a potential tool to assist in determining the degree to which such confounding might potentially affect the estimate of the effect size. It should be emphasized that a confounder must be a relatively strong risk factor for the disease to be strongly associated with the exposure of interest to create a substantial distortion in the risk estimate. In such cases, it is not sufficient to simply raise the possibility of confounding: one should make a persuasive argument explaining why a risk factor is likely to be a confounder, what its impact might be, and how important that impact might be to the interpretation of findings. (p. 23-25, FIFRA SAP Report, 22 April 2010)

Finally, it is important to distinguish between confounding, effect modification, synergy, and other mediating effects of covariates. Confounding is a bias that results from not controlling for a variable that is associated causally with the disease and associated – causally or non-causally -- with the exposure of interest. Epidemiologic researchers seek to minimize this bias. Effect modifiers -- on the other hand -- are variables that differentially affect the magnitude of the effect size, by strata (e.g., age, race/ethnicity, SES status, genetic polymorphisms). Effect modifiers may or may not also be confounders. Typically, they are modelled by either introducing interaction terms in multivariable models or by evaluating effect sizes by strata after stratifying the data by levels of the effect modifier. A study frequently needs to be specifically designed to evaluate effect modifiers in order to have a sufficient sample size in each population strata of interest. Epidemiologic researchers seek to understand effect modifiers (not minimize them, as they do with confounders) because they can be important in evaluating risk differences across population strata, in evaluating the association between exposure and the effect of interest, and in identifying susceptible

測定されていない交絡因子が結果に悪影響を及ぼすと考えられる場合、研究者は感度分析を実施 して、影響の範囲とその結果として得られる調整後の効果測定値の範囲を推定すべきである。こ のような感度分析は、一般的にほとんどの公表されている疫学研究では一様には行われていない が、既知ではあるが評価されていないリスク因子によるバイアスや潜在的な交絡因子の影響を推 定するために、利用可能な場合には使用することができる。

特定のばく露・疾病関連付けに応じて、ある因子はコントロールするために必要な交絡因子で ある場合とそうでない場合がある。交絡因子によって推定された効果量に大きな歪みが生じるた めには、交絡因子は、関係ある疾病が比較的強いリスク因子でなければならない<sup>16</sup>し、関係ある ばく露とも強固に関連付けられていなければならない。潜在的な交絡因子の評価は研究ごとに行 われ、測定されていない交絡因子が結果に悪影響を与えると考えられる場合には、研究者は感度 分析を行い、影響の範囲とその結果として得られる調整された効果評価の範囲を推定すべきであ る。観察疫学研究の質を評価する際、OPP は、関連する交絡因子が適切に同定、記述、評価、 解析されているかどうかを検討し、研究対象となっている特定の関連性を偏りのない推定が可能 であるかどうかを検討する。可能な場合は、交絡因子が推定された効果量の推定値に影響を及ぼ す範囲の判断を助けるツールとして感度分析を考慮する。交絡因子は、疾患の比較的強いリスク 因子でなければならず、リスク推定値に大きな歪みをもたらすためには、対象となるばく露と強 の可能性を提起するだけでは十分ではなく、なぜリスク因子が交絡因子となりうるのか、その影響が結果の解釈にとってどの程度重要なものなのかに ついて、説得力のある議論が必要である。(p.23・25、FIFRA SAP レポート、2010年4月22日)

最後に、共変量の交絡、効果修正、相乗効果、その他の媒介効果を区別することが重要である。 交絡因子とは、疾病と因果関係のある変数及び対象となるばく露と因果関係があるか、否かにか かわらず、関連する変数をコントロールしないことによって生じるバイアスである。疫学研究者 はこのバイアスを最小化しようと努める。一方、効果修飾因子とは、層化(例えば、年齢、人種 /民族、SESの状態、遺伝的多型)によって、効果量に異なる影響を与える変数である。効果修 飾因子は、交絡因子である場合もあればそうでない場合もある。一般的に、効果修飾因子は多変 量モデルに交互作用項を導入するか、効果修飾因子のレベルによってデータを層化した後、層化 に効果量を評価することによってモデル化される。対象となる各集団層において十分なサンプル サイズを確保するためには、効果修飾因子を評価するための特別な研究デザインが必要となるこ とが多い。疫学研究者は、母集団の層化にわたるリスクの違いの評価、ばく露と関係のある効果 の関連付けの評価、影響を受けやすい亜集団の特定が重要であることから、効果修飾因子を理解 することを目指す(交絡因子のように最小化するのではなく、効果修飾因子の理解に努めてい る)。

<sup>&</sup>lt;sup>16</sup> Consideration needs to be given not only to ensuring that the confounding factor is indeed a risk factor on its own but also to ensuring not only related to the exposure of interest. Adjusting for a factor that has an association with the disease of interest wholly or partly because of its association with the exposure of interest will lead to attenuation of the exposure-disease relationship if it truly exists.

<sup>16</sup> 交絡因子がそれ自体が本当にリスク因子であることを確認するだけでなく、関係のあるばく露との関連性だけではないことを確認することも考慮する必要がある。関係のある疾病との関連性を持つ因子の全部または一部を、関係のあるばく露との関連性のために調整することは、ばく露と疾病の関係が本当に存在する場合には、ばく露と疾病の関係を減衰させることにつながる。

subpopulations. Effect modifiers may or may not also be confounders. For example, smoking may be a confounder in a study associating lung cancer with a pesticide often used on tobacco, but it may also be an effect modifier if the risk of exposure to this pesticide is higher among smokers than non-smokers. Synergy is often introduced as a biological or pharmacological/toxicological concept rather than an epidemiological one and relates to the ability of two chemicals, together and acting jointly, to magnify or exaggerate the effect beyond that which would be seen considering the (mathematical) sum of each chemical's effects alone. In epidemiological and statistical terms, this is often expressed as effect modification or interaction.

#### 3. Statistical Analysis

Epidemiologic studies are designed to measure an association between a specific exposure and a disease. When evaluating the quality of pesticide epidemiology studies, OPP will also consider the statistical methods used. Specifically, OPP will consider the extent to which the analytic methods described in the study are appropriate to the research question; the completeness of the description of the statistical methods utilized; the appropriateness of the methods for identification, assessment and adjustment of potentially confounding variables in the exposure-disease relation; and, the description, extent of, and presentation of any sub-group analyses which may have been performed (including whether statistical corrections for multiple comparisons have been made).

Epidemiologic investigations typically utilize statistical modeling to estimate risk (e.g. generalized linear models such as logistic (for odds ratios) or Poisson (for count data) regression. To do so, researchers must consider not only the relevant main exposure and outcome variables, but also consider relevant confounding factors, and whether the association under investigation may differ by level of these factors, i.e., effect modification or interaction (Szklo et al., 2004). Upon identification of a potentially confounding variable -- one that substantively changes the magnitude and/or direction of the association under study -- adjustment through regression modeling can help to isolate the risk estimate of interest, i.e., the association under study. In addition, OPP will evaluate the stratification of statistical interaction. If the magnitude and direction of the association of interest differs greatly by level of a third variable, then the stratified results should be considered primary.

When performing statistical modeling when the outcome is rare or the sample size is relatively small, it is important to be cautious about including too many covariates in the model. Any resulting effect size estimate may be too high or too low and is unlikely to reflect the true estimate of effect. Such issues due to rare events or low sample sizes are also possible when conditional methods are used (e.g., conditional logistic regression when the design includes matching of the comparison group under study): if too few discordant pairs (or discordant sets) are observed, the estimated effect size may also be unreliable. Thus: while controlling for confounders and other covariates is important, the assessor must take care not to over-control or end up with too few degrees of freedom to produce a

効果修飾因子は交絡因子である場合もあればそうでない場合もある。例えば、タバコによく使用 される殺虫剤と肺がんを関連付ける研究では、喫煙は交絡因子になるかもしれないが、この殺虫 剤へのばく露のリスクが非喫煙者よりも喫煙者の方が高い場合には、効果修飾因子になるかもし れない。相乗効果は、疫学的な概念ではなく、生物学的または薬理学的/毒物学的な概念として 紹介されることが多く、2 つの化学物質が一緒になって共同で作用することで、各化学物質の効 果の(数学的な)合計を考慮した場合の効果を超えて、効果を拡大したり、増強したりする能力 に関係している。疫学や統計学の用語では、これは効果の修飾や相互作用として表現されること が多い。

#### 3. 統計解析

疫学研究は、特定のばく露と疾病との関連付けを評価することを目的としている。農薬疫学研 究の質を評価する際、OPP は使用された統計的手法も考慮する。具体的には、研究に記載され ている分析方法が研究課題に適切であるかどうか、使用された統計的方法の記述の完全性、ばく 露と疾病の関係における潜在的な交絡変数の特定、評価、調整のための方法の適切性、実施され た可能性のある小集団解析の説明、範囲、提示(多重比較のための統計的補正が行われているか どうかを含む)が考慮される。

疫学研究では通常、リスクを推定するために統計的モデル(例えば、ロジスティック回帰(オ ッズ比)やポアソン回帰(カウントデータ)のような一般化された線形モデル)を利用する。そ のためには、研究者は関連する主要なばく露変数と転帰変数だけでなく、関連する交絡因子を考 慮しなければならず、また、研究における関連付けがこれらの因子、すなわち、効果の修飾や相 互作用のレベルによって異なるかどうかを考慮しなければならない(Szklo 6、2004年)。交絡 の可能性のある変数(調査対象となる関連性の大きさや方向性を実質的に変化させる変数)が同 定された場合、回帰モデルによる調整を行うことで、目的のリスク推定値、すなわち調査対象と なる関連性を分離することができる。さらに、OPP は、研究における潜在的な効果修飾因子の レベルまたは統計的相互作用の評価による関連付けの層化を評価する。関係のある関連付けの規 模と方向性が第三の変数のレベルによって大きく異なる場合、層化された結果は一次的なものと みなされるべきである。

発現事象がまれな場合やサンプル規模が比較的小さい場合に統計的モデリングを行う場合、モ デルにおける共変量が多すぎないように注意することが重要である。結果として得られる効果量 の推定が高すぎたり、低すぎたりすることがあり、効果の真の推定を反映しているとは考えにく い。稀な事象やサンプル規模が小さいことによるこのような問題は、条件付き手法(例えば、デ ザインに研究における比較群の組み合わせを含む場合の条件付きロジスティック回帰)を使用す る場合にも起こり得る。すなわち不一致ペア(または不一致セット)の観察数が少なすぎると、 推定された効果量もまた信頼性が低くなる可能性がある。このように、交絡因子及びその他の共 変量をコントロールすることは重要であるが、信頼性の高い検定を行うために過度にコントロー ルしたり、自由度が少なくしすぎたりしないように評価者は注意しなければならない。 reliable test. In these cases, it may be more important to seek parsimonious models that adjust for only a smaller number of the most influential confounders and other covariates so that the effective sample size remains adequate.

Finally, it is important in any statistical modeling exercise to consider statistical significance in the context of clinical/biological/scientific significance of the result. It may be that some results are statistically significant but unimportant in a clinical/biological/ scientific context. The reverse can be true: it may be that results are not statistically significant but may be important in a clinical/biological/scientific context. The former may suggest a sample size that is larger than necessary while the latter may suggest one than is smaller than needed. The latter case may be important from a public health perspective and warrant further exploration, especially when the association is strong (despite it being imprecise)

#### 4. Potential Bias in Observational Research

Bias is a systematic error in the design or conduct of a study that gives rise to study results that are systematically different from the (unobserved) true situation. This contrasts with random errors which relate to sampling variability and precision (or, equivalently, confidence bounds) around the effect size measure, but which do not "drive" or "push" the result in one particular direction (e.g., either toward or away from the null).

Bias is a reflection of methodological imperfections in the design or conduct of the study and should be addressed or discussed by researchers as part of their analysis. There are a number of ways that bias can be introduced into a study: studies may be biased in the way in which participants are selected into the study (selection bias), or the way in which information about exposure and disease status is collected (information bias, including recall bias discussed earlier for case-control studies). One example of a common occupational selection bias is the "healthy worker effect" which can create an important bias in occupational epidemiology studies, leading to bias toward the null, and even below (creating the interpretation that the exposure is "protective") No study is totally devoid of bias and one should consider the extent to which authors of published studies described potential bias in the study, and how (if at all) they attempted to address it and characterize it in the study. Bias can result from differential or non-differential misclassification (Greenland, 1998). Differential misclassification (bias) means that misclassification has occurred in a way that depends on the values of other variables, while non-differential misclassification (bias) refers to misclassifications that do not depend on the value of other variables. Misclassification biases - either differential or non-differential - depend on the sensitivity and specificity of the study's methods used to categorize such exposures and can have a predictable effect on the direction of bias under certain (limited) conditions: this ability to characterize the direction of the bias based on knowledge of the study methods and analyses can be useful to the regulatory decision-maker since it may allow the decision maker to determine the extent to which, if any, the epidemiological effect sizes being considered (e.g., OR, RR) are likely underestimates or overestimates of the true effect

このような場合には、有効なサンプルサイズを十分に確保するため、最も影響力のある交絡因子 や他の共変量をより少ない数だけ調整して、より解析的なモデルを求めることがより重要である。

最後に、どのような統計モデリング演習においても、結果の臨床的/生物学的/科学的な意義 の文脈で統計的有意性を考慮することが重要である。統計的には有意だが、臨床/生物学的/科 学的な文脈では重要ではないということもある。逆に、統計的には有意ではないが、臨床的/生 物学的/科学的な文脈では重要な結果である場合もある。前者の場合はサンプルサイズが必要以 上に大きいことを示唆し、後者の場合は必要以上に小さなサンプル規模を示唆しているかもしれ ない。後者の場合は、公衆衛生の観点から重要であり、(不正確であるにもかかわらず)特に関 連付けが強固である場合には、さらなる調査が必要である。

#### 4. 観察研究における潜在的なバイアス

バイアスとは、(観察されていない)真の状況とは系統的に異なる研究結果をもたらす研究の デザインまたは実施における系統的な誤差のことである。これは、効果量の評価におけるサンプ リングの変動や精度(または同義で信頼限界)に関係するランダム誤差とは対照的であるが、結 果をある特定の方向(例えば、帰無仮説に向かって、または帰無仮説から離れて)に「追い込む (drive)」または「押し込む (push)」ようなことはない。

バイアスとは、研究のデザインや実施における方法論的な不完全性の反映であり、研究者は解 析の一部として、それに対処したり、議論したりすべきである。研究にバイアスが導入される方 法はいくつかある。研究は、参加者を研究に選択する方法(選択バイアス)や、ばく露や疾病に 関する情報を収集する方法(情報バイアス、先に説明した症例対照研究の想起バイアスを含む) にバイアスがかかっている可能性がある。一般的な職業選択バイアスの例としては、「健康な労 働者効果」があり、職域疫学研究において重要なバイアスを生じさせ、帰無値に向かってバイア スを生じさせ、さらにはそれ以下のバイアス(ばく露が「保護的」であるという解釈を生じさせ る)につながる。バイアスの全くない研究はなく、公表した研究の著者は研究における潜在的バ イアスどの程度説明したか、研究におけるバイアスを(もしあれば)どのように対処し、研究の 特徴を明らかにしたかを検討すべきである。バイアスは、差異的(differential)または非差異 的 (non-differential) な誤分類から生じる可能性がある (Greenland、1998 年)。差異的誤 分類(バイアス)とは、他の変数の値に依存する方法で誤分類が発生したことを意味し、非差異 的誤分類(バイアス)とは、他の変数の値に依存しない誤分類を意味する。誤分類バイアス(差 異的または非差異的のいずれか)は、そのようなばく露を分類するために使用される試験方法の 感度と特異度に依存し、特定の(限定された)条件の下でバイアスの方向性を予測可能な影響を 及ぼすことがある。研究の方法と解析の知識に基づいてバイアスの方向を特定できるということ は、規制当局の意思決定者にとって有用である。なぜなら、意思決定者は、検討されている疫学 的効果の大きさ(例:OR、RR)が、真の効果の大きさの過小評価または過大評価である可能性 がどの程度あるかを判断することができるからである17。

size<sup>17</sup>. It is not atypical to find degrees of misclassification in the range of 10 to 20 percent and it can be helpful in reviewing epidemiological studies to consider a form of sensitivity (or "what if") analysis which evaluates such a degree of misclassification -- and whether it is differential or non-differential – and the degree to which such misclassification might impact the odds ratio or relative risk with respect to both magnitude and direction<sup>18</sup>. (p.25, FIFRA EPA SAP report, 22 April, 2010). As mentioned earlier with respect to confounding, such quantitative sensitivity analysis is only rarely performed or practiced in published epidemiology studies, with bias instead more typically evaluated in a narrative manner without any quantitative assessment of its potential magnitude and the effect it may have on the epidemiological effect size estimates (Jurek at al., 2006). This may be due – in part -- to a general lack of availability of computational tools for such analysis by epidemiologists or their unfamiliarity with them. Such tools are becoming increasingly available and may be valuable in developing more rigorous quantitative methods for evaluation of potential biases.

#### 5. Interpretation of Null studies

"Null" studies -- or well-conducted studies which report no association between exposure to the pesticide and an adverse health outcome -- will be evaluated carefully for their potential usefulness in human health risk assessment. The study may report a null result either because the investigated association indeed does not in reality exist, or because the study was conducted failed to detect an association at a given predetermined level of significance. This latter result -the failure to detect an association -- should not necessarily be interpreted to mean that no association exists, but rather as simply one was not found in the particular study<sup>19,20</sup>. To evaluate which of these two conditions may be correct when reviewing "null" studies, one should consider other research reported concerning the same or similar research question, the manner in which exposure and outcome were assessed, the extent to which exposure misclassification may have biased the study to the null, the statistical methods used including the identification and analysis of confounding variables in the association, the extent to which the exposure is below a threshold at which an effect would occur or be detected, as well as the power of the study and its ability to detect an effect size of substantive interest. Statistical power refers to the probability that researchers may correctly identify that there is a difference between the two comparison groups, i.e., there is an association between exposure and disease, when in 誤分類の程度が 10~20%の範囲にあることは異例ではなく、このような誤分類の程度(それが 差異的か非差異的か)と、そのような誤分類の大きさと方向性の両方に関してオッズ比または相 対リスクに影響を与える可能性の程度を評価する感度(または「もしも」)解析の形態を検討す ることは、疫学研究をレビューする際に有用であると考えられる<sup>17</sup>。(p.25、FIFRA EPA SAP 報告書、2010年4月22日)。交絡因子に関して前述したように、このような定量的感度分析は、 公表されている疫学研究ではほとんど実施されておらず、パイアスの潜在的な規模や疫学的効果 量推定への影響の定量的な評価は行われずに、むしろ一般的には解説文で評価されている (Jurek at al., 2006)。これは次のような理由によるものである。その理由の一部は、疫学者が このような解析のための計算ツールを一般的に利用できないことや、そのようなツールに慣れて いないことにある。このようなツールは次第に利用可能になりつつあり、潜在的なパイアスを評 価するためのより厳密な定量的手法を開発する上で有用であると考えられる。

#### 5. 帰無研究の解釈

「帰無」研究、すなわち、農薬へのばく露と有害な健康影響との間に関連付けがないと報告す るよく行われている研究は、ヒト健康リスク評価に有用な可能性があるかどうか慎重に評価され る。研究が無効という結果になるのは、調査された関連付けが実際には存在しないか、あるいは、 実施された研究が所定の有意水準で関連付けを検出することができなかったためである。後者の 結果(関連性を検出できなかった)は、必ずしも関連付けが存在しないことを意味するものでは なく、特定の研究で関連付けが検出されなかったと解釈すべきである<sup>18,19</sup>。「帰無」研究をレビ ューする際に、これら 2 つの条件のどちらが正しいかを評価するためには、同一または類似の研 究課題について報告された他の研究、ばく露と発現事象の評価方法、ばく露の誤分類が研究を帰 無に偏らせた可能性の程度、関連付けの交絡変数の同定と分析を含む使用された統計的方法、影 響が発生する、あるいは影響が検出される閾値を下回っているばく露の程度、研究の検出力と実 質的な関係のある効果量を検出する能力を考慮する必要がある。統計的検出力とは、実際に真の 違い(または関連付け)がある場合、研究者が 2 つの比較群間に差があること、すなわち、ばく 露と疾病の間に関連付けがあることを正しく識別できる確率を意味する。

<sup>&</sup>lt;sup>17</sup> The direction of bias that results from the degree of non-differential misclassification will also depend on the categorization of exposure (either dichotomous or polytomous).

<sup>&</sup>lt;sup>18</sup> Such sensitivity analyses might be especially recommended for exposure misclassification biases which in many cases are expected to result in more substantive effects on the effect size estimate than those from confounding.

<sup>&</sup>lt;sup>19</sup> The old adage that "the absence of evidence does should not be interpreted as the evidence of absence" is true here.

<sup>&</sup>lt;sup>20</sup> See also the American Statistical Association's Statement on Statistical Significance and P-values at <u>https://www.amstat.org/asa/files/pdfs/P-ValueStatement.pdf</u>

<sup>17</sup> このような感度分析は、多くの場合、交絡因子よりも効果量推定に実質的な影響を及ぼすと予想されるばく露の誤分類バイアスに対して特に推奨されるかもしれない。

<sup>&</sup>lt;sup>18</sup>「エビデンスがないからといって、エビデンスがないと解釈すべきではない→エビデンスがないことを、ないことのエビデンスと解釈してはならない」という古い格言は、ここでは真実である。

<sup>&</sup>lt;sup>19</sup>米国統計協会の統計的意義と P 値に関する声明 <u>https://www.amstat.org/asa/files/pdfs/P-</u> ValueStatement.pdf も参照のこと。

fact there is in fact a true difference (or association). Studies that are "low powered" may falsely conclude there is no association, when an association actually exists<sup>21</sup>.

Finally, it is important to consider the effects of publication bias in any systematic review of the literature with respect to interpretation of null studies. The term publication bias refers to the tendency for the available published literature to disproportionately exclude such null studies. Studies that demonstrate such a "null" association between a disease or health outcome can be as equally informative as those that do provided that the study in question meets the quality criteria established as part of the epidemiological review process. These may include such factors as study design; the existence of an *a priori* hypothesis vs. an exploratory analysis; sample size and statistical power to detect an effect size of interest; proper ascertainment of outcome *vis-à-vis* sensitivity and specificity; the quality of the exposure assessment and the potential for differential and non-differential misclassification; adequacy of the measurement of key potential confounders and other forms of bias (information, selection, etc.); and evaluation of effect modifiers; appropriate statistical analyses, including consideration of and possible correction for multiple comparisons that a unsupported by a priori hypotheses, biological plausibility, or other supporting information.

#### 6. External Validity (Generalizability)

As noted above, *validity* generally refers to the extent that exposure estimates reflect true exposure levels (Checkoway et al., 2004). *External validity*, or *generalizability*, refers to the ability to extend the epidemiologic study results derived from a sample of the population (e.g., pesticide applicators) to other populations (e.g., all agricultural workers). To assess external validity, comparison of characteristics in the sample to the larger population (if known) can be made. Such evaluation should include not only demographic factors, but also whether exposures (e.g., dose, timing, duration) are similar and whether important effect modifiers (e.g., sensitivity of vulnerable populations) were considered. Generalizability is of particular importance because it is important to understand whether and how individual study results may be applied to the larger group or targeted sub-groups in regulatory risk assessment. For example, the AHS has reported statistical associations between some cancer and non-cancer health outcomes for some pesticide chemicals. OPP has an interest in evaluating the extent to which the reported findings may apply to pesticide applicators in states other than North Carolina and Iowa or to farm workers who primarily do post-application activities.

「低検出力」の研究は、関連付けが実際に存在しているのに、関連付けがないと誤って結論を下 すことがある<sup>20</sup>。

最後に、帰無研究の解釈に関しては、文献のシステマティックレビューにおける出版バイアス の影響を考慮することが重要である。出版バイアスとは、利用可能な公表文献が、そのような帰 無研究を不釣り合いに除外する傾向のことである。疾病または健康影響の間にこのような「帰無」 関連付けを示す研究は、研究課題が疫学的レビューブロセスの一部として確立された質の基準を 満たしていれば、その研究と同様に有益な情報を得ることができる。これらには、研究デザイン、 *優先*的仮説と探索的解析の比較、関係のある効果量を検出するためのサンプルサイズと統計的検 出力、感度と特異度に*対する*影響の適切な確認、ばく露評価の質と差異的・非差異的な誤分類の 可能性、主要な潜在的交絡因子とその他のバイアス(情報、選択等)の評価の適切性、効果修飾 因子の評価(優先的仮説による裏付けがない仮設、生物学的妥当性、またはその他の裏付け情報 についての多重比較の検討とその補正を含む適切な統計解析)などの要因が含まれる。

#### 6. 外的妥当性(一般化可能性)

上述したように、妥当性とは、一般的にはばく露推定が真のばく露レベルを反映している程度 を指す(Checkoway 6)。外的妥当性または一般化可能性とは、母集団のサンプル(例:農薬 散布者)から得られた疫学的研究結果を他の母集団(例:すべての農業従事者)に拡張する能力 のことである。外的妥当性を評価するために、サンプルの特性とより大きな集団(既知の場合) との比較を行うことができる。このような評価には、人口統計学的要因だけでなく、ばく露(例 えば、用量、時期、期間)が類似しているかどうか及び重要な影響修飾因子(例えば、脆弱者集 団の感受性)が考慮されているかどうかも含まれるべきである。一般化可能性は特に重要であり、 個々の研究結果が、規制当局のリスク評価において、より大きな集団または対象となる亜集団に 適用できるかどうか、またどのように適用できるかを理解することが重要である。例えば、AHS は、いくつかの農薬について、いくつかのがんとがん以外の健康影響との間に統計的な関連付け があることを報告している。OPP は、報告された知見が、ノースカロライナ州とアイオワ州以 外の州の農薬散布者や、主に散布後の作業を行う農業従事者にどの程度適用できるかを評価する ことに関心が持たれている。

<sup>&</sup>lt;sup>21</sup> Studies that are low-powered but find statistically significant effects may also be subject to the phenomenon of effect size magnification and this can be important to investigate as well. (Ioannidis, 2008).

<sup>&</sup>lt;sup>20</sup> 検出力は低くても統計的に有意な効果が見られる研究は、効果量の拡大という現象である可能 性があり、これを調査することが重要である(Ioannidis、2008年)。

#### V. HUMAN INCIDENT SURVEILLANCE DATA

Generally speaking, epidemiology studies on pesticides such as those described above focus on lower exposures (over a longer time period) that are less likely to result in acute clinical symptoms. OPP is also interested in exposures that are higher and occur over shorter-intervals (often on an acute "one-time" basis). This "human incident," or poisoning data can be useful for evaluating short term, high exposure scenarios that can be readily attributed to the pesticide in question.

OPP uses such "human incident information" for several purposes. Most broadly, the program uses incident data to inform risk assessment/risk management activities; this forms an integral part of our registration review activities under our Pesticide Registration Improvement Act (PRIA) responsibilities. To this end, OPP evaluates human incident data for trends over time and examines patterns in the severity and frequency of different pesticide exposures. In some cases, incident information can indicate need for additional information or additional risk management measures. Incident information can also help assess the success of risk mitigation actions after they are implemented, and incident information is an important part of OPP's performance accountability system to ensure the effectiveness of risk management actions that OPP has taken to protect human health and the environment. Lastly, incident information can be useful in providing real world use information with respect to usage practices and also in potentially targeting enforcement or educational activities, where appropriate.

OPP obtains this information from a variety of sources. Sources of human incident data include both (human) **medical case reports** appearing in the medical and toxicological literature as well as information from a variety of national **toxico-surveillance activities** for acute pesticide poisonings which are considered jointly to aid acute and chronic hazard identification and as an integral part of the risk assessment process.<sup>22</sup>

Medical case reports (first-hand accounts written by physicians) or medical case series (a compendium of medical case reports across individuals that share common source or symptomology) are valuable tools for analyzing all available evidence of health effects, and to complement the findings of animal studies and epidemiological studies. In addition, they can identify unusual or novel occurrences of an adverse health effects plausibly associated with use of a specific pesticide providing "advance notice" to the agency for toxico-vigilance purposes. Published case reports for pesticides typically describe the effects from an atypical (high exposure/dose, illegal, off-label) acute or short-term exposure. The reports are often anecdotal and can be highly selective in nature. They can, however, can be particularly valuable in identifying previously unidentified toxic effects in humans and in learning about the effects, health outcomes, and medical sequelae following high exposures. They frequently have more detailed medical information (including sequelae), detailed follow-up, and generally higher quality and/or quantitative

#### V. ヒトでの事例調査データ

一般的に言えば、上記のような農薬に関する疫学研究は、急性の臨床症状をもたらす可能性が 小さい低量ばく露(より長い期間にわたって)に焦点を当てている。OPP はまた、より高く、 より短い間隔(多くの場合、急性の"一回限り"で)のばく露に関心を持っている。この「ヒトで の事例」または中毒データは、問題となっているに起因すると考えられる短期的で高濃度の高量 ばく露シナリオを評価するのに有用である。

OPP はこのような「ヒトでの事例情報」をいくつかの目的で使用している。最も広い意味で は、OPP はリスク評価/リスク管理の活動に情報を提供するためにヒトでの事例データを使用 している。これは、農薬登録改善法(PRIA)の責任のもと、登録審査活動の重要な一部となっ ている。この目的のために、OPP は人の事例データを評価して経時的な傾向を調べ、さまざま な農薬ばく露の重大さの程度と頻度のパターンを調べている。場合によっては、事例情報は、追 加の情報や追加のリスク管理措置の必要性を示すことができる。また、事例情報は、リスク軽減 措置が実施された後の達成の評価にも役立ち、事例情報は、OPP がヒト健康と環境を保護する ために行ってきたリスク管理措置の有効性を保証するための OPP のパフォーマンス・アカウン タビリティ・システムの重要な部分である。最後に、事例情報は、使用方法に関する実際の使用 情報を提供する上で有用であり、また、必要に応じて、施行や教育の活動の対象となる可能性が ある。

OPP はこの情報を様々な情報源から入手している。ヒトでの事例データの情報源には、医学 的及び毒物学的文献に掲載されている(ヒトの)医学的症例報告や急性及び慢性のハザードの特 定を促進し、リスク評価プロセスに不可欠な共同で検討されている急性農薬中毒の様々な国の中 毒サーベイランス活動からの情報が含まれている<sup>21</sup>。

医学的症例報告(医師によって書かれた直接の証言)や医学的症例集積(共通の原因や症状を 持つ個人の症例報告をまとめたもの)は、健康影響に関する利用可能なすべてのエビデンスを解 析するための貴重なツールであり、動物試験や疫学研究の知見を補完するものでもある。さらに、 特定の農薬の使用に関連すると思われる有害な健康影響の稀な発生や新規の発生を特定すること ができ、中毒警戒の行政機関に「事前通知」を提供できる。公表されている農薬の症例報告は、 通常、非定型的な(高量ばく露/大量投与、違法、適用外)急性または短期のばく露による影響 を記述している。報告書はしばしば個々の事例に基づいており、その性質上、選択性が高い。し かし、これらの報告書は、ヒトにおいてこれまでに確認されていなかった毒性影響を特定し、高 量ばく露後の影響、健康影響及び医学的後遺症を知る上で、特に有用である。これらの研究には、 より詳細な医学的情報(後遺症を含む)や詳細な追跡調査が行われていることが多く、一般的に 用量に関する高い質及び/または定量的な情報が得られている。

<sup>&</sup>lt;sup>22</sup> OPP is aware of efforts by IPSC to consider human incident data in risk assessment. <u>http://www.who.int/ipcs/publications/methods/human data/en/index.html</u>

<sup>&</sup>lt;sup>21</sup> OPP は、IPSC がリスク評価においてヒトでの事例データを考慮する成果を認識している。 http://www.who.int/ipcs/publications/methods/human data/en/index.html

information about dose. If similarities are seen across multiple medical case studies or patterns emerge – in symptoms, exposure scenarios or usage practices -- these can provide valuable information for the risk assessment process and strengthen any findings. Medical case studies and series that include quantitative exposure information can be compared to exposure estimates in the risk assessment (which are based on labeled application rates and surrogate exposure information) to characterize margins of exposure expected from typical use, when appropriate.

The following considerations are evaluated in assessing medical case reports and medical case series:

- A detailed history of exposure (when, how, how much); time of onset of adverse effects; and signs and symptoms of the patient, are reported.
- Information on the product/chemical/pesticide, such as name, pesticide label, registration number, etc.
- Patient information (e.g. age, race, sex); underlying health conditions and use of any medications that can produce similar signs and symptoms; relevant medical history; and the presence of any risk factors.
- Description of events and how the diagnosis was made.
- Management and treatment of the patient, and laboratory data (before, during and after the therapy), including blood levels of pesticides and chemicals.
- Whether the medical report is reliable, reasonable and whether it is consistent with current knowledge, including other research, reviews and guidelines.
- Clinical course of the event and patient outcome (e.g. patient recovered and discharged from hospital; condition of patient after the discharge, any chronic health effects or premature death related to the pesticide or chemical exposure).

In addition to using medical case reports/series as a source of real-world exposure and toxicological information, OPP also engages in toxico-surveillance activities using a variety of pesticide poisoning incident databases are also available. Specifically, OPP has access to the following five human incident data sources: the *OPP Incident Data System* (IDS); the American Association of Poison Control Centers (PCC) summary reports from their *National Poison Data System* (NPDS); data from the EPA-funded *National Pesticide Information Center* (NPIC), currently at Oregon State University; the Centers for Disease Control and Prevention/National Institute for Occupational Safety and Health *Sentinel Event Notification System for Occupational Risk-Pesticides* (NIOSH SENSOR-Pesticides) and the *California Pesticide Illness Surveillance Program* (PISP). Each of these are described, in turn below:

OPP Incident Data System (IDS) is maintained by OPP and incorporates data submitted by registrants under FIFRA section 6(a)(2)<sup>23</sup>, as well as other incidents reported directly to EPA. OPP has compiled the pesticide related 複数の医療事例研究で類似点が見られたり、症状、ばく露シナリオ、使用方法などにパターン が見られた場合には、リスク評価プロセスと結果の裏付けに有用な情報を提供することができる。 医学的症例研究や定量的なばく露情報集積は、必要に応じて、典型的な使用から予想されるばく 露マージンを特性評価することで(ラベルに明示された適用率や代替ばく露情報に基づく)リス ク評価のばく露推定値と比較できる。

医学的症例報告や医学的症例集積を評価する際には、以下の点を考慮する。

ばく露の詳細な履歴(いつ、どのように、どのくらい)、健康影響の発現時期、患者の 徴候や症状が報告されている。

商品名、農薬表示、登録番号など、商品・化学品・農薬に関する情報。

患者情報(例:年齢、人種、性別);基本的な健康状態及び同様の徴候や症状をもたら す可能性のある医薬品の使用;関連する病歴及びリスク因子の有無。

疾病の説明と診断に至った経緯。

患者の管理・治療、農薬や化学物質の血中濃度などの検査データ(治療前、治療中、治 療後)。

医学的報告は信頼性があるか、妥当であるか。他の研究、レビュー、ガイドラインを含 む最新の知見と一致しているかどうか。

疾病の臨床経過及び患者の転帰(例:患者の回復及び退院;退院後の患者の状態、農薬 または化学物質へのばく露に関連した慢性的な健康影響または早期死亡)。

実際のばく露情報及び毒物学的情報の情報源として医学的症例の報告/集積を利用することに 加えて、OPP は様々な農薬中毒事例データベースを利用した中毒サーベイランス活動も行って いる。具体的には、OPP は以下の 5 つのヒトでの事例データソースにアクセスできる。OPP Incident Data System (IDS) 、American Association of Poison Control Centers (PCC) の National Poison Data System (NPDS) からの要約報告書、現在オレゴン州立大学にある EPA が資金提供している National Pesticide Information Center (NPIC) からのデータ、疾病管理 予防センター (Centers for Disease Control and Prevention) /National Institute for Occupational Safety and Health for Occupational Risk - Pesticides (NIOSH SENSOR-Pesticides) 及び California Pesticide Illness Surveillance Program (PISP) のデータ。以下、 それぞれについて順番に説明していく。

> OPP Incident Data System (IDS) は OPP が管理しており、FIFRA 第 6 条 (a)(2)<sup>22</sup>項に基づき登録者が提出したデータ及び EPA に直接報告されたその他の 事例を含んでいる。

<sup>&</sup>lt;sup>23</sup> Under FIFRA 6(a) (2), pesticide registrants are required to notify EPA if and when they become aware of "factual information regarding unreasonable adverse effects on the environment of the pesticide."

<sup>&</sup>lt;sup>22</sup> FIFRA 6(a)(2)に基づき、農薬登録者は、「農薬の環境への不適切な悪影響に関する事実情報」を知った場合には、EPA に通知するよう求められている。

incident reports in the IDS since 1992. The IDS includes reports of alleged human health incidents from various sources, including mandatory FIFRA Section 6 (a) (2) reports from registrants, other federal and state health and environmental agencies and individual consumers. IDS include information on incidents involving humans, plants, wild and domestic animals where there is a claim of an adverse effect. The vast majority of IDS reports are received by the agency in paper format. IDS entries act as a "pointers" to copies of original reports retained on microfilm and scanned images in OPP's Information Service Center.

While IDS includes both occupational and non-occupational incidents, the majority of incidents reported relate to non-occupational/residential scenarios The reports are obtained from across the U.S. and most incidents have all relevant product information (such as the EPA Registration Number) recorded. As IDS is populated mostly by information provided by pesticide registrants under their FIFRA 6(a)(2) reporting requirements, the agency has relatively high confidence in the identification of the specific product which is involved. Severity rankings are included for each incident (as specified by CFR §159.184). Symptom information is sometimes included in the narrative portion of the incident, but this information is usually not validated/confirmed by a healthcare professional. IDS also includes narrative information on exposure scenario and hazard information. Many companies use standardized, industry-developed Voluntary Incident Reporting Forms.

OPP collects and evaluates the data from the IDS and identifies potential patterns with respect to the extent and severity of the health effects due to pesticides exposure. While IDS reports are broad in scope and can in some cases contain detailed information, the system does not necessarily consistently capture detailed information about incident events, such as occupational exposure circumstances or medical outcome.

In addition, most cases data going into IDS is not validated or verified, though some reports are collected from calls to contract poison control centers. Nevertheless, incident information can provide an important post-marketing feedback loop to the agency following initial registration of the product: IDS incidents of a severe nature, or a suggested pattern or trend among less severe incidents can signal the agency to further investigate a particular chemical or product. Because IDS has such extensive coverage, it can assist in providing temporal trend information and determining whether risk mitigation has helped reduce potential pesticide exposure and decreased the number of potential incidents reported to IDS. Overall, IDS provides good information about national trends and frequency of incidents for pesticides and can provide valuable insights into the hazard and/or exposure potential of a pesticide.

OPP は 1992 年以来、IDS に農薬関連の事例報告をまとめている。IDS には、登録者、他の連邦・州の保健・環境機関及び個人消費者からの強制的な FIFRA 第6章(a)(2)報告を含む、様々な情報源から主張されたヒトでの健康影響事例の報告が含まれている。IDS には、ヒト、植物、野生動物、家畜への悪影響を主張している事例に関する情報が含まれている。IDS 報告の大部分は、政府機関が紙形式で受け取っている。IDSの項目は、OPPの情報サービスセンターにあるマイクロフィルムやスキャンした画像に保存されているオリジナルの報告書のコピーへの「ポインタ」として機能する。

IDS には職業上及び非職業上の両方の事例が含まれているが、報告された事例の 大部分は非職業/住居のシナリオに関するものである。全米から報告された事例 のほとんどは製品情報(EPA登録番号など)の記載に関連している。IDSはほと んどが FIFRA 6(a)(2)報告要件に基づき農薬登録者から提供された情報で構成さ れているため、政府機関は特定の製品を識別することに対して比較的高い信頼性 を持っている。重大さの程度の順位付けは、各事例について(CFR §159.184 で 規定されている)記載されている。症状情報は、事例の解説部分に含まれること があるが、この情報は通常、医療専門家による検証/確認を受けていない。IDS には、ばく露シナリオやハザード情報の解説情報も含まれている。多くの企業は、 標準化された、業界で開発された自主的な事例報告フォームを使用している。

OPP は IDS からデータを収集・評価し、農薬ばく露による健康影響の程度や重 大さの程度に関して潜在的なパターンを識別している。IDS の報告書は範囲が広 く、場合によっては詳細な情報を含むが、システムは必ずしも職業上ばく露状況 や医学的転帰などの発現事象に関する詳細な情報を一貫して把握しているわけで はない。

また、IDS に入る症例データのほとんどは、中毒管理センターへの電話からの収 集もあるが、確認・照合されない。とはいえ、事例情報は、製品の初期登録後、 製造販売後の重要なフィードバックルーブを政府機関に提供できる。重大な性質 の IDS 事例や、それほど重大ではない事例の間で示唆されたパターンや傾向は、 特定の化学物質や製品をさらに調査するように政府機関に求めることができる。 IDS はこのように広範囲をカバーしているため、一時的な傾向情報を提供し、リ スク軽減によって潜在的な農薬ばく露が減少し、IDS に報告された潜在的な事例 の数が減少したかどうかを判断するのに役立つ可能性がある。全体的に見ると、 IDS は農薬の全国的な傾向と事例の頻度に関する良好な情報を提供し、農薬のハ ザード及び/またはばく露の可能性について有用な予測を提供することができる。 **The National Poison Data System (NPDS)** -- formerly called the Toxic Effects Surveillance System (TESS) -- is maintained by the American Association of Poison Control Centers (AAPCC) and is supported with funding from several federal agencies. NPDS is a computerized information system with geographically specific and near real-time reporting. Although the main mission of Poison Control Centers is in helping callers respond to emergencies, NPDS data can help identify emerging problems in chemical product safety. Hotlines at 61 PCC's nationwide are open 24/7, 365 days a year and are staffed by specially trained nurses, pharmacists, and other clinical health care specialists to provide poisoning information. Using computer assisted data entry, standardized protocols, and strict data entry criteria, local callers report incidents. These reported incidents are retained locally and are updated in summary form to the national database maintained by AAPCC. Information calls are tallied separately and not counted as incidents. The PCC system covers nearly all the US and its territories and has undergone major computer enhancements since 2001.

NPDS includes mainly non-occupational incidents. NPDS does not include narrative information and the product information may not be complete. NPDS provides severity rankings and symptom information that are designated/recorded by trained specialists, and the agency has relatively high confidence in this information. NPDS also provides some information on the likelihood of the adverse effect being a result of the reported exposure. Overall, NPDS provides, as well as the hazard potential for particular pesticides. However, resource limitations permit the agency to only access AAPCC summary reports published each year (e.g., see <a href="http://www.aapcc.org/annual-reports">http://www.aapcc.org/annual-reports</a> ) and these serve as a supplement to other data sources for which the agency has more complete access.

#### □ <u>The National Pesticide Information Center (NPIC)</u>

(http://npic.orst.edu/index.html) is funded by EPA to serve as a source of objective, science-based pesticide information in response to inquiries and to respond to incidents. NPIC functions nationally during weekday business hours and is a cooperative effort between Oregon State University (currently) and EPA; it is intended to serve as a source of objective, science-based pesticide information and to respond to inquiries from the public and to incidents. Similar to Poison Control Centers, NPIC's primary purpose is not to collect incident data (about 10% of NPIC's annual calls are considered "incident" related), but rather to provide information to inquirers on a wide range of pesticide topics, and direct them to other sources for pesticide incident investigation and emergency treatment. Nevertheless, NPIC does collect information about incidents (approximately 4000 incidents per year) from inquirers and records that information in a database. NPIC is a source of national incident information, but generally receives fewer reports than IDS. Regardless, if a high frequency is observed in IDS for a given pesticide or

□ 全米中毒データシステム(NPDS)(以前は毒性影響監視システム(TESS)と 呼ばれていた)は、米国中毒管理センター協会(AAPCC)によって維持されて おり、いくつかの連邦政府機関からの資金援助を受けている。NPDSはコンピュ ータ化された情報システムで、地理的に特定されたほぼリアルタイムの報告が可 能である。中毒管理センターの主な任務は、緊急事態に対応する通報者を支援す ることであるが、NPDSのデータは、化学製品の安全性に関する新たな問題を特 定するのに役立つ。全国にある61の PCCのホットラインは、365日24時間年 中無休で開設されており、特別な訓練を受けた看護師、薬剤師及びその他の臨床 医療専門家が中毒情報を提供している。コンピュータによるデータ入力、標準化 されたプロトコル、厳格なデータ入力基準を使用して、現地の通報者が事例を報 告する。これらの報告された事例は現地で保存され、AAPCCによって維持され ている全国データベースに要約された形で更新される。情報通報は個別に集計さ れ、事例としてはカウントされない。PCCシステムは、ほぼすべての米国とそ の領土をカバーしており、2001年以来、コンピュータの大幅な強化が行われて きた。

NPDSには主に非職業上の事例が含まれている。NPDSには解説情報は含まれて おらず、製品情報は完全ではない。NPDSは、訓練を受けた専門家が指定/記録 した重大さの程度の順位と症状情報を提供しており、政府機関はこれらの情報に 対して比較的高い信頼性を持っている。NPDSはまた、報告されたばく露による 健康影響の可能性に関する情報も提供している。全体として、NPDSは全国的な 傾向、農薬の事例発生頻度、特定の農薬の潜在的ハザードについての良好な情報 を提供している。しかし、情報源の制限により、毎年発行される AAPCCのサマ リーレポート(例:<u>http://www.aapcc.org/annualreports/を参照)</u>にしかアク セスできず、これらのレポートは他の情報源を補完する役割を果たしているため、 NPDSはより完全なアクセスが可能となっている。

#### National Pesticide Information Center (NPIC)

(http://npic.orst.edu/index.html)は、EPA の資金提供を受けており、客観的で科 学的根拠に基づいた農薬情報を提供し、問い合わせに対応したり、事例に対応し たりすることを目的としている。NPIC は平日の営業時間内に全国的に機能して おり、オレゴン州立大学(現在)と EPA との間で協力している。中毒管理セン ターと同様に、NPIC の主な目的は事例データの収集ではなく(NPIC の年間の 問い合わせの約 10%は「事例」に関連していると考えられている)、むしろ幅 広い農薬に関する情報を問い合わせ者に提供し、農薬での事例の調査や緊急処置 のための他の情報源に誘導することである。とはいえ、NPIC では問い合わせる からの事例情報(年間約 4000 件)を収集し、データベースに記録している。 NPIC は全国の事例の情報源であるが、一般的に IDS に比べて報告件数は少ない。 product, NPIC provides a source of information that can prove valuable in determining consistency across national data sets.

As with IDS and PCC, the incidents in NPIC are mainly non-occupational. NPIC incidents include narratives and product information when the caller provides the information. Although the scope is national, there are significantly fewer incidents reported to NPIC than to NPDS or IDS but considerably more information is provided and the agency can request custom reports on an as-needed basis. Hazard information includes severity rankings, route of exposure and symptoms – which are recorded by trained personnel. NPIC also provides information on how likely the link between exposure and adverse effect is (which they call a certainty index). NPIC also publishes annual reports and analyses in the open literature which are valuable resources.

The Center for Disease Control and Prevention National Institute for Occupational Health (CDC/NIOSH) manages a pesticide surveillance program and database entitled the Sentinel Event Notification System for Occupational Risk (SENSOR)-Pesticides.<sup>24</sup> This database includes pesticide illness case reports in 12 states from 1998-2013. Participating states are: California, Florida, Iowa, Louisiana, Michigan, Nebraska, New Mexico, New York, North Carolina, Oregon, Texas and Washington. The participating states for a given year vary depending on state and federal funding for pesticide surveillance.

Cases of pesticide-related illnesses in the SENSOR-Pesticides database are ascertained from a variety of sources, including: reports from local Poison Control Centers, state Department of Labor workers' compensation claims when reported by physicians, reports from state Departments of Agriculture, and physician reports to state Departments of Health. Although both occupational and non-occupational incidents are included in the database, the SENSOR coordinators primarily focus their follow-up case investigation efforts on the occupational pesticide incidents. The SENSOR coordinator at the state Department of Health will follow-up with cases and work to obtain medical records in order to verify exposure scenario, symptoms, severity, and health outcome. Using standardized protocol and case definitions, SENSOR coordinators at state Departments of Health enter the incident interview description provided by the case, medical report, physician and patient into the SENSOR data system.

All SENSOR-Pesticides cases must report a minimum of two health effects in order to be included in the aggregate database that EPA uses for incident

特定の農薬や製品が IDS で高頻度に観察された場合でも、NPIC は全国のデータ セット間の整合性を判断する上で有用な情報源を提供している。

IDSやPCCと同様に、NPICの事例は主に非職業上のものである。NPICの事例 には、通報者が情報を提供する際に解説情報や製品情報が含まれている。対象範 囲は全国であるが、NPICに報告される事例の数は NPDSや IDSに比べてかな り少ない。一方、提供される情報量はかなり多く、必要に応じて政府機関がカス タムレポートを要求することも可能である。ハザード情報には、重大さの程度の 順位付け、ばく露経路、症状などが含まれており、これらは訓練を受けた担当者 によって記録される。また、ばく露と有害影響の関連性がどの程度であるかにつ いての情報も提供している(これを確実性指数と呼んでいる)。また、NPIC は 年次報告や解析結果を公開しており、有用な情報源となっている。

□ 疾病管理予防国立産業衛生研究所(CDC/NIOSH)は、SENSOR(Sentinel Event Notification System for Occupational Risk) - Pesticides と題した農薬監 視プログラムとデータベースを管理している<sup>23</sup>。このデータベースには、1998年 から2013年までの12の州における農薬による疾病症例報告が含まれている。参 加している州は、カリフォルニア州、フロリダ州、アイオワ州、ルイジアナ州、 ミシガン州、ネブラスカ州、ニューメキシコ州、ニューヨーク州、ノースカロラ イナ州、オレゴン州、テキサス州、ワシントン州である。ある年の参加州は、州 と連邦政府が農薬監視のために資金を提供しているかどうかによって異なる。

SENSOR・農薬データベース内の農薬関連の疾病症例は、様々な情報源(現地の 中毒管理センターからの報告、医師によって報告された際に農業従事者の補償請 求の州労働局からの報告、州農業局からの報告及び州保健局への医師の報告)か ら把握されている。職業上及び非職業上の事例の両方がデータベースに含まれて いるが、SENSOR 責任者は、主に職業上の農業従事者事例に関する追跡症例調 査の成果に焦点を当てている。州保健局の SENSOR 責任者は、症例を追跡し、 ばく露シナリオ、症状、重大さの程度、健康影響を確認するために、カルテを取 得する。標準化されたプロトコルと症例の定義を使用して、州保健局の SENSOR 責任者は、症例、カルテ、医師と患者によって提供された事例インタ ビュー解説を SENSOR データシステムに入力する。

すべての SENSOR-Pesticides の症例は、EPA が事例の解析に使用する集合デー タベースに含まれるために、最低2つの健康影響を報告しなければならない。

<sup>&</sup>lt;sup>24</sup> SENSOR-Pesticides webpage: <u>http://www.cdc.gov/niosh/topics/pesticides/overview.html</u>

Page 41

<sup>&</sup>lt;sup>23</sup> SENSOR-Pesticides $\mathcal{O}$   $\pi - \Delta \sim - \vec{\mathcal{V}}$ : http://www.cdc.gov/niosh/topics/pesticides/overview.html 41 $\sim - \vec{\mathcal{V}}$ 

analyses. Evidence for each case is evaluated, based on the NIOSH case classification matrix, for its causal relationship between exposure and illness. 98% of SENSOR-Pesticides cases are classified as definite, probable, or possible, and 2% of the cases are classified as suspicious. Unlikely, asymptomatic, and unrelated cases, as well as those with insufficient information, are not included in the SENSOR-Pesticides database.

Overall, SENSOR-Pesticides provides very useful information on both occupational and non-occupational incidents, and sometimes valuable insights into the hazard and/or exposure potential of a pesticide. SENSOR-Pesticides also conducts analyses of its own data and publishes these in the Morbidity and Mortality Weekly. Unlike the aforementioned databases and although it contains both non-occupational/residential and occupational incidents, SENSOR's has traditionally focused on occupational pesticide incidents, and is of particular value in providing that information. SENSOR-Pesticides data from 1998-2011 is available online at: <a href="http://wwwn.cdc.gov/Niosh-whc/Home/Pesticides">http://wwwn.cdc.gov/Niosh-whc/Home/Pesticides</a>.

The California Pesticide Illness Surveillance Program (PISP) is maintained by the State of California. This database documents pesticide-related illnesses and injuries. Case reports are received from physicians and via workers' compensation records. The local County Agricultural Commissioner investigates the circumstances of the exposure. Medical records and investigative findings are then evaluated by California's Department of Pesticide Regulation (DPR) technical experts and entered into an illness registry. All reported pesticide illnesses in the California PISP program are investigated by the county agricultural commissioners, and the DPR evaluates the reports and compiles them into a database, which is used to improve the state's program to protect workers and others from the adverse effects of pesticide exposure (http://apps.cdpr.ca.gov/calpig/).

Currently, OPP evaluates human incident data on a chemical-specific basis. Incidents from each database are analyzed for hazard potential (deaths, frequency of more severe incidents, and patterns/trends of reported symptoms) and exposure potential (frequency of incidents/ trends over time, patterns/trends of exposure scenarios, of factors affecting exposure or of products). When evaluating human incident data from the above databases, OPP considers several general criteria. OPP considers the relative severity and frequency of symptoms. Additionally, OPP generally has greater confidence in reports in which temporal association can be verified or are at least plausible. Lastly, other factors that are used to evaluate human incident data include evidence of an exposure response association, consistency in reported health effects, biological plausibility of reported health effects, elimination of alternative causes of health effects. Additionally, narratives of more severe incidents are often evaluated for any temporal association between time-of-exposure and effects reported to determine whether an association is supported by the circumstances. For example, a heart attack in an elderly individual that occurs three

各症例のエビデンスは、NIOSH の症例分類マトリックスに基づいて、ばく露と 疾病との因果関係について評価される。SENSOR-Pesticides の症例の 98%は、 確定、可能性高い、または可能性ありに分類され、2%は疑わしい症例に分類さ れている。可能性の低い症例、無症候性の症例、無関係の症例及び情報が不十分 な症例は、SENSOR-Pesticides のデータベースには含まれ いない。

全体的には、職業上及び非職業上の事例について非常に有用な情報を提供しており、時には農薬のハザードやばく露の可能性についての有用な予想を提供している。また、SENSOR-Pesticides は独自のデータの解析を行い、Morbidity and Mortality Weekly に公表している。前述のデータベースとは異なり、非職業上/住居上と職業上の両方の事例が含まれているが、SENSOR'S は伝統的に農業従事者での事例に焦点を当てており、その情報を提供する上で特に価値のあるものとなっている。1998 年から 2011 年までの SENSOR-Pesticides のデータはオンラインで入手可能である:http://wwwn.cdc.gov/Niosh-whc/Home/Pesticides。

□ カリフォルニア州農薬疾病サーベイランスプログラム(PISP) は、カリフォル ニア州によって管理されている。このデータベースは、農薬に関連した疾病や傷 害を記録している。症例報告は、医師からの報告と農業従事者補償記録を介して 行われる。現地の郡農業委員会がばく露の状況を調査する。カルテと調査結果は、 カリフォルニア州農薬規制局(DPR)の技術専門家によって評価され、疾病の登 録簿に登録される。カリフォルニア州の PISP プログラムで報告されたすべての 農薬による疾病は、郡の農業委員会によって調査され、DPR は報告書を評価し てデータベースにまとめ、農業従事者やその他の人々を農薬ばく露の悪影響から 保護するための州のプログラムを改善するために使用される (http://apps.cdpr.ca.gov/calpiq/)。

現在、OPP は化学物質別にヒトの事例データを評価している。各データベースからの事例は、 ハザードボテンシャル(死亡者数、より重大な事例の頻度、報告された症状のパターン/傾向) とばく露ボテンシャル(事例の頻度/経時的傾向、ばく露シナリオのパターン/傾向、ばく露に 影響を与える要因のパターン/傾向、または製品のパターン/傾向)について解析されている。 上記のデータベースからのヒトでの事例データを評価する際、OPP はいくつかの一般的な基準 を考慮している。OPP は症状の相対的な重大さの程度と頻度を考慮している。さらに、OPP は 一般的に、時間的な関連付けが確認できる報告を、あるいは少なくとも妥当と思われる報告を、 より信頼性の高いものとしている。最後に、ヒトの事例データを評価するために使用される他の 要因には、ばく露反応の関連付けのエビデンス、報告された健康影響の一貫性、報告された健康 影響の生物学的妥当性、医薬品の使用などの健康影響の代替原因の排除及び観察された症状や健 康影響の特異度が含まれる。さらに、より重大な事例の解説は、ばく露の時間と報告された影響 の間に時間的な関連付けがあるかどうかを評価し、関連付けが状況によって裏付けられているか どうかを判断することが多い。 months following an indoor pesticide application may be determined not to be a likely causal association. On the other hand, a severe incident occurring at or shortly after the time of exposure with symptoms consistent with known symptomology for the pesticide class and that occurs without prior medical history may suggest that causal inference is more justified.

In sum, then, incident data -- consisting of both medical case reports/case series appearing the medical and human toxicological literature and toxico-surveillance data derived from the databases that EPA either maintains, funds, or accesses -- can provide useful, complementary information that assists OPP in evaluating the real-world risks of pesticides.

#### VI. SUMMARY & CONCLUSIONS

This framework describes important factors in reviewing epidemiology and human incident data and describes a proposed WOE analysis for incorporating such data in pesticide human health risk assessment. OPP uses the best available data across multiple lines of evidence and from *in vitro*, *in vivo*, and *in silico* data sources. OPP uses a WOE approach when integrating data from multiple sources to take into account for quality, consistency, relevancy, coherence and biological plausibility using modified Bradford Hill criteria as an organizational tool. Application of WOE analysis is an integrative and interpretive process routinely used by EPA according to in scientific analysis outlined in its risk assessment guidelines. The WOE analysis also evaluates the quality of the combined data set and is consistent with the level of effort and complexity that is appropriate for a particular scientific assessment (U.S. EPA, 2002). OPP acknowledges that toxicology and risk assessment are currently undergoing transformational changes towards implementing the new vision of 21<sup>st</sup> century toxicity testing. As these transformation changes occur, OPP will update this approach as appropriate.

例えば、屋内での農薬散布後3か月に発生した高齢者の心臓発作は、因果関係があるとは判断されない。一方で、農薬種類に応じた既知の症状と一致する症状を伴うばく露時またはばく露後間もなく発生した重大な事例は、事前の病歴がなく発生した場合、因果関係の推測がより正当化されることを示唆している。

以上のことから、医学的文献やヒトの毒性学的文献に掲載されている医学的症例報告/症例シ リーズと、EPA が維持、資金提供またはアクセスしているデータベースから得られる中毒サー ベイランスデータの両方からなる事例データは、実社会での農薬のリスクを評価する際に OPP を支援する有用で補完的な情報を提供することが可能である。

#### VI. 要約と結論

このフレームワークでは、疫学とヒトでの事例データをレビューする際の重要な要素を説明し、 そのようなデータを農薬のヒト健康リスク評価に組み込むために提案されている WOE 解析につ いて説明している。OPP では、複数のエビデンスと、*in vitro、in vivo*及び*in silico*の情報源か ら得られた入手可能な最善のデータを使用する。OPP では、複数の情報源からのデータを統合 する際に、系統化されたツールとして修正された Bradford Hill 基準を用いて、品質、一貫性、 関連性、整合性、生物学的妥当性を考慮するため、WOE アプローチを使用している。WOE 解 析の適用は、リスク評価ガイドラインに概説されている科学的解析に従って EPA が日常的に使 用している統合的かつ解釈的なプロセスである。WOE 解析はまた、結合されたデータセットの 質も評価し、特定の科学的評価に適切である成果と複雑性のレベルと一致している(U.S.EPA、 2002 年)。OPP は、21 世紀の毒性試験の新たなビジョンの実施に向けて、現在、毒性学とリス ク評価が変革期にあることを認識している。これらの変革に伴い、OPP はこのアプローチを適 宜更新して行くであろう。

Hernandez-Jerez

## Abstract

In 2013, EFSA published a comprehensive systematic review of epidemiological studies published from 2006 to 2012 investigating the association between pesticide exposure and many health outcomes. Despite the considerable amount of epidemiological information available, the quality of much of this evidence was rather low and many limitations likely affect the results so firm conclusions cannot be drawn. Studies that do not meet the 'recognised standards' mentioned in the Regulation (EU) No 1107/2009 are thus not suited for risk assessment. In this Scientific Opinion, the EFSA Panel on Plant Protection Products and their residues (PPR Panel) was requested to assess the methodological limitations of pesticide epidemiology studies and found that poor exposure characterisation primarily defined the major limitation. Frequent use of case-control studies as opposed to prospective studies was considered another limitation. Inadequate definition or deficiencies in health outcomes need to be avoided and reporting of findings could be improved in some cases. The PPR Panel proposed recommendations on how to improve the quality and reliability of pesticide epidemiology studies to overcome these limitations and to facilitate an appropriate use for risk assessment. The Panel recommended the conduct of systematic reviews and meta-analysis, where appropriate, of pesticide observational studies as useful methodology to understand the potential hazards of pesticides, exposure scenarios and methods for assessing exposure, exposure-response characterisation and risk characterisation. Finally, the PPR Panel proposed a methodological approach to integrate and weight multiple lines of evidence, including epidemiological data, for pesticide risk assessment. Biological plausibility can contribute to establishing causation.

## Summary

The European Food Safety Authority (EFSA) asked the Panel on Plant Protection Products and their Residues (PPR Panel) to develop a Scientific Opinion on the follow-up of the findings of the External Scientific Report 'Literature review of epidemiological studies linking exposure to pesticides and health effects' (Ntzani et al., 2013). This report was based on a systematic review and meta-analysis of epidemiological studies published between 2006 and 2012 and summarised the associations found between pesticide exposure and 23 major categories of human health outcomes. Most relevant significant associations were found for liver cancer, breast cancer, stomach cancer, amyotrophic lateral sclerosis, asthma, type II diabetes, childhood leukaemia and Parkinson's disease. While the inherent weaknesses of the epidemiological studies assessed do not allow firm conclusions to be drawn on causal relationships, the systematic review raised a concern about the suitability of regulatory studies to inform on specific and complex human health outcomes.

The PPR Panel developed a Scientific Opinion to address the methodological limitations affecting the quality of epidemiological studies on pesticides. This Scientific Opinion is intended only to assist the peer review process during the renewal of pesticides under Regulation (EC) 1107/2009 where the evaluation of epidemiological studies, along with clinical cases and poisoning incidents following any kind of human exposure, if available, is a data requirement. Epidemiological data concerning exposures to pesticides in Europe will not be available before first approval of an active substance and so will not be expected to contribute to a draft assessment report (DAR). However, there is the possibility that earlier prior approval has been granted for use of an active substance in another jurisdiction and epidemiological studies. This type of data is more suited for the renewal process of active substances, also in compliance with Regulation (EC) 1141/2010 which indicates that 'The dossiers submitted for renewal should include new data relevant to the active substance and new risk assessments'.

In this Opinion, the PPR Panel proposed a methodological approach specific for pesticide active substances to make appropriate use of epidemiological data for risk assessment purposes, and proposed recommendations on how to improve the quality and reliability of epidemiological studies on pesticides. In addition, the PPR Panel discussed and proposed a methodology for the integration of epidemiological evidence with data from experimental toxicology as both lines of evidence can complement each other for an improved pesticide risk assessment process.

First, the opinion introduces the basic elements of observational epidemiological studies<sup>1</sup> and contrasts them with interventional studies which are considered to provide the most reliable evidence in epidemiological research as the conditions for causal inference are usually met. The major observational study designs are described together with the importance of a detailed description of pesticide exposure, the use of validated health outcomes and appropriate statistical analysis to model exposure–health relationships. The external and internal study validity is also addressed to account for the role of chance in the results and to ascertain whether factors other than exposure can distort the associations found. Several types of human data can contribute to the risk assessment process of pesticides, particularly to support hazard identification. Besides formal epidemiological studies, other sources of human data such as case series, disease registries, poison control centre information, occupational health surveillance data and post-marketing surveillance programmes, can provide useful information for hazard identification, particularly in the context of acute, specific health effects.

However, many of the existing epidemiological studies on pesticides exposure and health effects suffer from a range of methodological limitations or deficiencies (Terms of Reference (ToR) 1). The Panel notes that the complexity of studying associations between exposure to pesticides and health outcomes in observational settings among humans is more challenging than in many other disciplines of epidemiology. This complexity lies in some specific characteristics in the field of pesticide epidemiology such as the large number of active substances in the market (around 480 approved for use in the European Union (EU)), the difficulties to measure exposure, and the frequent lack of quantitative (and qualitative) data on exposure to individual pesticides. The systematic appraisal of epidemiological evidence carried out in an EFSA external scientific report (Ntzani et al., 2013) identified a number of methodological limitations. Poor exposure characterisation primarily defines the major limitation of most existing studies because of the lack of direct and detailed exposure assessment to specific pesticides (e.g. use of generic pesticide definitions). Frequent use of case–control studies as

<sup>&</sup>lt;sup>1</sup> This Opinion deals only with observational studies (also called epidemiological studies) and vigilance data. In contrast, interventional studies (also called experimental studies, such as randomised clinical trials) are outside the scope of this Opinion.

opposed to prospective studies is also a limitation. Inadequate definition or deficiencies in health outcomes, deficiencies in statistical analysis and poor quality reporting of research findings were identified as other limitations of some pesticide epidemiological studies. These limitations are to some extent responsible for heterogeneity or inconsistency of data that challenge drawing robust conclusions on causality. Given the small effect sizes for most of the outcomes addressed by Ntzani et al. (2013), the contribution of bias in the study design can play a role.

The PPR Panel also provides a number of refinements (ToR 2) and recommendations (ToR 3) to improve future pesticide epidemiological studies that will benefit the risk assessment. The quality and relevance of epidemiological research can be enhanced by (a) an adequate assessment of exposure, preferentially by using personal exposure monitoring or biomarker concentrations of specific pesticides (or combination of pesticides) at an individual level, reported in a way that minimises misclassification of exposure and allows for dose-response assessment; (b) a sufficiently valid and reliable outcome assessment (well defined clinical entities or validated surrogates); (c) adequately accounting for potentially confounding variables (including other known exposures affecting the outcomes); (d) conducting and reporting subgroup analysis (e.g. stratification by gender, age, etc.). A number of reporting guidelines and checklists developed specifically for studies on environmental epidemiology are of interest for epidemiological studies assessing pesticide exposures. This is the case for extensions of the modified STROBE (STrengthening the Reporting of OBservational studies in Epidemiology) criteria, among others, which includes recommendations on what should be included in an accurate and complete report of an observational study.

Exposure assessment can be improved at the individual level (direct and detailed exposure assessment to specific pesticides in order to provide a reliable dosimeter for the pesticide of concern that can be supplemented with other direct measures such as biomonitoring). Besides, exposure can be assessed at population level by using registered data that can then be linked to electronic health records. This will provide studies with unprecedented sample size and information on exposure and subsequent disease. Geographical information systems (GIS) and small area studies might also serve as an additional way to provide estimates of residential exposures. These more generic exposure assessments have the potential to identify general risk factors and may be important both informing overall regulatory policies, and for identification of matters for further epidemiological research. The development of -omic technologies also presents intriguing possibilities for improving exposure assessment through measurement of a wide range of molecules, from xenobiotics and metabolites in biological matrices (metabolomics) to complexes with DNA and proteins (adductomics). Omics have the potential to measure profiles or signatures of the biological response to the cumulative exposure to complex chemical mixtures and allows a better understanding of biological pathways. Health outcomes can be refined by using validated biomarkers of effect, that is, a quantifiable biochemical, physiological or any other change that, is related to level of exposure, is associated with a health impairment and also helps to understand a mechanistic pathway of the development of a disease.

The incorporation of epidemiological studies into regulatory risk assessment (ToR 4) represents a major challenge for scientists, risk assessors and risk managers. The findings of the different epidemiological studies can be used to assess associations between potential health hazards and adverse health effects, thus contributing to the risk assessment process. Nevertheless, and despite the large amount of available data on associations between pesticide exposure and human health outcomes, the impact of such studies in regulatory risk assessment is still limited. Human data can be used for many stages of risk assessment; however, a single (not replicated) epidemiological study, in the absence of other studies on the same pesticide active substance, should not be used for hazard characterisation unless it is of high quality and meets the 'recognised standards' mentioned in the Regulation (EU) No 1107/2009. As these 'recognised standards' are not detailed in the Regulation, a number of recommendations should be considered for optimal design and reporting of epidemiological studies to support regulatory assessment of pesticides. Although further specific guidance will be helpful, this is beyond the ToR of this Opinion. Evidence synthesis techniques, such as systematic reviews and meta-analysis (where appropriate) offer a useful approach. While these tools allow generation of summary data, increased statistical power and precision of risk estimates by combining the results of all individual studies meeting the selection criteria, they cannot overcome methodological flaws or bias of individual studies. Systematic reviews and meta-analysis of observational studies have the capacity of large impact on risk assessment as these tools provide information that strengthens the understanding of the potential hazards of pesticides, exposure scenarios and methods for assessing exposure, exposure-response characterisation and risk characterisation. Although systematic reviews

are also considered a potential tool for answering toxicological questions, their methodology would need to be adapted to the different lines of evidence.

Study evaluation should be performed within a best evidence synthesis framework as it provides an indication on the nature of the potential biases each specific study may have and an assessment of overall confidence in the epidemiological database. This Opinion reports the study quality parameters to be evaluated in single epidemiological studies and the associated weight (low, medium and high) for each parameter. Three basic categories are proposed as a first tier to organise human data with respect to risk of bias and quality: (a) low risk of bias and high/medium reliability; (b) medium risk of bias and medium reliability; (c) high risk of bias and low reliability because of serious methodological limitations or flaws that reduce the validity of results or make them largely uninterpretable for a potential causal association. These categories are intended to parallel the reliability and relevance rating of each stream of evidence according to the EFSA peer review of active substances: acceptable, supplementary and unacceptable. Risk assessment should not be based on results of epidemiological studies that do not meet well-defined data quality standards in order to meet the 'recognised standards' mentioned in the Regulation (EU) No 1107/2009.

Epidemiological studies provide complementary data that can be integrated together with data from *in vivo* laboratory animal studies, mechanistic *in vitro* models and ultimately *in silico* technology for pesticide risk assessment (ToR 4). The combination of all these lines of evidence can contribute to a Weight-of-Evidence (WoE) analysis in the characterisation of human health risks with the aim of improving decision-making. Although the different sets of data can be complementary and confirmatory, and thus serve to strengthen the confidence of one line of evidence on another, they may individually be insufficient and pose challenges for characterising properly human health risks. Hence, all four lines of evidence (epidemiology, animal, *in vitro*, *in silico*) make a powerful combination, particularly for chronic health effects of pesticides, which may take decades to be clinically manifested in an exposed human population.

The first consideration is how well the health outcome under consideration is covered by existing toxicological and epidemiological studies on pesticides. When both types of studies are available for a given outcome/endpoint, both should be assessed for strengths and weaknesses before being used for risk assessment. Once the reliability of available human evidence (observational epidemiology and vigilance data), experimental evidence (animal and *in vitro* data) and non-testing data (*in silico* studies) has been evaluated, the next step involves weighting these sources of data. This opinion proposed an integrated approach where all lines of evidence are considered in an overall WoE framework to better support the risk assessment. This framework relies on a number of principles highlighting when one line should take precedence over another. The concordance or discordance between human and experimental data should be assessed in order to determine which data set should be given more weight, regardless of whether the data comes from human or experimental studies. The more challenging situation is when study results are not concordant. In such cases, the reasons for the difference should be considered and efforts should be made to develop a better understanding of the biological basis for the contradiction.

Human data on pesticides can help verify the validity of estimations made based on extrapolation from the full toxicological database regarding target organs, dose–response relationships and the reversibility of toxic effects, and to provide reassurance on the extrapolation process without direct effects on the definition of reference values. Thus, pesticide epidemiological data can form part of the overall WoE of available data using modified Bradford Hill criteria as an organisational tool to increase the likelihood of an underlying causal relationship.

## 1. Introduction

# **1.1.** Regulatory data requirements regarding human health in pesticide risk assessment

Regulatory authorities in developed countries conduct a formal human risk assessment for each registered pesticide based on mandated toxicological studies, done according to specific study protocols, and estimates of likely human exposure.

In the European Union (EU), the procedure for the placing of plant protection products (PPP) on the market is laid down by Commission Regulation No 1107/2009<sup>2</sup>. Commission Regulations No 283/2013<sup>3</sup> and 284/2013<sup>4</sup> set the data requirements for the evaluation and re-evaluation of active substances and their formulations.

The data requirements regarding mammalian toxicity of the active substance are described in part A of Commission Regulation (EU) No 283/2013 for chemical active substances and in part B for microorganisms including viruses. With regard to the requirements for pesticide active substances, reference to the use of human data may be found in different chapters of Section 5 related to different end-points. For instance, data on toxicokinetics and metabolism that include *in vitro* metabolism studies on human material (microsomes or intact cell systems) belong to Chapter 5.1 that deals with studies of absorption, distribution, metabolism and excretion in mammals; *in vitro* genotoxicity studies performed on human material are described in Chapter 5.4 on genotoxicity testing and specific studies such as acetylcholinesterase inhibition in human volunteers are found in Chapter 5.7 on neurotoxicity studies. Chapter 5.8 refers to supplementary studies on the active substance, and some specific studies, such as pharmacological or immunological investigations.

Although the process of pesticide evaluation is mainly based on experimental studies, human data could add relevant information to that process. The requirements relating to human data are mainly found in Chapter 5.9 'Medical data' of Regulation (EU) No 283/2013. It includes medical reports following accidental, occupational exposure or incidents of intentional self-poisoning as well as monitoring studies such as on surveillance of manufacturing plant personnel and others. The information may be generated and reported through official reports from national poison control centres as well as epidemiological studies published in the open literature. The Regulation requires that 'relevant' information on the effects of human exposure, where available, shall be used to confirm the validity of extrapolations regarding exposure and conclusions with respect to target organs, dose–response relationships, and the reversibility of adverse effects.

Regulation (EU) No 1107/2009 equally states that, 'where available, and supported with data on levels and duration of exposure, and conducted in accordance with recognised standards, epidemiological studies are of particular value and must be submitted'. However, it is clear that there is no obligation for the petitioners to conduct epidemiological studies specific for the active substance undergoing the approval or renewal process. Rather, according to Regulation (EC) No 1107/2009, applicants submitting dossiers for approval of active substances shall provide 'scientific peer-reviewed public available literature [...]. This should be on the active substance and its relevant metabolites dealing with side-effects on health [...] and published within the last ten years before the date of submission of the dossier'.

In particular, epidemiological studies on pesticides should be retrieved from the literature according to the EFSA Guidance entitled 'Submission of scientific-peer reviewed open literature for the approval of pesticide active substances under Regulation (EC) No 1107/2009' (EFSA, 2011a), which follows the principles of the Guidance 'Application of systematic review methodology to food and feed safety assessments to support decision-making' (EFSA, 2010a). As indicated in the EFSA Guidance, 'the process of identifying and selecting scientific peer-reviewed open literature for active substances, their metabolites, or plant protection products' is based on a literature review which is systematic in the approach.

The submission of epidemiological studies and more generally of human data by the applicants in Europe has especially previously sometimes been incomplete and/or has not been performed in

<sup>&</sup>lt;sup>2</sup> Regulation (EC) No 1107/2009 of the European Parliament and of the Council of 21 October 2009 concerning the placing of plant protection products on the market and repealing Council Directives 79/117/EEC and 91/414/EEC. OJ L 309, 24.11.2009, p. 1–50.

<sup>&</sup>lt;sup>3</sup> Commission Regulation (EU) No 283/2013, of 1 March 2013, setting out the data requirements for active substances, in accordance with Regulation (EC) No 1107/2009 of the European Parliament of the Council concerning the placing of plant protection products on the market. OJ L 93, 3.4.2013, p. 1–84.

<sup>&</sup>lt;sup>4</sup> Commission Regulation (EU) No 284/2013 of 1 March 2013 setting out the data requirements for plant protection products, in accordance with Regulation (EC) No 1107/2009 of the European Parliament and of the Council concerning the placing of plant protection products on the market. OJ L 93, 3.4.2013, p. 85–152.

compliance with current EFSA Guidance (EFSA, 2011a). This is probably owing to the fact that a mandatory requirement to perform an (epidemiological) literature search according to specific EFSA Guidance is relatively recent, e.g. introduced for AIR-3 substances (Regulation AIR-3: Reg. (EU) No 844/2012; Guidance Document SANCO/2012/11251 – rev.4).

The integration of epidemiological data with toxicological findings in the peer review process of pesticides in the EU should be encouraged but is still lacking. A recent and controversial example is the one related to the evaluation of glyphosate in which significant efforts were made to include epidemiological studies in the risk assessment, but the conclusion was that these studies provided very limited evidence of an association between glyphosate and health outcomes.

In the case of the peer review of 2,4-D, most of epidemiological data were not used in the risk assessment because it was critical to know the impurity profile of the active substance and this information was not available in the publications (as happens frequently in epidemiological studies). In conclusion, within the European regulatory system there is no example of a pesticide active substance approval being influenced by epidemiological data.

Now that a literature search including epidemiological studies is mandatory and guidance is in place (EFSA, 2011a), a more consistent approach can facilitate risk assessment. However, no framework has been established on how to assess such epidemiological information in the regulatory process. In particular, none of the classical criteria used for the evaluation of these studies is included in the current regulatory framework (e.g. study design, use of odd ratios and relative risks, potential confounders, multiple comparisons, assessment of causality). It follows that specific criteria or guidance for the appropriate use of epidemiological findings in the process of writing and peer reviewing Draft Assessment Reports (DARs) or Renewal Assessment Reports (RAR) is warranted. The EFSA Stakeholder Workshop (EFSA, 2015a) anticipated that the availability of more robust and methodologically sound studies presenting accurate information on exposure would bolster the regulation of pesticides in the EU.

Another potential challenge is synchronisation between the process of renewal of active substances and the output of epidemiological studies. Indeed, the planning, conduct, and analysis of epidemiological studies often require a substantial amount of time, especially where interpretation of data is complex.

## **1.2.** Background and Terms of Reference as provided by the requestor

In 2013, the European Food Safety Authority (EFSA) published an External scientific report 'Literature review on epidemiological studies linking exposure to pesticides and health effects' carried out by the University of Ioannina Medical School (Ntzani et al., 2013). The report is based on a systematic review of epidemiological studies published between 2006 and 2012 and summarises the association between pesticide exposure and any health outcome examined (23 major categories of human health outcomes). In particular, a statistically significant association was observed through fixed and random effect meta-analyses between pesticide exposure and the following health outcomes: liver cancer, breast cancer, stomach cancer, amyotrophic lateral sclerosis, asthma, type II diabetes, childhood leukaemia and Parkinson's disease.

Despite the large number of research articles and analyses (> 6,000) available, the authors of the report could not draw any firm conclusions for the majority of the health outcomes. This observation is in line with previous studies assessing the association between the use of pesticides and the occurrence of human health adverse effects which all acknowledge that such epidemiological studies suffer from a number of limitations and large heterogeneity of data. The authors especially noted that broad pesticides definitions in the epidemiological studies limited the value of the results of meta-analyses. Also, the scope of the report did not allow the in-depth associations between pesticide exposure and specific health outcomes. Nonetheless, the report highlights a number of health outcomes where further research is needed to draw firmer conclusions regarding their possible association with pesticide exposures.

Nevertheless, the outcomes of the External scientific report are in line with other similar studies published in Europe,<sup>5,6</sup> and raise a number of questions and concerns, with regard to pesticide exposure and the associations with human health outcomes. Furthermore, the results of the report

<sup>&</sup>lt;sup>5</sup> France: INSERM report 2013: Pesticides – effets sur la santé.

<sup>&</sup>lt;sup>6</sup> UK: COT report 2011: Statement on a systematic review of the epidemiological literature on para-occupational exposure to pesticides and health outcomes other than cancer, and COT report 2006: Joint Statement on Royal Commission on Environmental Pollution report on crop spraying and the health of residents and bystanders.

open the way for discussion on how to integrate results from epidemiological studies into pesticide risk assessments. This is particularly important for the peer-review team at EFSA dealing with the evaluation of approval of plant protection products for which the peer-review needs to evaluate epidemiological findings according to EU Regulation No 283/2013. The regulation states that applicants must submit 'relevant' epidemiological studies, where available.

For the Scientific Opinion, the PPR Panel will discuss the associations between pesticide exposure and human health effects observed in the External scientific report (Ntzani et al., 2013) and how these findings could be interpreted in a regulatory pesticide risk assessment context. Hence, the PPR Panel will systematically assess the epidemiological studies collected in the report by addressing major data gaps and limitations of the studies and provide related recommendations.

The PPR Panel will specifically:

- collect and review all sources of gaps and limitations, based on (but not necessarily limited to) those identified in the External scientific report in regard to the quality and relevance of the available epidemiological studies.
- 2) based on the gaps and limitations identified in point 1, propose potential refinements for future epidemiological studies to increase the quality, relevance and reliability of the findings and how they may impact pesticide risk assessment. This may include study design, exposure assessment, data quality and access, diagnostic classification of health outcomes, and statistical analysis.
- 3) identify areas in which information and/or criteria are insufficient or lacking and propose recommendations for how to conduct pesticide epidemiological studies in order to improve and optimise the application in risk assessment. These recommendations should include harmonisation of exposure assessment (including use of biomonitoring data), vulnerable population subgroups and/or health outcomes of interest (at biochemical, functional, morphological and clinical level) based on the gaps and limitations identified in point 1.
- 4) discuss how to make appropriate use of epidemiological findings in risk assessment of pesticides during the peer review process of draft assessment reports, e.g. weight-ofevidence (WoE) as well as integrating the epidemiological information with data from experimental toxicology, adverse outcome pathways (AOP), mechanism of actions, etc.

The PRAS Unit will consult the Scientific Committee on the consensual approach to EFSA's overarching scientific areas,<sup>7</sup> including the integration of epidemiological studies in risk assessment.

## **1.3.** Interpretation of the Terms of Reference

In the Terms of Reference (ToR), EFSA requested the PPR Panel to write a scientific Opinion on the follow up of the results from the External Scientific Report on a systematic review of epidemiological studies published between 2006 and 2012 linking exposure to pesticides and human health effects (Ntzani et al., 2013). According to EU Regulation No 283/2013, the integration of epidemiological data into pesticide risk assessment is important for the peer review process of DAR and RAR of active substances for EU approval and their intended use as plant protection products.

In its interpretation of the terms of reference, the PPR Panel will then develop a Scientific Opinion to address the methodological limitations identified in epidemiological studies on pesticides and to make recommendations to the sponsors of such studies on how to improve them in order to facilitate their use for regulatory pesticide risk assessment, particularly for substances in the post-approval period. The PPR Panel notes that experimental toxicology studies also present limitations related to their methodology and quality of reporting; however, the assessment of these limitations is beyond the ToR of this Opinion.

This Scientific Opinion is intended to assist the peer review process during the renewal of pesticides under Regulation 1107/2009 where the evaluation of epidemiological studies, along with clinical cases and poisoning incidents following any kind of human exposure, if available, represent a data requirement. Epidemiological data concerning exposures to pesticides in Europe will not be available before first approval of an active substance (with the exception of incidents produced during the manufacturing process, which are expected to be very unlikely) and so will not be expected to contribute to a DAR. However, there is the possibility that earlier prior approval has been granted for use of an active substance in another jurisdiction and epidemiological data from that area may be considered relevant. Regulation (EC) No 1107/2009 requires a search of the scientific peer-reviewed

<sup>&</sup>lt;sup>7</sup> According to article 28 of Regulation (EC) No 178/2002.

open literature, where it is expected to retrieve existing epidemiological studies. It is therefore recognised that epidemiological studies are more suitable for the renewal process of active substances, also in compliance with the provision of the EC regulation 1141/2010 indicating that 'The dossiers submitted for renewal should include new data relevant to the active substance and new risk assessments to reflect any changes in data requirements and any changes in scientific or technical knowledge since the active substance was first included in Annex I to Directive 91/414/EEC'.

The PPR Panel will specifically address the following topics:

- 1) Review inherent weaknesses affecting the quality of epidemiological studies (including gaps and limitations of the available pesticide epidemiological studies) and their relevance in the context of regulatory pesticide risk assessment. How can these weaknesses be addressed?
- 2) What are potential contributions of epidemiological studies that complement classical toxicological studies conducted in laboratory animal species in the area of pesticide risk assessment?
- 3) Discuss and propose a methodological approach specific for pesticide active substances on how to make appropriate use of epidemiological studies, focusing on how to improve the gaps and limitations identified.
- 4) Propose refinements to practice and recommendations for better use of the available epidemiological evidence for risk assessment purposes. Discuss and propose a methodology for the integration of epidemiological information with data from experimental toxicology.

This Scientific Opinion, particularly Section 2–4, is not intended to address the bases of epidemiology as a science. Those readers willing to deepen into specific aspects of this science are encouraged to read general textbook of epidemiology (e.g. Rothman et al., 2008).

It should be taken into account that this Opinion is focussed only on pesticide epidemiology studies in the EU regulatory context and not from a general scientific perspective. Therefore, the actual limitations and weaknesses of experimental toxicology studies will not be addressed herein.

## **1.4.** Additional information

In order to fully address topics 1–4 above (Section 1.3), attention has been paid to a number of relevant reviews of epidemiological studies and the experience of other National and International bodies with knowledge of epidemiology in general and in applying epidemiology to pesticide risk assessment specifically. Detailed attention has been given to these studies in Annex A and drawn from the experience of the authors that have contributed constructively to understanding in this area. Also Annex A records published information that has been criticised for its lack of rigour showing how unhelpful some published studies may be. The lessons learned from such good (and less-good) practice have been incorporated into the main text by cross-referring to Annex A. In this way, this Scientific Opinion has the aim of clearly distilling and effectively communicating the arguments in the main text without overwhelming the reader with all the supporting data which is nevertheless accessible.

In addition, Annex B contains a summary of the main findings of a project that EFSA outsourced in 2015 to further investigate the role of human biological monitoring (HBM) in occupational health and safety strategies as a tool for refined exposure assessment in epidemiological studies and to contribute to the evaluation of potential health risks from occupational exposure to pesticides (Bevan et al., 2017).

## 2. General framework of epidemiological studies on pesticides

This section introduces the basic elements of epidemiological studies on pesticides and contrasts them with other types of studies. For more details general textbook on epidemiology are recommended (Rothman et al., 2008; Thomas, 2009).

## 2.1. Study design

Epidemiology studies the distribution and determinants of health outcomes in human or other target species populations, to ascertain how, when and where diseases occur. This can be done through observational studies and intervention studies (i.e. clinical trials),<sup>8</sup> which compare study

<sup>&</sup>lt;sup>8</sup> In this opinion, 'human data' includes observational studies, also called epidemiological studies, where the researcher is observing natural relationships between factors and health outcomes without acting upon study participants. Vigilance data also fall under this concept. In contrast, intervention studies (also referred to as experimental studies) are outside the scope of this Opinion, and their main feature is that the researcher intercedes as part of the study design.

groups subject to differing exposure to a potential risk factor. Both types of studies are carried out in a natural setting, which is a less controlled environment than laboratories.

Information on cases of disease occurring in a natural setting can also be systematically recorded in the form of case reports or case series of exposed individuals only. Although case series/reports do not compare study groups according to differing exposure, they may provide useful information, particularly on acute effects following high exposures, which makes them potentially relevant for hazard identification.

In randomised clinical trials, the exposure of interest is randomly allocated to subjects and, whenever possible, these subjects are blinded to their treatment, thereby eliminating potential bias due to their knowledge about their exposure to a particular treatment. This is why they are called intervention studies. Observational epidemiological studies differ from clinical intervention studies in that the exposure of interest is not randomly assigned to the subjects enrolled and participants are often not blinded to their exposure. This is why they are called observational. As a result, randomised clinical trials rank higher in terms of design as they provide unbiased estimates of average treatment effects.

The lack of random assignment of exposure in observational studies represents a key challenge, as other risk factors that are associated with the occurrence of disease may be unevenly distributed between those exposed and non-exposed. This means that known confounders need to be measured and accounted for. However, there is always the possibility that unknown or unmeasured confounders are left unaccounted for, although unknown confounders cannot be addressed. Furthermore, the fact that study participants are often unaware of their current or past exposure or may not recall these accurately in observational studies (e.g. second-hand smoke, dietary intake or occupational hazards) may result in biased estimates of exposure if it is based on self-report. As an example, it is not unlikely that when cancer cases and controls are asked whether they have previously been exposed to a pesticide the cancer cases may report their exposure differently from controls, even in cases where the past exposures did not differ between the two groups.

Traditionally, designs of observational epidemiological studies are classified as either ecological, cross-sectional, case–control or cohort studies. This approach is based on the quality of exposure assessment and the ability to assess directionality from exposure to outcome. These differences largely determine the quality of the study (Rothman and Greenland, 1998; Pearce, 2012).

- **Ecological studies** are observational studies where either exposure, outcome or both are measured on a group but not at individual level and the correlation between the two is then examined. Most often, exposure is measured on a group level while the use of health registries often allows for extraction of health outcomes on an individual level (cancer, mortality). These studies are often used when direct exposure assessment is difficult to achieve and in cases where large contrast in exposures are needed (comparing levels between different countries or occupations). Given the lack of exposure and/or outcome on an individual level, these studies are useful for hypothesis generation but results generally need to be followed up using more rigorous design in either humans or use of experimental animals.
- In **cross-sectional studies**, exposure and health status are assessed at the same time, and prevalence rates (or incidence over a limited recent time) in groups varying in exposure are compared. In such studies, the temporal relationship between exposure and disease cannot be established since the current exposure may not be the relevant time window that leads to development of the disease. The inclusion of prevalent cases is a major drawback of (most) cross-sectional studies, particularly for chronic long-term diseases. Cross-sectional studies may nevertheless be useful for risk assessment if exposure and effect occur more or less simultaneously or if exposure does not change over time.
- **Case–control studies** examine the association between estimates of past exposures among individuals that already have been diagnosed with the outcome of interest (e.g. cases) to a control group of subjects from the same population without such outcome. In population-based incident case–control studies, cases are obtained from a well-defined population, with controls selected from members of the population who are disease free at the time a case is incident. The advantages of case–control studies are that they require less sample sizes, time and resources compared to prospective studies and often they are the only viable option when studying rare outcomes such as some types of cancer. In case–control studies, past exposure is most often not assessed based on 'direct' measurement but rather through less certain measurements such as a recall captured through interviewer or self-administered

questionnaires or proxies such as job descriptions titles or task histories. Although case–control studies may allow for proper exposure assessment, these studies are prone to recall-bias when estimating exposure. Other challenges include the selection of appropriate controls; as well as the need for appropriate confounder control.

In **cohort studies**, the population under investigation consists of individuals who are at risk of developing a specific disease or health outcome at some point in the future. At baseline and at later follow-ups (prospective cohort studies) relevant exposures, confounding factors and health outcomes are assessed. After an appropriate follow-up period, the frequency of occurrence of the disease is compared among those differently exposed to the previously assessed risk factor of interest. Cohort studies are therefore by design prospective as the assessment of exposure to the risk factor and covariates of interest are measured before the health outcome has occurred. Thus, they can provide better evidence for causal associations compared to the other designs mentioned above. In some cases, cohort studies may be based on estimates of past exposure. Such retrospective exposure assessment is less precise than direct measure and prone to recall bias. As a result, the quality of evidence from cohort studies varies according to the actual method used to assess exposure and the level of detail by which information on covariates were collected. Cohort studies are particularly useful for the study of relatively common outcomes. If sufficiently powered in terms of size, they can also be used to appropriately address relatively rare exposures and health outcomes. Prospective cohort studies are also essential to study different critical exposure windows. An example of this is longitudinal birth cohorts that follow children at regular intervals until adult age. Cohort studies may require a long observation period when outcomes have a long latency prior to onset of disease. Thus, such studies are both complex and expensive to conduct and are prone to loss of follow-up.

## **2.2.** Population and sample size

A key strength of epidemiological studies is that they study diseases in the very population about which conclusions are to be drawn, rather than a proxy species. However, only rarely will it be possible to study the whole population. Instead, a sample will be drawn from the reference population for the purpose of the study. As a result, the observed effect size in the study population may differ from that in the population if the former does not accurately reflect the latter. However, observations made in a non-representative sample may still be valid within that sample but care should then be made when extrapolating findings to the general population.

Having decided how to select individuals for the study, it is also necessary to decide how many participants should minimally be enrolled. The sample size of a study should be large enough to warrant sufficient statistical power. The standard power (also called sensitivity) is 80%, which means the ability of a study to detect an effect of a given magnitude when that effect actually exists in the target population; in other words, there is 80% probability of drawing the right conclusion from the results of the analyses and a corresponding probability of 20% or drawing the wrong conclusion and missing a true effect. Power analysis is often used to calculate the minimum sample size required to likely detect an effect of a given size. Small samples are likely to constitute an unrepresentative sample. The statistical power is also closely related to risk inflation, which needs to be given special attention when interpreting statistically significant results from small or underpowered studies (see Annex D).

Epidemiological studies, like toxicological studies in laboratory animals, are often designed to examine multiple endpoints unlike clinical trials that are designed and conducted to test one single hypothesis, e.g. efficacy of a medical treatment. To put this in context, for laboratory animal toxicology test protocols, OECD guidance for pesticides may prescribe a minimum number of animals to be enrolled in each treatment group. This does not guarantee adequate power for any of the multitude of other endpoints being tested in the same study. It is thus important to appropriately consider the power of a study when conducting both epidemiology and laboratory studies.

## 2.3. Exposure

The quality of the exposure measurements influences the ability of a study to correctly ascertain the causal relationship between the (dose of) exposure and a given adverse health outcome.

In toxicological studies in laboratory animals, the 'treatment regime' i.e. dose, frequency, duration and route are well defined beforehand and its implementation can be verified. This often allows

expression of exposure in terms of external dose administered daily via oral route for example in a 90day study, by multiplying the amount of feed ingested every day by a study animal with the intended (and verified) concentration of the chemical present in the feed. Also, in the future, the internal exposure has to be determined in the pivotal studies.

In the case of pesticides, estimating exposure in a human observational setting is difficult as the dose, its frequency and duration over time and the route of exposure are not controlled and not even well known.

Measuring the intensity, frequency and duration of exposure is often necessary for investigating meaningful associations. Exposure may involve a high dose over a relatively short period of time, or a low-level prolonged dose over a period from weeks to years. While the effects of acute, high-dose pesticide exposure may appear within hours or days, the effects of chronic, low-dose exposures may not appear until years later. Also, a disease may require a minimal level of exposure but increase in probability with longer exposure.

There may be differences in absorption and metabolism via different routes (dermal, inhalation and oral). While dermal or inhalation are often the routes exposure occurs in occupational settings, ingestion (food, water) may be the major route of pesticide exposure for the general population. Pharmacokinetic differences among individuals may result in differing systemic or tissue/organ doses even where the absorbed external doses may appear similar.

## 2.4. Health outcomes

The term health outcome refers to a disease state, event, behaviour or condition associated with health that is under investigation. Health outcomes are those clinical events (usually represented as diagnosis codes, i.e. International Classification of Diseases (ICD) 10) or outcomes (i.e. death) that are the focus of the research. Use of health outcomes requires a well-defined case definition, a system to report and record the cases and a measure to express the frequency of these events.

A well-defined case definition is necessary to ensure that cases are consistently diagnosed, regardless of where, when and by whom they were identified and thus avoid misclassification. A case definition involves a standard set of criteria, which can be a combination of clinical symptoms/signs, sometimes supplemented by confirmatory diagnostic tests with their known sensitivity and specificity. The sensitivity of the whole testing procedure (i.e. the probability that a person with an adverse health condition is truly diagnosed) must be known to estimate the true prevalence or incidence.

The clinical criteria may also involve other characteristics (e.g. age, occupation) that are associated with increased disease risk. At the same time, appropriately measured and defined phenotypes or hard clinical outcomes add validity to the results.

Disease registries contain clinical information of patients on diagnosis, treatment and outcome. These registries periodically update patient information and can thus provide useful data for epidemiological research. Mortality, cancer and other nation-wide health registries generally meet the case-definition requirements and provide (almost) exhaustive data on the incident cases within a population. These health outcomes are recorded and classified in national health statistics databases, which depend on accepted diagnostic criteria that are evolving and differ from one authority to another. This may confound attempts to pool data usefully for societal benefit. Registry data present many opportunities for meaningful analysis, but the degree of data completeness and validity may challenge making appropriate inferences. Also, changes in coding conventions over the lifetime of the database may have an impact on retrospective database research.

Although the disease status is typically expressed as a dichotomous variable, it may also be measured as an ordinal variable (e.g. severe, moderate, mild or no disease) or as a quantitative variable for example by measuring molecular biomarkers of toxic response in target organs or physiological measures such as blood pressure or serum concentration of lipids or specific proteins.

The completeness of the data capture and its consistency are key contributors to the reliability of the study. Harmonisation of diagnostic criteria, data storage and utility would bring benefits to the quality of epidemiological studies.

A surrogate endpoint is used as substitute for a well-defined disease endpoint, an outcome measure, commonly a laboratory measurement (biomarker of response). These measures are considered to be on the causal pathway for the clinical outcome. In contrast to overt clinical disease, such biological markers of health may allow to detect subtle, subclinical toxicodynamic processes. For such outcomes, detailed analytical protocols for quantification should be specified to enable comparison or replication across laboratories. The use of AOPs can highlight differences in case definitions.

Although surrogate outcomes may offer additional information, the suitability of the surrogate outcome examined needs to be carefully assessed. In particular, the validity of surrogate outcomes may represent a major limitation to their use (la Cour et al., 2010). Surrogate endpoints that have not been validated should thus be avoided.

When the health status is captured in other ways, such as from self-completed questionnaires or telephone interviews, from local records (medical or administrative databases) or through clinical examination only, these should be validated to demonstrate that they reflect the underlying case definition.

## 2.5. Statistical analysis and reporting

Reporting in detail materials, methods and results, and conducting appropriate statistical analyses are key steps to ensure quality of epidemiological studies. Regarding statistical analysis, one can distinguish between descriptive statistics and modelling of exposure–health outcome relationship.

## **2.5.1.** Descriptive statistics

Descriptive statistics aim to summarise the important characteristics of the study groups, such as exposure measures, health outcomes, possible confounding factors and other relevant factors. The descriptive statistics often include frequency tables and measures of central tendency (e.g. means and medians) and dispersion (e.g. variance and interquartile range) of the parameters or variables studied.

## 2.5.2. Modelling exposure-health outcome relationship

Modelling of the exposure–health relationship aims to assess the possible relationship between the exposure and the health outcome under consideration. In particular, it can evaluate how this relationship may depend on dose and mode of exposure and other possible intervening factors.

Statistical tests determine the probability that the observations found in scientific studies may have occurred as a result of chance. This is done by summarising the results from individual observations and evaluating whether these summary estimates differ significantly between, e.g. exposed and non-exposed groups, after taking into consideration random errors in the data.

For dichotomous outcomes, the statistical analysis compares study groups by assessing whether there is a difference in disease frequency between the exposed and control populations. This is usually done using a relative measure. The relative risk (RR) in cohort studies estimates the relative magnitude of an association between exposure and disease comparing those that are exposed (or those that have a higher exposure level) with those that are not exposed (or those that have a lower exposure level). It indicates the likelihood of developing the disease in the exposed group relative to those who are not (or less) exposed. An odds ratio (OR), generally an outcome measure in case– control and cross-sectional studies, represents the ratio of the odds of exposure between cases and controls (or diseased and non-diseased individuals in a cross-sectional study) and is often the relative measure used in statistical testing. Different levels or doses of exposure can be compared in order to see if there is a dose–response relationship. For continuous outcome measures, mean or median change in the outcome are often examined across different level of exposure; either through analyses of variance or through other parametric statistics.

While the statistical analysis will show that observed differences are significantly different or not significantly different, both merit careful reflection (Greenland et al., 2016).

**Interpretation of the absence of statistically significant difference.** Failure to reject the null hypothesis does not necessarily mean that no association is present because the study may not have sufficient power to detect it. The power depends on the following factors:

- sample size: with small sample sizes, statistical significance is more difficult to detect, even if true;
- variability in individual response or characteristics, either by chance or by non-random factors: the larger the variability, the more difficult to demonstrate statistical significance;
- effect size or the magnitude of the observed difference between groups: the smaller the size of the effect, the more difficult to demonstrate statistical significance.

**Interpretation of statistically significant difference.** Statistical significance means that the observed difference is not likely due to chance alone. However, such a result still merits careful consideration.

- Biological relevance. Rejection of the null hypothesis does not necessarily mean that the association is biologically meaningful, nor does it mean that the relationship is causal (Skelly, 2011). The key issue is whether the magnitude of the observed difference (or 'effect size') is large enough to be considered biologically relevant. Thus, an association that is statistically significant may be or may be not biologically relevant and vice versa. While epidemiological results that are statistically significant may be dismissed as 'not biologically relevant', non-statistically significant results are seldom determined to be 'biologically relevant'. Increasingly, researchers and regulators are looking beyond statistical significance for evidence of a 'minimal biologically important difference' for commonly used outcomes measures. Factoring biological significance relevance into study design and power calculations, and reporting results in terms of biological as well as statistical significance will become increasingly important for risk assessment (Skelly, 2011). This is the subject of an EFSA Scientific Committee guidance document outlining generic issues and criteria to be taken into account when considering biological relevance (EFSA Scientific Committee, 2017a); also a framework is being developed to consider biological relevance at three main stages related to the process of dealing with evidence (EFSA Scientific Committee, 2017b).
- <u>Random error</u>. Evaluation of statistical precision involves consideration of random error within the study. Random error is the part of the study that cannot be predicted because that part is attributable to chance. Statistical tests determine the probability that the observations found in scientific studies have occurred as a result of chance. In general, as the number of study participants increases, precision (often expressed as standard error) of the estimate of central tendency (e.g. the mean) is increased and the ability to detect a statistically significant difference, if there is a real difference between study groups, i.e. the study's power, is enhanced. However, there is always a possibility, at least in theory, that the results observed are due to chance only and that no true differences exist between the compared groups (Skelly, 2011). Very often this value is set at 5% (significance level).
- <u>Multiple testing</u>. As mentioned previously when discussing sample size, modelling of the exposure-health relationship is in principle hypothesis-driven, i.e. it is to be stated beforehand in the study objectives what will be tested. However, in reality, epidemiological studies (and toxicological studies in laboratory animals) often explore a number of different health outcomes in relation to the same exposure. If many statistical tests are conducted, some 5% of them will be statistically significant by chance. Such testing of multiple endpoints (hypotheses) increases the risk of false positive results and this can be controlled for by use of Bonferroni, Sidak or Benjamini–Hochberg corrections or other suitable methods. But this is often omitted. Thus, when researchers carry out many statistical tests on the same set of data, they can conclude that there are real differences where in fact there are none. Therefore, it is important to consider large number of statistical significance and biological significance notes that the assumptions derived from a statistical analysis should be related to the study design (EFSA, 2011b).
- Effect size magnification. An additional source of bias, albeit one that is lesser known, is that which may result from small sample sizes and the consequent low statistical power. This lesser known type of bias is 'effect size magnification' which can result from low powered studies. While it is generally widely known that small, low-powered studies can result in false negatives since the study power is inadequate to reliably detect a meaningful effect size, it is less well known that these studies can result in inflation of effect sizes if those estimated effects pass a statistical threshold (e.g. the common p < 0.05 threshold used to judge statistical significance). This effect –also known as effect size magnification is a phenomenon by which a 'discovered' association (i.e. one that has passed a given threshold of statistical significance) from a study with suboptimal power to make that discovery will produce an observed effect size that is artificially and systematically inflated. This is because smaller, low-powered studies are more likely to be affected by random variation among individuals than larger ones. Mathematically, conditional on a result passing some predetermined threshold of statistical significance, the estimated effect size is a biased estimate of the true effect size, with the magnitude of this bias inversely related to power of the study.</p>

As an example, if a trial were run thousands of times, there will be a broad distribution of observed effect sizes, with smaller trials systematically producing a wider variation in observed effect sizes than larger trials, but the median of these estimated effect sizes is close to the true

effect size. However, in a small and low powered study, only a small proportion of observed effects will pass any given (high) statistical threshold of significance and these will be only the ones with the greatest of effect sizes. Thus, when these smaller, low powered studies with greater random variation do indeed find a significance-triggered association as a result of passing a given statistical threshold, they are more likely to overestimate the size of that effect. What this means is that research findings of small and significant studies are biased in favour of finding inflated effects. In general, the lower the background (or control or natural) rate, the lower the effect size of interest, and the lower the power of the study, the greater the tendency towards and magnitude of inflated effect sizes.

It is important to note, however, that this phenomenon is only present when a 'pre-screening' for statistical significance is done. The bottom line is that if it is desired to estimate a given quantity such as an OR or RR, 'pre-screening' a series of effect sizes for statistical significance will result in an effect size that is systematically biased away from the null (larger than the true effect size). To the extent that regulators, decision-makers, and others are acting in this way – looking for statistically significant results in what might be considered a sea of comparisons and then using those that cross a given threshold of statistical significance to evaluate and judge the magnitude of the effect – will likely result in an exaggerated sense of the magnitude of the hypothesised association. Additional details and several effect size simulations are provided in Annex D of this document.

**Confounding** occurs when the relationship between the exposure and disease is to some extent attributable to the effect of another risk factor, i.e. the confounder. There are several traditionally recognised requirements for a risk factor to actually act as a confounder as described by McNamee (2003) and illustrated below. The factor must:

- be a cause of the disease, or a surrogate measure of the cause, in unexposed people; factors satisfying this condition are called 'risk factors';
- be correlated, positively or negatively, with exposure in the study populations independently from the presence of the disease. If the study population is classified into exposed and unexposed groups, this means that the factor has a different distribution (prevalence) in the two groups;
- not be an intermediate step in the causal pathway between the exposure and the disease

Confounding can result in an over- or underestimation of the relationship between exposure and disease and occurs because the effects of the two risk factors have not been separated or 'disentangled'. In fact, if strong enough, confounding can also reverse an apparent association. For instance, because agriculture exposures cover many different exposure categories, farmers are likely to be more highly exposed than the general population to a wide array of risk factors, including biological agents (soil organisms, livestock, farm animals), pollen, dust, sunlight and ozone amongst others, which may act as potential confounding factors.

A number of procedures are available for controlling confounding, both in the design phase of the study or in the analytical phase. For large studies, control in the design phase is often preferable. In the design phase, the epidemiological researcher can limit the study population to individuals that share a characteristic which the researcher wishes to control. This is known as 'restriction' and in fact removes the potential effect of confounding caused by the characteristic which is now eliminated. A second method in the design phase through which the researcher can control confounding is by 'matching'. Here, the researcher matches individuals based on the confounding variable which ensures that this is evenly distributed between the two comparison groups.

Beyond the design phase, at the analysis stage, control for confounding can be done by means of either stratification or statistical modelling. One means of control is by stratification in which the association is measured separately, under each of the confounding variables (e.g. males and females, ethnicity or age group). The separate estimates can be 'brought together' statistically – when appropriate – to produce a common OR, RR or other effect size measure by weighting the estimates measured in each stratum (e.g. using Mantel–Haenszel approaches). This can be done at the cost of reducing the sample size for the analysis. Although relatively easy to perform, there can be difficulties associated with the inability of this stratification to deal with multiple confounders simultaneously. For these situations, control can be achieved through statistical modelling (e.g. multiple logistic regression).

Regardless of the approaches available for control of confounding in the design and analysis phases of the study described above, it is important – prior to any epidemiological studies being initiated in the field – that careful consideration be given to confounders because researchers cannot control for a variable which they have not considered in the design or for which they have not collected data.

Epidemiological studies – published or not – are often criticised for ignoring potential confounders that may possibly either falsely implicate or inappropriately negate a given risk factor. Despite these critiques, rarely is an argument presented on the likely size of the impact of the bias from such possible confounding. It should be emphasised that a confounder must be a relatively strong risk factor for the disease to be strongly associated with the exposure of interest to create a substantial distortion in the risk estimate. It is not sufficient to simply raise the possibility of confounding; one should make a persuasive argument explaining why a risk factor is likely to be a confounder, what its impact might be and how important that impact might be to the interpretation of findings. It is important to consider the magnitude of the association as measured by the RR, OR, risk ratio, regression coefficient, etc. since strong relative risks are unlikely to be due to unmeasured confounding, while weak associations may be due to residual confounding by variables that the investigator did not measure or control in the analysis (US-EPA, 2010b).

Effect modification. Effects of pesticides, and other chemicals, on human health can hardly be expected to be identical across all individuals. For example, the effect that any given active substance might have on adult healthy subjects may not be the same as that it may have on infants, elderly, or pregnant women. Thus, some subsets of the population are more likely to develop a disease when exposed to a chemical because of an increased sensitivity. For this, the term 'vulnerable subpopulation' has been used, which means children, pregnant women, the elderly, individuals with a history of serious illness and other subpopulations identified as being subject to special health risks from exposure to environmental chemicals (i.e. because of genetic polymorphisms of drug-metabolising enzymes, transporters or biological targets). The average effect measures the effect of an exposure averaged over all subpopulations. However, there may be heterogeneity in the strength of an association between various subpopulations. For example, the magnitude of the association between exposure to chemical A and health outcome B may be stronger in children than in healthy adults, and absent in those wearing protective clothing at the time of exposure or in those of different genotype. If heterogeneity is truly present, then any single summary measure of an overall association would be deficient and possibly misleading. The presence of heterogeneity is assessed by testing for the presence of statistically significant interaction between the factor and the effect in the various subpopulations. But, in practice, this requires large sample size.

Investigating the effect in subpopulations defined by relevant factors may advance knowledge on the effect on human health of the risk factor of interest.

## 2.6. Study validity

When either a statistically significant association or no such significant association between, for example, pesticide exposures and a health outcome is observed, there is a need to also evaluate the validity of a research study, assessing factors that might distort the true association and/or influence its interpretation. These imperfections relate to systematic sources of error that result in a (systematically) incorrect estimate of the association between exposure and disease. In addition, the results from a single study takes on increased validity when it is replicated in independent investigations conducted on other populations of individuals at risk of developing the disease.

**Temporal sequence.** Any claim of causation must involve the cause preceding in time the presumed effect. Rothman (2002) considered temporality as the only criterion that is truly causal, such that lack of temporality rules out causality. While the temporal sequence of an epidemiological association implies the necessity for the exposure to precede the outcome (effect) in time, measurement of the exposure is not required to precede measurement of the outcome. This requirement is easier met in prospective study designs (i.e. cohort studies), than when exposure is assessed retrospectively (case–control studies) or assessed at the same time than the outcome (cross-sectional studies). However, also in prospective studies, the time sequence for cause and effect and the temporal direction might be difficult to ascertain if a disease developed slowly and initial forms of disease were difficult to measure (Höfler, 2005).

The generalisability of the result from the population under study to a broader population should also be considered for study validity. While the random error discussed previously is considered a precision problem and is affected by sampling variability, **bias** is considered a validity issue. More

specifically, bias issues generally involve methodological imperfections in study design or study analysis that affect whether the correct population parameter is being estimated. The main types of bias include selection bias, information bias (including recall bias and interviewer/observer bias) and confounding. An additional potential source of bias is effect size magnification, which has already been mentioned.

**Selection bias** concerns a systematic error relating to validity that occurs as a result of the procedures and methods used to select subjects into the study, the way that subjects are lost from the study or otherwise influence continuing study participation.

Typically, such a bias occurs in a case–control study when inclusion (or exclusion) of study subjects on the basis of disease is somehow related to the prior exposure status being studied. One example might be the tendency for initial publicity or media attention to a suspected association between an exposure and a health outcome to result in preferential diagnosis of those that had been exposed compared to those that had not. Selection bias can also occur in cohort studies if the exposed and unexposed groups are not truly comparable as when, for example, those that are lost from the study (loss to follow-up, withdrawn or non-response) are different in status to those who remain. Selection bias can also occur in cross-sectional studies due to selective survival: only those that have survived are included in the study. These types of bias can generally be dealt with by careful design and conduct of a study (see also Sections 4, 6 and 8).

The 'healthy worker effect' (HWE) is a commonly recognised selection bias that illustrates a specific bias that can occur in occupational epidemiology studies: workers tend to be healthier than individuals from the general population overall since they need to be employable in a workforce and can thus often have a more favourable outcome status than a population-based sample obtained from the general population. Such a HWE bias can result in observed associations that are masked or lessened compared to the true effect and thus can lead to the appearance of lower mortality or morbidity rates for workers exposed to chemicals or other deleterious substances.

**Information bias** concerns a systematic error when there are systematic differences in the way information regarding exposure or the health outcome are obtained from the different study groups that result in incorrect or otherwise erroneous information being obtained or measured with respect to one or more covariates being measured in the study. Information bias results in misclassification which in turn leads to incorrect categorisation with respect to either exposure or disease status and thus the potential for bias in any resulting epidemiological effect size measure such as an OR or RR.

Misclassification of exposure status can result from imprecise, inadequate or incorrect measurements; from a subject's incorrect self-report; or from incorrect coding of exposure data.

Misclassification of disease status can, for example, arise from laboratory error, from detection bias, from incorrect or inconsistent coding of the disease status in the database, or from incorrect recall. Recall bias is a type of information bias that concerns a systematic error when the reporting of disease status is different, depending on the exposure status (or vice versa). Interviewer bias is another kind of information bias that occurs where interviewers are aware of the exposure status of individuals and may probe for answers on disease status differentially – whether intended or not – between exposure groups. This can be a particularly pernicious form of misclassification – at least for case–control studies – since a diseased subject may be more likely to recall an exposure that occurred at an earlier time period than a non-diseased subject. This will lead to a bias away from null value (of no relation between exposure and disease) in any effect measure.

Importantly, such misclassifications as described above can be 'differential' or 'non-differential' and these relate to (i) the degree to which a person that is truly exposed (or diseased) is correctly classified as being truly exposed or diseased and (ii) the degree to which an individual who is truly not exposed (or diseased) is correctly classified in that way. The former is known as 'sensitivity' while the latter is referred to as 'specificity' and both of these play a role in determining the existence and possible direction of bias. Differential misclassification means that misclassification has occurred in a way that depends on the values of other variables, while non-differential misclassification refers to misclassifications that do not depend on the value of other variables.

What is important from an epidemiological perspective is that misclassification biases – either differential or non-differential – depend on the sensitivity and specificity of the study's methods used to categorise such exposures and can have a predictable effect on the direction of bias under certain (limited) conditions: this ability to characterise the direction of the bias based on knowledge of the study methods and analyses can be useful to the regulatory decision-maker since it allows the decision maker to determine whether the epidemiological effect sizes being considered (e.g. OR, RR) are likely underestimates or overestimates of the true effect size. While it is commonly assumed by some that

non-differential misclassification bias produces predictable biases towards the null (and thus systematically under-predicts the effect size), this is not necessarily the case. Also, the sometimes common assumption in epidemiology studies that misclassification is non-differential (which is sometimes also paired with the assumption that non-differential misclassification bias is always towards the null) is not always justified (e.g. see Jurek et al., 2005).

When unmeasured confounders are thought to affect the results, researchers should conduct sensitivity analyses to estimate the range of impacts and the resulting range of adjusted effect measures (US-EPA, 2010b). Quantitative sensitivity (or bias) analyses are, however, not typically conducted in many epidemiological studies, with most researchers instead describing various potential biases qualitatively in the form of a narrative in the discussion section of a paper.

It is often advisable that the epidemiological investigator performs sensitivity analysis to estimate the impact of biases, such as exposure misclassification or selection bias, by known but unmeasured risk factors or to demonstrate the potential effects that a missing or unaccounted for confounder may have on the observed effect sizes (see Lash et al., 2009; Gustafson and McCandless, 2010). Sensitivity analyses should be incorporated in the list of criteria for reviewing epidemiological data for risk assessment purposes.

# 3. Key limitations of the available epidemiological studies on pesticides

3.1. Limitations identified by the authors of the EFSA external scientific report

The EFSA External scientific report (Ntzani et al., 2013; summarised in Annex A) identified a plethora of epidemiological studies which investigate diverse health outcomes. In an effort to systematically appraise the epidemiological evidence, a number of methodological limitations were highlighted. In the presence of these limitations, robust conclusions could not be drawn, but outcomes for which supportive evidence from epidemiology existed were highlighted for future investigation. The main limitations identified included (Ntzani et al., 2013):

- Lack of prospective studies and frequent use of study designs that are prone to bias (casecontrol and cross-sectional studies). In addition, many of the studies assessed appeared to be insufficiently powered.
- Lack of detailed exposure assessment, at least compared to many other fields within epidemiology. The information on specific pesticide exposure and co-exposures was often lacking, and appropriate biomarkers were seldom used. Instead, many studies relied on broad definition of exposure assessed through questionnaires (often not validated).
- Deficiencies in outcome assessment (broad outcome definitions and use of self-reported outcomes or surrogate outcomes).
- Deficiencies in reporting and analysis (interpretation of effect estimates, confounder control and multiple testing).
- Selective reporting, publication bias and other biases (e.g. conflict of interest).

The observed heterogeneity in the results within each studied outcome was often large. However, heterogeneity is not always a result of biases and may be genuine and consideration of *a priori* defined subgroup analysis and meta-regression should be part of evidence synthesis efforts. Occupational studies, which are of particular importance to pesticide exposure, are also vulnerable to the healthy worker effect, a bias resulting in lower morbidity and mortality rates within the workforce than in the general population. The healthy worker effect tends to decline with increasing duration of employment and length of follow-up.

Studies with sufficient statistical power, detailed definition of pesticide exposure, data for many health outcomes and transparent reporting are rare, apart from the Agricultural Health Study (AHS) and other similarly designed studies. It is important to note that several of these methodological limitations have not been limited to pesticide exposure studies and, most importantly, are not specific in epidemiology and have been observed in other specific fields including in animal studies (Tsilidis et al., 2013).

Given the wide range of pesticides with various definitions found in the EFSA External scientific report, it is difficult to harmonise this information across studies. Although heterogeneity of findings across studies can be as informative as homogeneity, information needs to be harmonised such that replication can be assessed and summary effect sizes be calculated. This does not mean that if there is

genuine heterogeneity the different studies cannot be pooled. Limited conclusions can be made from a single study. Nonetheless, the report highlighted a number of associations between pesticides and health effects that merit further consideration and investigation. Of interest is the fact that a considerable proportion of the published literature focused on pesticides no longer approved for use in the EU and in most developed countries e.g. studies focusing solely on DDT and its metabolites constituted almost 10% of the eligible studies (Ntzani et al., 2013). These may still be appropriate since they may persist as pesticide residues or because they continue to be used in developing countries. Also, the report focused on epidemiological evidence in relation to any health outcome across an approximately 5-year window. Although the report is valuable in describing the field of epidemiological assessment of pesticide–health associations, it is not able to answer specific disease-pesticide guestions thoroughly. A more in-depth analysis of specific disease endpoints associated with pesticides exposure is needed, where this information is available, and studies published earlier than the time window covered by the EFSA External scientific report should be also included.

#### 3.2. Limitations in study designs

For ethical reasons, randomised controlled trials are not allowed to test the safety of low dose pesticide exposure in the EU. Therefore, information on potential adverse health consequences in humans has to be extracted using observational studies.

For diseases with long-latency periods, measurement of exposure at one time point may not accurately reflect the long-term exposure which is needed to develop such diseases. This is particularly important for non-persistent pesticides, whose levels in biological samples are not constant but vary quite often. Thus, those studies that claim an association between a single measurement in urine samples and a long latency outcome should be carefully interpreted.

Among the 795 studies reviewed in the Ntzani report, 38% were case-control studies and 32% cross-sectional studies. As a result, evidence on potential adverse health consequences of pesticide exposure is largely based on studies that lack prospective design at least for outcomes that have long latency periods. For the cross-sectional studies, directionality cannot be assessed and observed associations may often reflect reverse causation (is the disease caused by the exposure, or does the disease influence the exposure?). Although reverse causation is a potential problem of cross-sectional studies in many fields of epidemiology, in pesticide epidemiology, it is less of an issue, because in most situations it is unlikely that a disease will cause exposure to pesticides.

Although case–control studies are frequently used for rare outcomes, such as several cancers, their main limitation is that they are prone to recall bias and they have to rely on retrospective assessment of exposure. However, they can still provide useful information, especially for rare outcomes. It is important to examine whether results from case–control and prospective studies converge. This was, for example, the case amongst studies that were conducted to examine associations between intake of *trans*-fatty acids and cardiovascular disease (EFSA, 2004), where both case–control and prospective studies consistently reported positive associations. The effect estimates between the two study designs were systematically different with prospective studies reporting more modest effect sizes but both study designs reached similar conclusions. As for pesticides, similar values have been observed for the magnitude of association between Parkinson's disease and pesticide exposure irrespective of the study design (reviewed in Hernández et al., 2016).

#### **3.3.** Relevance of study populations

Because the environmentally relevant doses of pesticides to which individuals are exposed are lower than those required to induce observed toxicity in animal models, the associated toxic effects need to be understood in the context of differences of susceptibility of subpopulations. Potentially vulnerable groups are at an increased risk against exposure to low levels of pesticides than healthy individuals, sometimes during sensitive windows of exposure. This is the case of genetic susceptibility, which represents a critical factor for risk assessment that should be accounted for (Gómez-Martín et al., 2015). Genetic susceptibility largely depends on functional genetic polymorphisms affecting toxicokinetics (e.g. genes encoding xenobiotic metabolising enzymes and membrane transporters) and/or toxicodynamics (e.g. different receptor gene polymorphisms). This genetic variability should be considered on the basis of a plausible scientific hypothesis.

While different disorders, particularly neurodegenerative diseases (Parkinson's disease, Alzheimer's disease, amyotrophic lateral sclerosis) have been linked to exposures to environmental factors (e.g.

pesticides), in many instances the genetic architecture of the disorder has not been taken into account. The prevalence of specific gene mutations may reach 5–10% and sometimes over 20% of cases in certain populations (Gibson et al., 2017), so that the links of these diseases to pesticide exposure may be heavily influenced by genetic structure within populations under study. Given the small effect sizes for many of these disorders, the underlying effects of specific genes not accounted for in the study design may modify the disease risk estimates. Hence, associations with pesticide exposure may need to be evaluated in the light of common genetic influences known to be associated with a spectrum of neurodegenerative diseases. However, genetic variation by itself does not predispose people for an increased pesticide exposure.

A subgroup of population of special interest is represented by children, because their metabolism, physiology, diet and exposure patterns to environmental chemicals differ from those of adults and can make them more susceptible to their harmful effects. The window(s) of biologic susceptibility remain unknown for the most part, and would be expected to vary by mechanism. Gender-based susceptibility also merits consideration in case of pesticide-related reproductive toxicity and endocrine disruption. Those subgroups are currently considered during the risk assessment process but may deserve more attention to provide additional protection.

#### **3.4.** Challenges in exposure assessment

The main limitations of epidemiological studies conducted on pesticides derive from uncertainty in exposure assessment. Limitations include the fact that most currently approved pesticides tend to have short elimination half-lives and that their use involves application of various formulations depending on the crop and season. As a result, accurate assessment needs to capture intermittent long-term exposure of these non-persistent chemicals as well as being able to quantify exposure to individual pesticides.

Numerous studies have assessed internal exposure by measuring urinary non-active metabolites common for a large group of pesticides (for example, dialkyl phosphates for organophosphates, 3-phenoxybenzoic acid for pyrethroids or 6-chloronicotinic acid for neonicotinoids). These data should not be utilised to infer any risk because: (a) a fraction of these metabolites might reflect direct exposure through ingestion of preformed metabolites from food and other sources, rather than ingestion of the parent compound and (b) the potency of the different parent pesticides can vary by orders of magnitude. Thereby, HBM data based on those urine metabolites can be unhelpful unless they are paired with other data indicating the actual pesticide exposure.

Ideally exposure should be quantified on an individual level using biomarkers of internal dose. As most available biomarkers reflect short term (few hours or days) exposure and given the cost and difficulty of collecting multiple samples over time, many studies quantify exposure in terms of external dose. Quantitative estimation of external dose needs to account for both frequency and duration of exposure and should preferably be done on an individual but not group level. Often external exposure is quantified using proxy measures such as:

- subject- or relative-reported jobs, job titles, tasks or other lifestyle habits which are being associated with the potential exposure to or actual use of pesticides in general;
- handling of a specific product or set of products and potential exposure to these as documented through existing pesticide records or diaries or estimated from crops grown;
- environmental data: environmental pesticide monitoring, e.g. in water, distance from and/or duration of residence in a particular geographical area considered to be a site of exposure.

In many cases, these proxy measures are recorded with use of questionnaires, which can be either interviewer-administered or based on self-report. However, questionnaire data often rely on individual recall and knowledge and are thus potentially subject to both recall bias and bias introduced by the interviewer or study subjects. These sources of bias can to some extent be quantified if the questionnaires are validated against biomarkers (that is, to what extent do individual questions predict biomarker concentrations in a sub-sample of participants). If the exposure is assessed retrospectively the accuracy of the recall is for obvious reasons more likely to be compromised and impossible to validate. When exposure is based on records, similar difficulties may occur due to, e.g. incomplete or inaccurate records.

In many previous studies, duration of exposure is often used as a surrogate of cumulative exposure, assuming that exposure is uniform and continuous over time (e.g. the employment period) but this assumption must be challenged for pesticides. Although for some chemicals the exposure patterns may be fairly constant, exposures for the large number of pesticides available in the market

will vary with season, by personal protective equipment (PPE) and by work practices, and in many cases, uses are not highly repetitive. At an individual level, exposures can vary on a daily and even hourly basis, and often involve several pesticides. This temporal variability can result in particularly high variation in systemic exposures for pesticides with short biological half-lives and considerable uncertainty in extrapolating single or few measurements to individual exposures over a longer term. Hence, many repeated measurements over time may be required to improve exposure estimates.

### **3.5.** Inappropriate or non-validated surrogates of health outcomes

Self-reported health outcomes are frequently used in epidemiological research because of the difficulty of verifying responses in studies with large samples and limited funds, among other reasons. Although a number of studies have examined agreement between self-reported outcomes and medical records, the lack of verification of such metrics can lead to misclassification, particularly in large population-based studies, which may detract from reliability of the associations found.

Reliance on clinically manifested outcomes can increase the likelihood that individuals who have progressed along the toxicodynamic continuum from exposure to disease but have not yet reached an overt clinical disease state will be misclassified as not having the disease (Nachman et al., 2011). Thereby, delay in onset of clinical symptoms following exposure may cause underreporting where clinical assessment alone is used at an inappropriate point in time.

In the case of carcinogenesis, there are some examples where subclinical outcomes have been assessed as preneoplastic lesions with potential to progress to neoplastic conditions. This is the case of monoclonal gammopathy of undetermined significance (MGUS), which has been associated with pesticide exposure in the AHS (Landgren et al., 2009), as this condition has a 1% average annual risk of progression to malignant multiple myeloma (Zingone and Kuehl, 2011). However, it is difficult to predict if and when an MGUS will progress to multiple myeloma. Since there are studies indicating that pesticide exposure may be associated with the risk of precancerous lesions in animal research, a combined epidemiological analysis of both preneoplastic and neoplastic outcomes may increase the power of such an analysis.

Surrogate outcomes may seem an attractive alternative to clinically relevant outcomes since there may be various surrogates for the same disease and they may occur sooner and/or be easier to assess, thereby shortening the time to diagnosis. A valid surrogate endpoint must, however, be predictive of the causal relationship and accurately predict the outcome of interest. In addition, these surrogates should be relevant to the mode of action of a pesticide such that they should be anchored to established toxicological endpoints to support their predictivity. Although surrogate markers may correlate with an outcome, they may not capture the effect of a factor on the outcome. This may be because the surrogate may not be causally or strongly related to the clinical outcome, but only a concomitant factor, and thus may not be predictive of the clinical outcome. The validity of surrogate outcomes may thus represent a major limitation to their use (la Cour et al., 2010).

However, concerns arise as to whether critical regulatory decisions can be made based on epidemiological studies that did not directly measure the adverse health outcome but valid surrogates instead. The use of surrogates as replacement endpoints should be considered only when there is substantial evidence to establish their reliability in predicting clinical meaningful effects.

# **3.6.** Statistical analyses and interpretation of results

The statistical analyses and the interpretation of scientific findings that appear in the epidemiological literature on the relationship between pesticides and health outcomes do not substantially deviate from those reported in other fields of epidemiological research. Therefore, the advantages and limitations of epidemiological studies presented in Section 2.5 also apply to the epidemiological studies on pesticides.

The few distinctive features of the epidemiological studies on pesticides include the following: (a) sparse use of appropriate statistical analyses in the presence of measurement errors when assessing exposure to pesticides and (b) paucity of information on other important factors that may affect the exposure–health outcome relationship. These features are expanded on in the following paragraphs.

a) Statistical analyses in the presence of measurement errors

The difficulties inherent in correctly measuring exposure are frequent in many areas of epidemiological research, such as nutritional epidemiology and environmental epidemiology. It is not

easy to gauge the short- and long-term exposure outside controlled laboratory experimental settings. In large populations, individuals are exposed to a variety of different agents in a variety of different forms for varying durations and with varying intensities.

Unlike nutritional or environmental epidemiology, however, pesticide epidemiology has so far made little use of statistical analyses that would appropriately incorporate measurement errors, despite their wide availability and sizable literature on the topic. A direct consequence of this is that the inferential conclusions may not have been as accurate and as precise as they could have been if these statistical methods were utilised (Bengtson et al., 2016; Dionisio et al., 2016; Spiegelman, 2016).

#### b) Information on other important factors of interest

Identifying and measuring the other relevant factors that might affect an outcome of interest is a recurrent and crucial issue in all fields of science. For example, knowing that a drug effectively cures a disease on average may not suffice if such drug is indeed harmful to children or pregnant women. Whether or not age, pregnancy and other characteristics affect the efficacy of a drug is an essential piece of information to doctors, patients, drug manufacturers and drug-approval agencies alike.

Pesticide epidemiology provides an opportunity for careful identification, accurate measuring and thorough assessment of possible relevant factors and their role in the exposure-health outcome relationship. Most often, relevant factors have been screened as potential confounders. When confounding effects were detected, these needed to be adjusted for in the statistical analyses. This has left room for further investigations that would shed light on this important issue by reconsidering data that have already been collected and that may be collected in future studies. The statistical methods in the pesticide literature have been mainly restricted to standard applications of basic regression analyses, such as binary probability and hazard regression models. Potentially useful analytical approaches, such as propensity score matching, mediation analyses, and causal inference, would be helpful for pesticide epidemiology (Imbens and Rubin, 2015).

# 4. Proposals for refinement to future epidemiological studies for pesticide risk assessment

This section is aimed at addressing methods for assessment of available pesticide epidemiological studies and proposals for improvement of such studies to be useful for regulatory purposes.

When considering the potential regulatory use of epidemiological data, many of the existing epidemiological studies on pesticides exposure and health effects suffer from a range of methodological limitations or deficiencies which limit their value in the assessment of individual active substances. Epidemiological studies on pesticides exposure and health effects would ideally generate semi-quantitative data or be able to have greater relevance to quantitative risk assessment with respect to the output from prediction models. This would allow epidemiological results to be expressed in terms more comparable to the quantitative risk assessments, which are more typically used in evaluating the risks of pesticides. The question arises how such epidemiological data could be considered for risk assessment when judged in comparison to the predictive models. A precisely measured quantitative dose–response relationship is presently rarely attainable as a result of current pesticide epidemiological studies.

The quality, reliability and relevance of the epidemiological evidence in relation to pesticide exposure and health effects can be enhanced by improving (a) the quality of each individual study and (b) the assessment of the combined evidence accrued from all available studies.

# 4.1. Assessing and reporting the quality of epidemiological studies

The quality and relevance of epidemiological research should be considered when selecting epidemiological studies from the literature for use in risk assessment. The quality of this research can be enhanced by (US-EPA, 2012; Hernández et al., 2016):

- a) an adequate assessment of exposure, preferentially biomarker concentrations at individual level reported in a way which will allow for a dose–response assessment;
- b) a reasonably valid and reliable outcome assessment (well-defined clinical entities or validated surrogates);
- c) an adequate accounting for potentially confounding variables (including exposure to multiple chemicals);
- d) the conduct and reporting of subgroup analysis (e.g. stratification by gender, age, ethnicity).

It is widely accepted that biomedical research is subject to and suffers from diverse limitations. An assessment of weaknesses in the design, conduct and analysis of epidemiology research studies on pesticides is essential to identify potentially misleading results and identify reliable data.

Guidelines and checklists help individuals meet certain standards by providing sets of rules or principles that guide towards the best behaviour in a particular area. Several tools and guidelines have been developed to aid the assessment of epidemiological evidence; however, there is no specific tool for assessing studies on pesticides. Although these studies have special considerations around exposure assessment that require specific attention, standard epidemiological instruments for critical appraisal of existing studies may apply. Existing reporting guidelines usually specify a minimum set of information needed for a complete and clear account of what was done and what was found during a research study focusing on aspects that might have introduced bias into the research (Simera et al., 2010).

A number of tools were specifically designed for quality appraisal of observational epidemiological studies, such as the Newcastle–Ottawa scale (NOS) and the Research Triangle Institute (RTI) item bank. The latter is a practical and validated tool which consists of a checklist of 29 questions for evaluating the risk of bias and precision of epidemiological studies of chemical exposures. In addition, the Biomonitoring, Environmental Epidemiological research that use biomonitoring to assess short-lived chemicals (LaKind et al., 2015), but it can also be used for persistent chemicals and environmental measures as its main elements are cross-cutting and are more broadly applicable. Two earlier efforts to develop evaluative schemes focused on epidemiology research on environmental chemical exposures and neurodevelopment (Amler et al., 2006; Youngstrom et al., 2011).

Regarding guality of reporting, the Enhancing the QUAlity and Transparency Of health Research (EQUATOR) Network, officially launched in June 2008, is an international initiative that promotes transparent and accurate reporting of health research studies. It currently lists over 90 reporting guidelines with some of them being specific for observational epidemiological studies (e.g. Strengthening the Reporting of OBservational studies in Epidemiology (STROBE)). The STROBE statement includes recommendations on what should be included in an accurate and complete report of an observational study including cross-sectional, case-control and cohort studies using a checklist of 22 items that relate to the title, abstract, introduction, methods, results and discussion sections of articles (von Elm et al., 2007). The STROBE statement has been endorsed by a growing number of biomedical journals which refer to it in their instructions for authors. Table 1 presents a summary of the main features that STROBE proposes to be taking into account when assessing the quality of reporting epidemiological studies. Extensions to STROBE are available including the STROBE Extension to Genetic Association studies (STREGA) initiative and the STROBE-ME statement for assessment of molecular epidemiology studies. Since the STROBE checklist mentions only in a general way exposure and health outcomes, the PPR Panel recommends that an extension of the STROBE statement be developed, for inclusion in the EQUATOR network library, specifically relevant to the area of pesticide exposure and health outcomes. This would greatly assist researchers and regulatory bodies in the critical evaluation of study guality.

Factor	Item	Recommendation	
Title and Abstract			
	1	<ul><li>a) Indicate the study's design with a commonly used term in the title of the abstract</li><li>b) Provide in the abstract an informative and balanced summary of what was done and what was found</li></ul>	
Introduction			
Background/rationale	2	2 Explain the scientific background and rationale for the investigation being reported	
Objectives	3	State specific objectives, including prespecified hypotheses	
Methods			
Study design	4	Present key elements of study design early in the paper	
Setting	5	Describe the setting, locations and relevant dates, including periods of recruitment, exposure, follow-up and data collection	

Table 1:	Main features of the STROBE tool to	assess quality of reporting of epidemiological studies
----------	-------------------------------------	--

STROBE Statement	Items		
Factor	Item	Recommendation	
Participants	6	<ul> <li>a) Cohort study – Give the eligibility criteria, and the sources and methods of selection of participants. Describe methods of follow-up Case-control study – Give the eligibility criteria, and the sources and methods of case ascertainment and control selection. Give the rationale for the choice of cases and controls Cross-sectional study – Give eligibility criteria, and the sources and methods of selection of participants</li> <li>b) Cohort study – For matched studies, give matching criteria and the number of exposed and unexposed Case-control study – For matched studies, giving matching criteria and the number of controls per case</li> </ul>	
Variables	7	Clearly define all outcomes, exposures, predictors, potential confounders and effect modifiers. Give diagnostic criteria, if applicable	
Data sources/ measurements	8*	For each variable of interest, give sources of data and details of methods of assessment (measurement). Describe comparability of assessment methods if there is more than one group	
Bias	9	Describe any efforts to address potential sources of bias	
Study size	10	Explain how the study size was arrived at	
Quantitative variables	11	Explain how quantitative variables were handled in the analyses. If applicable, describe which groupings were chosen and why	
Statistical methods	12	<ul> <li>a) Describe all statistical methods, including those used to control for confounding</li> <li>b) Describe any methods used to examine subgroups and interactions</li> <li>c) Explain how missing data were addressed</li> <li>d) Cohort study – If applicable, explain how loss to follow-up was addressed Case-control study – If applicable, explain how matching of cases and controls was addressed</li> <li>Cross-sectional study – If applicable, describe analytical methods taking account of sampling strategy</li> <li>e) Describe any sensitivity analyses</li> </ul>	
Results			
Participants	13*	<ul> <li>a) Report numbers of individuals at each stage of study – e.g. numbers potentially eligible, examined for eligibility, confirmed eligible, included in the study, completing follow-up and analysed</li> <li>b) Give reasons for non-participation at each stage</li> <li>c) Consider use of a flow diagram</li> </ul>	
Descriptive data	14*	<ul> <li>a) Give characteristics of study participants (e.g. demographic, clinical, social) and information on exposures and potential confounders</li> <li>b) Indicate number of participants with missing data for each variable of interest</li> <li>c) <i>Cohort study</i> – Summarise follow-up time (e.g. average and total amount)</li> </ul>	
Outcome data	15*	Cohort study – Report numbers of outcome events or summary measures over time Case–control study – Report numbers in each exposure category, or summary measures of exposure Cross-sectional study – Report numbers of outcome events or summary measures	
Main results	16	<ul> <li>a) Give unadjusted estimates and, if applicable, confounder-adjusted estimates and their precision (e.g. 95% confidence interval). Make clear which confounders were adjusted for and why they were included</li> <li>b) Report category boundaries when continuous variables were categorised</li> <li>c) If relevant, consider translating estimates of relative risk into absolute risk for a meaningful time period</li> </ul>	

STROBE Statement Items			
Factor Item Recommendation		Recommendation	
Other analyses	17	Report other analyses done – e.g. analyses of subgroups and interactions, and sensitivity analyses	
Discussion			
Key results	18	Summarise key results with reference to study objectives	
Limitations	19	Discuss limitations of the study, taking into account sources of potential bias or imprecision. Discuss both direction and magnitude of any potential bias	
Interpretation	20	Give a cautious overall interpretation of results considering objectives, limitations, multiplicity of analyses, results from similar studies, and other relevant evidence	
Generalisability	21	Discuss the generalisability (external validity) of the study results	
Other information			
Funding	22	Give the source of funding and the role of the funders for the present study and, if applicable, for the original study on which the present article is based	

\*: Give information separately for cases and controls in case-control studies and, if applicable, for exposed and unexposed groups in cohort and cross-sectional studies.

Selective reporting can occur because non-significant results or unappealing significant results may not be published. Investigators should avoid the selective reporting of significant results and high-risk estimates. In this regard, standardisation of reporting of epidemiological studies could help to reduce or avoid selective reporting. The STROBE statement and similar efforts are useful tools for this purpose. Although some epidemiological research will remain exploratory and *post hoc* in nature, this should be clarified in the publications and selective reporting minimised, so that epidemiological findings could be interpreted in the most appropriate perspective (Kavvoura et al., 2007).

Preregistration of studies and prepublication of protocols are the measures taken by some Journal editors and Ethics Committees to reduce reporting bias and publication bias in clinical trials on pharmaceuticals. Although a similar proposal has been suggested for observational epidemiological studies in order to be conducted as transparently as possible to reduce reporting bias and publication bias, there is no consensus among epidemiologists (Pearce, 2011; Rushton, 2011). In contrast, a number of initiatives have been undertaken by professional societies to foster good epidemiological practice. This is the case, for example, of the International Epidemiological Association (IEA, 2007) or the Dutch Society for Epidemiology on responsible epidemiologic Research Practice (DSE, 2017).

Data quality assessment of formal epidemiological studies is based solely on the methodological features of each individual study rather than on the results, regardless of whether they provide evidence for or against an exposure/outcome association. However, for risk assessment, it is important to assess not only the quality of study methods but also the quality of the information they provide. Indeed, good studies may be dismissed during the formal quality assessment by the poor reporting of the information.

# 4.2. Study design

Well conducted prospective studies with appropriate exposure assessment provide the most reliable information and are less prone to biases. When prospective studies are available, results from studies of less robust design can give additional support. In the absence of prospective studies the results from cross-sectional and case-control studies should be considered but interpreted with caution. However, it is acknowledged that a well-designed case-control study may be superior to a less well designed cohort study. Analytical approaches should be congruent with the study design, and assumptions that the statistical methods required should be carefully evaluated.

Ideally observational studies for long-term diseases should be prospective and designed such that the temporal separation between the exposure and the health outcome is appropriate with respect to the time it takes to develop the disease. For outcomes such as cancer or cardiovascular diseases, which often have a long latency period (> 10 years), exposure should be assessed more than once prior to the outcome assessment. For other outcomes with a shorter latency period, such as immune function disturbances, the appropriate temporal separation may be in the range of days or weeks and a single exposure assessment may be adequate. In short, the ideal design of a study depends on the latency period for the outcome under consideration. The expected latency period then determines both the length of follow-up and the frequency for which the exposure has to be quantified.

# 4.3. Study populations

The EU population, which exceeds 500 million people, can be assumed to be fairly heterogeneous and so expected to include a number of more sensitive individuals that may be affected at lower doses of pesticide exposure. To address this, in stratified sampling, the target population is divided into subgroups following some key population characteristics (e.g. sex, age, geographic distribution, ethnicity or genetic variation) and a random sample is taken within each subgroup. This allows subpopulations to be represented in a balanced manner in the study population.

Vulnerable populations should then be examined in epidemiological studies either through subgroup or sensitivity analysis. However, such analyses need to be defined *a priori*. In case of ad hoc subgroup sensitivity analysis, the statistical thresholds should be adjusted accordingly and the replication of results should follow. Evidence of vulnerable subpopulations would ideally involve prospective studies that include assessment of biomarkers of exposure, subclinical endpoints and disease incidence over time.

It may be impossible to find a threshold of a toxic-induced increase in disease in the population because a large number of people are in a preclinical state and would be sensitive to the low end of the dose-response curve. For that to be evident, the epidemiology data would need to characterise the relationship between chemical exposure and risk of disease in a broad cross-section of the population (or look at precursor lesions or key events) and allow a robust examination of a low-dose slope.

On the basis of the degree of evidence relevant to a vulnerable subpopulation, consideration should be given to whether dose-response assessment will focus on the population as a whole or will involve separate assessments for the general population and susceptible subgroups. If it is the population as a whole, the traditional approach is to address variability with uncertainty factors; it may also be possible to analyse the effect of variability on risk by evaluating how the risk distribution of the disease shifts in response to the toxicant. In essence, the risk distribution based on a subclinical biomarker is an expression of toxicodynamic variability that can be captured in dose-response assessment.

The alternative approach is to address vulnerable subpopulations as separate from the general population and assign them unique potencies via dose–response modelling specific to the groups that might be based on actual dose–response data for the groups, on adjustments for specific toxicokinetic or toxicodynamic factors, or on more generic adjustment or uncertainty factors. For a pesticide, if it is known that a particular age group, disease (or disease-related end-point), genetic variant or co-exposure creates unique vulnerability, efforts should be made to estimate the potency differences relative to the general population and on that basis to consider developing separate potency values or basing a single value on the most sensitive group or on the overall population with adjustments for vulnerable groups.

#### 4.4. Improvement of exposure assessment

The difficulties often associated with pesticide exposure assessment in epidemiological studies have been highlighted above. The description of pesticide exposure (in particular quantitative information on exposure to individual pesticides) is generally reported in insufficient detail for regulatory purposes and this limitation is difficult to overcome, especially for diseases with a long latency period (e.g. many cancers and neurodegenerative disorders).

It is noteworthy that the methods necessary to conduct exposure monitoring are to be submitted by the applicant in the dossier. The regulation requirements do ask for validated methods that can be used for determining exposure. The Commission Regulation (EU) No 283/2013, setting out the data requirements for active substances, in accordance with Regulation (EC) No 1107/2009 of the European Parliament and of the Council concerning the placing of PPP on the market, addresses information on methods of analysis required to support both pre-approval studies and post-approval monitoring. In this context, the post-approval requirements are the most relevant and the regulation literally states:

'4.2. Methods for post-approval control and monitoring purposes – Methods, with a full description, shall be submitted for:

 a) the determination of all components included in the monitoring residue definition as submitted in accordance with the provisions of point 6.7.1 in order to enable Member States to determine compliance with established maximum residue levels (MRLs); they shall cover residues in or on food and feed of plant and animal origin;

- b) the determination of all components included for monitoring purposes in the residue definitions for soil and water as submitted in accordance with the provisions of point 7.4.2;
- c) the analysis in air of the active substance and relevant breakdown products formed during or after application, unless the applicant shows that exposure of operators, workers, residents or bystanders is negligible;
- d) the analysis in body fluids and tissues for active substances and relevant metabolites.

As far as practicable these methods shall employ the simplest approach, involve the minimum cost, and require commonly available equipment. The specificity of the methods shall be determined and reported. It shall enable all components included in the monitoring residue definition to be determined. Validated confirmatory methods shall be submitted if appropriate. The linearity, recovery and precision (repeatability) of methods shall be determined and reported.

Data shall be generated at the LOQ and either the likely residue levels or ten times the LOQ. The LOQ shall be determined and reported for each component included in the monitoring residue definition. For residues in or on food and feed of plant and animal origin and residues in drinking water, the reproducibility of the method shall be determined by means of an independent laboratory validation (ILV) and reported'.

From this, it can be concluded that the requirements exist, but are somewhat less stringent for human biomonitoring than for monitoring of residues in food and feed.

Failure to use these existing methods restricts the potential for the use of epidemiological evidence in the regulation of specific pesticides. It is therefore important that those contemplating future studies carefully consider approaches to be used to avoid misclassification of exposure, and to conduct appropriate detailed exposure assessments for specific pesticides, which allow for sound dose– response analyses, and demonstrate the validity of the methods used.

A given exposure may have a different health impact depending on the period in the lifespan when exposure takes place. Greater attention needs to be paid to exposures occurring during periods of potential susceptibility for disease development by ensuring that the exposure assessment adequately addresses such critical times. This may be particularly relevant for studies involving neurodevelopment, obesity or allergic responses, which are complex multistage developmental processes that occur either prenatally or in the early post-natal life. For this reason, measurement of the exposure at one single time period may not properly characterise relevant exposures for all health effects of the environmental factors, and thus, the possibility arises of needing to measure the exposure at several critical periods of biological vulnerability to environmental factors. It is particularly challenging to construct an assessment of historical exposure swhich may deviate from current exposures, in both the range of chemicals and intensity of exposure and also co-exposure to other substances which are not included in the scope of study.

There are advantages and disadvantages to all methods of measuring pesticide exposure, and specific study designs and aims should be carefully considered to inform a specific optimal approach.

Exposure assessment can be improved at the *individual* level in observational research by using:

a) Personal exposure monitoring: This can be used to document exposures as readings measure pesticide concentration at the point of contact. Personal exposure monitors have been costly and burdensome for study participants. However, technological advances have recently driven personal exposure monitoring for airborne exposures to inexpensive, easy to use devices and these are suitable for population research. Personal exposure monitors that are specific to pesticide exposure could involve sensors to measure airborne concentrations, 'skin' patches to measure dermal concentrations, indoor home monitors that capture dust to measure other means of exposure. These mobile technology advances can be employed to provide observational studies with detailed and robust exposure assessments. Such equipment is now increasingly being adapted to serve large-scale population research and to capture data from large cohort studies. These coupled with other technological advances, such as real time data transfers via mobile phones and mobile phone applications to capture lifestyle and other habits, could bring next generation observational studies far more detailed and robust exposure assessments compared to current evidence. However, the generation of huge volumes of data can pose organisational, statistical and technical challenges, particularly with extended follow-up times. Ethics and personal data protection issue should be taken into account, and local regulations may prevent extensive use of such technologies. However, use of such personal monitors only provides information for one of the different potential routes of exposure.

b) **Biomarkers of exposure** (human biomonitoring (HBM)). An alternative and/or complementary approach is to ascertain the internal dose, which is the result of exposure via different routes (dermal,

inhalation and dietary exposure). These biomarkers have the potential to play an important role in assessing aggregate exposure to pesticides and informing cumulative risk assessment. Biomonitoring requires measurements in biological samples of concentrations of chemical under consideration (parent or metabolites) or markers of pathophysiologic effects thereof (such as adducts). However, challenges may include uncertainties relating to extrapolation of measured concentrations in biological samples to relevant doses.

Although biomonitoring has the potential to provide robust estimates of absorbed doses of xenobiotics, modern pesticides and their metabolites are eliminated from the body relatively quickly, with excretion half-lives typically measured in a few days (Oulhote and Bouchard, 2013). Consequently, use of biomarkers is both resource intensive and intrusive. The process is even more intrusive when it has to be conducted repeatedly on large numbers of individuals to monitor exposures over long durations.

Nevertheless, because of the potential to provide accurate integrated estimates of absorbed doses, biological monitoring of pesticides and their metabolites can be usefully employed to calibrate other approaches of exposure assessment. A good example of such an approach is that used by the Agricultural Health Study (Thomas et al., 2010; Coble et al., 2011; Hines et al., 2011). Also, HBM methods can be used with other forms of exposure assessment for the construction of long exposure histories.

Biomonitoring improves the precision in characterisation of exposure and allows the investigation of changes in exposure that occur at environmentally relevant exposure concentrations. Data collected in large-scale biomonitoring studies can be useful in setting reference ranges to assist in exposure classification in further epidemiological studies. Biomonitoring data also provide critical information for conducting improved risk assessment and help to identify subpopulations at special risk for adverse outcomes.

Biobanks, as repositories of biological samples, can be exploited to assess biomarkers of exposure with the aim of investigating early exposure–late effect relationships. That is, whether exposures occurring during early life are critical for disease development later in life (e.g. neurobehavioral impairment, children tumours, immunotoxic disorders, etc.) and to retrospectively assess health risks according to current health guidelines.

The results of measurements of metabolite levels in human matrices, e.g. urine, blood or hair do not provide the complete story with respect to the actual received dose. Additional assessment, possibly employing physiological-based toxicokinetic (PBTK) approaches, may be required to estimate the total systemic or tissue/organ doses. A PBTK model is a physiologically based compartmental model used to characterise toxicokinetic behaviour of a chemical, in particular for predicting the fate of chemicals in humans. Data on blood flow rates, metabolic and other processes that the chemical undergoes within each compartment are used to construct a mass-balance framework for the PBTK model. PBTK models cannot be used only to translate external exposures into an internal (target) dose in the body, but also to infer external exposures from biomonitoring data. Furthermore, PBTK models need to be validated.

Toxicokinetic processes (ADME) determine the 'internal concentration' of an active substance reaching the target and help to relate this concentration/dose to the observed toxicity effect. Studies have been prescribed by the current regulations, but it would be beneficial to survey all the evidence, be it from *in vitro*, animal or human studies, about toxicokinetic behaviour of an active substance. Further discussion on quality assurance issues and factors to consider in relation to HBM studies is present in the report of the EFSA outsourced project (Bevan et al., 2017).

Exposure assessment can also be improved at the *population* level in observational research by using:

a) Larger epidemiological studies that make use of novel technologies and big data availability, such as **registry data** or data derived from large databases (including administrative databases) on health effects and pesticide usage, could provide more robust findings that might eventually be used for informed decision-making and regulation. Much effort needs to concentrate around the use of registered data which may contain records of pesticide use by different populations, such as farmers or other professional users that are required to maintain.<sup>9</sup> Such data could be further linked to

<sup>&</sup>lt;sup>9</sup> Regulation 1107/2009 Article 67 states: Record-keeping 1. Producers, suppliers, distributors, importers, and exporters of plant protection products shall keep records of the plant protection products they produce, import, export, store or place on the market for at least 5 years. Professional users of plant protection products shall, for at least 3 years, keep records of the plant protection products they use, containing the name of the plant protection product, the time and the dose of application, the area and the crop where the plant protection product was used. They shall make the relevant information contained in these records available to the competent authority on request. Third parties such as the drinking water industry, retailers or residents, may request access to this information by addressing the competent authority. The competent authorities shall provide access to such information in accordance with applicable national or Community law.

electronic health records (*vide supra*) and provide studies with unprecedented sample size and information on exposure and subsequent disease and will eventually be able to answer robustly previously unanswered questions. At the same time, information on active substances needs to be better captured in these registries and large databases. Dietary pesticide residue exposure can be estimated more accurately by using spraying journal data in combination with supervised residue trials. This method has the advantage of including more comprehensive and robust source data, more complete coverage of used pesticides and more reliable and precise estimates of residues below standard limit of quantification (LOQ) (Larsson et al., 2017).

b) Novel sophisticated approaches to **geographical information systems** (GIS) and small area studies might also serve as an additional way to provide estimates of residential exposures. Exposure indices based on GIS (i.e. residential proximity to agricultural fields and crop surface with influence around houses), when validated, may represent a useful complementary tool to biomonitoring and have been used to assess exposure to pesticides with short biological half-lives (Cornelis et al., 2009). As some such exposures maybe influenced by wind direction, amongst other factors, this should be taken into account through a special analysis of outcomes to make best of use of the approach. Also, these indices could be more representative, albeit non-specific, measures of cumulative exposure to non-persistent pesticides for long periods of time than biomonitoring data (González-Alzaga et al., 2015).

As already discussed, to be useful for the regulatory risk assessments of individual compounds epidemiological exposure assessments should provide information on specific pesticides. However, epidemiological studies which include more generic exposure assessments also have the potential to identify general risk factors and suggest inferences of causal associations in relevant human populations. Such observations may be important both informing overall regulatory policies, and for identification of matters for further epidemiological research.

Recent advances in modern technologies make it possible to estimate pesticide exposures to an unprecedented extent using novel analytical strategies:

a) The development of the so called **-omic techniques**, such as metabolomics and adductomics, also presents intriguing possibilities for improving exposure assessment through measurement of a wide range of molecules, from xenobiotics and metabolites recorded over time in biological matrices (blood, saliva, urine, hair, nails, etc.), to covalent complexes with DNA and proteins (adductomics) and understanding biological pathways. These methodologies could be used in conjunction with other tools. There is also both interest and the recognition that further work is required before such techniques can be applied in regulatory toxicology. The use of the exposome (the totality of exposures received by an individual during life) might be better defined by using 'omics' technologies and biomarkers appropriate for human biomonitoring. Nevertheless, important limitations have to be acknowledged because of the lack of validation of these methodologies and their cost, which limits their use at large scale.

b) Environmental exposures are traditionally assessed following 'one-exposure-one-health-effect' approach. In contrast, the **exposome** encompass the totality of human environmental exposures from conception onward complementing the genetics knowledge to characterise better the environmental components in disease aetiology. As such, the exposome includes not only any lifetime chemical exposures but also other external and or internal environmental factors, such as infections, physical activity, diet, stress and internal biological factors (metabolic factors, gut microflora, inflammation and oxidative stress). A complete exposome would have to integrate many external and internal exposures from different sources continuously over the life course. However, a truly complete exposome will likely never be measured. Although all these domains of the exposome need to be captured by using different approaches than the traditional ones, it is envisaged that no single tool will be enough to this end.

The more holistic approach of exposure is not intended to replace the traditional 'one-exposureone-health-effect' approach of current epidemiological studies. However, it would improve our understanding of the predictors, risk factors and protective factors of complex, multifactorial chronic diseases. The exposome offers a framework that describes and integrates, holistically, the environmental influences or exposures over a lifetime (Nieuwenhuijsen, 2015).

Collaborative research and integration of epidemiological or exploratory studies forming large consortia are needed to validate these potential biomarkers and eventually lead to improved exposure assessment. The incorporation of the exposome paradigm into traditional biomonitoring approaches offers a means to improve exposure assessment. Exposome-wide association studies (EWAS) allow to measurement of thousands of chemicals in blood from healthy and diseased people, test for disease

associations and identify useful biomarkers of exposure that can be targeted in subsequent investigations to locate exposure sources, establish mechanisms of action and confirm causality (Rappaport, 2012). After identifying these key chemicals and verifying their disease associations in independent samples of cases and controls, the chemicals can be used as biomarkers of exposures or disease progression in targeted analyses of blood from large populations.

In relation to the exposome concept, the -omics technologies have the potential to measure profiles or signatures of the biological response to the cumulative exposure to complex chemical mixtures. An important advance would be to identify a unique biological matrix where the exposome could be characterised without assessing each individual exposure separately in a given biological sample. The untargeted nature of omics data will capture biological responses to exposure in a more holistic way and will provide mechanistic information supporting exposure-related health effects. Importantly, omics tools could shed light on how diverse exposures act on common pathways to cause the same health outcomes.

While improved exposure assessment increases the power to detect associations, in any individual study it is necessary to maximise the overall power of the study by optimising the balance between the resource used for conducting an exposure assessment for each subject and the total number of subjects.

#### 4.5. Health outcomes

For pesticides, the health outcomes are broad as these chemicals have not shown a particular effect in relation to just one single disease area. For each health outcome, multiple definitions may exist in the literature with a varying degree of validation and unknown reproducibility across different databases, which are limited by the lack of generalisability. A proper definition of a health outcome is critical to the validity and reproducibility of observational epidemiological studies, and the consistency and clarity of these definitions need to be considered across studies. While prospective observational studies have explicit outcome definitions, inclusion and exclusion criteria and standardised data collection, retrospective studies usually rely on identification of health outcomes based largely on coded data, and classification and coding of diseases may change over time. Detailed description of the actual codes used to define key health outcomes and the results of any validation efforts are valuable to future research efforts (Stang et al., 2012; Reich et al., 2013). An example of coded diseases is the ICD-10, which for instance can be used as a tool to standardise the broad spectrum of malignant diseases.

In some surveillance studies, it is preferable to use broader definitions with a higher sensitivity to identify all potential cases and then apply a narrower and more precise definition with a high positive predictive value to reduce the number of false positives and resulting in more accurate cases. In contrast, in formal epidemiological studies, a specific event definition is used and validated to determine its precision; however, the 'validation' does not test alternative definitions, so it is not possible to determine sensitivity or specificity.

Surrogate endpoints should be avoided unless they have been validated. Some criteria to assess the validity of a surrogate outcome include:

- The surrogate has been shown to be in the causal pathway of the disease. This can be supported by the following evidence: correlation of biomarker response to pathology and improved performance relative to other biomarkers; biological understanding and relevance to toxicity (mechanism of response); consistent response across mechanistically different compounds and similar response across sex, strain and species; the presence of dose– response and temporal relationship to the magnitude of response; specificity of response to toxicity; that is, the biomarker should not reflect the response to toxicities in other tissues, or to physiological effects without toxicity in the target organ.
- At least one well conducted trial using both the surrogate and true outcome (Grimes and Schulz, 2005; la Cour et al., 2010). Several statistical methods are used to assess these criteria and if they are fulfilled the validity of the surrogate is increased. However, many times some uncertainty remains, making it difficult to apply surrogates in epidemiological studies (la Cour et al., 2010).

The data on health outcomes over the whole EU is potentially very extensive. If it can be managed effectively, it will open the prospect of greater statistical power for epidemiological studies assessing deleterious effects using very large sample sizes. Necessary prerequisites for these studies which may

detect new subtle effects, chronic effects or effects on subpopulations when stratified are beyond the remit of risk assessment. They include trans-national approaches to health informatics where harmonised diagnostics, data storage and informatics coupled with legally approved access to anonymised personal data for societal benefit are established. Health records should include adequate toxidrome classification. The latter may in turn require improvements in medical and paramedical training to ensure the quality of the input data.

Another opportunity for biological monitoring to be employed is where the investigation involves the so-called biomarkers of effect. That is a quantifiable biochemical, physiological, or other change that, depending on the magnitude, is associated with an established or possible health impairment or disease. Biomarkers of effect should reflect early biochemical modifications that precede functional or structural damage. Thus, knowledge of the mechanism ultimately leading to toxicity is necessary to develop specific and useful biomarkers, and vice versa, an effect biomarker may help to explain a mechanistic pathway of the development of a disease. Such biomarkers should identify early and reversible events in biological systems that may be predictive of later responses, so that they are considered to be preclinical in nature. Advances in experimental -omics technologies will show promise and provide sound information for risk assessment strategies, i.e. on mode of action, response biomarkers, estimation of internal dose and dose–response relationships (DeBord et al., 2015). These technologies must be validated to assess their relevance and reliability. Once validated, they can be made available for regulatory purposes.

# 5. Contribution of vigilance data to pesticides risk assessment

In addition to the formal epidemiological studies discussed in Sections 2–4, other human health data can be generated from ad hoc reports or as a planned process, i.e. through monitoring systems that have been implemented at the national level by public health authorities or authorisation holders. Consistent with Sections 2–4, this section first reviews how such a monitoring system should operate, what the current situation is regarding the monitoring of pesticides and what recommendations for improvement can be made.

# 5.1. General framework of case incident studies

A continuous process of collection, reporting and evaluation of adverse incidents has the potential to improve the protection of health and safety of users and others by reducing the likelihood of the occurrence of the same adverse incident in different places at later times, and also to alleviate consequences of such incidents. This obviously also requires timely dissemination of the information collected on such incidents. Such a process is referred to as vigilance.<sup>10</sup>

For example in the EU, the safety monitoring of medicines is known as pharmacovigilance; the pharmacovigilance system operates between the regulatory authorities in Member States, the European Commission and the European Medicines Agency (EMA). In some Member States, regional centres are in place under the coordination of the national Competent Authorities. Manufacturers and health care professionals report incidents to the Competent Authority at the national level, which ensures that any information regarding adverse reactions is recorded and evaluated centrally and also notifies other authorities for subsequent actions. The records are then centralised by the EMA which supports the coordination of the European pharmacovigilance system and provides advice on the safe and effective use of medicines.

# 5.2. Key limitations of current framework of case incident reporting

Several EU regulations require the notification and/or collection and/or reporting of adverse events caused by pesticides in humans (occurring after acute or chronic exposure in the occupational setting, accidental or deliberate poisoning, etc.). These include:

• Article 56 of EC Regulation 1107/2009 requires that 'The holder of an authorisation for a plant protection product shall immediately notify the Member States [...] In particular, potentially

<sup>&</sup>lt;sup>10</sup> The concept of <u>survey</u> refers to a single effort to measure and record something, and <u>surveillance</u> refers to repeated standardized surveys to detect trends in populations in order to demonstrate the absence of disease or to identify its presence or distribution to allow for timely dissemination of information. <u>Monitoring</u> implies the intermittent analysis of routine measurements and observations to detect changes in the environment or health status of a population, but without eliciting a response. <u>Vigilance</u> is distinct from surveillance and mere monitoring as it implies a process of paying close and continuous attention, and in this context addresses specifically post marketing events related to the use of a chemical.

harmful effects of that plant protection product, or of residues of an active substance, its metabolites, a safener, synergist or co-formulant contained in it on human health [...] shall be notified. To this end the authorisation holder shall record and report all suspected adverse reactions in humans, in animals and the environment related to the use of the plant protection product. The obligation to notify shall include relevant information on decisions or assessments by international organisations or by public bodies which authorise plant protection products or active substances in third countries'.

Article 7 of EC Directive 128/2009 establishing a framework for Community action to achieve
the sustainable use of pesticides requires that: '2. <u>Member States</u> shall put in place systems for
gathering information on pesticide acute poisoning incidents, as well as chronic poisoning
developments where available, among groups that may be exposed regularly to pesticides such
as operators, agricultural workers or persons living close to pesticide application areas. 3. To
enhance the comparability of information, <u>the Commission</u>, in cooperation with the Member
States, shall develop by 14 December 2012 a strategic guidance document on monitoring and
surveying of impacts of pesticide use on human health and the environment'. However, at the
time of publishing this scientific opinion, this document has still not been released.

There are three additional regulations that apply, although indirectly, to pesticides and reporting:

- EC Regulation 1185/2009 concerning statistics on pesticides requires that Member States shall collect data on pesticide sales and uses according to a harmonised format. The statistics on the placing on the market shall be transmitted yearly to the Commission and the statistics on agricultural use shall be transmitted every 5 year.
- Article 50 of Regulation (EC) 178/2002, laying down the general principles and requirements of food law, set up an improved and broadened rapid alert system covering food and feed (RASFF). The system is managed by the <u>Commission</u> and includes as members of the network Member States, the Commission and the Authority. It reports on non-authorised occurrences of pesticides residues and food poisoning cases.
- Article 45 (4) of EC Regulation 1272/2008 (CLP Regulation): importers and downstream users placing hazardous chemical mixtures on the market of an EU Member State will have to submit a notification to the Appointed Body/Poison Centre of that Member State. The notification needs to contain certain information on the chemical mixture, such as the chemical composition and toxicological information, as well as the product category to which the mixture belongs. The inclusion of information on the product category in a notification allows Appointed Bodies/Poison Centres to carry out comparable statistical analysis (e.g. to define risk management measures), to fulfil reporting obligations and to exchange information among MS. The product category is therefore not used for the actual emergency health response as such, but allows the identification of exposure or poisoning trends and of possible measures to prevent future poisoning cases. When formally adopted, the new Regulation will apply as of 1 January 2020.

While there are substantial legislative provisions, to this date a single unified EU 'phytopharmacovigilance'<sup>11</sup> system akin to the pharmacovigilance system does not exist for PPP. Rather, a number of alerting systems have been developed within the EU to alert, notify, report and share information on chemical hazards that may pose a risk to public health in Member States. These systems cover different sectors including medicines, food stuffs, consumer products, industrial accidents, notifications under International Health Regulations (IHR) and events detected by EU Poisons Centres and Public Health Authorities. Each of these systems notify and distribute timely warnings to competent authorities, public organisations, governments, regulatory authorities and public health officials to enable them to take effective action to minimise and manage the risk to public health (Orford et al., 2014).

In the EU, information on acute pesticide exposure/incident originates mainly from data collected and reported by Poison Control Centres (PCC's). PCC's collect both cases of acute and chronic exposure/poisoning they are aware of, in the general population and in occupational settings. Cases are usually well-documented and information includes circumstances of exposure/incident, description of the suspected causal agent, level and duration of exposure, the clinical course and treatment and an assessment of the causal relationship. In severe cases, the toxin and/or the metabolites are usually

<sup>&</sup>lt;sup>11</sup> 'phytovigilance' would refer to a vigilance system for plants; as pesticides are intended to be 'medicines' for crops, the term 'phytopharmacovigilance' is considered to be the more appropriate one here. Furthermore, it is a broad term used in France covering soil, water, air, environment, animal data, etc.

measured in blood or urine. However, follow-up of cases reported to the centres merits further attention to identify potential long-term protracted effects.

There are two key obstacles to using Poison Centres data: official reports from national Poisons Centres are not always publicly available and when they are, there is a large heterogeneity in the format of data collections and coding, and assessment of the causal relationship. Indeed, each Member State has developed its own tools for collection activities resulting in difficulties for comparing and exchanging exposure data. In 2012, the European Commission funded a collaborative research and development project to support the European response to emerging chemical events: the Alerting and Reporting System for Chemical Health Threats, Phase III (ASHTIII) project. Among the various tools and methodologies that were considered, methods to exchange and compare exposure data from European PCC's were developed. As a feasibility study, work-package 5 included the development of a harmonised and robust coding system to enable Member States to compare pesticide exposure data. However, results of a consultation with the PCC community showed that further coordination of data coding and collection activities is supported. It was concluded that more support and coordination is required at the EU and Member States level so that exposures data can be compared between Member States (Orford et al., 2015).

In addition to data collected by PCC's, several Member States have set up programmes dedicated to occupational health surveillance.<sup>12</sup> The purpose of these programmes is to identify the kinds of jobs, types of circumstances and pesticides that cause health problems in workers in order to learn more about occupational pesticide illnesses and injuries and how to prevent them. They are based on voluntary event notification by physicians (sometimes self-reporting by users) of any case of suspected work-related pesticide injury or illness or poisoning. In addition to medical data, information gathered includes data regarding type of crop, mode of application, temperature, wind speed, wearing of personal protection equipment, etc. Once collected, these data are examined and a report is released periodically; they provide a useful support to evaluate the safety of the products under re-registration. These data also highlight emerging problems and allow definition of evidence-based preventive measures for policy-makers. At EU level, the European Agency for Safety and Health at Work (EU-OSHA)<sup>13</sup> has very little in the way of monitoring of occupational pesticide-related illnesses data. In the USA, a programme specifically dedicated to pesticides funded and administered by the National Institute for Occupational Safety and Health (NIOSH) is in operation in a number of States.<sup>14</sup>

In summary, currently human data may be collected in the form of case reports or case series, poison centres information, coroner's court findings, occupational health surveillance programmes or post-marketing surveillance programmes. However, not all this information is present in the medical data submitted by applicants mainly because the different sources of information are diverse and heterogeneous by nature, which makes some of them sometimes not accessible.

- Data collected through occupational health surveillance of the plant production workers or if they do so, the medical data are quite limited being typically basic clinical blood measurements, physical examinations, potentially with simple indications of how and where exposed took place, and there usually is no long-term follow up. Furthermore, worker exposures in modern plants (especially in the EU) are commonly very low, and often their potential exposure is to a variety of pesticides (unless it is a facility dedicated to a specific chemical).
- Moreover, the reporting of data from occupational exposure to the active substances during manufacture is often combined with results from observations arising from contact with the formulated plant protection product as the latter information results from case reports on poisoning incidents and epidemiological studies of those exposed as a result of PPP use. Indeed, the presence of co-formulants in a plant protection product can modify the acute toxicological profile. Thus, to facilitate proper assessment, when reporting findings collected in humans it should be clearly specified whether it refers to the active substance per se or a PPP.

With regard to the requirements of specific data on diagnoses of poisoning by the active substance or formulated plant protection products and proposed treatments, which are also part of chapter 5.9 of the EC Regulation 283/2013, information is often missing or limited to those cases where the toxic mode of action is known to occur in humans and a specific antidote has been identified.

<sup>&</sup>lt;sup>12</sup> For example: Phyt'attitude in France is a vigilance programme developed by the Mutualité Sociale Agricole: http://www.msa. fr/lfr/sst/phyt-attitude

<sup>&</sup>lt;sup>13</sup> https://osha.europa.eu/en/about-eu-osha

<sup>&</sup>lt;sup>14</sup> SENSOR programme: https://www.cdc.gov/niosh/topics/pesticides/overview.html

# 5.3. Proposals for improvement of current framework of case incident reporting

In order to avoid duplication and waste of effort, a logical next step would be to now develop, with all concerned public and private sector actors, an EU 'phytopharmacovigilance' system for chemicals similar to the ones that have been put in place for medicines. This network could be based on committed and specifically trained occupational health physicians and general practitioners in rural areas, and resources should be allocated by Member States to establish and to successfully maintain the system. Indeed such a network would be useful in detecting acute effects; it would also act as a sentinel surveillance network for specific health effects (such as asthma, sensitisation, etc.) or for the detection of emerging work-related disease. In fact, while much experience has already been gained on how to gradually build such a system, it is nevertheless envisioned that this will take a number of years to be put in place. Several difficulties will arise because of the nature of the data collected (the sources of information are potentially diverse), the quality and completeness of the collected information for every case (especially the circumstances), the grading of severity and accountability of the observed effects (the link between the observed effect and the product). Rules should be defined so that they are identical from one 'evaluator' to another. The network should be stable over time (e.g. continuity in national organisations involved, consistent methodology employed, etc.), to ensure that the phytopharmacovigilance system fully complies with the objectives, i.e. monitoring changes over time. The use of phytopharmacovigilance data is unlikely to be limited to risk assessment purposes and may have an impact on risk management decisions (e.g. revisions in the terms and conditions of product authorisations or ultimately product withdrawal); this should be clear to all stakeholders from the outset.

Such a system may not merit being established solely for chemicals that are (predominantly) used as pesticides. However, given the legislative provisions already in place for pesticides, its development may need to be prioritised for pesticides.

In conclusion, the European Commission together with the Member States should initiate the development of an EU-wide vigilance framework for pesticides. These should include:

- harmonisation of human incident data collection activities at the EU level;
- coordination of the compilation of EU-wide databases;
- improving the collaboration between Poison Centres and regulatory authorities at national level in order to collect all the PPP poisonings produced in each Member State;
- guidance document on monitoring the impact of pesticide use on human health with harmonisation of data assessment for causal relationships;
- regular EU-wide reports.

# 6. Proposed use of epidemiological studies and vigilance data in support of the risk assessment of pesticides

This section briefly reviews the risk assessment process (Section 6.1) based on experimental studies and discusses what information epidemiological studies could add to that process. Next, the assessment of the reliability of epidemiological studies is addressed in Section 6.2. In Section 6.3, the relevance of one or more studies found to be reliable is assessed.

# 6.1. The risk assessment process

Risk assessment is the process of evaluating risks to humans and the environment from chemicals or other contaminants and agents that can adversely affect health. For regulatory purposes, the process used to inform risk managers consists of four steps (EFSA, 2012a). On the one hand, information is gathered on the nature of toxic effects (hazard identification) and the possible dose– response relationships between the pesticide and the toxic effects (hazard characterisation). On the other hand, information is sought about the potential exposure of humans (consumers, applicators, workers, bystanders and residents) and of the environment (exposure assessment). These two elements are weighed in the risk characterisation to estimate that populations be potentially exposed to quantities exceeding the reference dose values, that is, to estimate the extra risk of impaired health in the exposed populations. Classically, this is used to inform risk managers for regulatory purposes.

a) Step 1. Hazard identification.

Epidemiological studies and vigilance data are relevant for hazard identification as they can point to potential link between pesticide exposure and health. In this context, epidemiological data can provide invaluable information in 'scanning the horizon' for effects not picked up in experimental models. Importantly, these studies also provide information about potentially enhanced risks for vulnerable population subgroups, sensitive parts of the lifespan, and gender selective effects.

b) Step 2. *Hazard characterisation* (dose–response assessment). As previously discussed a classic dose–response framework is not normally considered when using epidemiological data as the exposure dose is rarely assigned. The challenge presented when high quality epidemiological studies are available is to see whether these can best be integrated into the scheme as numerical input. A dose–response framework is rarely considered when using epidemiological data for risk assessment of pesticides. However, previous scientific opinions of the EFSA CONTAM Panel have used epidemiology as basis for setting reference values, particularly in the case of cadmium, lead, arsenic and mercury, which are the most well-known and data rich (EFSA, 2009a,b, 2010b, 2012b). Even when they may not form the basis of a dose–response assessment, vigilance and epidemiological data may provide supportive evidence to validate or invalidate a dose–response study carried out in laboratory animals. Characterisation of the relationships between varying doses of a chemical and incidences of adverse effects in exposed populations requires characterisation of exposure or dose, assessment of response and selection of a dose–response model to fit the observed data in order to find a no-effect level. This raises two questions: can a dose–response be derived from epidemiological data to identify a no-effect level. If not, can epidemiological information otherwise contribute to the hazard characterisation?

Understanding dose–response relationships could also be relevant where adverse health outcomes are demonstrated to be associated with uses with higher exposures than EU good plant protection practice would give rise to, but where no association is observed from uses with lower exposures. It is clear that in this context the statistical summary of an epidemiological study defining RR or OR is potentially useful quantitative information to feed into the hazard characterisation process, when the study design meets the necessary standards.

c) Step 3. *Exposure assessment*. Data concerning the assessment of exposure are often hard to estimate in complex situations where a variety of uncontrolled 'real-world' factors confound the analysis. As discussed previously, contemporary biological monitoring is rarely carried out in the general human population for practical reasons including high cost, test availability and logistics. However, it is anticipated that in the near future biomonitoring studies and data on quantitative exposure to pesticides will increase.

Step 4. *Risk characterisation*. In this final step, data on exposure are compared with health-based reference values to estimate the extra risk of impaired health in the exposed populations. Human data can indeed help verify the validity of estimations made based on extrapolation from the full toxicological database regarding target organs, dose–response relationships and the reversibility of toxic effects, and to provide reassurance on the extrapolation process without direct effects on the definition of reference values (London et al., 2010).

Epidemiological data might also be considered in the context of uncertainty factors (UFs). An UF of 10 is generally used on animal data to account for interspecies variability of effects and this is combined with a further factor of 10 to account for variation in susceptibility of different parts of the human population. However, there are cases where only human data are considered (when this is more critical than animals data) and a single factor of 10 for intraspecies variability will apply. It is noted that at this moment Regulation (EC) No 1107/2009 Article 4(6) stipulates that: 'In relation to human health, no data collected on humans shall be used to lower the safety margins resulting from tests on animals'. The implication of this is that for risk assessment epidemiological data may only be used to increase the level of precaution used in the risk assessment, and not to decrease UFs even where relevant human data are available.

# 6.2. Assessment of the reliability of individual epidemiological studies

Factors to be considered in determining how epidemiology should be considered for a WoE assessment are described below and have been extensively outlined by available risk of bias tools for observational epidemiological studies.<sup>15</sup> The following examples represent factors to look for not an exhaustive list:

• *Study design and conduct*. Was the study design appropriate to account for the expected distributions of the exposure and outcome, and population at risk? Was the study conducted primarily in a hypothesis generating or a hypothesis-testing mode?

<sup>&</sup>lt;sup>15</sup> Assessing Risk of Bias and Confounding in Observational Studies of Interventions or Exposures: Further Development of the RTI Item Bank (https://www.ncbi.nlm.nih.gov/books/NBK154464/) and Cochrane handbook.

- *Population*. Did the study sample the individuals of interest from a well-defined population? Did the study have adequate statistical power and precision to detect meaningful differences for outcomes between exposed and unexposed groups?
- *Exposure assessment*. Were the methods used for assessing exposure valid, reliable and adequate? Was a wide range of exposures examined? Was exposure assessed at quantitative level or in a categorical or dichotomous (e.g. ever vs never) manner? Was exposure assessed prospectively or retrospectively?
- *Outcome assessment*. Were the methods used for assessing outcomes valid, reliable and adequate? Was a standardised procedure used for collecting data on health outcomes? Were health outcomes ascertained independently from exposure status to avoid information bias?
- *Confounder control*: were potential confounding factors appropriately identified and considered? How were they controlled for? Were the methods used to document these factors valid, reliable and adequate?
- *Statistical analysis*. Did the study estimate quantitatively the independent effect of an exposure on a health outcome of interest? Were confounding factors appropriately controlled in the analyses of the data?
- Is the *reporting* of the study adequate and following the principles of transparency and the guidelines of the STROBE statement (or similar tools)?

Study evaluation should provide an indication on the nature of the potential limitations each specific study may have and an assessment of overall confidence in the epidemiological database.

Furthermore, the nature and the specificity of the outcome with regards to other known risk factors can influence the evaluation of human data for risk assessment purposes, particularly in case of complex health endpoints such as chronic effects with long induction and latency periods.

Table 2 shows the main parameters to be evaluated in single epidemiological studies and the associated weight (low, medium and high) for each parameter. Specific scientific considerations should be applied on a case-by-case basis, but it would be unrealistic to implement these criteria in a rigid and unambiguous manner.

Parameter	High	Moderate	Low
Study design and conduct	Prospective studies. Prespecified hypothesis (compound and outcome specific)	Case–control studies. Prospective studies not adequately covering exposure or outcome assessment	Cross-sectional, ecological studies Case–control studies not adequately covering exposure or outcome assessment
Population	Random sampling. Sample size large enough to warrant sufficient power Population characteristics well defined (including vulnerable subgroups)	Questionable study power, not justified in detail Non-representative sample of the target population Population characteristics not sufficiently defined	No detailed information on how the study population was selected Population characteristics poorly defined
Exposure assessment	Accurate and precise quantitative exposure assessment (human biomonitoring or external exposure) using validated methods Validated questionnaire and/or interview for chemical-specific	Non-valid surrogate or biomarker in a specified matrix and external exposure Questionnaire and/or interview for chemical-specific exposure	Poor surrogate Low-quality questionnaire and/or interview; information collected for groups of chemicals No chemical-specific exposure information collected;
	exposure answered by subjects	answered by subjects or proxy individuals	
Outcome Assessment	Valid and reliable outcome assessment. Standardised and validated in study population Medical record or diagnosis confirmed	Standardised outcome, not validated in population, or screening tool; or, medical record non-confirmed	Non-standardised and non-validated health outcome Inappropriate or self-reported outcomes.

Table 2:	Study quality	considerations for	weighting	epidemiological	observational studies <sup>(a),(</sup>	(b)
----------	---------------	--------------------	-----------	-----------------	--	-----

Parameter	High	Moderate	Low
Confounder control	Adequate control for important confounders relevant to scientific question, and standard confounders Careful consideration is given to clearly indicated confounders	Confounders are partially controlled for Moderately control of confounders and standard variables Not all variables relevant for scientific question are considered	No control of potential confounders and effect modifiers in the design and analysis phases of the study
Statistical Analysis	Appropriate to study design, supported by adequate sample size, maximising use of data, reported well (not selective) Statistical methods to control for confounding are used and adjusted and unadjusted estimates are presented. Subgroups and interaction analysis are conducted	Acceptable methods, analytic choices that lose information, not reported clearly Post hoc analysis conducted but clearly indicated	Only descriptive statistics or questionable bivariate analysis is made Comparisons not performed or described clearly Deficiencies in analysis (e.g. multiple testing)
Reporting	Key elements of the Material and Methods, and results are reported with sufficient detail Numbers of individuals at each stage of study is reported A plausible mechanism for the association under investigation is provided	Some elements of the Material and Methods or results are not reported with sufficient detail Interpretation of results moderately addressed	Deficiencies in reporting (interpretation of effect estimates, confounder control) Selective reporting Paucity of information on relevant factors that may affect the exposure-health relationship. Misplaced focus of the inferential objectives Not justified conclusions

(a): Overall study quality ranking based on comprehensive assessment across the parameters.

(b): Adapted from US-EPA (2016), based in turn on Muñoz-Quezada et al. (2013) and LaKind et al. (2014).

If the above assessment is part of the evidence synthesis exercise, where epidemiological research is being assessed and quantitatively summarised, it permits more accurate estimation of absolute risk related to pesticide exposure and further quantitative risk assessment.

In the particular case of pesticide epidemiology data, three basic categories are proposed as a first tier to organise human data with respect to risk of bias and reliability<sup>16</sup>: (a) low risk of bias and high reliability (all or most of the above quality factors have been addressed with minor methodological limitations); (b) medium risk of bias and medium reliability (many of the above quality factors have been addressed with moderate methodological limitations); (c) high risk of bias and low reliability, because of serious methodological limitations or flaws that reduce the validity of results or make them largely uninterpretable for a potential causal association. The latter studies are considered unacceptable for risk assessment mainly because of poor exposure assessment, misclassification of exposure and/or health outcome, or lack of statistical adjustment for relevant confounders. Risk assessment should not be based on results of epidemiological studies that do not meet well-defined data quality standards. Furthermore, results of exploratory research will need to be confirmed in future research before they can be used for risk assessment.

# 6.3. Assessment of strength of evidence of epidemiological studies

This section briefly discusses some important issues specifically related to combining and summarising results from different epidemiological studies on the association between pesticides and human health.

The approach for weighting epidemiological studies is mainly based on the modified Bradford Hill criteria, which are a group of conditions that provide evidence bearing on a potentially causal relationship between an incidence and a possible consequence (strength, consistency, specificity, temporality, biological gradient, plausibility, coherence, experiment and analogy) (Table 3). Clearly, the

<sup>&</sup>lt;sup>16</sup> These categories are in accordance with those currently used by EFSA for the peer review of pesticide active substances: acceptable, supplementary and unacceptable.

more of these criteria that are met the stronger the basis for invoking the association as evidence for a meaningful association. However, Bradford Hill was unwilling to define what causality was and never saw the criteria as sufficient or even absolutely necessary but simply of importance to consider in a common-sense evaluation.

Table 3:	Considerations for WoE analysis based on the modified Bradford Hill criteria for evidence	
	integration	

Category	Considerations
Strength of Association	The assessment of the strength of association (not only the magnitude of association but also statistical significance) requires examination of underlying methods, comparison to the WoE in the literature and consideration of other contextual factors including the other criteria discussed herein
Consistency of Association	Associations should be consistent across multiple independent studies, particularly those conducted with different designs and in different populations under different circumstances. This criterion also applies to findings consistent across all lines of evidence (epidemiology, animal testing, <i>in vitro</i> systems, etc.) in light of modern data integration
Specificity	The original criteria of evidence linking a specific outcome to an exposure can provide a strong argument for causation has evolved and may have new and interesting implications within the context of data integration. Data integration may elucidate some mechanistic specificity among the varied outcomes associated with complex exposures. The lack of specificity can help to narrow down specific agents associated with disease
Temporality	Evidence of a temporal sequence between exposure to an agent and appearance of the effect within an appropriate time frame constitutes one of the best arguments in favour of causality. Thus, study designs that ensure a temporal progression between the two measures are more persuasive in causal inference
Biological Gradient (Dose–response)	Increased effects associated with greater exposures, or duration of exposures, strongly suggest a causal relationship. However, its absence does not preclude a causal association
Biological Plausibility	Data explained and supported by biologically plausible mechanisms based on experimental evidence strengthen the likelihood that an association is causal. However, lack of mechanistic data should not be taken as evidence against causality
Coherence	The interpretation of evidence should make sense and not to conflict with what is known about the biology of the outcome in question under the exposure-to-disease paradigm. If it does, the species closest to humans should be considered to have more relevance to humans
Experimental Evidence	Results from randomised experiments provide stronger evidence for a causal association than results based on other study designs. Alternatively, an association from a non- experimental study may be considered as causal if a randomised prevention derived from the association confirms the finding
Sequence of Key events	Provide a clear description of each of the key events (i.e. measurable parameters from a combination of <i>in vitro</i> , <i>in vivo</i> or human data sources) that underlie the established MoA/AOP for a particular health outcome. A fully elucidated MoA/AOP is a not requirement for using epidemiology studies in human health risk assessment

Adapted from Höfler (2005), Fedak et al. (2015) and US-EPA (2016).

For predictive causality, care must be taken to avoid the logical fallacy *post hoc ergo propter hoc* that states 'Since event Y followed event X, event Y must have been caused by event X'. Höfler (2005) quotes a more accurate 'counterfactual' definition as follows 'but for E, D will not occur or would not have occurred, but given E it will/would have occurred'. Yet, more detailed descriptions using symbolic logic are also available (Maldonado and Greenland, 2002). Rothman and Greenland (2008) stated that 'the only *sine qua non* for a counterfactual effect is the condition that the cause must precede the effect. If the event proposed as a result or "effect" precedes its cause, there may be an association between the events but certainly no causal relationship'.

#### 6.3.1. Synthesis of epidemiological evidence

Systematic reviews and meta-analysis of observational studies can provide information that strengthens the understanding of the potential hazards of pesticides, exposure–response characterisation, exposure scenarios and methods for assessing exposure, and ultimately risk characterisation (van den Brandt, 2002). Systematic reviews entail a detailed and comprehensive plan

and search strategy defined *a priori* aimed at reducing bias by identifying, appraising and synthesising all relevant studies on a particular topic. The major steps of a systematic review are as follows: formulation of the research question; definition of inclusion and exclusion criteria; search strategy for studies across different databases; selection of studies according to predefined strategy; data extraction and creation of evidence tables; assessment of methodological quality of the selected studies; including the risk of bias; synthesis of data (a meta-analysis can be performed if studies allow); and interpretation of results and drawing of conclusions (EFSA, 2010a). Evidence synthesis is, however, challenging in the field of pesticide epidemiology as standardisation and harmonisation is difficult. Nonetheless, evidence synthesis should play a pivotal role in assessing the robustness and relevance of epidemiological studies.

Statistical tools have been developed that can help assess this evidence. When multiple studies on nearly identical sets of exposures and outcomes are available, these can provide important scientific evidence. Where exposure and outcomes are quantified and harmonised across studies, data from individual epidemiological studies with similar designs can be combined to gain enough power to obtain more precise risk estimates and to facilitate assessment of heterogeneity. Appropriate systematic reviews and quantitative synthesis of the evidence needs to be performed regularly (e.g. see World Cancer Research Fund approach to continuous update of meta-analysis for cancer risk factor<sup>17</sup>). Studies should be evaluated according to previously published criteria for observational research and carefully examine possible selection bias, measurement error, sampling error, heterogeneity, study design, and reporting and presentation of results.

Meta-analysis is the term generally used to indicate the collection of statistical methods for combining and contrasting the results reported by different studies (Greenland and O'Rourke, 2008). Meta-analysis techniques could be used to examine the presence of diverse biases in the field such as small study effects and excess significance bias. Meta-analyses, however, do not overcome the underlying biases that may be associated with each study design (i.e. confounding, recall bias or other sources of bias are not eliminated). The extent to which a systematic review or meta-analysis can draw conclusions about the effects of a pesticide depends strongly on whether the data and results from the included studies are valid, that is, on the quality of the studies considered. In particular, consistent findings among original studies resulting from a consistent bias will produce a biased conclusion in the systematic review. Likewise, a meta-analysis of invalid studies may produce a misleading result, yielding a narrow confidence interval around the wrong effect estimate.

In addition to summarising the basic study characteristics of the literature reviewed, a typical metaanalysis should include the following components: (a) the average effect size and effect size distribution for each outcome of interest and an examination of the heterogeneity in the effect size distributions; (b) subgroup analysis in which the variability present in the effect size distribution is systematically analysed to identify study characteristics that are associated with larger or smaller effect sizes; (c) publication bias analysis and other sensitivity analyses to assess the validity of conclusions drawn (Wilson and Tanner-Smith, 2014).

In a meta-analysis, it is important to specify a model that adequately describes the effect size distribution of the underlying population of studies. Meta-analysis using meaningful effect size distributions will help to integrate quantitative risk into risk assessment models. The conventional normal fixed- and random-effects models assume a normal effect size population distribution, conditionally on parameters and covariates. Such models may be adequate for estimating the overall effect size, but surely not for prediction if the effect size distribution exhibits a non-normal shape (Karabatsos et al., 2015).

#### 6.3.2. Meta-analysis as a tool to explore heterogeneity across studies

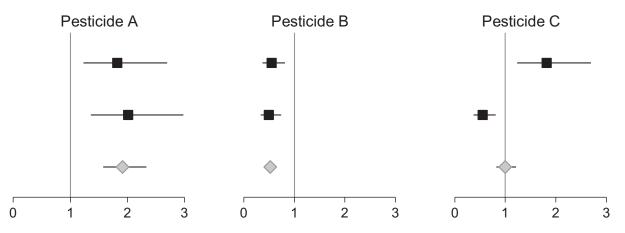

When evaluating the findings of different studies, many aspects should be carefully evaluated. Researchers conducting meta-analyses may tend to limit the scope of their investigation to the determination of the size of association averaged over the considered studies. The motivation often is that aggregating the results yields greater statistical power and precision for the effect of interest. Because individual estimates of effect vary by chance, some variation is expected. However, estimates must be summarised only when meaningful. An important aspect that is often overlooked is heterogeneity of the strength of associations across subgroups of individuals. Heterogeneity between

<sup>&</sup>lt;sup>17</sup> World Cancer Research Fund International. Continuous Update Project (CUP) http://www.wcrf.org/int/research-we-fund/ continuous-update-project-cup

studies needs to be assessed and quantified when present (Higgins, 2008). In meta-analysis, heterogeneity among results from different studies may indeed be as informative as homogeneity. Exploring the reasons underlying any observed inconsistencies of findings is generally conducive of great understanding.

Figure 1 shows three forest plots from a fictitious example in which each of three pesticides (A, B and C) is evaluated in meta-analysis of two studies. It is assumed that both studies for each pesticide are of the highest quality and scientific rigor. No biases are suspected.

**Figure 1:** Forest plots from a fictitious example in which each of three pesticides (A, B and C) is evaluated in a meta-analysis of two studies. The x-axis in each plot represents the estimated risk ratio of the disease of interest comparing exposed and unexposed individuals. The squares denote the estimated risk ratio in each study and the grey diamonds the summarised risk ratio. The horizontal lines indicate 95% confidence intervals

The following text contains short comments on the interpretation of the results in Figure 1, one pesticide at a time.

- Exposure to pesticide A seems to double the risk of the disease. The results are consistent between the two studies and the confidence intervals do not contain the null value, one. These results, however, do not imply that (a) the risk ratio would be about 2 in any other study that was conducted on the same exposure and disease; or that (b) the risk ratio is two in any group of individuals (e.g. males or females, young or old).
- Exposure to pesticide B seems to halve the risk of the disease. The results are consistent between the two studies and the confidence intervals do not contain the null value, one. These results, however, do not imply that (a) the risk ratio would be about a half in any other study that was conducted on the same exposure and disease; or that (b) the risk ratio is about a half in any group of individuals (e.g. males or females, young or old).
- Exposure to pesticide C seems to double the risk of the disease in one study and to halve the risk in the other. The results are inconsistent between the two studies and the confidence intervals do not contain the null value, one. These results, however, do not imply that (a) the risk ratio would be about one in any other study that was conducted on the same exposure and disease; or that (b) the risk ratio is about one in any group of individuals (e.g. males or females, young or old).

What evidence can the results shown in Figure 1 provide?

The risk ratio reported by any study can be generalised to other populations only if all the relevant factors have been controlled for (Bottai, 2014; Santacatterina and Bottai, 2015). In this context, relevant factors are variables that are stochastically dependent with the health outcome of interest. For example, cardiovascular diseases are more prevalent among older subjects than among younger individuals. Age is therefore a relevant factor for cardiovascular diseases. The evidence provided by the results shown in Figure 1 are potentially valid only if this step was taken in each of the studies considered. If that was the case for the studies, then, there is evidence that exposure to pesticide A doubles the risk in the specific group of individuals considered by each of the two studies. If the risk ratios are summary measures over the respective study populations, then none of the findings should be generalised. However, if the risk ratios for pesticide A were not adjusted for any factor, and the underlying populations were very different

across the two studies, then there would still be evidence that there may be no relevant factors and pesticide A doubles the risk in any subgroup of individuals. Pesticide B appears to halve the risk, and the estimated confidence intervals are narrower for pesticide B than for pesticide A. Generalisability of the findings, however, holds for pesticide B under the conditions stated above for pesticide A. As for pesticide C, the forest plot provides evidence that exposure to this pesticide raises the risk of the disease in the group of individuals in one of the studies and decreases it in the group considered in the other study. Again, if the risk ratios are summary measures over the respective study populations, then none of the findings should be generalised. Investigating the reasons behind the inconsistency between the two studies on pesticide C can provide as much scientific insight as investigating the reasons behind the similarity between the studies on pesticide A or pesticide B.

In general, the overall summary measures provided by forest plots, such as the silver diamonds in each of the three panels of Figure 1, are of little scientific interest. When evaluating the findings of different studies, many aspects should be carefully evaluated. An important aspect that is often overlooked is heterogeneity of the strength of associations across subgroups of individuals. When information about subgroup analysis is provided in the publications that describe a study, this should be carefully evaluated. Sensitivity analyses should complement the results provided by different studies. These should aim to evaluate heterogeneity and the possible impact of uncontrolled for relevant factors along with information and sampling error. A synoptic diagram is displayed in Figure 2.

#### Bias

• Information error, such as measurement error, effect size magnification

#### Relevant Factors

- Which were considered and which were not considered
- How were they distributed in each study
- What population is the resulting inference on

#### Sampling Error

• Standard errors, not p-values, of the estimates of the parameters of interest

Sensitivity Analyses

• Range of the parameters of interest that are consistent with observed data

#### 6.3.3. Usefulness of meta-analysis for hazard identification

Human data can be used for many stages of risk assessment. Single epidemiological studies, if further studies on the same pesticide are not available, should not be used as a sole source for hazard identification, unless they are high quality studies (according to criteria shown in Table 2). Evidence synthesis techniques which bring together many studies, such as systematic reviews and meta-analysis (where appropriate) should be utilised instead. Although many meta-analyses have been carried out for the quantitative synthesis of data related to chronic diseases, their application for risk assessment modelling is still limited.

Importantly, evidence synthesis will provide a methodological assessment and a risk of bias assessment of the current evidence highlighting areas of uncertainties and identifying associations with robust and credible evidence.

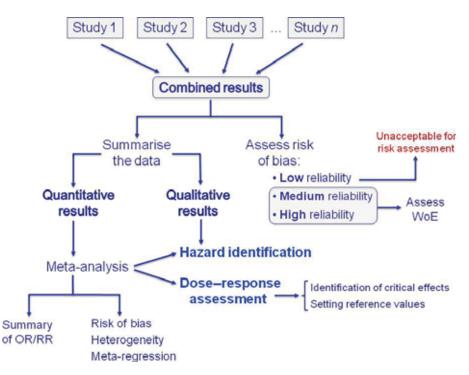

Figure 3 shows a simple methodology proposed for the application of epidemiological studies into risk assessment. The first consideration is the need of combining different epidemiological studies

addressing the same outcome. This can be made following criteria proposed by EFSA guidance for systematic reviews (EFSA, 2010a). Then, the risk of bias is assessed based on the factors described in Section 6.2 for a WoE assessment, namely: study design and conduct, population, exposure assessment, outcome assessment, confounder control, statistical analysis and reporting of results. Those studies categorised as of low reliability will be considered unacceptable for risk assessment. The remaining studies will be weighted and used for hazard identification.

If quantitative data are available, a meta-analysis can be conducted to create summary data and to improve the statistical power and precision of risk estimates (OR, RR) by combining the results of all individual studies available or meeting the selection criteria. As meta-analyses determine the size of association averaged over the considered studies, they provide a stronger basis for hazard identification. Moreover, under certain circumstances, there is the possibility to move towards risk characterisation metrics because these measured differences in health outcomes (OR, RR) can be converted to dose–response relationships (Nachman et al., 2011). Although quite unusual in practice, this would allow for the identification of critical effects in humans and/or setting reference values without the need of using animal extrapolation.

Since heterogeneity is common in meta-analyses, there is a need to assess which studies could be combined quantitatively. Heterogeneity can be genuine, representing diverse effects in different subgroups, or might represent the presence of bias. If heterogeneity is high (I<sup>2</sup> greater than 50%), individual studies should not be combined to obtain a summary measure because of the high risk of aggregating bias from different sources. Sources of heterogeneity should be explored through sensitivity analysis and/or meta-regression. Furthermore, the presence of diverse biases in the meta-analysis should be examined, such as small study effects, publication bias and excess significance bias. It is important to find models that adequately describe the effect size distribution of the underlying studied populations.

6.3.4. Pooling data from similar epidemiological studies for potential dose-response modelling

As in other fields of research, findings from a single epidemiological study merit verification through replication. When the number of replications is abundant, it may be worthwhile to assess the entire set of replicate epidemiological studies through a meta-analysis and ascertain whether, for key outcomes, findings are consistent across studies. Such an approach will provide more robust conclusions about the existence of cause-effect relationships.

Once a hazard has been identified, the next step in risk assessment is to conduct a dose-response assessment to estimate the risk of the adverse effect at different levels of exposure and/or the concentration level below which no appreciable adverse health effect can be assumed for a given population. However, this step requires fully quantitative (or at least semi-quantitative) exposure data at an individual level. Summary estimates resulting from quantitative synthesis would be more informative for risk assessment if they present an OR for a given change in the continuous variable of exposure (or per a given percentile change in exposure) as this allows for relative comparisons across studies and could be of help to derive health-based reference values. Only within such a framework can data from human studies with similar designs be merged to gain enough power to model proper dose-response curves (Greenland and Longnecker, 1992; Orsini et al., 2012).

Conversely, meta-analytical approaches may be of limited value if a combined OR is calculated based on meta-analyses interpreting exposure as a 'yes' or a 'no' (ever vs never) because exposures are not necessarily to active ingredients in the same proportion in all studies included. Even though in these cases, meta-analyses may consistently find an increased risk associated with pesticide exposure, for risk assessment the exposure needs to characterise the effect of specific pesticide classes or even better individual pesticides as their potency may differ within the same class (Hernández et al., 2016).

This approach would allow points of departure to be identified (e.g. benchmark doses (BMD)) and would be relevant for the integration of epidemiological studies into quantitative risk assessment. Although BMD modelling is currently used for analysing dose–response data from experimental studies, it is possible to apply the same approach to data from observational epidemiological studies (Budtz-Jørgenson et al., 2004). The EFSA Scientific Committee confirmed that the BMD approach is a scientifically more advanced method compared to the no observed-adverse-effect level (NOAEL) approach for deriving a Reference Point, since it makes extended use of the dose–response data from experimental and epidemiological studies to better characterise and quantify potential risks. This approach, in principle, can be applicable to human data (EFSA Scientific Committee, 2017b), although the corresponding guidelines are yet to be developed.

Dose–response data from observational epidemiological studies may differ from typical animal toxicity data in several respects and these differences are relevant to BMD calculations. Exposure data often do not fall into a small number of well-defined dosage groups. Unlike most experimental studies, observational studies may not include a fully unexposed control group, because all individuals may be exposed to some extent to a chemical contaminant. In this case, the BMD approach still applies since fitting a dose–response curve does not necessarily require observations at zero exposure. However, the response at zero exposure would then need to be estimated by low-dose extrapolation. Hence, the BMD derived from epidemiological data can be strongly model-dependent (Budtz-Jørgensen et al., 2001).

Epidemiology data need to be of sufficient quality to allow the application of the BMD approach, especially in terms of assigning an effect to a specific pesticide and its exposure. Clear rules and guidance, and definition of model parameters need to be considered for such a BMD approach, which might differ from BMD approaches from controlled experimental environments. Although the BMD modelling approach has been applied to epidemiological data on heavy metals and alcohol (Lachenmeier et al., 2011), currently, few individual studies on pesticides are suitable for use in dose–response modelling, much less in combination with other studies. However, future studies should be conducted and similarly reported so that they could be pooled together for a more robust assessment.

# 7. Integrating the diverse streams of evidence: human (epidemiology and vigilance data) and experimental information

This section first considers in Section 7.1 the different nature of the main streams of evidence, i.e. originating either from experimental studies or from epidemiological studies. The approach used is that recommended by the EFSA Scientific Committee Guidance on WoE (EFSA Scientific Committee, 2017b), which distinguishes three successive phases to assess and integrate these different streams of information: reliability, relevance and consistency. The first step, consists in the assessment of the reliability of individual studies be they epidemiological (addressed in Section 6) or experimental (beyond the scope of this Scientific Opinion). Then, the relevance (strength of evidence) of one or more studies found to be reliable is assessed using principles of epidemiology (addressed in Section 6) and toxicology. Next, Section 7.2 considers how to bring together different streams of relevant information from epidemiological and experimental studies, which is considered in a WoE approach, to assess consistency and biological plausibility for humans.

# 7.1. Sources and nature of the different streams of evidence Comparison of experimental and epidemiological approaches

In the regulatory risk assessment of pesticides, the information on the toxic effects is based on the results of a full set of experiments as required by Regulation (EC) 283/2013 and 284/2013, and conducted according to OECD guidelines. They are carried out *in vivo* or *in vitro*, so there will always be some high-quality experimental data available for pesticides as required to be provided by applicants under Regulation (EC) 1107/2009. A number of categories are established for rating the reliability of each stream of evidence according to the EFSA peer review of active substances: acceptable, supplementary and unacceptable. The data quality and reliability of *in vivo* or *in vitro* toxicity studies should be assessed using evaluation methods that better provide more structured support for determining a study's adequacy for hazard and risk assessments. Criteria have been proposed for conducting and reporting experimental studies to enable their use in health risk assessment for pesticides (Kaltenhäuser et al., 2017).

Animal (*in vivo*) studies on pesticide active substances conducted according to standardised test guidelines and good laboratory practices (GLP, e.g. OECD test guidelines) are usually attributed higher reliability than other research studies. Notwithstanding, since there is no evidence that studies conducted under such framework have a lower risk of bias (Vandenberg et al., 2016), evidence from all relevant studies, both GLP and non-GLP, should also be considered and weighted. Thus, data from peer-reviewed scientific literature should be taken into account for regulatory risk assessment of pesticide active substances, provide they are of sufficient quality after being assessed for methodological reliability. Their contribution to the overall WoE is influenced by factors including test organism, study design and statistical methods, as well as test item identification, documentation and reporting of results (Kaltenhäuser et al., 2017).

The internal validity of *in vitro* toxicity studies should be evaluated as well to provide a better support for determining a study's adequacy for hazard and risk assessments. *In silico* modelling can be used to derive structure–activity relationships (SAR) and to complement current toxicity tests for the identification and characterisation of the mode or mechanisms of action of the active substance in humans. These alternative toxicity testing (and non-testing) approaches could be helpful in the absence of animal data, e.g. to screen for potential neurodevelopmental or endocrine disruption effects of pesticides, and to increase confidence in animal testing. Considering the demand for minimising the number of animal studies for regulatory purposes, non-animal testing information can provide relevant stand-alone evidence that can be used in the WoE assessment.

A number of toxicological issues are amenable for systematic review, from the impact of chemicals on human health to risks associated with a specific exposure, the toxicity of chemical mixtures, the relevance of biomarkers of toxic response or the assessment of new toxicological test methods (Hoffmann et al., 2017). For instance, in a previous Scientific Opinion EFSA used a systematic review for the determination of toxicological mechanisms in the frame of AOP approach (Choi et al., 2016; EFSA Scientific Committee, 2017c).

Besides toxicity data on the active substance, such data may also be required on metabolites or residues if human exposure occur through the diet or drinking water. Results from these studies are then considered in relation to expected human exposures estimated through food consumption and other sources of exposure. The strength of this approach is that *in vivo* studies account for potential toxic metabolites, though not always animal metabolic pathways parallels the ones of humans.

Experimental studies in laboratory animals are controlled studies where confounding is eliminated by design, which is not always the case with epidemiological studies. Animals used in regulatory studies are, however, typically inbred, genetically homogeneous and due to the controlled environment they lack the full range of quantitative and qualitative chemical susceptibility profiles. Nevertheless, animal surrogates of human diseases are being challenged by their scientific validity and translatability to humans, and the lack of correlation often found between animal data and human outcomes can be attributed to the substantial interspecies differences in disease pathways and disease-induced changes in gene expression profiles (Esch et al., 2015). Thereby, many experimental models do not capture complex multifactorial diseases making animal-to-human extrapolation subject to considerable uncertainty. Current risk assessment is therefore by its nature predictive and may be insufficient because it is chemical-specific and humans are exposed to a large number of chemicals from environmental, dietary and occupational sources or because of different toxicokinetic differences. In recognition of the uncertain nature of animal-to-human extrapolation, the regulatory risk assessment advice does not just consider the relevant point(s) of departure (NOAEL, LOAEL or BMDL) that have

been identified as safe but lowers these values using uncertainty factors (UFs) to propose safe reference dose values, either for acute or chronic toxicity.

Given the limitations of studies in laboratory animals, epidemiological studies in the 'real world' are needed, even if they have limitations of their own. Epidemiological studies incorporate the true (or estimated) range of population exposures, which usually are intermittent and at inconsistent doses instead of occurring at a consistent rate and dose magnitude (Nachman et al., 2011). Since epidemiological studies are based on real-world exposures, they provide insight into actual human exposures that can then be linked to diseases, avoiding the uncertainty associated with extrapolation across species. Hence, it can be said that they address the requirements of Regulation 1107/2009 Article 4, which stipulates that the risk assessment should be based on good plant protection practice and realistic use conditions. Thus, epidemiological studies assist problem formulation and hazard/risk characterisation whilst avoiding the need for high dose extrapolation (US-EPA, 2010).

Epidemiological studies therefore provide the opportunity to (a) identify links with specific human health outcomes that are difficult to detect in animal models; (b) affirmation of the human relevance of effects identified in animal models; (c) ability to evaluate health effects for which animal models are unavailable or limited (Raffaele et al., 2011). Epidemiological evidence will be considered over experimental animal evidence only when sufficiently robust pesticide epidemiological studies are available. However, in epidemiological studies, there are always a variety of factors that may affect the health outcome and confound the results. For example, when epidemiological data suggest that exposures to pesticide formulations are harmful they usually cannot identify what component may be responsible due to the complexity of accurately assessing human exposures to pesticides. While some co-formulants are not intrinsically toxic, they can be toxicologically relevant if they change the toxicokinetics of the active substance. In addition, confounding by unmeasured factor(s) associated with the exposure can never be fully excluded; however, a hypothetical confounder (yet unrecognised) may not be an actual confounder and has to be strongly associated with disease and exposure in order to have a meaningful effect on the risk (or effect size) estimate, which is not always the case.

Many diseases are known to be associated with multiple risk factors; however, a hazard-by-hazard approach is usually considered for evaluating the consequences of individual pesticide hazards on vulnerable systems (Figure 4A). Specifically, single-risk analysis allows a determination of the individual risk arising from one particular hazard and process occurring under specific conditions, while it does not provide an integrated assessment of multiple risks triggered by different environmental stressors (either natural or anthropogenic) (Figure 4B). Risk assessment would benefit by developing procedures for evaluating evidence for co-occurrence of multiple adverse outcomes (Nachman et al., 2011), which is more in line with what happens in human setting. For these reasons, if appropriately conducted, epidemiological studies can be highly relevant for the risk assessment process.

# A Classical <u>single hazard</u> approach: driven by regulatory frameworks

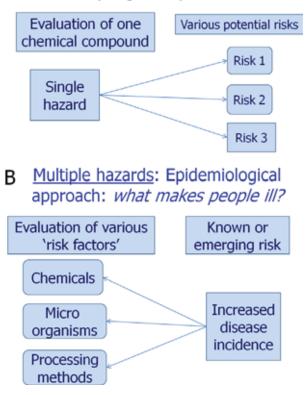

Figure 4: Role of epidemiological studies when compared to classical toxicological studies

In parallel with epidemiological data, vigilance data can provide an additional stream of evidence, especially for acute toxicity. Cases are usually well-documented and information can be used at different steps of the risk assessment; these include: level and duration of exposure, clinical course and assessment of the causal relationship. In severe cases, the toxin and/or the metabolites are usually measured in blood or urine which allows for comparison with animal data and in some cases for setting toxicological values.

In summary, experimental studies or epidemiological studies and vigilance data represent two different approaches to collect and assess evidence i.e. one emanating from controlled exposures (usually to a single substance) using experimental study design and a relatively homogeneous surrogate population, the other reflecting the changes observed in a heterogeneous target population from mixed (and varying) exposure conditions using non-experimental study design (ECETOC, 2009). Epidemiology and toxicology each bring important and different contributions to the identification of human hazards. This makes both streams of evidence complementary, and their combination represents a powerful approach. Animal studies should always inform the interpretation of epidemiological studies and vice versa; hence, they should not be studied and interpreted independently.

# 7.2. Principles for weighting of human observational and laboratory animal experimental data

Following the identification of reliable human (epidemiological or vigilance) studies and the assessment of the relevance of the pooled human studies, the separate lines of evidence that were found to be relevant need to be integrated with other lines of evidence that were equally found to be relevant.

The first consideration is thus how well the health outcome under consideration is covered by toxicological and epidemiological studies. When both animal and human studies are considered to be available for a given outcome/endpoint, this means that individual studies will first have been assessed for reliability and strength of evidence (Sections 6.2 and 6.3, respectively, for epidemiological studies)

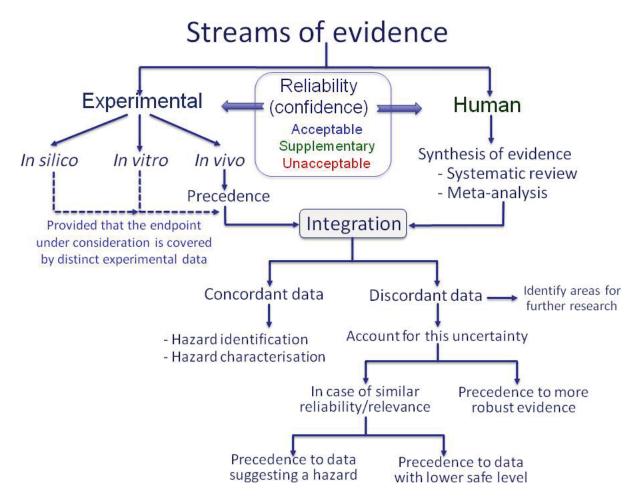

prior to the weighting of the various sources of evidence. Although the different sets of data can be complementary and confirmatory, individually they may be insufficient and pose challenges for characterising properly human health risks. Where good observational data are lacking, experimental data have to be used. Conversely, when no experimental data is available, or the existing experimental data were found not to be relevant to humans, the risk assessment may have to rely on the available and adequate observational studies.

A framework is proposed for a systematic integration of data from multiple lines of evidence (in particular, human and experimental studies) for risk assessment (Figure 5). Such integration is based on a WoE analysis accounting for relevance, consistency and biological plausibility using modified Bradford Hill criteria (Table 3). For a comparative interpretation of human and animal data, this framework should rely on the following principles (adapted from ECETOC, 2009; Lavelle et al., 2012):

- Although the totality of evidence should be assessed, only the studies that are found to be reliable (those categorised as acceptable or supplementary evidence) are considered further. If the data from the human or the experimental studies is considered to be of low reliability (categorised as unacceptable), no risk assessment can be conducted.
- A WoE approach should be followed where several lines of evidence are found to be relevant. For pesticide active substances, experimental studies following OECD test guidelines are deemed high reliability unless there is evidence to the contrary. The strength of evidence from animal studies can be upgraded if there is high confidence in alternative pesticide toxicity testing or non-testing methods (e.g. *in vitro* and *in silico* studies, respectively). As for epidemiological evidence, the conduct of meta-analysis provides a more precise estimate of the magnitude of the effect than individual studies and also allows for examining variability across studies (see Section 6.3).
- Next, the studies that are found to be more relevant for the stage being assessed are to be given more weight, regardless of whether the data comes from human or animal studies. Where human data are of highest relevance, and supported by a mechanistic scientific foundation, they should take precedence for each stage of the risk assessment. When human and experimental data are of equal or similar relevance, it is important to assess their concordance (consistency across the lines of evidence) in order to determine whether and which data set may be given precedence.
  - In case of concordance between human and experimental data, the risk assessment should use all the data as both yield similar results in either hazard identification (e.g. both indicate the same hazard) or hazard characterisation (e.g. both suggest similar safe dose levels). Thus, both can reinforce each other and similar mechanisms may be assumed in both cases.
  - In case of non-concordance, the framework needs to account for this uncertainty. For hazard identification, the data suggesting the presence of a hazard should generally take precedence. For dose-response, the data resulting in the lower acceptable level should take precedence. In every situation of discordance, the reasons for this difference should be considered. If the reason is related to the underlying biological mechanisms, or toxicokinetic differences between humans and animal models, then confidence in the risk assessment will increase. Conversely, if the reason cannot be understood or explained, then the risk assessment may be less certain. In such cases, efforts should be made to develop a better understanding of the biological basis for the contradiction.

**Figure 5:** Methodology for the integration of human and animal data for risk assessment

Epidemiological studies provide complementary data to analyse risk and should be contextualised in conjunction with well-designed toxicological *in vivo* studies and mechanistic studies. The overall strength of the evidence achieved from integrating multiple lines of evidence will be at least as high as the highest evidence obtained for any single line. This integrated approach provides explicit guidance on how to weight and integrate toxicological and epidemiological evidence. This is a complex task that becomes even more difficult when epidemiological data deal with multifactorial, multihit, chronic diseases for which toxicological models, or disease-specific animal models, are limited.

# 7.3. Weighting all the different sources of evidence

The WHO/IPCS defines the WoE approach as a process in which all of the evidence considered relevant for risk assessment is evaluated and weighted (WHO/IPCS, 2009). The WoE approach, taking the risk assessment of chemical substances as an example, requires the evaluation of distinct lines of evidence (*in vivo, in vitro, in silico,* population studies, modelled and measured exposure data, etc.). The challenge is to weight these types of evidence in a systematic, consistent and transparent way (SCENIHR, 2012). The weighting may be formally quantitative or rely on categorisation according to criterion referencing of risk.

An EFSA Working Group was established to provide transparent criteria for the use of the WoE approach for the evaluation of scientific data by EFSA's Panels and Scientific Committee (EFSA, 2015b). The aim of this Working Group was to provide support to stakeholders on how individual studies should be selected and weighted, how the findings integrated to reach the final conclusions and to identify uncertainties regarding the conclusions.

The WoE approach is not consistently considered in the risk assessment of pesticides in the peer review process of DAR or RAR. Expert judgement alone, without a structured WoE approach, has been more commonly used. A few examples can be found, such as the peer review of glyphosate (EFSA, 2015c), where the rapporteur Member State (RMS) considered all the data either from industry or

from public literature, including epidemiological data, and took a specific WoE approach with established *ad hoc* criteria and considering all data available for proposing an 'overall' NOAEL for each endpoint of toxicity explored.

The US-EPA has recently applied specific criteria for the WoE approach to the peer review of the pesticide chlorpyrifos by following the 'Framework for incorporating human epidemiologic & incident data in health risk assessment'. In this specific case, a WoE analysis has been conducted to integrate quantitative and qualitative findings across many lines of evidence including experimental toxicology studies, epidemiological studies and physiologically based pharmacokinetic and pharmacodynamic (PBPK-PD) modelling. Chlorpyrifos was also used as an example for the EFSA Guidance on literature search under Regulation (EC) No 1107/2009. In addition, an EFSA conclusion (EFSA, 2014a) took into consideration the US-EPA review (2011) to revise its first conclusion produced in 2011.

In sum, a broader WoE approach can be applied to evaluate the available scientific data using modified Bradford Hill criteria as an organisational tool to increase the likelihood of an underlying causal relationship (Table 3). Although epidemiology increasingly contributes to establishing causation, an important step to this end is the establishment of biological plausibility (US-EPA, 2010; Adami et al., 2011; Buonsante et al., 2014).

# 7.4. Biological mechanisms underlying the outcomes

A biological mechanism describes the major steps leading to a health effect following interaction of a pesticide with its biological targets. The mechanism of toxicity is described as the major steps leading to an adverse health effect. An understanding of all steps leading to an effect is not necessary, but identification of the key events following chemical interaction is required to describe a mechanism (of toxicity in the case of an adverse health effect). While many epidemiological studies have shown associations between pesticide exposures and chronic diseases, complementary experimental research is needed to provide mechanistic support and biological plausibility to the human epidemiological observations. Experimental exposures should be relevant to the human population provided that the biologic mechanisms in laboratory animals occur in humans.

Establishing biological plausibility as part of the interpretation of epidemiological studies is relevant and should take advantage of modern technologies and approaches (Section 7.6). In this context, the AOP framework can be used as a tool for systematically organising and integrating complex information from different sources to investigate the biological mechanisms underlying toxic outcomes and to inform the causal nature of links observed in both experimental and observational studies (Section 7.5).

The use of data to inform specific underlying biological mechanisms or pathways of the potential toxic action of pesticides is limited since only selected pesticide chemicals have been investigated for biological function in relation to a specific health outcome. It may be possible to formulate a mode of action (MoA) hypothesis, particularly where there is concordance between results of comparable animal studies or when different chemicals show the same pattern of toxicity. It is essential to identify the toxicant and the target organ as well as the dose–response curve of the considered effect and its temporal relationship. If the different key events leading to toxicity and a MoA hypothesis can be identified, it is sometimes possible to evaluate the plausibility of these events to humans (ECETOC, 2009).

Sulfoxaflor is an example where MoA has been extensively studied and has been also widely used as an example during the ECHA/EFSA MOA/HRF workshop held in November 2014. Sulfoxaflor induced hepatic carcinogenicity in both rats and mice. Studies to determine the MoA for these liver tumours were performed in an integrated and prospective manner as part of the standard battery of toxicology studies such that the MoA data were available prior to, or by the time of, the completion of the carcinogenicity studies. The MoA data evaluated in a WoE approach indicated that the identified rodent liver tumour MoA for sulfoxaflor would not occur in humans. For this reason, sulfoxaflor is considered not to be a potential human liver carcinogen.

Furthermore, sometimes MoA data may indicate a lack of possible effects. If there are biological data that indicate an adverse effect is not likely to occur in humans, this should inform the interpretation of epidemiological studies. Nevertheless, while primary target site selectivity between pests and humans plays an important role in pesticides safety, secondary targets in mammals must also be considered.

In the case of exposure to multiple pesticides, the decision to combine risks can be taken if the pesticides share a common mechanism of toxicity (act on the same molecular target at the same target tissue, act by the same biochemical mechanism of action, and share a common toxic intermediate) which may cause the same critical effect or just based on the observation that they share the same target organ (EFSA 2013a,b). However, cumulative risk assessment is beyond the scope of this Opinion.

# 7.5. Adverse Outcome Pathways (AOPs)

The AOP methodology provides a framework to collect and evaluate relevant chemical, biological and toxicological information in such a way that is useful for risk assessment (OECD, 2013). An AOP may be defined as the sequence of key events following the interaction of a chemical with a biological target (molecular initiating event (MIE)) to the *in vivo* adverse outcome relevant to human health. All these key events are necessary elements of the MoA and should be empirically observable or constitute biologically based markers for such an event. An AOP is therefore a linear pathway from one MIE to one adverse outcome at a level of biological organisation relevant to risk assessment. The goal of an AOP is to provide a flexible framework to describe the cascade of key events that lead from a MIE to an adverse outcome in a causal linkage (EFSA PPR Panel, 2017). The 'key events' must be experimentally measurable and the final adverse effect is usually associated with an *in vivo* OECD Test Guideline. However, in some cases the adverse outcome may be at a level of biological organisation below that of the apical endpoint described in a test guideline (OECD, 2013).

A particular MIE may lead to several final adverse effects and, conversely, several MIEs may converge in the same final adverse effect. However, each AOP will have only one MIE and one final adverse effect, but may involve an unlimited number of intermediate steps (Vinken, 2013). It should be noted that key events at different levels of biological organisation provide a greater WoE than multiple events at the same level of organisation (OECD, 2013).

The essential biochemical steps involved in a toxic response are identified and retrieved from an indepth survey of relevant scientific literature or from experimental studies. Any type of information can be incorporated into an AOP, including structural data, 'omics-based' data and *in vitro*, *in vivo* or *in silico* data. However, *in vivo* data are preferred over *in vitro* data and endpoints of interest are preferred to surrogate endpoints (Vinken, 2013). The AOPs identified must not be incompatible with normal biological processes, since they need to be biologically plausible.

Qualitative AOPs (intended as an AOP including the assembly and evaluation of the supporting WoE following the OECD guidance for AOP development) should be the starting and standard approach in the process of integration of epidemiology studies into risk assessment by supporting (or identifying the lack of support for) the biological plausibility of the link between exposure to pesticides affecting the pathway and the adverse outcome. Accordingly, qualitative AOPs may be developed solely for the purpose of hazard identification, to support biological plausibility of epidemiological studies based on mechanistic knowledge (EFSA PPR Panel, 2017).

The AOP framework is a flexible and transparent tool for the review, organisation and interpretation of complex information gathered from different sources. This approach has the additional advantage of qualitatively characterising the uncertainty associated with any inference of causality and identifying whether additional mechanistic studies or epidemiological research would be more effective in reducing uncertainty. The AOP framework is therefore a useful tool for risk assessment to explore whether an adverse outcome is biologically plausible or not. For the purpose of analysing the biological plausibility, AOPs can serve as an important tool, particularly when the regulatory animal toxicological studies are negative but the evaluation of the apical endpoint (or relevant biomarkers) observed in epidemiological studies is considered inadequate based on the AOP. By means of mechanistically describing apical endpoints, the AOP framework is chemically agnostic, if complemented by the MoA and/or Integrated Approach on Testing and Assessment (IATA) framework, it will support the chemical specific risk assessment (EFSA PPR Panel, 2017).

AOP and MoA data can be used to assess the findings of epidemiological studies to weight their conclusions. Whether those findings are inconsistent with deep understanding of biological mechanisms, or simply empirical, they should be given less weight than other findings that are consistent with AOP or MoA frameworks once established. However, there are relatively few examples of well-documented AOPs and a full AOP/MoA framework is not a requirement for using epidemiological studies in risk assessment.

AOPs are thus a critical element to facilitate moving towards a mechanistic-based risk assessment instead of the current testing paradigm relying heavily on apical effects observed in animal studies. Shifting the risk assessment paradigm towards mechanistic understanding would reduce limitations of the animal data in predicting human health effects for a single pesticide, and also support the current efforts being made on cumulative risk assessment of pesticide exposure (EFSA PPR Panel, 2017).

# **7.6.** Novel tools for identifying biological pathways and mechanisms underlying toxicity

The elucidation of toxicity pathways brings the opportunity of identifying novel biomarkers of early biological perturbations in the toxicodynamic progression towards overt disease, particularly from advances in biomonitoring, in -omics technologies and systems biology (toxicology). The revolution of omics in epidemiology holds the promise of novel biomarkers of early effect and offers an opportunity to investigate mechanisms, biochemical pathways and causality of associations.

The growing recognition of the value of biomonitoring data in epidemiological investigations may help to reduce misclassification by providing objective measures of exposure and outcome. As long as biomarker data for exposure, outcome and susceptibility are increasingly generated, epidemiology will have a greater impact in the understanding of toxicodynamic progression as a function of pesticide exposure and eventually in risk assessment. A challenge for risk assessors will be to acknowledge where subtle and early changes along the toxicodynamic pathway are indicative of increased potential for downstream effects (Nachman et al., 2011). Omics data can be used for gaining insight to the MoA by identifying pathways affected by pesticides and as such can assist hazard identification, the first step in risk assessment.

Transcriptomic, metabolomic, epigenomic and proteomic profiles of biological samples provide a detailed picture, sometimes at individual molecule resolution, of the evolving state of cells under the influence of environmental chemicals, thus revealing early mechanistic links with potential health effects. Nowadays, the challenges and benefits that advances in -omics techniques can bring to regulatory toxicology are still being explored (Marx-Stoelting et al., 2015). Clear rules for assessing the specificity of these biomarkers are necessary.

Those -omic applications most relevant and advanced in the context of toxicology are analysis of MoA and the derivations of AOP, and biomarker identification, all of which potentially assist epidemiology too. For example, (a) transcriptomics: comparing gene expression (mRNA) profiles can be used for biomarker discovery, grouping expressed genes into functional groups (Gene Ontology categories) or for Gene Set Analysis. Such techniques may provide varying information regarding biological mechanisms. (b) Proteomics: studying the protein profile of samples, with sophisticated analysis of protein quantity and post-translational modifications which may be associated with changes in biological pathways following exposure and possible disease development, utilising informatics and protein databases for identification and quantification. (c) Metabolomics uses nuclear magnetic resonance spectroscopy or mass-spectrometry based techniques to produce data which are analysed via software, and databases, to identify markers (molecular signatures and pathways) that correlate with exposure or disease. (d) The use of the exposome (the totality of exposures received by an individual during life) might be better defined by using -omics technologies and biomarkers appropriate for human biomonitoring. Nevertheless, important limitations stemming from the lack of validation of these methodologies and their cost limit their use at large scale.

The application of -omics technologies to environmental health research requires special consideration to study design, validation, replications, temporal variance and meta-data analysis (Vlaanderen et al., 2010). For larger studies, intra-individual variability in the molecular profiles measured in biological samples should show less variability than the interindividual variation in profiles of gene expression, protein levels or metabolites, which are highly variable over time. It is important that these inter-individual variations should not be larger than variation related to exposure changes, but it is not certain if this will be true.

The biologically meaningful omics signatures identified by performing omics-exposure and omicshealth association studies provide useful data for advanced risk assessment. This approach supports moving away from apical toxicity endpoints towards earlier key events in the toxicity pathway resulting from chemical-induced perturbation of molecular/cellular responses (NRC, 2007).

# 7.7. New data opportunities in epidemiology

The current technological landscape permits the digitisation and storage of unprecedented amount of data from many sources, including smart phones, text messages, credit card purchases, online activity, electronic medical records, global positioning system (GPS) and supermarket purchasing data. While some of these data sources may provide valuable information for risk assessment, many of them contain personal information that can outpace legal frameworks and arise questions about the ethics of its use for scientific or regulatory purposes. A specific example is constituted by data containing

personal information related to health, which are considered sensitive or especially protected, such as electronic medical records, information from occupational or environmental questionnaires, geographic location, health or social security number, etc. These various forms of health information are being easily created, stored and accessed. Big data provide researchers with the ability to match or link records across a number of data sources. Linking of big data sources of health and heritable information offers great promise for understanding disease predictors (Salerno et al., 2017); however, there are challenges in using current methods to process, analyse and interpret the data systematically and efficiently or to find relevant signals in potential oceans of noise, as noted by the Board on Environmental Studies and Toxicology of the National Academies of Sciences, Engineering, and Medicine in its 2017 report.<sup>18</sup>

In addition, medico-administrative data, such as drug reimbursements drawn from National Health Insurance or hospital discharge databases, can be cross-linked with data on agricultural activities drawn from agricultural census or geographical mapping. It is acknowledged that in several instances this information can be obtained at group level only, and an important challenge will be to obtain data at individual level and/or on individual habits.

Biobanks also constitute new data sources from healthy or diseased populations. They consist of an organised collection of human biological specimens and associated information stored for diverse research purposes. These biosamples are available for application of novel technologies with potential for generating data valuable for exposure assessment or exposure reconstruction. If studies' design and conduct are harmonised, data and samples can be shared between biobanks to promote powerful pooled analyses and replications studies (Burton et al., 2010).

Large scale epidemiological studies with deep phenotyping provide also unprecedented opportunities to link well phenotyped study participants with the aforementioned data. For example, UK Biobank, has recruited over 500,000 individuals with questionnaire, medical history and physical measurements data as well as stored blood and urine samples with available genome wide association data for all 500,000 participants, and linkage to Hospital Episode Statistics, national registry data and primary care records. To gain information on air pollution and noise levels, the postcode of participants has been linked to air pollution or noise estimates. In addition, piloting of personal exposure monitoring will take place in order to collect individual level data on these exposures. These approaches could be extended to gain information on pesticide exposure, either through geographical linkage, linkage with purchasing and occupational registries, and personal exposure monitoring. Similar biobanks exist in many other EU countries (http://www.bbmri-eric.eu/BBMRI-ERIC has collected most EU studies).

# 8. Overall recommendations

# 8.1. Recommendations for single epidemiological studies:

The following recommendations for improving epidemiological studies are aimed to conform to the 'recognised standards' mentioned in Regulation (EU) No 1107/2009 to make them of particular value to risk assessment of pesticides ('where available, and supported with data on levels and duration of exposure, and conducted in accordance with recognised standards, epidemiological studies are of particular value and must be submitted'). Accordingly, these recommendations can indeed not be considered as a practical guidance for researchers on how to conduct such studies, but for those who are planning to conduct a study for further use in pesticide risk assessment.

#### a) Study design (including confounding)

- 1) Since prospective epidemiological designs provide stronger evidence for causal inference, these studies are encouraged over the other designs for pesticide risk assessment.
- 2) Future epidemiological studies should be conducted using the appropriate sample size in order to properly answer the question under investigation. A power analysis should thus be performed at the study design stage.
- Future studies should take into consideration heterogeneity, subpopulations, exposure windows and susceptibility periods and conditions (pregnancy, development, diseases, etc.).

<sup>&</sup>lt;sup>18</sup> National Academies of Sciences, Engineering, and Medicine; Division on Earth and Life Studies; Board on Environmental Studies and Toxicology; Committee on Incorporating 21st Century Science into Risk-Based Evaluations. Washington (DC): National Academies Press (US); 2017 Jan.

- 4) A wide range of potential confounding variables (including co-exposure to other chemicals, lifestyle, socioeconomic factors, etc.) should be measured or accounted for during the design stage (e.g. matching) of the study.
- 5) Consideration of host factors that may influence toxicity and act as effect modifiers. These will include genetic polymorphisms data (e.g. paraoxonase-1 genotype) or nutritional factors (e.g. iodine status) among others.
- 6) Collaboration between researchers is encouraged to build-up consortia that enhance the effectiveness of individual cohorts.

Collection and appropriately storage of relevant biological material should be undertaken for future exposure assessment, including the use of novel technologies.

- **b) Exposure** (measurement, data transformation for reporting and statistical analysis):
  - 1) Collection of specific information on exposure should avoid as far as possible broad definitions of exposure, non-specific pesticide descriptions and broad exposures classifications such as 'never' *vs.* 'ever' categories. Nevertheless, these categories may be valuable under certain circumstances, e.g. to anticipate a class effect.
  - 2) Studies which only look at broad classes of pesticides (generic groups of unrelated substances), or 'insecticides', 'herbicides', etc. or even just 'pesticides' in general are of much less use (if any) for risk assessment. Studies that investigate specific named pesticides and co-formulants are more useful for risk assessment.
  - 3) Pesticides belonging to the same chemical class or eliciting the same mode of toxic action or toxicological effects might be grouped in the same category. Further refinement with information on frequency, duration and intensity of exposure might help in estimating exposure patterns.
  - 4) In occupational epidemiology studies, operator and worker behaviour and proper use of PPE should be adequately reported as these exposure modifiers may significantly change exposures and thereby potential associations.
  - 5) Improving the accuracy of exposure measurement is increasingly important, particularly for cohort studies. Long-term cohort studies which cover the etiologically relevant time period should improve the accuracy of measures of exposures by use of repeated biologic measures or repeated updates of self-reported exposures.
  - 6) Indirect measures of environmental exposure for wider populations, including records on pesticide use, registry data, GIS, geographical mapping, etc., as well as data derived from large databases (including administrative databases) may be valuable for exploratory studies. If these data are not available, records/registries should be initiated. Likewise, estimation of dietary exposure to pesticide from food consumption databases and levels of pesticide residues from monitoring programmes can be used as well. As with direct exposure assessment, each method of indirect measurement should be reviewed for risk of bias and misclassification and weighted appropriately.
  - 7) Whenever possible, exposure assessment should use direct measurements of exposure to named pesticides in order to establish different levels of exposure (e.g. personal exposure metering/biological monitoring), possibly in conjunction with other methods of exposure assessment which are more practicable or even necessary for large studies and historical exposures. New studies should explore novel ways of personal exposure monitoring. Results should be expressed using standardised units to normalise exposure across populations
  - 8) The characterisation of exposure assessment over time can benefit by undertaken a more comprehensive exposure monitoring strategy coupled with information on exposure determinants over a longer time period collected from questionnaires or job-exposure matrices supported by biomonitoring data. Exposure assessment models can be comprehensively supported by HBM studies, which would allow identification of the critical exposure parameters. If such case, adjustments can then be made to the parameter assumptions within the models, leading to more realistic evaluations of exposure.
  - 9) The use of the exposome concept and metabolomics in particular hold great promise for next-generation epidemiological studies both for better exposure measurement (biomarkers of exposure), for identification of vulnerable subpopulations and for biological interpretation of toxicity pathways (biomarkers of disease).

10) Improved knowledge on exposure (and toxicity) to pesticide mixtures will be beneficial for comprehensive risk assessment. Consideration of the joint action of combined exposures to multiple pesticides acting on common targets, or eliciting similar adverse effects, is relevant for cumulative risk assessment. This requires all the components of the mixture to be known as well as an understanding of the MoA, dose–response characteristics and potential interactions between components. Characterisation of the exposure is a key element for combined exposure to multiple pesticides where the pattern and magnitude of exposure changes over time.

#### c) Adverse Outcomes (measurement, data transformation for reporting and statistical analysis):

- 1) Self-reported health outcomes should be avoided or confirmed by independent, blinded assessment of disease status by a medical expert assigned to the study.
- 2) Outcomes under study should be well defined and surrogate endpoints should be avoided unless they have been validated. Care must be taken when definitions of diseases and subclasses of diseases change over time (cancer, neurodegenerative disorders, etc.).
- 3) Use should be made of biological markers of early biological effect to improve the understanding of the pathogenesis of diseases. These quantitative biological parameters from mechanistic toxicology will enhance the usefulness of epidemiology because they improve the study sensitivity, reduce misclassification and enhance human relevance as compared to findings from studies in experimental animals. Since these refined endpoints are early events in the toxicodynamic pathway and often measured on a continuous scale, they might be preferable to more overt and traditional outcomes.
- 4) The use of biomarkers of effect may be helpful in assessing aggregate exposure to pesticides and informing cumulative risk assessment.
- 5) Developing read across methods allowing health outcomes to be identified using epidemiological studies and to link acute and chronic incidents records with experimental findings.
- **d) Statistical** (descriptive statistics, modelling of exposure–effect relationship):
  - 1) Statistical analysis should be based on *a priori* defined analytical (statistical) protocols, to avoid post hoc analyses for exploratory studies and report all the results, regardless of whether they are statistically significant or not.
  - 2) Data should be reported in such a way that permit, where appropriate, mathematical modelling to estimate individual/population exposures and dose–response assessment irrespective of whether direct or indirect measures are used.
  - 3) Reports should include both unadjusted and adjusted proportions and rates of outcome of interest across studies that are based on underlying populations with different structure of relevant factors and exposures.
  - 4) Possible relevant factors, and their role in the exposure-health outcome relationship, should be carefully identified, accurately measured and thoroughly assessed. Most often, relevant factors have been screened as potential confounders. When confounding effects were detected, these needed to be adjusted for using appropriate statistical methods that include sensitivity analysis.
  - 5) Potentially useful analytical approaches, such as propensity score matching, mediation analyses, and causal inference are encouraged to be applied in pesticide epidemiology.
  - 6) When the association between a given pesticide exposure and a disease is found to be statistically significant, particularly in (presumed) low powered studies, it would be general good practice to perform a power analysis/design calculation to determine the degree to which the statistically significant effect size estimate (e.g. OR or RR) may be artificially inflated or magnified.<sup>19</sup>

<sup>&</sup>lt;sup>19</sup> Additional information on power and sample size recommendations and related issues including effect size magnification and design calculations are provided in Annex D to this report. Specifically, a power calculation requires 3 values to be clearly reported by epidemiological studies: (i) the number of subjects in the non-exposed group (including individuals with and without the disease of interest); (ii) the number of subjects in the exposed group (also including individuals with and without the disease of interest); (iii) the number of diseased subjects in the non-exposed group.

#### e) Reporting of results:

- 1) These should follow practices of good reporting of epidemiological research outlined in the STROBE statement and in the EFSA guideline on statistical reporting (EFSA, 2014b) and include the further suggestions identified in this Opinion including effect size inflation estimates.
- 2) Although some epidemiological research will remain exploratory and post hoc in nature, this should be acknowledged and supported by appropriate statistical analysis.
- Epidemiological studies are encouraged to provide access to raw data for further investigations and to deposit their full results and scripts or software packages used for analyses.
- 4) Report, or deposit using online sources, all results along with scripts and statistical tools used to allow the reproducibility of results to be tested.
- 5) Report all sources of funding and adequately report financial and other potential conflicts of interest.

As a general recommendation, the PPR Panel encourages development of guidance for epidemiological research in order to increase its value, transparency and accountability for risk assessment.<sup>20</sup> An increased quality of epidemiological studies, together with responsible research conduct and scientific integrity, will benefit the incorporation of these studies into risk assessment.

#### 8.2. Surveillance

- 1) Increase the reporting of acute and chronic incidents by setting up post-marketing surveillance programmes (occupational and general population) as required by article 7 of EU directive 2009/128; this should be fulfilled by developing surveillance networks with occupational health physicians and by boosting the collaboration between national authorities dealing with PPP and poison control information centres.
- 2) Develop a valid method for assessing the weight/strength of the causal relationship ('imputability') for acute and chronic incidents, and develop glossaries and a thesaurus to support harmonised reporting between EU member states.
- Harmonised data from member states should be gathered at the EU level and examined periodically by the Commission/EFSA and a report should be released focussing on the most relevant findings.
- 4) Develop an EU-wide vigilance framework for pesticides.
- 5) There is scope for training improvements regarding pesticide toxidromes in toxicology courses for medical and paramedical staff responsible for diagnostic decisions, data entry and management.

#### 8.3. Meta-analysis of multiple epidemiological studies

- 1) Evidence from epidemiological studies might be pooled by taking into account a thorough evaluation of the methods and biases of individual studies, an assessment of the degree of heterogeneity among studies, development of explanations underlying any heterogeneity and a quantitative summary of the evidence (provided that it is consistent).
- 2) For every evidence synthesis effort, studies should be reviewed using relevant risk of bias tools. Studies with different designs, or with different design features, may require (some) different questions for risk of bias assessments.
- 3) Evidence syntheses should not be restricted to specific time frames; they should include the totality of evidence. These efforts are more relevant if focused on specific health outcome or disease categories.
- 4) In evidence synthesis efforts, beyond the quantitative synthesis of the effect sizes, there should be consideration on the calculated predictive intervals, small study effects and asymmetry bias, conflicts of interest, confounding, excess significance bias,<sup>21</sup> and heterogeneity estimates.

<sup>&</sup>lt;sup>20</sup> An example is the guideline developed by the Dutch Society for Epidemiology on responsible epidemiologic Research Practice (2017).

<sup>&</sup>lt;sup>21</sup> Excess significance bias refers to the situation in which there are too many studies with statistically significant results in the published literature on a particular outcome. This pattern suggests strong biases in the literature, with publication bias, selective outcome reporting, selective analyses reporting, or fabricated data being possible explanations (Ioannidis and Trikalinos, 2007).

- 5) In the presence of heterogeneity, studies with highly selected populations, albeit unrepresentative of their respective populations, may prove valuable and deserve consideration as they may represent genuine and not statistical heterogeneity.
- 6) A more consistent reporting such as for age, race and gender across studies would enhance the meta-analyses.
- 7) Where quantitative data of individual pesticides are available from epidemiological studies, they can be combined or pooled for dose-response modelling, which could enable development of quantitative risk estimates and points of departure (BMDL, NOAEL).
- 8) International consortium of cohort studies should be encouraged to support data pooling to study disease–exposure associations that individual cohorts do not have sufficient statistical power to study (e.g. AGRICOH).

# 8.4. Integration of epidemiological evidence with other sources of information

- 1) All lines of evidence (epidemiology, animal, *in vitro* data) should be equally scrutinised for biases.
- 2) Validated and harmonised methods should be developed to combine observational studies, animal/basic science studies and other sources of evidence for risk assessment.
- 3) Experimental and human data should both contribute to hazard identification and to dose–response assessment.
- 4) A systematic integration of data from multiple lines of evidence should be based on a WoE analysis accounting for relevance, consistency and biological plausibility using modified Bradford Hill criteria. The principles underlying this framework are described in Section 7.2 and summarised in Figure 5.
- 5) Epidemiological findings should be integrated with other sources of information (data from experimental toxicology, mechanism of action/AOP) by using a WoE approach. An integrated and harmonised approach should be developed by bringing together animal, mechanistic and human data in an overall WoE framework in a systematic and consistent manner.
- 6) The AOP framework offers a structured platform for the integration of various kinds of research results.
- 7) Animal, *in vitro* data and human data should be assessed as a whole for each endpoint. A conclusion can be drawn as to whether the results from the experiments are confirmed by human data for each endpoint and this could be included in the RARs.

#### 9. Conclusions

This Scientific Opinion is intended to help the peer review process during the renewal of pesticides authorisation (and, where possible, during the approval process) under Regulation 1107/2009 which requires a search of the scientific peer-reviewed open literature, including existing epidemiological studies. These are more suitable for the renewal process of active substances, also in compliance with Regulation 1141/2010, which indicates that the dossiers submitted for renewal should include new data relevant to the active substance.

The four key elements of the terms of reference are repeated below and the parts of the text addressing the individual terms are identified in order. As they follow from the text passages grouped with each of the ToRs the recommendations relevant to each of the ToRs are also indicated as follows.

'The PPR Panel will discuss the associations between pesticide exposure and human health effects observed in the External scientific report (Ntzani et al., 2013) and how these findings could be interpreted in a regulatory pesticide risk assessment context. Hence, the PPR Panel will systematically assess the epidemiological studies collected in the report by addressing major data gaps and limitations of the studies and provide recommendations thereof'.

'The PPR Panel will specifically':

- 1) Collect and review all sources of gaps and limitations, based on (but not necessarily limited to) those identified in the External Scientific report in regard to the quality and relevance of the available epidemiological studies. Responses in Section 3 pp. 20–24, Section 5.2 pp. 33–35: no Recommendations appropriate.
- 2) Based on the gaps and limitations identified in point 1, propose potential refinements for future epidemiological studies to increase the quality, relevance and reliability of the findings

and how they may impact pesticide risk assessment. This may include study design, exposure assessment, data quality and access, diagnostic classification of health outcomes, and statistical analysis. Responses in Section 4 pp 24–33: recommendations in Sections 8.1, 8.2 and 8.3 pp. 54–58.

- 3) Identify areas in which information and/or criteria are insufficient or lacking and propose recommendations for how to conduct pesticide epidemiological studies in order to improve and optimise the application in risk assessment. These recommendations should include harmonisation of exposure assessment (including use of biomonitoring data), vulnerable population sub-groups and/or health outcomes of interest (at biochemical, functional, morphological and clinical level) based on the gaps and limitations identified in point 1. Responses in Sections 4.2–4.5 pp. 27–33, Section 5.3 pp. 36: recommendations in Section 8.1 c) 1–4, pp. 56.
- 4) Discuss how to make appropriate use of epidemiological findings in risk assessment of pesticides during the peer review process of draft assessment reports, e.g. WoE as well as integrating the epidemiological information with data from experimental toxicology, AOPs, mechanism of actions, etc. Responses in Sections 6.2 and 6.3 pp. 37–45 and 7 pp. 45–54: Responses in Section 8.4 pp. 58.

As explained above, appropriate epidemiological data and post-approval surveillance may usefully contribute to the risk assessment framework by hazard identification, and – with methodological improvements – hazard characterisation. It can be improved by contributions from WoE analysis, Uncertainty analysis, and identification and estimation of biases. It is the responsibility of applicants to collect the available relevant literature, to consider its relevance and quality using relevant EFSA criteria including those for systematic review and to introduce discussion of the outcomes within the DAR, RAR and post-approval frameworks that are prescribed under EU law.

The definition of appropriate quality will require analysis of sample size, statistical procedures, estimates of effect size inflation, assessment of biases and their contribution to the conclusions drawn.

The nature of the studies will require consideration at all relevant points in the risk assessment process so that for example epidemiological data on reproductive topics will be considered alongside laboratory animal studies designed to reveal reproductive effects and in the context of recommendation for labelling for reproductive toxicity (for ECHA).

Unless there is history of use in countries outside the EU, the relevant epidemiological studies will be restricted in their effect on the DAR but the RAR and Surveillance framework is potentially able to benefit from epidemiology progressively as time after first approval passes and from prior use of Active Ingredients in other jurisdictions. It is recommended that RAR and surveillance protocols should reflect this difference.

The specific recommendations listed above follow from detailed arguments based on an analysis of present and foreseen **s**trengths **w**eaknesses **o**pportunities and **t**hreats related to the use of epidemiological data in risk assessment. Broadly these are as follows:

#### Strengths. Include:

- The fact that the evidence concerns human specific risks.
- That health outcomes are integrated measures of the effects of all exposure to toxins.
- The ability to elicit subjective experience from potentially affected people.

#### Weaknesses. Include:

- The exposures to pesticides are usually complex; contribution of a specific active ingredient is not easily deciphered.
- The exposures occur in various settings where precisely controlled conditions are lacking.
- Most data reflect the responses of mixed populations.
- Many data show low level associations that are inconsistently repeatable and require sophisticated analysis.

**Opportunities**. Despite the range of limitations described in this Opinion, which apply to many available published epidemiological studies, there are opportunities to benefit risk assessment of pesticides. These include:

• The access to very large numbers of potentially exposed individuals for studies that may reveal subtle health effects and reveal the experience of sensitive sub-groups.

- The prospect of improving exposure estimation using biomonitoring and new molecular approaches to establish tissue burdens of potential toxins and their residues.
- The possibility of fully integrating human data into the conventional risk assessment based on responses in laboratory animals.
- Utilising WoE, AOP, Expert judgement, Expert Knowledge Elicitation (EKE) and Uncertainty Analysis to evaluate differences in the quality of potentially relevant data.
- The opportunity to engage professional epidemiologists and statisticians to refine interpretation of epidemiological findings and to recommend improved designs to tackle difficult areas such as chronic and combined exposure risks and dose–response data.
- A major information technology opportunity exists in pooling data from a variety of national sources. Once the relevant legal, methodological and ethical issues are overcome much more valuable data can be collected. When this data is made available, in a form that can be used in a 'big data' setting for societal benefit there will be potential for significant improvements in epidemiological studies. First, however, it will be necessary to preserve individual privacy and essential commercial confidentiality. Once these obstacles are overcome the statistical power of epidemiological studies can be improved and applied to identify and possibly characterise hazards better. These aims can be realised effectively by agreed actions at a high EU level. Interstate approval for providing data and interactive platforms will need to be backed by harmonisation of population health information, food consumption data, active substance and co-formulant spatial and temporal application data. Such rich data can be expected to assist in increasing consistency, a criterion that strengthens evidence of causality and reliability. It promises larger sample sizes for epidemiological studies that will be better able to identify vulnerable groups that may require special protection from pesticide toxicity.

#### Threats. Include:

- Widespread perception of risk levels to the human population or to wildlife and the environment that are unrealistic and that cause negative consequences in societies.
- Poor experimental design yielding false positive or false negative conclusions that undermine data from other valid sources.
- Failure to respond to emerging risks as a result of ineffective surveillance or unwillingness to make appropriate anonymised data available for societal benefit.
- Waste of data through failure to collect appropriate information regarding exposure (specifically occupational exposure) by registries (cancer or congenital anomalies) or surveillance programmes which hinders linking health outcomes to exposure.
- Waste of data through failure to harmonise diagnostic criteria, failure to record data in a sufficiently detailed combinable form for integrated analysis, poor training of medical and paramedical staff in relevant toxidromes that will allow optimum quality of data entered into Health Statistics Databases.

#### **Glossary and Abbreviations**

ADI	Acceptable daily intake. A measure of the amount of a pesticide in food or
	drinking water that can be ingested (orally) on a daily basis over a lifetime without an appreciable health risk.
ADME	Abbreviation used in pharmacology (and toxicology) for absorption, distribution, metabolism, and excretion of a chemical o pharmaceutical compound and
	describes its disposition within an organism.
AOP	Adverse Outcome Pathway. A structured representation of biological events
	leading to adverse effects relevant to risk assessment.
ARfD	Acute Reference Dose. An estimate of the amount a pesticide in food or drinking water (normally expressed on a body weight basis) that can be ingested in a
	period of 24 hours or less without appreciable health risks to the consumer on the basis of all known facts at the time of the evaluation.
Biomarker	Also known as 'biological marker'. A characteristic that is objectively measured and evaluated as an indication of normal biologic processes, pathogenic processes or pharmacologic responses to a therapeutic intervention

BMD	Benchmark Dose. A threshold dose or concentration that produces a predetermined change in response rate of an adverse effect (the benchmark response or BMR) compared to background. The lower 95% confidence limit is calculated (BMDL) to be further used as a point of departure to derive health-based reference values.
НВМ	Human biomonitoring. The measurement of a chemical and/or its metabolites in human biological fluids or tissues. Also referred as to the internal dose of a chemical resulting from integrated exposures from all exposure routes.
Human data	They include observational studies (also called epidemiological studies) where the researcher is observing natural relationships between factors and health outcomes without acting upon study participants. Vigilance data also fall under this concept. In contrast, interventional studies (also called experimental studies or randomised clinical trials), where the researcher intercedes as part of the study design, are outside the scope of this opinion.
IARC	International Agency for Research on Cancer. An agency of the World Health Organization whose role is to conduct and coordinate research into the causes and occurrence of cancer worldwide.
LOAEL	Lowest-observed-adverse-effect level. The lowest concentration or amount of a chemical stressor evaluated in a toxicity test that shows harmful effects (e.g. an adverse alteration of morphology, biochemistry, function, or lifespan of a target organism).
NOAEL	No observed-adverse-effect level. Highest dose at which there was not an observed toxic or adverse effect.
OR	Odds ratio. A measure of association between an exposure and an outcome. The OR represents the odds that an outcome will occur given a particular exposure, compared to the odds of the outcome occurring in the absence of that exposure.
PBTK-TD	Physiologically based toxicokinetic/toxicodynamic modelling is a mathematical modelling approach aimed at integrating <i>a priori</i> knowledge of physiological processes with other known/observed information to mimic the fates and effects of compounds in the bodies of humans, preclinical species and/or other
РРР	organisms. Plant Protection Product. The term 'pesticide' is often used interchangeably with 'plant protection product', however, pesticide is a broader term that also covers non plant/crop uses, for example biocides.
RR	Relative risk. Ratio of the probability of an event (e.g. developing a disease) occurring in an exposed group to the probability of the event occurring in a comparison, non-exposed group.
RMS	Rapporteur member state. The member state of the European Union initially in charge of assessing and evaluating a dossier on a pesticide active substance toxicological assessment.
Sensitivity	The ability of a test to correctly classify an individual as 'diseased'. Probability of being test positive when disease present.
Specificity	The ability of a test to correctly classify an individual as disease-free. Probability of being test negative when disease absent.
Surrogate endpoint	A biomarker intended to substitute for a clinical endpoint
AHS	Agricultural Health Study
ASHTIII	Alerting and Reporting System for Chemical Health Threats, Phase III
BEES-C	Biomonitoring, Environmental Epidemiology, and Short-Lived Chemicals
DAR	draft assessment report
DDE	dichlorodiphenyldichloroethylene
DDT	dichlorodiphenyltrichloroethane

# Annex A – Pesticide epidemiological studies reviewed in the EFSA External Scientific Report and other reviews

The extensive evidence gathered by the EFSA External Scientific Report (Ntzani et al., 2013) highlights that there is a considerable amount of information available on pesticide exposure and health outcomes from epidemiological studies. Nonetheless, the quality of this evidence is usually low and many biases are likely to affect the results to an extent that firm conclusions cannot be made. In particular, exposure epidemiology has long suffered from poor measurement and definition and in particular for pesticides this has always been exceptionally difficult to assess and define.

#### A.1. The EFSA External scientific report

#### A.1.1. Methodological quality assessment

The External Scientific Report consists of a comprehensive systematic review of all the epidemiological studies published between 1 January 2006 and 30 September 2012, investigating the association between pesticide exposure and the occurrence of any human health-related outcomes.

The methodological assessment of eligible studies (to evaluate risk of bias associated with each study) was focused on: study design, study population, level of details in exposure definition and the methods of exposure measurement and the specificity of the measurement. Efforts undertaken to account for confounders through matching or multivariable models, blinded exposure assessment and well-defined and valid outcome assessment were considered.

The elements of the methodological appraisal were considered from the Research Triangle Institute (RTI; Research Triangle Park, NC, USA) item bank, a practical and validated tool for evaluating the risk of bias and precision of observational studies. Those elements are described below (Table A.1).

Table A.1:	Elements from the Research Triangle Institute (RTI; Research Triangle Park, NC, USA)
	item bank for methodological appraisal of epidemiological studies

Question	High risk	Low risk
Study design (prospective, retrospective, mixed, NA)	Retrospective, mixed, NA	Prospective
Inclusion/exclusion criteria clearly stated (yes, partially, no)	No	Yes
Authors mention power calculations (yes, no)		Yes
Level of detail in describing exposure (high, medium, low)	Low	High
Robust measurement of exposure. (biomarker (yes); small area ecological measures, job titles, questionnaire (partial); was based on large area ecological measures (no)	No	Yes
Were measures of exposure specific? yes; based on broader, chemically- related groups (partial); based on broad groupings of diverse chemical and toxicological properties (no)	No	Yes
Attempt to balance the allocation between the groups (e.g., through stratification, matching)	No	Yes
Adjustment performed for potential confounders (yes, some, no)	No	Yes
Assessors blinded to exposure status (for cohort studies)	No	Yes
Outcomes assessed using valid and reliable measures, implemented consistently across all study participants?	No	Yes
Sample size	Low	Тор
Rough quality assessment	>6 answers high risk	>6 asnwers low risk

Quantitative synthesis of the results was attempted when there were 5 or more eligible studies per examined outcome and when there was no substantial heterogeneity among the published evidence. Publication bias was assessed using funnel plots which allowed to visually inspect asymmetry when more than 10 studies were included in the meta-analysis.

Toxicological data was not reviewed or discussed in the External Scientific Report.

#### A.1.2. Inclusion/exclusion criteria

All types of pesticides, including those banned in the EU, were considered to enhance the totality of the epidemiological evidence available at the time of the review.

Exclusion criteria:

- Studies without control populations (case reports, case series) and ecological studies
- Pesticide poisoning or accidental high dose exposure
- Studies with no quantitative information on effect estimates
- Studies with different follow-up periods and examining the same outcome, only the one with the longest follow-up was retained to avoid data duplication.
- Studies referred to the adverse effects of substances used as therapy for various medical conditions (e.g. warfarin-based anticoagulants)
- Studies on solvents and other non-active ingredients (e.g. co-formulants) in pesticides
- Studies examining the association between exposure and biomarkers of exposure were not considered eligible as they do not examine health outcomes
- Studies/analyses investigating exposure to pesticides: arsenic, hexachlorocyclohexane (HCH)  $\alpha$  or  $\beta$ , lead, dioxins and dioxin-like compounds including polychlorinated biphenyls (PCBs) were not considered
- Narrative reviews were excluded but not systematic reviews or meta-analyses.

Publications reporting series of acute poisonings or clinical cases, biomonitoring studies unrelated to health effects, or studies conducted on animals or human cell systems were not included; only epidemiological studies addressing human health effects were selected. Publications that lacked quantitative data for measuring associations were also excluded.

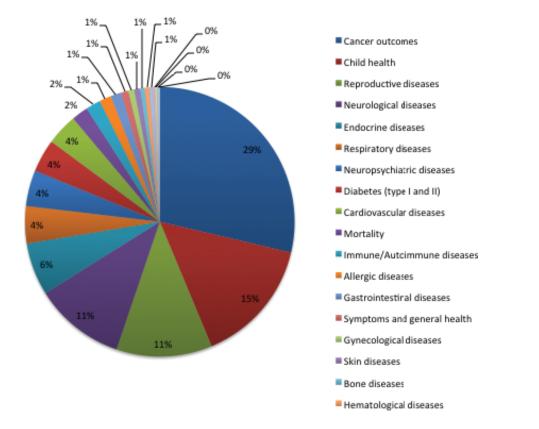

Cohort studies, case–control studies and cross-sectional studies were included. Each study underwent an assessment of its eligibility based on a method including 12 criteria such as study design, precise description of the inclusion/exclusion criteria, level of detail in describing exposure, robustness in the measurement of exposure, adjustment for potential confounding factors, method of assessment of the health outcome, sample size, etc. Among these 12 criteria, three were related to the degree of precision in the description/measurement of exposure, which may explain why a large number of epidemiological studies were not selected.

#### A.1.3. Results

Overall, 602 individual publications were included in the scientific review. These 602 publications corresponded to 6,479 different analyses. The overwhelming majority of evidence comes from retrospective or cross-sectional studies (38% and 32%, respectively) and only 30% of studies had a prospective design. Exposure assessment varied widely between studies and overall 46% measured biomarkers of pesticides exposure and another 46% used questionnaires to estimate exposure to pesticides. Almost half of the studies (49%) were based in America. Most studies examined associations between occupational exposure to pesticides and health effects. The entire spectrum of diseases associated with pesticides has not been studies before. The report examined a wide variety of outcomes (Figure A.1). The largest proportion of studies pertains to cancer outcomes (N = 164) and outcomes related to child health (N = 84).

374

**Figure A.1:** Major outcome categories and corresponding percentage of studies examining those outcomes among the publications reviewed by the EFSA external scientific report (Ntzani et al., 2013)

Despite the large volume of available data and the large number (> 6,000) of analyses available, firm conclusions were not made for the majority of the outcomes studied. This was due to several limitations of the data collected as well as to inherent limitations of the review itself. As mentioned above, the review studied the whole range of outcomes examined in relation to pesticides during an approximately 5 years' period. Thus, only recent evidence was reviewed and the results of the meta-analyses performed should be cautiously interpreted as they do not include all the available evidence. It is therefore capable of highlighting outcomes which merit further in-depth analysis in relation to pesticides by looking at the entire literature (beyond 5 years) and by focusing on appraising the credibility of evidence selected. The limitations of the studies itself are in line with other field of environmental epidemiology and focus around the exposure assessment, the study design, the statistical analysis and reporting. In particular:

a) **Exposure assessment**: The assessment of exposure is perhaps the most important methodological limitation of the studies reviewed in the ESR. Studies used different methods for exposure assessment and assignment. Most studies were based on self-reported exposure to pesticides, defined as 'ever versus never' use or as 'regular versus non-regular' use. Such methods suffer from high misclassification rates and do not allow for dose–response analysis. This is especially the case for retrospective studies where misclassification would be differential with higher exposures reported in participants with disease (recall bias) (Raphael, 1987). While questionnaires might be capable of differentiating subjects with very high and very low exposure levels, they are not capable of valid exposure classification across an exposure gradient, thus not allowing the study of dose–response relationships. Also, questionnaire for exposure assessment need to be validated for use in epidemiological studies. Nonetheless, a vast proportion of studies use in house version of non-validated questionnaires which may suffer from content (the questionnaire does not cover all sources of exposure to the hazard of interest) or criterion validity (e.g. through inaccurate recall or misunderstanding of questions) (Coggon, 1995).

Although the range of categories of pesticide studied is wide, studies very often concentrate on a broadly defined pesticide category, so that it is difficult to know what type of pesticide the population is exposed to.

Exposure to pesticides was defined as reported use of pesticides by the study participant or by government registry data. These derive from self-administered questionnaires, interviewer administrated questionnaires, job exposure matrices (JEM), by residential status (proximity to pesticide exposure), by detecting biomarkers associated with pesticide exposure or by other means as defined by each study.

Studies often examine pesticides that have already been banned in western populations and the EU. The use of biomarkers as means of exposure assessment is infrequent, but still available in almost half of the studies.

b) **Study design**: As mentioned above, the majority of evidence comes form case-control studies and cross-sectional studies. Cross-sectional, and in part also case-control studies, cannot fully assess the temporal relationships and thus are less able to provide support regarding the causality of associations.

c) **Outcomes examined**: The definition of clinical outcomes displayed large variability in eligible epidemiological studies, which can further cause the variability in results. Perhaps most important in this setting is the use of a great number of surrogate outcomes examined. Surrogate outcomes are biomarkers or physical measures that are generally accepted as substitutes for, or predictors of, specific clinical outcomes. However, often these surrogate outcomes are not validated and do not meet the strict definitions of surrogate outcomes. Such outcomes can be defined as possible predictors of clinical outcomes but do not fulfil the criteria for a surrogate outcome. It is essential to appraise the evidence around non-validated surrogate outcomes by taking into account the implicit assumptions of these outcomes.

A great variety of assessed outcomes covering a wide range of pathophysiologies was observed. 'Hard' clinical outcomes as well as many surrogate outcomes included in the database reflect the different methodologies endorsed to approach the assessed clinical research questions. The different outcomes were divided into 23 major disease categories, with the largest proportion of studies addressing cancer and child health outcomes.

The adverse health effects assessed included:

- a) major clinical outcomes, such as cancer, respiratory (allergy), reproductive (decreased fertility, birth defects) and neurodegenerative (Parkinson's disease);
- b) clinical surrogate outcomes, e.g. neurodevelopmental impairment (assessed by neurocognitive scales);
- c) laboratory surrogate outcomes (e.g. liver enzyme changes).

For many adverse health effects attributed to pesticide exposure, there exist contradictory or ambiguous studies. Whether this results from lack of consistency or real heterogeneity warrants further clarification.

#### d) Statistical analysis:

Simultaneous exposure to multiple agents (heavy metals, solvents, suspended particulate matter etc.) from different sources is common. It may introduce further bias in the results as all of them may produce adverse health outcomes. Thus, it is essential to account for confounding from exposure to multiple agents in order to delineate true associations but this has not been possible in the overwhelming majority of evidence assessed in the EFSA external scientific report.

In addition, the evidence collected and appraised in the EFSA external scientific report (Ntzani et al., 2013) is likely to suffer from selective reporting and multiple testing. The studies reported a very wide range of analyses; 602 publications resulted in 6,000 analyses. The amount of multiple hypothesis testing is enormous. These analyses need to be adjusted for multiple hypothesis testing else, otherwise the results suffer from high false positive rate. Even when studies present only one analysis, selective reporting is always a possibility as has been shown in other epidemiological fields as well. In addition, when interpreting results one should also take into account that, especially for certain outcomes (e.g. cancers), the majority of evidence comes from single study populations and the Agricultural Health Study in particular.

#### A.1.4. Conclusion of the EFSA External Scientific Report

Regardless of the limitations highlighted above, the External Scientific Report (Ntzani et al., 2013) showed consistent evidence of a link between exposure to pesticides and Parkinson's disease and childhood leukaemia, which was also supported by previous meta-analyses. In addition, an increased risk was also found for diverse health outcomes less well studied to date, such as liver cancer, breast cancer and type II diabetes. Effects on other outcomes, such as endocrine disorders, asthma and allergies, diabetes and obesity showed increased risks and should be explored further.

Childhood leukaemia and Parkinson's disease are the two outcomes for which a meta-analysis after 2006 was found consistently showing an increased risk associated with pesticide exposure. Nonetheless, the exposure needs to be better studied to disentangle the effect of specific pesticide classes or even individual pesticides. Significant summary estimates have also been reported for other outcomes (summarised in Table A.2). However, as they represent studies from 2006 onwards results should be regarded as suggestive of associations only and limitations especially regarding the heterogeneity of exposure should always been taken into consideration. Data synthesis and statistical tools should be applied to these data in relation to specific outcomes, after the update of the results to include publications before 2006, in order to quantify the amount of bias that could exist and isolate outcomes where the association with pesticides is well supported even when estimates of bias are taken into account. Similarly, outcomes where further evidence is needed to draw firm conclusions need to be highlighted.

Health outcome		Meta-analysis results	I <sup>2</sup>
Leukaemia	6	1.26 (0.93; 1.71)	59.4%
Hodgkin lymphoma	7	1.29 (0.81–2.06)	81.6%
Childhood leukaemia (exposure to pesticides during pregnancy)	6	1.67 (1.25–2.23)	81.2%
Childhood leukaemia (exposure to insecticides during pregnancy)	5	1.55 (1.14–2.11)	65%
Childhood leukaemia (exposure to insecticides during pregnancy – update Turner, 2010)	9	1.69 (1.35–2.11)	49.8%
Childhood leukaemia (exposure to unspecified pesticides during pregnancy)	5	2.00 (1.73–2.30)	39.6%
Childhood leukaemia (exposure to unspecified pesticides during pregnancy – update Turner, 2010)	11	1.30 (1.06–1.26)	26.5%
Childhood leukaemia (exposure to pesticides during childhood)	7	1.27 (0.96–1.69)	61.1%
Childhood leukaemia (exposure to insecticides during childhood – update Turner, 2010)	8	1.51 (1.28–1.78)	0%
Childhood leukaemia (exposure to unspecified pesticides during childhood – update Turner, 2010)	11	1.36 (1.19–1.55)	0%
Breast cancer (DDE exposure)	5	1.13 (0.81–1.57)	0%
Breast cancer	11	1.24 (1.08–1.43)	0%
Testicular cancer (DDE exposure)	5	1.40 (0.82–2.39)	59.5%
Stomach cancer	6	1.79 (1.30–2.47)	0%
Liver cancer	5	2.50 (1.57–3.98)	25.4%
Cryptorchidism	8	1.19 (0.96–1.49)	23.9%
Cryptorchidism (DDT exposure)	4	1.47 (0.98–2.20)	51%
Hypospadias (general pesticide exposure)	6	1.01 (0.74–1.39)	71.5%
Hypospadias (exposure to specific pesticides)	9	1.00 (0.84–1.18)	65.9%
Abortion	6	1.52 (1.09–2.13)	63.1%
Parkinson's disease	26	1.49 (1.28–1.73)	54.6%
Parkinson's disease (DDT exposure)	5	1.01 (0.78–1.30)	0%
Parkinson's disease (paraquat exposure)	9	1.32 (1.09–1.60)	34.1%
Amyotrophic lateral sclerosis	6	1.58 (1.31–1.90)	10%
Asthma (DDT exposure)	5	1.29 (1.14–1.45)	0%
Asthma (paraquat exposure)	6	1.40 (0.95–2.06)	53.3%
Asthma (chlorpyrifos exposure)	5	1.03 (0.82–1.28)	0%
Type 1 diabetes (DDE exposure)	8	1.89 (1.25–2.86)	49%
Type 1 diabetes (DDT exposure)	6	1.76 (1.20–2.59)	76.3%
Type 2 diabetes (DDE exposure)	4	1.29 (1.13–1.48)	0%

 Table A.2:
 Summary of meta-analyses performed in the report

N = number of studies considered for the meta-analysis; in the column of meta-analysis results, the numbers represent the statistical estimate for the size of effect (odds ratio (OR), or relative risk (RR)) with the corresponding 95% confidence interval (CI). I<sup>2</sup> represents the percentage of total variation across studies that is due to heterogeneity.

#### A.2. The INSERM report

In September 2013, the French National Institute of Health and Medical Research (INSERM) released a literature review carried out with a group of experts on the human health effects of exposure to pesticides.<sup>22</sup> Epidemiological or experimental data published in the scientific literature up to June 2012 were analysed. The report was accompanied by a summary outlining the literature analysis and highlighting the main findings and policy lines, as well as the recommendations.

The INSERM report is composed of four parts: (1) exposure assessment, with a detailed description of direct and indirect methods to assess exposure in epidemiological studies; (2) epidemiology, with an inventory and analysis of epidemiological studies available in the literature up to 2012, and a scoring system to assess the strength of presumed association; (3) toxicology, with a review of toxicological data (metabolism, mode of action and molecular pathway) of some substances and assessment of biological plausibility; (4) recommendations.

The vast majority of substances identified by the INSERM report as having a presumed moderate or strong association with the occurrence of health effects are chemicals that are now prohibited. This is mainly driven by the fact that the majority of the diseases examined are diseases of the elderly; therefore, the studies performed to date are based on persons who were old at the time of the study and exposed many years ago. By definition, it is not yet possible to investigate the potential long term effects of many of the more recent products.

These substances belong to the group of organochlorine insecticides, such as DDT or toxaphene, or insecticides with cholinesterase-inhibiting properties, such as terbufos or propoxur.

Of the seven approved active substances identified by the INSERM expert appraisal report (the herbicides 2,4-D, MCPA, mecoprop, glyphosate, the insecticide chlorpyrifos, and the foliar fungicides mancozeb and maneb), all had a presumed moderate or weak association with haematopoietic cancers. Two of them (the foliar fungicides mancozeb and maneb) had a presumed weak association with Parkinson's disease and two (chlorpyrifos and glyphosate) had a presumed association with developmental impairment identified as weak or moderate in the expert appraisal.

## A.2.1. Description of methods to assess exposure in epidemiological studies

Different methods (direct and indirect) have been developed to assess exposure, such as biological or environmental monitoring data, ad hoc questionnaires, job- or crop-exposure matrices, analysis of professional calendars, sales data, land use data, etc. According to the authors, these various tools can be combined with each other but, to date none has been validated as a reference method for estimating exposure in the context of occupational pesticide exposure assessment.

#### A.2.2. Epidemiology

The group of experts from INSERM carried out an inventory and analysis of epidemiological studies available in the literature, examining the possible association between pesticide exposure and health outcomes: eight cancer sites (non-Hodgkin lymphoma, leukaemia, lymphoma, multiple myeloma, prostate, testis, brain, melanoma), three neurodegenerative diseases (Parkinson's disease, Alzheimer's disease, amyotrophic lateral sclerosis), cognitive or depressive disorders, effects on reproductive function (fertility, pregnancy and child development) and childhood cancers. These are health outcomes that have been identified in previous studies as potentially related to pesticide exposure.

Epidemiological studies addressing primarily farmers, pesticide applicators and workers of the pesticide manufacturing industries, as well as the general population when it was relevant, were selected.

The INSERM group of experts established a hierarchy in the relevance of the studies, placing the meta-analysis at the top, then the systematic review, then the cohort study, and finally, the case-control study. Based on this hierarchy, a scoring system was defined to assess the strength of presumption of the association between exposure and the occurrence of health outcomes from the analysis of the study results; for each disease or pathological condition investigated, this score may vary depending on the quality, type and number of available studies, as, for example:

(++): strong presumption: based on the results of a meta-analysis, or several cohort studies or at least one cohort study and two case–control studies, or more than two case–control studies;

<sup>&</sup>lt;sup>22</sup> INSERM. Pesticides. Effets sur la santé. Collection expertise collective, Inserm, Paris, 2013.

(+): moderate presumption: based on the results of a cohort study or a nested case–control study or two case–control studies;

 $(\pm)$ : weak presumption: based on the results of one case–control study. This synthesis takes the work beyond the status of a simple mapping exercise.

#### A.2.3. Toxicological data

Toxicological data that were considered in the literature review were mainly those regarding metabolism, mode of action and molecular pathways. None of the studies provided as part of the procedures for placing products on the market were considered except if they were published in the open literature.

When substances were clearly identified in the epidemiological studies, a scoring system was defined to assess the biological plausibility from the study results: coherence with pathophysiological data and occurrence of health outcome.

(++): hypothesis supported by 3 mechanisms of toxicity;

(+): hypothesis supported by at least one mechanism of toxicity.

#### A.2.4. Findings

The major results of the INSERM report are summarised in Tables A.3-A.6.

### **Table A.3:** Statistically significant associations between occupational exposure to pesticides and health outcomes in adults (health outcomes that were analysed in the review)

Health outcome	come Type of population with significant risk excess	
NHL	Farmers, operators, manufacturing plant personnel	++
Prostate cancer	Farmers, operators, manufacturing plant personnel	++
Multiple myeloma	Farmers, operators	++
Parkinson's disease	Occupational and non-occupational exposure	++
Leukaemia	Farmers, operators, manufacturing plant personnel	+
Alzheimer's disease	Farmers	+
Cognitive disorders <sup>(b)</sup>	Farmers	+
Fertility and fecundability disorders	Occupational exposure	+
Hodgkin lymphoma	Agricultural workers	±
Testicular cancer	Agricultural workers	±
Brain cancer (glioma, meningioma)	Agricultural workers	±
Melanoma	Agricultural workers	±
Amyotrophic lateral sclerosis	Farmers	±
Anxiety, depression <sup>(b)</sup>	Farmers, farmers with a history of acute poisoning, operators	±

(a): Scoring system: strong presumption (++), moderate presumption (+), weak presumption ( $\pm$ ).

(b): Almost all pesticides were organophosphates.

**Table A.4:** Associations between occupational or home use exposure to pesticides and cancers or developmental impairment in children (health outcomes that were analysed in the review) (only statistically significant associations are shown)

Health outcome	Health outcome Type of exposure and population with significant risk excess		
Leukaemia	Occupational exposure during pregnancy, prenatal exposure (residential)	++	
Brain cancer	Occupational exposure during pregnancy	++	
Congenital malformation	Occupational exposure during pregnancy; Residential exposure during pregnancy (agricultural area, home use)	++ +	
Fetal death	Occupational exposure during pregnancy	+	
Neurodevelopment	Residential exposure during pregnancy (agricultural area, home use, food) <sup>(b)</sup> ; Occupational exposure during pregnancy	++ ±	

(a): Scoring system: strong presumption (++), moderate presumption (+), weak presumption ( $\pm$ ). (b): Organophosphates.

### **Table A.5:** Findings related to approved active substances: epidemiological assessment and biological plausibility

Active substance Classification		Strength of presumption <sup>(a)</sup>	Biological plausibility <sup>(b)</sup>	
Organophosphates Insecticide				
Chlorpyrifos	Acute Tox cat 3	Leukaemia (+)	Yes (++)	
		Neurodevelopment (+)	Yes (++)	
		NHL ( $\pm$ )	Yes (++)	
Dithiocarbamates <i>Fungicid</i> e				
Mancozeb/Maneb	Repro cat 2	Leukaemia (+)	?	
		Melanoma (+)	?	
		Parkinson's disease	Yes (+)	
		(in combination with paraquat) ( $\pm$ )		
Phenoxy herbicides Herbicide	5		·	
2,4-D	Acute Tox cat 4	NHL (+)	?	
MCPA	Acute Tox cat 4	NHL (±)	?	
Mecoprop	Acute Tox cat 4	$NHL(\pm)$	?	
Aminophosphonate <i>Herbicide</i>	glycine			
Glyphosate		NHL (+)	?	
<i>,</i> ,		Fetal death $(\pm)$	?	

(a): Scoring system: strong presumption (++), moderate presumption (+), weak presumption ( $\pm$ ).

(b): Scoring system: (++): hypothesis supported by 3 different known mechanisms of toxicity, (+): hypothesis supported by at least one mechanism of toxicity.

Table A.6:	Findings related to non-approved active substances: epidemiological assessment and
	biological plausibility

Active substance	Ban in the EU	IARC classification	Strength of presumption <sup>(a)</sup>	Biological plausibility <sup>(b)</sup>
Dieldrin	1978	3 or 2 (US-EPA)	$\operatorname{NHL}^{(c)}(\pm)$ Prostate cancer (±) Parkinson's disease (±)	Yes (+) Yes (+) ?
DDT/DDE	1978	2B	NHL (++) Testicular cancer (+) Child growth (++) Neurodevelopment (±) Impaired sperm parameters (+)	Yes (+) ? ? ?
Chlordane	1978	2B	NHL (±) Leukaemia (+) Prostate cancer (±) Testicular cancer (+)	Yes (+) Yes (+) Yes (+) ?
Lindane (γ-HCH)	2002/2004/2006/2007	2B <sup>(d)</sup>	NHL (++) Leukaemia (+)	Yes (++) Yes (++)

(d): Technical mixture ( $\alpha$ -,  $\beta$ -, and  $\gamma$ -HCH).

#### A.2.5. Recommendations

The analysis of the available epidemiological and mechanistic data on some active substances suggests several recommendations for developing further research:

a) Knowledge on population exposure to pesticides should be improved

- 1) Collect information about use of active substances by farmers
- 2) Conduct field studies to measure actual levels of exposure
- 3) Monitor exposure during the full occupational life span
- 4) Measure exposure levels in air (outdoor and indoor), water, food, soil
- 5) Collect information on acute poisonings
- 6) Improve analytical methods for biomonitoring and external measurements
- 7) Allow researchers to have access to extensive formulation data (solvents, co-formulants, etc.).
- b) Research potential links between exposure and health outcomes
  - 1) Characterise substances or groups of substances causing health outcomes
  - 2) Focus on susceptible individuals or groups of individuals (gene polymorphism of enzymes, etc.)
  - 3) Focus on exposure windows and susceptibility (pregnancy, development)
  - 4) Bridge the gap between epidemiology and toxicology (mode of action)
  - 5) Improve knowledge on mixture toxicity
  - 6) Foster new approaches of research (in vitro and in silico models, omics, etc.).

#### A.3. Similarities and differences between the EFSA External Scientific Report and the INSERM report

The two reports discussed herein have used different methodologies. Yet, their results and conclusions in many cases agree. The INSERM report is limited to predefined outcomes and it attempted to investigate the biological plausibility of epidemiological studies by reviewing toxicological data as well, meanwhile the EFSA report is a comprehensive systematic review of all available epidemiological studies that were published during an approximately 5 year window.

The differences between the reports are shown in Table A.7 and are related to the time period of search (i.e. both reports did not assess the same body of published data), different criteria for eligibility of studies and different approaches to summarising the evidence across and within outcomes.

Overall, the INSERM report identified a greater number of associations with adverse health effects than the EFSA report. However, a well-documented association with pesticide exposure was claimed by both reports for the same health outcomes (childhood leukaemia, Parkinson's disease).

# A.4. The Ontario College of Family Physicians Literature review (OCFPLR)

In 2004, the Ontario College of Family Physicians (Ontario, Canada) reviewed the literature published between 1992 and 2003 on major health effects associated with pesticide exposure. The authors concluded that positive associations exist between solid tumours and pesticide exposures as shown in Table A.8. They noted that in large well-designed cohort studies these associations were consistently statistically significant, and the relationships were most consistent for high exposure levels. They also noted that dose–response relationships were often observed, and they considered the quality of studies to be generally good.

Endpoint	Associations identified by the Ontario College, pesticide (if differentiated), study type, (no. of studies/total no. of studies)				
A) Cancer					
1. Lung	-ve cohort (1/1) +ve case-control (1/1) +ve carbamate, phenoxy acid, case-control (1/1)				
2. Breast	+ve case-control (2/4) +ve ecological (1/1) +ve triazine, ecological (1/1) -ve atrazine, ecological (1/1)				
3. Colorectal					
4. Pancreas	+ve cohort (1/1) +ve case_control (2/2)				
5. Non-Hodgkin's lymphoma	+ve cohort (9/11) +ve case_control (12/14) +ve ecological (2/2)				
6. Leukaemia	+ve cohort (5/6) +ve case_control (8/8) -ve ecological (1/1) +ve lab study (1/1)				
7. Brain	+ve cohort (5), similar case-control (5)				
8. Prostate	+ve cohort (5/5) case-control (2/2) ecological (1/1)				
9. Stomach					
10. Ovary					
11. Kidney	+ve pentachlorophenol cohort (1/1) +ve cohort (1/1) +ve case-control (4/4)				
12. Testicular					
B) Non-Cancer					
1) Reproductive effects	+ve glyphosate				
Congenital malformations	+ve pyridyl derivatives				
Fecundity/time to pregnancy	Suggest impaired				
Fertility					
Altered growth	Possible +ve association, but further study required				
Fetal death	Suggested association				
Mixed outcomes					
2) Genotoxic/immunotoxic Chromosome aberrations	+ve Synthetic pyrethroids (1) +ve organophosphates (1) +ve fumigant and insecticide applicators				
NHL rearrangements	+ve fumigant and herbicide applicators				
3) Dermatologic					
4) Neurotoxic Mental & emotional impact	+ve				
Functional nervous system impact	+ ve organophosphate/carbamate poisoning				
Neurodegenerative impacts (PD)	+ve cohort (4/4) +ve case_control (2/2) +ve ecological (1/1)				

+ve: positive; -ve: negative.

The report concluded that there was compelling evidence of a link between pesticide exposure and the development of non-Hodgkin's lymphoma (NHL), and also clear evidence of a positive association between pesticide exposure and leukaemia. The authors also claimed to have found consistent findings of a number of nervous system effects, arising from a range of exposure time courses.

Such strong conclusions found favour with Non-Governmental organisations (NGOs) and raised questions among some Regulatory Authorities. The Advisory Committee on Pesticides (ACP), at that time an UK government independent advisory committee, was asked to provide an evaluation of the outcome of the Ontario College review. The committee membership included one epidemiologist and the committee consulted five other epidemiologists involved in providing independent advice to other government committees. They all agreed that the review had major shortcomings (e.g. exact search strategy and selection criteria not specified, selective reporting of results, inadequate understanding and consideration of relevant toxicology, insufficient attention to routes and levels of exposure, not justified conclusions, etc.). Overall, the conclusions of the Ontario College review were considered not to be supported by the analysis presented. In 2012, the Ontario review authors published an update of their evaluation; in their second report they used a very similar approach but offered more detail concerning the inclusion criteria used. This example is a reminder of the risk of over interpretation of epidemiological studies. In particular, a causal inference between exposure and the occurrence of adverse health effects is often made, but this represents an association that should be further assessed.

385

#### Annex B – Human biomonitoring project outsourced by EFSA<sup>23</sup>

In 2015, EFSA outsourced a project to further investigate the role of HBM in occupational health and safety strategies as a tool for refined exposure assessment in epidemiological studies and to contribute to the evaluation of potential health risks from occupational exposure to pesticides. It was in fact recognised that exposure assessment is a key part of all epidemiological studies and misclassification of exposure and use of simple categorical methods are known to weaken the ability of a study to determine whether an association between contact and ill-health outcome exists; at present, this limits integration of epidemiological findings into regulatory risk assessment.

The consortium formed by Risk & Policy Analysts Limited (RPA), IEH Consulting Limited (IEH) and the Health&Safety Laboratory (HSL) carried out a systematic literature review for the period 1990–2015 with the aim to provide an overview on the use of HBM as a tool for occupational exposure assessment refinement, identifying advantages, disadvantages and needs for further development (first objective). The search identified 2096 publications relating to the use of HBM to assess occupational exposure to pesticides (or metabolites). The outcome of the search (Bevan et al., 2017) indicated that over the past 10–20 years there has been an expansion in the use of HBM, especially into the field of environmental and consumer exposure analysis. However, further improvement of the use of HBM for pesticide exposure assessment is needed, in particular with regards to: development of strategies to improve or standardise analytical quality, improvement of the availability of reference material for metabolites, integration of HBM data into mathematical modelling, exposure reconstruction, improvements in analytical instrumentation and increased availability of human toxicology data.

The contractors performed a review of available HBM studies/surveillance programmes conducted in EU/US occupational settings to identify pesticides (or metabolites) both persistent and not persistent, for which biomarkers of exposure (and possibly effect) were available and validated (second objective). A two-tiered screening process that included quality scoring for HBM, epidemiological and toxicological aspects, was utilised to identify the most relevant studies, resulting in 178 studies for critical review. In parallel with the screening of identified studies, a Master Spreadsheet was designed to collate data from these papers, which contained information relating to: study type; study participants; chemicals under investigation; biomarker quality check; analytical methodology; exposure assessment; health outcome/toxicological endpoint; period of follow-up; narrative of results; risk of bias and other comments.

HBM has been extensively used for monitoring worker exposure to a variety of pesticides. Epidemiological studies of occupational pesticide use were seen to be limited by inadequate or retrospective exposure information, typically obtained through self-reported questionnaires, which can potentially lead to exposure misclassification. Some examples of the use of job exposure or crop exposure matrices were reported. However, little validation of these matrix studies against actual exposure data had been carried out. Very limited data was identified that examined seasonal exposures and the impact of PPE, and many of the studies used HBM to only assess one or two specific compounds. A wide variety of exposure models are currently employed for health risk assessments and biomarkers have also often been used to evaluate exposure estimates predicted by a model.

From the 178 publications identified to be of relevance, 41 individual studies included herbicides, and of these, 34 separate herbicides were identified, 15 of which currently have approved for use in the EU. Similarly, of the 90 individual studies that included insecticides, 79 separate insecticides were identified, of which 18 currently have approved for use in the EU. Twenty individual studies included fungicides, with 34 separate fungicides being identified and of these 22 currently have approved for use in the EU. The most studied herbicides (in order) were shown to be: 2,4-D > atrazine > metolachlor = MCPA > alachlor = glyphosate. Similarly, the most studied insecticides (in order) were: chlorpyrifos > permethrin > cypermethrin = deltamethrin > malathion, and the most studied fungicides were: captan > mancozeb > folpet.

Current limitations comprised the limited number of kinetic data from humans, particularly with respect to the ADME of individual pesticides in human subjects, which would allow more accurate HBM sampling for all routes of exposure. A wider impact of this is on the development of PBPK models for the risk assessment of pesticides, which rely on toxicokinetic data, and on validation of currently used exposure assessment models. Further limitations currently impacting on the use of HBM in this field are a lack of large prospective cohort studies to assess long term exposure to currently used pesticides.

<sup>&</sup>lt;sup>23</sup> Bevan et al. (2017).

The evidence identified has been used to help formulate recommendations on the implementation of HBM as part of the occupational health surveillance for pesticides in Europe. Some key issues were considered that would need to be overcome to enable implementation. These included the setting of priorities for the development of new specific and sensitive biomarkers, the derivation and adoption of health-based guidance values, development of QA schemes to validate inter-laboratory measurements, good practice in field work and questionnaire design, extension of the use of biobanking and the use of HBM for post-approval monitoring of pesticide safety.

387

# Annex C – Experience of international regulatory agencies in regards to the integration of epidemiological studies for hazard identification

#### C.1. WHO-International Agency for Research on Cancer (IARC)

The IARC Monographs on the Evaluation of Carcinogenic Risks to Humans of the International Agency for Research on Cancer (IARC) is a programme established four decades ago to assess environmental exposures that can increase the risk of human cancer. These include individual chemicals and chemical mixtures, occupational exposures, physical agents, biological agents and lifestyle factors.

IARC assembles international interdisciplinary Working Groups of scientists to review and assess the quality and strength of evidence from scientific publications and perform a hazard evaluation to assess the likelihood that the agents of concern pose a cancer risk to humans. In particular, the tasks of IARC Working Group Members include the evaluation of the results of epidemiological and other experimental studies on cancer, to evaluate data on the mechanisms of carcinogenesis and to make an overall evaluation of the carcinogenicity of the exposure to humans.

The Monographs are widely used and referenced by governments, organisations, and the public around the world to set preventive and control public health measures.

The Preamble<sup>24</sup> to the IARC Monographs explains the scope of the programme, the scientific principles and procedures used in developing a Monograph, the types of evidence considered and the scientific criteria that guide the evaluations. The scope of the monographs broadened to include not only single chemicals but also groups of related chemicals, complex mixtures, occupational exposures, physical and biological agents and lifestyle factors. Thus, the title of the monographs reads 'Evaluation of carcinogenic risks to humans'.

Relevant epidemiological studies, cancer bioassays in experimental animals, mechanistic data, as well as exposure data are critically reviewed. Only reports that have been published or accepted for publication in the openly available scientific literature are included. However, the inclusion of a study does not imply acceptance of the adequacy of the study design or of the analysis and interpretation of the results. Qualitative aspects of the available studies are carefully scrutinised.

Although the Monographs have emphasised hazard identification, the same epidemiological and experimental studies used to evaluate a cancer hazard can also be used to estimate a dose–response relationship. A Monograph may undertake to estimate dose–response relationships within the range of the available epidemiological data, or it may compare the dose–response information from experimental and epidemiological studies.

The structure of a Monograph includes the following sections:

- 1) Exposure data
- 2) Studies of cancer in humans
- 3) Studies of cancer in experimental animals
- 4) Mechanistic and other relevant data
- 5) Summary
- 6) Evaluation and rationale.

Human epidemiological data are addressed in point 2, where all pertinent epidemiological studies are assessed. Studies of biomarkers are included when they are relevant to an evaluation of carcinogenicity to humans.

The IARC evaluation of epidemiological studies includes an assessment of the following criteria: types of studies considered (e.g. cohort studies, case–control studies, correlation (or ecological) studies and intervention studies, case reports), quality of the study (e.g. bias, confounding, biological variability and the influence of sample size on the precision of estimates of effect), meta analysis and pooled analyses, temporal effects (e.g. temporal variables, such as age at first exposure, time since first exposure, duration of exposure, cumulative exposure, peak exposure), use of biomarkers in epidemiological studies (e.g. evidence of exposure, of early effects, of cellular, tissue or organism responses), and criteria for causality.

With specific reference to causality, a judgement is made concerning the strength of evidence that the agent in question is carcinogenic to humans. In making its judgement, the Working Group

<sup>&</sup>lt;sup>24</sup> http://monographs.iarc.fr/ENG/Preamble/CurrentPreamble.pdf

considers several criteria for causality (Hill, 1965). A strong association (e.g. a large relative risk) is more likely to indicate causality. However, it is recognised that weak associations may be important when the disease or exposure is common. Associations that are replicated in several studies of different design under different exposure conditions are more likely to represent a causal relationship than isolated observations from single studies. In case of inconsistent results among different investigations, possible reasons (e.g. differences in exposure) are sought, and high quality studies are given more weight compared to less methodologically sound ones. Risk increasing with the exposure is considered to be a strong indication of causality, although the absence of a clear dose–response effect is not necessarily evidence against a causal relationship. The demonstration of a decline in risk after cessation of or reduction in exposure also supports a causal interpretation of the findings. Temporality, precision of estimates of effect, biological plausibility and coherence of the overall data are considered. Biomarkers information may be used in an assessment of the biological plausibility of epidemiological observations. Randomised trials showing different rates of cancer among exposed and unexposed individuals provide particularly strong evidence for causality.

When epidemiological studies show little or no indication of an association between an exposure and cancer, a judgement of lack of carcinogenicity can be made. In those cases, studies are scrutinised to assess the standards of design and analysis described above, including the possibility of bias, confounding or misclassification of exposure. In addition, methodologically sound studies should be consistent with an estimate of effect of unity for any observed level of exposure, provide a pooled estimate of relative risk near to unity, and have a narrow confidence interval. Moreover, no individual study nor the pooled results of all the studies should show any increasing risk with increasing level of exposure. Evidence of lack of carcinogenicity can apply only to the type(s) of cancer studied, to the dose levels reported, and to the intervals between first exposure and disease onset observed in these studies. Experience with human cancer indicates that the period from first exposure to the development of clinical cancer is sometimes longer than 20 years, and latent periods substantially shorter than 30 years cannot provide evidence for lack of carcinogenicity.

Finally, the body of evidence is considered as a whole, in order to reach an overall evaluation which summarises the results of epidemiological studies, the target organs or tissues, dose–response associations, evaluations of the strength of the evidence for human and animal data, and the strength of the mechanistic evidence.

At the end of the overall evaluation, the agent is assigned to one of the following groups: Group 1, the agent is carcinogenic to humans; Group 2A, the agent is probably carcinogenic to humans; Group 2B, the agent is possibly carcinogenic to humans; Group 3, the agent is not classifiable as to its carcinogenicity to humans; Group 4, the agent is probably not carcinogenic to humans.

The categorisation of an agent is a matter of scientific judgement that reflects the strength of the evidence derived from studies in humans and in experimental animals and from mechanistic and other relevant data. These categories refer only to the strength of the evidence that an exposure is carcinogenic and not to the extent of its carcinogenic activity (potency).

For example, Group 1: The agent is carcinogenic to humans. This category is used when there is sufficient evidence of carcinogenicity in humans. Exceptionally, an agent may be placed in this category when evidence of carcinogenicity in humans is less than sufficient but there is sufficient evidence of carcinogenicity in experimental animals and strong evidence in exposed humans that the agent acts through a relevant mechanism of carcinogenicity.

Although widely accepted internationally, there have been criticisms of the classification of particular agents in the past, and more recent criticisms have been directed at the general approach adopted by IARC for such evaluations possibly motivating publication of a rebuttal (Pearce et al., 2015).

## C.2. The experience of US-EPA in regards to the integration of epidemiological studies in risk assessment

The US Environmental Protection Agency's Office of Pesticide Programs (OPP) is the governmental organisation in the US responsible for registering and regulating pesticide products.<sup>25</sup> As part of this activity and prior to any permitted use of a pesticide, OPP evaluates the effects of pesticides on human health and the environment. EPA receives extensive hazard and exposure information to characterise

<sup>&</sup>lt;sup>25</sup> See https://www.epa.gov/pesticide-science-and-assessing-pesticide-risks for general information on pesticide science and assessing pesticide risks.

the risks of pesticide products through the Federal Insecticide, Fungicide, and Rodenticide Act (FIFRA) and the Federal Food, Drug, and Cosmetic Act (FFDCA). Information on the toxic effects of pesticides is generally derived from studies with laboratory animals conducted by pesticide registrants and submitted to EPA.

In the past, information from well-designed epidemiology studies on pesticides has not been typically available to inform EPA's evaluations of potential risks that might be associated with exposure to pesticides. With an increasing number of epidemiology studies entering the literature which explore the putative associations between pesticides exposure and health outcomes, EPA is putting additional emphases on this source of information. This is especially true for the wealth of studies deriving from the Agricultural Health Study<sup>26</sup> (AHS), a large, well-conducted prospective cohort study following close to 90,000 individuals over more than 20 years and from the Children's Environmental Health and Disease Prevention Research Centers.<sup>27</sup> EPA intends to make increasing use of these epidemiology studies in its human health risk assessment with the goal of using such epidemiological information in the most scientifically robust and transparent way.

#### C.2.1. OPP Epidemiological Framework Document

As an early first step in this process, EPA-OPP developed a proposed epidemiological framework document released as a draft in 2010, 'Framework for Incorporating Human Epidemiologic and Incident Data in Health Risk Assessment' (US-EPA, 2010a). The 2010 draft framework was reviewed favourably by the FIFRA Scientific Advisory Panel (SAP) in February, 2010 (US-EPA, 2010b). This document was recently updated in 2016 to the 'Office of Pesticide Programs' Framework Document for Incorporating Human Epidemiology and Incident Data in Risk Assessments for Pesticides' (US-EPA, 2016). The revised and updated 2016 Framework document proposes that human information like that found in epidemiology studies (in addition to human incident databases, and biomonitoring studies) along with experimental toxicological information play a significant role in this new approach by providing insight into the effects caused by actual chemical exposures. In addition, epidemiological/ molecular epidemiological data can guide additional analyses, identify potentially susceptible populations and new health effects and potentially confirming existing toxicological observations. The concepts in the 2016 Framework are based on peer-reviewed robust principles and tools and rely on many existing quidance documents and frameworks (Table C.1) for reviewing and evaluating epidemiology data. It is also consistent with updates to the World Health Organization/International Programme on Chemical Safety mode of action (MoA)/human relevance framework which highlight the importance of problem formulation and the need to integrate information at different levels of biological organisation (Meek et al., 2014). Furthermore, it is consistent with recommendations by the National Academy of Sciences' National Research Council (NAS/NRC) in its 2009 report Science and Decisions (NRC, 2009) in that the framework describes the importance of using problem formulation at the beginning of a complex scientific analysis. The problem formulation stage is envisioned as starting with a planning dialogue with risk managers to identify goals for the analysis and possible risk management strategies. This initial dialogue provides the regulatory context for the scientific analysis and helps define the scope of such an analysis. The problem formulation stage also involves consideration of the available information regarding the pesticide use/usage, toxicological effects of concern, exposure pathways, and duration along with key gaps in data or scientific information.

 Table C.1:
 Key guidance documents and frameworks used by OPP (from US-EPA, 2016)

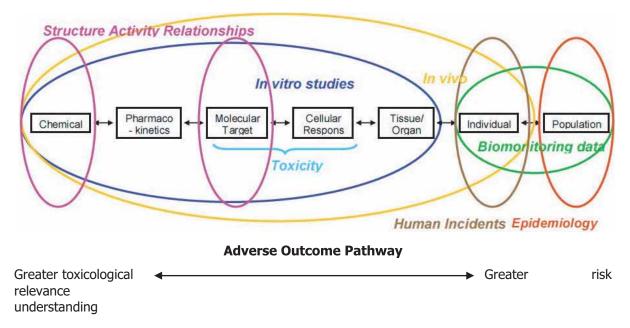

Briefly, this EPA Framework document describes the scientific considerations that the Agency will weigh in evaluating how such epidemiological studies and scientific information can be integrated into risk assessments of pesticide chemicals and also in providing the foundation for evaluating multiple lines of scientific evidence in the context of the understanding of the adverse outcome pathway (or MoA). The framework relies on and espouses standard practices in epidemiology, toxicology and risk assessment, but allows for the flexibility to incorporate information from new or additional sources. One of the key components of the Agency's framework is the use the MoA framework/adverse outcome pathway concept as a tool for organising and integrating information from different sources to inform the causal nature of links observed in both experimental and observational studies. MoA (Boobis et al., 2008; Simon et al., 2014; Meek et al., 2014) and adverse outcome pathway (Ankley et al., 2010) provide important concepts in the integrative analysis discussed in the Framework document. Both a MoA and an adverse outcome pathway are based on the premise that an adverse effect caused by exposure to a compound can be described by a series of causally linked biological key events that result in an adverse human health outcome, and have as their goal a determination of how exposure to environmental agents can perturb these pathways, thereby causing a cascade of subsequent key events leading to adverse health effects.

A number of concepts in the Framework are taken from two reports from the National Academies, *Science and Decisions: Advancing Risk Assessment* (NAS 2009) and *Toxicity Testing on the 21st Century* (NAS 2007). These two NRC reports advocate substantial changes in how toxicity testing is performed, how such data are interpreted, and ultimately how regulatory decisions are made. In particular, the 2007 report on 21st century toxicity testing advocates a decided shift away from the current focus of using apical toxicity endpoints to using toxicity pathways to better inform toxicity testing, risk assessment, and decision-making.

The MoA framework begins with the identification of the series of key events that are along the causal path and established on weight of evidence using criteria based on those described by Bradford Hill taking into account factors such as dose–response, temporal concordance, biological plausibility, coherence and consistency. Specifically, the modified Bradford Hill Criteria (Hill, 1965) are used to evaluate the experimental support that establishes key events within a MoA or an adverse outcome pathway, and explicitly considers such concepts as strength, consistency, dose response, temporal

concordance, and biological plausibility in a weight of evidence analysis. Using this analytic approach, epidemiological findings can be evaluated in the context of other human information and experimental studies to evaluate consistency, reproducibility, and biological plausibility of reported outcomes and to identify areas of uncertainty and future research. Figure C.1 below (adapted from NRC, 2007) suggests how different types of information relate to each other across multiple levels of biological organisation (ranging from the molecular level up to population-based surveillance) and is based on the rapidly evolving scientific understanding of how genes, proteins, and small molecules interact to form molecular pathways that maintain cell function in humans.

### Figure C.1: Source to Outcome Pathway: Chemical effects across levels of biological organisation (adapted from NRC, 2007)

#### C.2.2. Systematic reviews: Fit for purpose

The National Academies' National Research Council (NRC) in its review of EPA's IRIS program defines systematic review as 'a scientific investigation that focuses on a specific question and uses explicit, prespecified scientific methods to identify, select, assess, and summarise the findings of similar but separate studies'.<sup>28</sup> In recent years, the NRC has encouraged the agency to move towards systematic review processes to enhance the transparency of scientific literature reviews that support chemical-specific risk assessments to inform regulatory decision-making.<sup>29</sup>

Consistent with NRC's recommendations, EPA-OPP employs fit-for-purpose systematic reviews that rely on transparent methods for collecting, evaluating and integrating the scientific data supporting its decisions. As such, the complexity and scope of each systematic review will vary among risk assessments. EPA-OPP starts with scoping/problem formulation followed by data collection, data evaluation, data integration and summary findings with critical data gaps identified.

Systematic reviews often use statistical (e.g. meta-analysis) and other quantitative techniques to combine results of the eligible studies, and can use a semi-quantitative scoring system to evaluate the levels of evidence available or the degree of bias that might be present. For EPA's Office of Pesticide Programs, such a Tier III (systematic review) assessment conducted as part of its regulatory review process would involve review of the pesticide chemical undergoing review and a specific associated suspected health outcome (as suggested by the initial Tier II assessment).

A number of federal and other organisations in the US are evaluating or have issued guidance documents for methods to conduct such systematic reviews and a number of frameworks have been

<sup>&</sup>lt;sup>28</sup> http://dels.nas.edu/Report/Review-Integrated-Risk/18764

'Review of the Environmental Protection Agency's Draft IRIS Assessment of Formaldehyde' available for download at https://www.nap.edu/catalog/13142/review-of-the-environmental-protection-agencys-draft-iris-assessment-of-formaldehyde; See also NRC, 2014. 'Review of EPA's Integrated Risk Information System (IRIS) Process' available for download at https:// www.nap.edu/catalog/18764/review-of-epas-integrated-risk-information-system-iris-process

developed. These include the EPA IRIS programs' approach,<sup>30</sup> the National Toxicology Programs' Office of Health Assessment and Translation (NTP/OHAT) approach<sup>31</sup> the Cochran Collaboration's approach,<sup>32</sup> the Campbell Collaboration and the Navigation Guide,<sup>33</sup> with this latter described in a series of articles in the journal *Environmental Health Perspectives*. Each broadly shares four defined steps: data collection, data evaluation, data integration, and summary/update. For example, The Cochrane Collaboration in its Cochrane Handbook for Systematic Reviews of Interventions for evidence-based medicine lists a number of the important key characteristics of a systematic review to be (from US-EPA, 2016):

- a clearly stated set of objectives with predefined eligibility criteria for studies;
- an explicit, reproducible methodology;
- a systematic search that attempts to identify all studies that would meet the eligibility criteria;
- an assessment of the validity of the findings from the identified studies;
- a systematic presentation and synthesis of the characteristics and findings of the included studies.

As described and elaborated in the following sections of this Annex, OPP's approach to review and integration of epidemiological data into pesticide risk assessments takes a tiered approach which each tier appropriately fit-for-purpose in the sense that is considers 'the usefulness of the assessment for its intended purpose, to ensure that the assessment produced is suitable and useful for informing the needed decisions (US-EPA, 2012) and that required resources are matched or balanced against any projected or anticipated information gain from further more in-depth research. A Tier 1 assessment is either a scoping exercise or an update to a scoping exercise in which a research and evaluation is limited to studies derived from the AHS. A Tier II assessment involves a broader search of the epidemiological literature, comprehensive data collection, and a deeper, more involved data evaluation and is more extensive but is generally limited in scope to epidemiology and stops short of multidisciplinary integration across epidemiology, human poisoning events, animal toxicology and adverse outcome pathways. A Tier III assessment is a complete systematic review with data integration and more extensive data evaluation and extraction and may involve more sophisticated epidemiological methods such as meta-analysis and meta-regression, causal inference/causal diagrams, and quantitative bias and sensitivity analyses, among others.

#### C.2.3. Current and Anticipated Future EPA Epidemiology Review Practices

### C.2.3.1. Tier I (Scoping & Problem Formulation) and Tier II (more extensive literature search)

Currently at EPA, epidemiology review of pesticides is conducted in a tiered process as the risk assessment develops, as briefly described above. The purpose of this early Tier I/scoping epidemiology report is to ensure that highly relevant epidemiology studies are considered in the problem formulation/scoping phase of the process and, if appropriate, fully reviewed in the (later) risk assessment phase of the process. In Tier I, EPA-OPP focuses on well-known high quality cohort studies which focus on pesticide issues, particularly the Agricultural Health Study (AHS). The AHS is a federally funded study that evaluates associations between pesticide exposures and cancer and other health outcomes and represents a collaborative effort between the US National Cancer Institute (NCI), the National Institute of Environmental Health Sciences (NIEHS), CDC's National Institute of Occupational Safety and Health (NIOSH) and the US EPA. The AHS participant cohort includes more than 89,000 licensed commercial and private pesticide applicators and their spouses from Iowa and North Carolina. Enrolment occurred from 1993 to 1997, and data collection is ongoing. The AHS maintains on its website a list of publications associated with and using the AHS cohort (see https://aghealth.nih.gov/ news/publications.html).

If the pesticide of interest has been investigated as part of the AHS (www.aghealth.org), a preliminary (Tier I/scoping) review of these studies is performed early on in the evaluation as the

<sup>&</sup>lt;sup>30</sup> See https://www.epa.gov/iris/advancing-systematic-review-workshop-December-2015

<sup>&</sup>lt;sup>31</sup> See http://ntp.niehs.nih.gov/pubhealth/hat/noms/index-2.html and NTP's 'Handbook for Conducting a Literature-based Assessment Using OHAT Approach for Systematic Review and Evidence Integration' at https://ntp.niehs.nih.gov/ntp/ohat/pub s/handbookjan2015\_508.pdf

<sup>&</sup>lt;sup>32</sup> See http://handbook.cochrane.org/

<sup>&</sup>lt;sup>33</sup> See http://ehp.niehs.nih.gov/1307175/

docket (or 'dossier') is opened as part of EPA's 'Scoping' analysis. In this early Tier I/scoping phase, basic epidemiological findings and conclusions from the Agricultural Health Study are described in a Tier I/scoping document which is designed to simply summarise in brief form the pertinent conclusions of various AHS study authors if there are AHS findings relevant to a the pesticide undergoing review; this Tier I scoping review is not designed to offer detailed content, critical evaluation, or evidence synthesis, and may only touch on summarised highlights of the relevant AHS -related journal articles. If other high-quality non-AHS studies are available like those from the Children's Environmental Health and Disease Prevention Research Centres, these may be similarly summarised in this Tier I/scoping epidemiological review as well. Again, no critique or synthesis of the literature is offered. In some cases, the Tier I/scoping review may conclude that no additional epidemiological review of available evidence is further required. Alternatively, it may recommend that further review is necessary as part of a more involved Tier I/update or Tier II assessment.

A <u>Tier I/update assessment</u> is generally completed 1" to 3 years following the completion of the Tier I/scoping assessment and is issued, like the Tier II discussed below, along with and as part of the Draft Human Health Risk Assessment. Tier I/update assessments perform a thorough review of the available literature in the AHS. A Tier I/update assessment reviews, summarises and evaluates in a qualitative, narrative summary (including reported measures of association), the applicable studies that are listed on the AHS website.<sup>34</sup> Reviews are generally in the form of a narrative, focusing on the key aspects of studies and their conclusions and include EPA OPP commentary along with summary EPA OPP conclusions and recommendations for further study, if necessary.

#### C.2.3.2. Tier II (more extensive literature search)

A Tier II assessment is a more complete review of the available epidemiological evidence and is generally done only if the earlier Tier I/scoping document suggests a potential for a specific concern (e.g. a specific and credible exposure-disease hypothesis has been advanced and needs to be further evaluated as part of a more detailed assessment). A Tier II epidemiology assessment, similar to the Tier I/update, is generally completed 1" to 3 years following the completion of the Tier I assessment and is issued along with and as part of OPP's Draft Human Health Risk Assessment; the Tier II evaluation is considered to be a qualitative narrative review that incorporates certain elements of a systematic review. For example, a Tier II assessment will include a thorough and complete literature search that is broader than that of the Tier I/update, including not only the AHS database, but also such databases as PubMed, Web of Science, Google Scholar and Science Direct, and sometimes others using standardised, transparent and reproducible query language for which specialised professional library and information science support is obtained.<sup>35</sup> Evidence synthesis by EPA – albeit generally in a qualitative and narrative form – also occurs in a Tier II assessment, and overall conclusions regarding the body of epidemiological literature are made. In addition, the Tier II assessment may indicate areas in which further epidemiological data and studies with respect to specific hypothesised exposure-health outcome is of interest for future work. The Tier II assessment document will not generally attempt to integrate the epidemiological findings with other lines of evidence such as that from animal toxicology studies or information from MoAs/AOPs which may be done (separately) to some degree as part of the risk assessment. To the extent that the Tier II assessment identifies specific health outcomes putatively associated with a given pesticide, further investigation and integration across disciplines can subsequently be done as part of a more comprehensive Tier III assessment (see below).

#### C.2.3.3. Tier III (Full Systematic Review with Data Integration)

While a Tier II assessment examines a wide range of health outcomes appearing in the epidemiological literature that are hypothesised to be associated with a given pesticide chemical, a Tier III assessment might encompass a broader (multidisciplinary) and sometimes more quantitative/statistical evaluation of at the epidemiological evidence for the association of interest, and it attempts to more

<sup>&</sup>lt;sup>34</sup> https://aghealth.nih.gov/news/publications.html

<sup>&</sup>lt;sup>35</sup> Additional searches conducted under the rubric of epidemiology and biomonitoring/exposure could be done using the NHANES Exposure Reports (http://www.cdc.gov/exposurereport/); TOXNET (http://toxnet.nlm.nih.gov/); CDC NBP Biomonitoring Summaries (http://www.cdc.gov/biomonitoring/biomonitoring\_summaries.html); ICICADS (http://www.inchem.org/pages/cicad s.html); ATSDR Toxicological Profiles (http://www.atsdr.cdc.gov/toxprofiles/index.asp); IARC Monographs (http://monographs. iarc.fr/ENG/Monographs/PDFs/; EFSA's Draft Assessment Report Database (http://dar.efsa.europa.eu/dar-web/provision); and Biomonitoring Equivalents (https://blog.americanchemistry.com/2014/07/biomonitoring-equivalents-a-valuable-scientific-toolfor-making-better-chemical-safety-decisions/

formally integrate this with animal toxicology and MoA/AOP information. Such a Tier III assessment could take the form of a systematic review of the epidemiological literature which would be performed together with evaluation of toxicity and adverse outcome pathways. For pesticide chemicals from AHS, a Tier III analysis would also ideally incorporate the results of evaluations from other high-quality epidemiological investigations and incorporate 'Weight of the Evidence' to a greater degree to reflect a more diverse set of information sources. Results from these investigations would be used to evaluate replication and consistency with results from the AHS. Early AHS findings in a number of cases were based on only a small number of participants that had developed specific outcomes or a relatively few number of years over which the participants have been followed. As the AHS cohort ages, the release of second evaluations of some chemicals from AHS will be based on additional years of follow-up and a greater number of cases that are expected to provide a more robust basis for interpreting positive and negative associations between exposure and outcome. In addition, the AHS is increasingly generating a substantial amount of biochemical, genetic marker, and molecular data to help interpret results from the epidemiological studies. Such results may further clarify AHS findings, provide evidence for a biological basis linking exposures to outcomes, or suggest additional laboratory and observational research that might strengthen evidence for mechanisms underlying causal pathways. In addition, Tier III analyses also may take advantage of efforts to bring together information and results from international cohort studies in the International Agricultural Cohort Consortium (AgriCOH) in which AHS is a member. AgriCOH is actively working to identify opportunities and approaches for pooling data across studies, and the availability of these other cohort data should aid in assessing reproducibility and replication of exposure-outcome relationships as EPA considers, evaluates and weighs the epidemiological data.

# C.2.4. OPP's open literature searching strategies and evaluation of study quality

An important aspect of the systematic review approach is the thorough, systematic, and reproducible searching of the open epidemiological literature such that much of the literature that meets the established eligibility criteria can be located.<sup>36</sup> OPP uses specific databases as part of their literature search and has specific guidance on their conduct (for example, OPP's open literature search guidance for human health risk assessments<sup>37</sup>). Evaluation of all relevant literature, application of a standardised approach for grading the strength of evidence, and clear and consistent summative language will typically be important components (NRC, 2011). In addition, a high quality exposure assessment is particularly important for environmental and occupational epidemiology studies.

A second important component of the above systematic review approach is the assessment of the validity of the findings from the identified studies. Generally speaking, the quality of epidemiological research, sufficiency of documentation of the study (study design and results), and relevance to risk assessment will be considered when evaluating epidemiology studies from the open literature for use in agency risk assessments. When considering individual study quality, various aspects of the design, conduct, analysis and interpretation of the epidemiology studies are important. These include (from US-EPA, 2016):

- 1) clear articulation of the hypothesis, or a clear articulation of the research objectives if the study is hypothesis-generating in nature;
- adequate assessment of exposure for the relevant critical windows of the health effects, the range of exposure of interest for the risk assessment target population, and the availability of a dose/exposure-response trend from the study, among other qualities of exposure assessment;
- 3) reasonably valid and reliable outcome ascertainment (the correct identification of those with and without the health effect in the study population);
- 4) appropriate inclusion and exclusion criteria that result in a sample population representative of the target population, and absent systematic bias;
- 5) adequate measurement and analysis of potentially confounding variables, including measurement or discussion of the role of multiple pesticide exposure, or mixtures exposure in the risk estimates observed.

<sup>&</sup>lt;sup>36</sup> Some advocate looking at the grey or unpublished literature to lessen potential issues associated with publication bias.

<sup>&</sup>lt;sup>37</sup> See https://www.epa.gov/pesticide-science-and-assessing-pesticide-risks/guidance-identifying-selecting-and-evaluating-open and specifically p. 10 of the document 'Guidance for Considering and Using Open Literature Toxicity Studies to Support Human Health Risk Assessment' dated 28.8.2012 at https://www.epa.gov/sites/production/files/2015-07/documents/lit-studies.pdf for Special Notes on Epidemiologic Data.

- overall characterisation of potential systematic biases in the study including errors in the selection of participation and in the collection of information, including performance of sensitivity analysis to determine the potential influence of systematic error on the risk estimates presented;
- 7) adequate statistical power for the exposure–outcome assessment, or evaluation of the impact of statistical power of the study if under-powered to observed effects, and appropriate discussion and/or presentation of power estimates; and
- 8) use of appropriate statistical modelling techniques, given the study design and the nature of the outcomes under study.

## Annex D – Effect size magnification/inflation

As described in the main text of this document, a potential source of bias may result if a study has low power. This lesser known type of bias is known 'effect size magnification'. While it is as widely known that, generally small, low-powered studies can result in false negatives since the study power is inadequate to reliably detect a meaningful effect size, it is less well known that these studies can result in inflation of effect sizes if those estimated effects are required to pass a statistical threshold (e.g. the common p < 0.05 threshold used for statistical significance) to be judged important, relevant, or 'discovered'. This effect – variously known as effect size magnification, the 'winners curse', truth inflation, or effect size inflation – is a phenomenon by which a 'discovered' association (i.e. one that has passed a given threshold of statistical significance to be judged meaningful) from a study with suboptimal power to make that discovery will produce an observed effect size that is artificially and systematically inflated.

Such truth inflation manifests itself as (systematic) bias away from the null in studies that achieve statistical significance in instances where studies are underpowered (Reinhart, 2015). This is because low-powered (and thus generally smaller) studies are more likely to have widely varying results and thus be more likely to be affected by random variation among individuals than larger ones. More specifically, the degree of effect size magnification that may be observed in any study depends, in part, on how widely varying the results of a study is expected to be and this depends on the power of the study; low powered studies tend to produce greater degrees of effect size magnification in results that are found to be statistically significant (or pass other threshold criteria) than higher powered studies.

As an example of this 'effect size magnification' concept and why it may come about, it is useful to imagine a trial run thousands of times with variable sample sizes. In this case, there will be a broad distribution of observed effect sizes. While the observed medians of these estimated effect sizes are expected to be close to the true effect size, the smaller trials will necessarily systematically produce a wider variation in observed effect sizes than larger trials. However, in low powered studies, only a small proportion of observed effects will pass any given (high) statistical threshold of significance and these will be only the ones with the greatest of effect sizes. Thus, when these generally smaller, low powered studies with greater random variation do indeed find a significance-triggered association as a result of passing a given statistical threshold, they are more likely to overestimate the size of that effect. What this means is that research findings of low-powered and statistically significant studies are biased in favour of finding inflated effects. As summarised by Gelman and Carlin (2014): 'when researchers use small [underpowered]<sup>38</sup> samples and noisy measurements to study small effects..., a significant result is often surprisingly likely to be in the wrong direction and to greatly overestimate an effect'. In general, it can be shown that low background (or control or natural) rates, low effect sizes of interest, and smaller sample sizes in the study end to produce lower power in the study and this leads to a greater tendency towards and magnitude of (any) inflated effect sizes.

It is important to note that the effect size inflation phenomenon is a general principle applicable to discovery science in general and is not a specific affliction or malady of epidemiology (Ioannidis, 2005; Lehrer, 2010; Button, 2013; Button et al., 2013; Gelman and Carlin, 2014; Reinhart, 2015). It is often seen in studies in pharmacology, in gene studies, in psychological studies, and in much of the most-often cited medical literature. When researchers have limited ability to increase the sample size such as in most epidemiological studies, effect size magnification is not a function or fault of the research or research design, but rather a function of how that the results of that research are interpreted by the user community. Thus, unlike other possible biases such as selection or information bias in epidemiology studies, the bias is not intrinsic to the study or its design, but rather characteristic of how that study is interpreted.

In order to determine (and quantify) the potential degree of effect size magnification for any given study that produces a statistically significant result, the reviewer must perform various power calculations. More specifically, when the association between a chemical exposure and a disease is found to be statistically significant, a power analysis can be done to determine the degree to which the statistically significant effect size estimate (e.g. odds ratio, relative risk or rate ratio) may be artificially inflated.

<sup>&</sup>lt;sup>38</sup> [italics added]

www.efsa.europa.eu/efsajournal

In order to perform the requisite power calculation, the reviewer must know or obtain four values:

- 1) the number of subjects in non-exposed group;
- 2) the number of subjects in the exposed group;
- 3) the number of individuals with the disease of interest (or cases) in the non-exposed group; and
- 4) a target value of interest to detect a difference of a given (predetermined) size in a comparison of two groups (e.g. exposed vs. not exposed)

The first three listed values are provided in or must be obtained from the publication while the target value of interest (typically an OR or RR in epidemiology studies) is selected by the risk managers (and is ultimately a policy decision).<sup>39</sup> This Annex examines this effect size inflation phenomenon in a quantitative way using simulations. The annex uses two example published studies and simulations of hundreds of trials to evaluate the degree to which effect size magnification may play a role in producing biased effect sizes (such as odds ratios, rate ratios or relative risks) due to low power.

The first example uses data from Agricultural Health Study prospective cohort publication examining diazinon exposure and lung cancer and illustrates the effect size magnification issue for a calculated RR. The second example uses ever-never data from a case–control study studying malathion exposure and NHL and illustrates the effect size magnification concept from the point of view of an estimated OR.

#### An Example Illustrating Effect Size Magnification and Relative Risk (Jones et al. (2015))

The power associated with a comparison between those that are not exposed to diazinon to those that are exposed at the highest tertile (T) can be computed from the information provided in the AHS study publication 'Incidence of solid tumours among pesticide applicators exposed to the organophosphate insecticide diazinon in the Agricultural Health Study - an updated analysis' by Jones et al. (2015) for lung cancer. The number of subjects at each exposure level was provided in the article (non-exposed group: N = 17710, and T(ertile)1, T2 and T3 were categorised based on exposure distribution; specifically: N of each tertile = (2,350 + 2,770)/3 = 1,710 from the publication's Table 1 where: (a) the value of 2,350 represents the number in the lowest exposed *level* and (b) the value of 2,770 represents the number of the two highest exposed levels when the exposed subjects were dichotomously categorised. Since we have (i) the number of subjects in the reference non-exposed group = 17,710; (ii) the number of subjects in each of the exposed groups (tertiles) = 1710; and (iii) the number of diseased individuals (lung cancer) in the reference non-exposed group = 199 (from Table 3 of the cited publication), we can calculate the power of the comparisons between T1 vs non-exposed, T2 vs non-exposed and T3 vs non-exposed that were presented in the article, given the assumption that any true Rate Ratio = 1.2, 1.5, or 2.0, etc.

Here, we are interested in evaluating the power associated with the estimated background rate of 199/17710 (= 0.011237), and, as a form of sensitivity analysis, one half of this background rate (or 0.005617), and twice this rate (0.022473) for detecting (admittedly arbitrary) relative rates of (possible regulatory interest of) 1.2, 1.5, 2.0 and 3.0 among the subjects in each tertile of the diazinon exposed individuals. This analysis was performed using Stata statistical software and is shown below in both tabular and graphical format for true Rate Ratios of 1.2, 1.5, 2.0 and 3.0 for

<sup>&</sup>lt;sup>39</sup> This target value is an effect size of interest, often expressed as either a relative risk (for cohort studies) or an odds rate (for case control studies). That is, the target value is generally an OR or RR of a given magnitude that the risk manager desires to detect with a given degree of confidence. The higher the OR or RR, the greater the magnitude of the estimated association between exposure and the health outcome. While there are not strict guidelines about what constitutes a 'weak' association vs a 'strong' one - and it undoubtedly can be very context-dependent - values less than or equal to about 1 (or sometimes  $\leq$  1.2) are considered to be `null' or `essentially null' (this ignores the possibility of a protective effect which in some contexts – for example, vaccination efficacy - may be appropriate to consider). Values less than 2 or 3 are often considered by some as 'weak'. Values greater than 2 (or 3) and up to about 5 might be considered 'moderate', and values greater than 5 are considered by some to be 'large'. Monson (1990) describes as a guide to the strength of association a rate ratio of 1.0–1.2 as 'None', of from 1.2 to 1.5 as 'Weak', of from 1.5 to 3.0 as 'Moderate', and of 3.0-10.0 as 'Strong'. Other authors use Cohen's criteria to describe ORs of 1.5 as 'small' and 5 as 'large', with 3.5 as 'medium' in epidemiology (Cohen and Chen, 2010). Others describe 1.5 as 'small', 2.5 as 'medium' or 'moderate', 4 as 'large' or 'strong' and 10 as 'very large' or 'very strong' (Rosenthal, 1996) Taube (1995) discusses some of the limitations of environmental epidemiology in detecting weak associations (also see invited commentary illustrating counter-arguments in Wynder (1997). It should be recognized that none of the demarcation lines are 'hard' and there can be legitimate disagreements about where these are drawn and how these are considered and interpreted. Regardless, these can be very much context-dependent and the above demarcations should not be regarded as in any way official or definitive.

1/2x-, 1x- (shown below in bold/shaded) and 2x- the (observed) background rate of 199 diseased individuals/17,710 persons<sup>40</sup>:

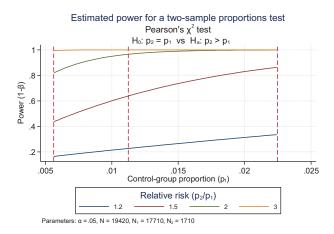

Results of p	Results of power analysis for a one-sided, two-sample proportions test ( $\alpha = 0.05$ ) <sup>(a)</sup>

17,710	1,710	0.02247	0.06742	3.0	1		

Stata code used to generate the above power calculation results: power two proportions ('= 0.5 \* 199/ 17710'= 199/17710'= 2 \* 199/17710), test(chi2) RR (1.2 1.5 2.0 3.0) n1(17710) n2 (1710) one-sided table(N1: 'N control' N2: 'N exposed' p1: 'proportion control' p2: 'proportion exposed' RR: 'relative risk' power: 'power').

(a): One-sided test  $\alpha = 0.05$  Ho: p2 = p1 vs Ha: p2 > p1; N<sub>controls</sub> = 17,710, N<sub>exposed</sub> = 1,710; Number of Iterations = 1,000 (data sets).

(b): Representing 1/2x-, 1x- and 2x- the observed background rate of lung cancer of 199/17710 in Jones et al. (2015). Highlighted/bolded region in table above represents power associated with this 1x observed background rate of lung cancer in cited study.

These values can be graphed as shown below<sup>41</sup>:

Graph showing estimated power for a (one-sided) two-sample proportions test evaluating power as a function of control-group proportion at true RRs of 1.2-, 1.5-, 2.0- and 3.0. Dashed red vertical lines represent control group proportions at 1/2x of that observed, 1x of that observed and 2x of that observed and illustrate sensitivity of the power to these background rate assumptions.

<sup>41</sup> Stata code for generating the above graph: power twoproportions (' = 0.5 \* 199/17710'(0.0001) '= 2 \* 199/17710'), test(chi2) rrisk(1.2 1.5 2.0 3.0) n1(17710) n2(1710)graph (recast(line) xline('= 0.5 \* 199/17710' '=199/17710' '= 2 \* 199/17710', lpattern (dash)) legend(rows(1)size(small)) ylabel(0.2(0.2)1.0)) one sided.

<sup>&</sup>lt;sup>40</sup> The RRs of 1.2, 1.5, 2.0 and 3.0 were selected somewhat arbitrarily to illustrate the power associated with a series of relative risks that might be of interest to the risk manager/decision-maker. The values of RR or OR = 2.0 and 3.0 are considered by some to be a demarcation between weaker effect sizes and stronger effect sizes. The RR value of 1.2 is what some consider 'near to or essentially null', and the RR of 1.5 is an intermediate value between these. In determining whether the epidemiological evidence suggests a relationship between an exposure and a health outcome, a risk manager might consider the 'essentially null' RR of 1.2 from a robust study with acceptable statistical power (generally considered 80–90%) as sufficient evidence for failing to find an association and, in effect, may provide supporting evidence for a conclusion of no observable association between the exposure and the outcome.

As can be seen in the above table and graph, this study had a power of about 23% at 1x the background rate (control-group proportion, equal to 199 diseased individuals/17,710 subjects = 0.011237) to detect a RR of 1.2. To detect an RR of 1.5, there is about 64% power. If the true background rate were in reality twice the observed background rate ( $2 \times 0.011237 = 0.022473$ ), we would have about 86% power to be able to detect a RR of 1.5 and essentially 100% power to detect an RR of 2.0.<sup>42</sup>

Given the above, SAS was used to simulate the degree to which there may be effect size magnification (aka effect size inflation) given *true* relative risks of 1.2, 1.5, 2.0 and 3.0. The table below illustrates the power analysis for diazinon and lung cancer which shows the extent of the effect size magnification from the simulation results. The analysis presented in the table below parallels that done by Ioannidis (2008) and presented in his Table 2 for a set of hypothetical results passing the threshold of formal statistical significance to illustrate the effect size magnification concept.

SAS simulation results illustrating effect size magnification given true odds ratios of 1.2, 1.5, 2.0	
and 3.0 <sup>(a)</sup>	

True values Proportion of diseased individuals in control RR				Distribution of observed significant RRs				
		N analysed data sets	Power <sup>(b)</sup>	N	10th percentile	Median (% inflation)	90th percentile

	2	1,000	1	1,000	1.7	2.0 (0)	2.3	
	3	1,000	1	1,000	2.6	3.0 (0)	3.4	

Poisson regression model was used to compare the rate of (relative risks) between the groups. The EXACT Test was used in the analysis of some data sets when the generalised Hessian matrix is not positive definite (due to a zero cases in one of the groups). (a): One-sided test,  $\alpha = 0.05$ , N Controls = 17,710, N diazinon Exposed = 1,710, Number of iterations = 1,000 (data sets).

(b): The power resulting from this simulation may be close but not precisely match the power calculated from built-in procedures in statistical software such as SAS (PROC POWER) or Stata (power two-proportion). This may be due to the number of data sets simulated being of insufficient size. However, 1,000 iterations is sufficient to adequately estimate the power and to illustrate the degree of effect size magnification given a statistically significant result (here,  $\alpha \le 0.05$ ).

Note that – given a statistically significant result at p < 0.05 – the percent effect size inflation at the median of the statistically significant results varies from 0% to 42% depending on both the rate of lung cancer among individuals not exposed to diazinon (i.e. proportion of diseased individuals in the non-exposed group) and the true relative risk (ranging from 1.2 to 3.0). For example, if the **true RR** of a tertile of exposed vs non-exposed were 1.2, where the non-exposed group has a rate of lung cancer of 0.011237 (bolded row in the above table), half of the **observed** statistically significant RRs would be above the median of 1.6 and half would be below 1.6; this represents a median inflation of 33% over the true RR of 1.2 used in the simulation.

For the background rate found in the Jones et al. (2015) study (0.011237), a true RR of 1.2 that was found to be statistically significant would instead were the study to be repeated be observed to vary from 1.4 (at the 10th percentile) to 1.8 (at the 90th percentile) with the aforementioned median of 1.6. When the **true RR** is 2 or 3, the power is greater than 80% (as seen in the above table) and the median of observed RR is close to the true RR and the range of observed RRs are narrow. As the true RR increases to 3, the study's power increases such that the effect size inflation disappears and the median from the simulations indeed reflects the true RR.

<sup>&</sup>lt;sup>42</sup> Said another way, if the true (but unknown) background rate were actually twice the observed background rate, we could reasonably conclude (with 86% confidence) if no statistically significant relationship was found that the true OR did not exceed 1.5.

# An Example Illustrating Effect Size Magnification and Odds Ratios in an Ever/Never Analysis (Waddell, et al. 2001)

Sometimes comparisons between exposed group vs non-exposed group are presented in an 'ever/never' comparison as opposed to a comparison based on some other categorisation or grouping such as terciles or quartiles. This exposure category-based analysis might be done because there are an insufficient number of cases to break the exposure categories into small (more homogenous) exposure classifications or groupings or because the measurements of exposure are not available or are less reliable (such as in case-control studies). In these situations, we similarly need (i) the total number of subjects in non-exposed group; (ii) the number of subjects in exposed group; (iii) the number of diseased individuals in the non-exposed group in order to calculate the power of the comparison between exposed group vs non-exposed group at some; (iv) given or preselected odds ratios.

To illustrate how a power and effect size magnification analysis might be done for a case–control study using ever-never exposure categorisations, a study investigating the association between malathion and NHL (Waddell et al., 2001) was selected. Here, we have (i) the number of subjects in the reference non-exposed group = 1,018 (from Table 1: non-farmers = 243 diseased individuals + 775 non-diseased individuals); (ii) the number of subjects in the exposed group = 238 (from Table 4: malathion exposed individuals = 91 exposed cases + 147 non-exposed controls); (iii) the number of diseased individuals in the reference non-exposed group = 243 (from Table 1: 243 diseased individuals in the non-farmer or non-exposed group), we can similarly calculate the power of the comparisons between the ever vs never exposed, given the assumption that any true OR = 1.2, 1.5, 2.0, etc.

As was described above for lung cancer and diazinon, we estimated a power of 30.5% to detect an OR of 1.2 at the study-estimated NHL proportion of 0.2387 among non-farmers (non-exposed), as illustrated in the table below:

Results of p	Results of power analysis for a one-sided, two-sample proportions test ( $\alpha = 0.05$ ) <sup>(a)</sup>					
N <sub>control</sub>	N <sub>exposed</sub>	Proportion control <sup>(b)</sup>	Proportion exposed	Odds Ratio	Power	
1,018	238	0.1194	0.1399	1.2	0.2279	
1,018	238	0.1194	0.1689	1.5	0.647	
1,018	238	0.1194	0.2133	2.0	0.9693	
1,018	238	0.1194	0.2891	3.0	1	
1,018	238	0.2387	0.2734	1.2	0.3047	
1,018	238	0.2387	0.3199	1.5	0.8149	
1,018	238	0.2387	0.3854	2.0	0.9971	
1,018	238	0.2387	0.4847	3.0	1	
1,018	238	0.4774	0.523	1.2	0.3522	
1,018	238	0.4774	0.5781	1.5	0.8779	
1,018	238	0.4774	0.6463	2.0	0.9992	
1,018	238	0.4774	0.7327	3.0	1	

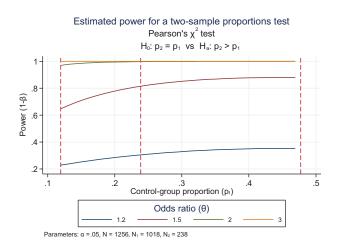

Stata code used to generate the above results: power two-proportions ('= 0.5 \* 243/1018' '= 243/ 1018' '= 2 \* 243/1018'), test(chi2) OR (1.21.52.03.0) n1(1,018) n2(238) one-side table(N1: 'N control' N2: 'N exposed' p1: 'proportion control' p2' proportion exposed' OR: 'odds ratio' power: 'power').

(a): One-sided test  $\alpha = 0.05$  Ho: p2 = p1 vs Ha: p2 > p1;  $N_{controls} = 1,018$ ,  $N_{exposed} = 238$ , Number of iterations = 1,000 (data sets). (b): Representing 1/2x-, 1x- and 2x- the observed background rate of lung cancer of 243/1018 in Waddell et al. (2001). Highlighted, bolded region in table above represents power associated with this 1x observed background rate of NHL in cited study.

Such power relations for malathion and NHL are graphed below<sup>43</sup> – as was done in the above AHS prospective cohort study for diazinon and lung cancer – with the middle vertical dotted line in the graph showing power at the NHL proportion of 0.2387 among non-farmers/non-exposed and the left-hand and right-hand vertical dashed lines representing a form of sensitivity analysis at one-half and twice the NHL proportion among non-farmers/non-exposed, respectively.

<sup>&</sup>lt;sup>43</sup> Stata code for generating the graph: power two proportions ('= 0.5 \* 243/1018'(0.01) '= 2 \* 243/1018'), test(chi2) OR (1.2 1.5 2.0 3.0) n1(1018) n2(238)graph(recast (line) x-line('= 0.5 \* 243/1018' '= 243/1018' '= 2 \* 243/1018', lpattern(dash)) legend(rows(1)size(small)) y-label(0.2(0.2)1.0)) one sided.

Graph showing estimated power for a (one-sided) two-sample proportions test evaluating power as a function of control-group proportion at true RRs of 1.2-, 1.5-, 2.0- and 3.0. Dashed red vertical lines represent control group proportions at 1/2x of that observed, 1x of that observed and 2x of that observed and illustrates the sensitivity of the power to these background rate assumptions.

At the study-estimated NHL proportion of 0.2387 among non-farmers/non-exposed, the power (one-sided) to detect ORs of 1.2, 1.5, 2.0 and 3.0 is shown to be 30.5%, 81.5%, 99.7% and > 99.9%, respectively. Note that Waddell et al. (2001) reported an OR of 1.6 with a 95% CI of 1.2–2.2, based on 91 NHL cases who used malathion and 243 cases that were among non-farmers who did not.

Given the above, SAS was used to simulate the degree to which effect size magnification may exist given *true* odds ratios of 1.2, 1.5, 2.0 and 3.0. Below is a SAS-generated table for the power analysis for malathion and NHL showing the magnitude of the effect size magnification from the SAS-based simulation results.

True values			Distribution of observed significant ORs				
Proportion of diseased individuals in non-exposed group	OR	N analysed data sets	Power <sup>(b)</sup>	N	10th percentile	Median (% inflation)	90th percentile
0.1194 (1/2 background)	1.2	1,000	0.22	220	1.4	1.5 (25)	1.8
	1.5	1,000	0.66	661	1.5	1.7 (13)	2.0
	2	1,000	0.97	972	1.6	2.0 (0)	2.5
	3	1,000	1.0	1,000	2.4	3.0 (0)	3.7
0.2387 (1 $\times$ background)	1.2	1,000	0.32	323	1.3	1.4 (17)	1.6
	1.5	1,000	0.81	812	1.4	1.6 (7)	1.8
	2	1,000	1.0	997	1.6	2.0 (0)	2.4
	3	1,000	1.0	1,000	2.5	3.0 (0)	3.6
0.4774 (2 $\times$ background)	1.2	1,000	0.34	337	1.3	1.4 (17)	1.6
	1.5	1,000	0.87	872	1.3	1.5 (0)	1.8
	2	1,000	1.0	1,000	1.6	2.0 (0)	2.5
	3	1,000	1.0	1,000	2.4	3.0 (0)	3.7

SAS simulation results illustrating effect size magnification given true odds ratios of 1.2, 1.5, 2.0,	,
and 3.0 <sup>(a)</sup>	

The logistic regression model was used to compute the odds ratios for the two groups. The EXACT Test was used in the analysis of some data sets when the maximum likelihood estimate did not exist (perhaps due to a zero cases in one of the groups). (a): One-sided test,  $\alpha = 0.05$ , N non-exposed = 1,018, N malathion exposed = 238, N iterations = 1,000 (data sets).

(b): The power resulting from this simulation may be close but not match exactly with the power calculated from built-in procedures in statistical software such as SAS (PROC POWER) or Stata (power two-proportion). This may be due to number of data sets simulated being of insufficient size. However, 1,000 iterations are sufficient to adequately estimate the power and to illustrate the degree of effect size magnification given a statistically significant result (here,  $\alpha \leq 0.05$ ).

Note that – given a statistically significant result at p < 0.05 – the median effect size varies from 1.4 to 3, depending on the NHL proportion in the non-exposed group, and the true odds ratio (ranging from 1.2 to 3.0). For example, if the true OR for a NHL proportion among non-farmers of 0.2387 was 1.2 (bolded row in the table), half of the *observed statistically significant* ORs would be above the median of 1.4 and half would be below. Further, most (90%) of the statistically significant ORs would be observed to be above 1.3, and a few (10%) would be observed even to be above 1.6.

In sum, then, the power of an epidemiological study is an important factor that should considered by regulators and others evaluating such studies. A study that is sufficiently powered will not only be more likely to detect a true effect of a given size if it is indeed present (the classic definition of power which relates to the issue of a Type II error or a false negative) but will also be less likely to magnify or exaggerate the effect if it is not there but (by chance) crosses a preselected threshold (such as the 0.05 level for statistical significance). If a study is suitably powered (say, 80% or more), the observed effect size is more likely to be a reflect a true effect size and any observed chance variation in this effect size will reflect a distribution symmetrically centred around the unknown true value. The take home message from these simulations and the original work by Ioannidis and extensions by Gelman and Carlin (2014) is that a study should be not only suitably powered to avoid a false negative (Type II error) but also suitably powered to avoid a magnification of the effect size for those effect sizes that are statistically significant (or pass some other threshold). Gelman and Carlin (2014) go further, stating that such 'retrospective design calculations may be more relevant for statistically significant findings than for nonsignificant findings. The interpretation of a statistically significant result can change drastically depending on the plausible size of the underlying effect'. Note that if a study is suitably powered, there is NO systematic risk inflation, but the effect estimates for underpowered studies that produce statistically significant effects are prone to what might be substantial risk inflation, the interpretation of which depends on realistic estimates of the true (underlying) effect.

Ideally, then, published literature studies should conduct and document power analyses. Short of that, published literature should provide adequate information for the reader to perform such power calculations (or, as Gelman and Carlin (2014) term them: (retrospective) design calculations). In the two examples provided above, the authors did provide sufficient information for the reader to calculate power and the potential for effect size magnification. This is not always the case. Sometimes information used for power calculations are only partially provided in the publications or provided information was structured in a way that does not permit such calculations.<sup>44,45</sup> For example, if authors use number of cases instead of level of exposure to determine tertiles or quartiles (which would be evidenced by a constant number of cases between groups) or if authors group multiple cancer outcomes together and use that number to determine tertiles, then the power (or design) calculations illustrated here are not possible since the required inputs are not able to be derived. Since the counts and data which are tabulated and reported are not necessarily standardised among authors and publications, one strong recommendation would be for publications to require reporting (even if in supplementary or online data) the necessary information to estimate power such that such evaluations can be done by both peer reviewers and interested readers.

<sup>&</sup>lt;sup>44</sup> For example, in the review of the association between malathion exposure vs aggressive prostate cancer presented in the publication 'Risk of Total and Aggressive Prostate Cancer and Pesticide Use in the Agricultural Health Study' by Stella Koutros et al. (2012), the Panel was not able to calculate the power of the comparison between the malathion-exposed groups vs non-exposed group because critical information was not provided in the published article. From the publication and the supplemental document of the publication, we were able to easily find the number of <u>cases</u> in the non-exposed group (Table 2 in the main article), but the number of <u>subjects</u> in the non-exposed group or at each exposed level (i.e., quartile) appeared not to be available. We attempted to derive the number of subjects in the non-exposed group and number of subjects in each quartile from the information in Table 1 of the supplemental document of the article but were not able to do so since the information in Table 1 was presented in a way that was not consistent with many other AHS publications in that the exposed subjects were categorized into groups based on the quartiles of number of cases.

<sup>&</sup>lt;sup>45</sup> Sometimes, information used for power calculations may have only been <u>partially</u> provided in the publications. For example, we calculated the powers associated with various thyroid cancer comparisons from the information provided in the AHS study publication 'Atrazine and Cancer Incidence Among Pesticide Applicators in the Agricultural Health Study (1994–2007)', by Laura Beane-Freeman et al. (2011). In this publication, the authors did not categorize the subjects into quartiles based on exposure but instead categorized or grouped the subjects based on the total number of *all* cancer *cases <u>combined</u>*. In this way, the number of cases of all types of cancer was the same between categorized groups and thus both the number of *cases* of any specific cancer of interest (e.g. thyroid, here) was not the same between groups and the number of *subjects* was not the same between groups. In this example, the publication provided (i) the reference Q1: N = 9,523, (ii) total subjects in Q2, Q3 and Q4: N = 26,834 (Table 1) and (iii) the number of thyroid cancer cases in the reference Q1 = 3 (Table 2). The exact number of subjects in each of the compared groups (Q2, Q3 or Q4) was, however, not available.

While the above analysis suggests that potential implications of the effect size inflation phenomenon are important considerations in evaluating epidemiological studies, it is important to remember a number of caveats regarding the phenomenon and how its consideration should enter into any interpretation of epidemiological studies.

- First, while this phenomenon would tend to inflate effect sizes for underpowered studies for which the effect of interest passes a statistical (or other) threshold, there are other biases that may be present that bias estimates in the other direction, *towards* the null. This bias might be referred to as effect size *suppression*. Perhaps, the most well-known of these is non-differential misclassification bias discussed in the main body of the text. This can commonly (but not always) produce predictable biases towards the null, thereby systematically under-predicting the effect size. Recognising that this is not always true and there are potentially countervailing or counteracting factors like effect size magnification (at least for small underpowered studies) is an important step forward. Specifically, underpowered studies can result in biased estimates in a direction away from the null to a degree that that can potentially offset (and possibly more than offset) any biases towards the null that may result, for example, from non-differential misclassification bias. Regardless, what is of critical importance is to recognise that adequately powered studies are necessary to be able to have at least some minimal degree of confidence in the estimate of the effect size for a statistically significant result.
- Secondly and as stated in the main body of the text effect size magnification is linked to a focused effort on the part of the researcher (or regulators interpreting such a study) on identifying effects that pass a given threshold of significance (e.g. p < 0.05) or achieve a certain size (e.g. OR > 3) when that study is underpowered. This phenomenon, then, is of most concern when a 'pre-screening' for statistical significance (or effect size). To the extent that regulators, decision-makers and others avoid acting by focusing on only those associations that 'pass' some predetermined statistical threshold and then use that effect size to evaluate and judge the magnitude of the effect without acknowledging that it might be inflated if the study is underpowered, the phenomenon is of lesser concern. Note that effect size magnification is not a function or fault of the research or research design, but rather a function of how that research is interpreted by the user community.

Unfortunately, there is sometimes a tendency for attention to focus on effect sizes that are greater than a given size or that pass a certain statistical threshold and are as such 'discovered'. As recommended by Ioannidis with respect to how these 'discoveries' should be considered (Ioannidis, 2008):

'At the time of the first postulated discovery, we usually cannot tell whether an association exists at all, let alone judge its effect size. As a starting principle, one should be cautious about effect sizes. Uncertainty is not conveyed simply by CIs (no matter if these are 95%, 99% or 99.9%).

For a new proposed association, credibility and accuracy of the proposed effect varies depending on the case. One may ask the following questions: does the research community in the field adopt widely statistical significance or similar selection thresholds for claiming research findings? Did the discovery arise from a small study? Is there room for large flexibility in the analyses? Are we unprotected from selective reporting (e.g. was the protocol not fully available upfront?). Are there people or organisations interested in finding and promoting specific "positive" results? Finally, are the counteracting forces that would deflate effects minimal?'

Thirdly, it should be remembered that the effect size inflation phenomenon is a general principle applicable to discovery science in general and is not a specific affliction or malady of epidemiology (Ioannidis, 2005; Lehrer, 2010; Button, 2013; Button et al., 2013; Reinhart, 2015). As indicated earlier, it is often seen in studies in pharmacology, in gene studies, in psychological studies, and in much of the most-often cited medical literature. Such truth inflation occurs in instances where studies are small and underpowered because such studies have widely varying results. It can be particularly problematic in instances where many researchers are performing similar studies and compete to publish 'new' or 'exciting' results (Reinhart, 2015).

#### Summary and Conclusions

Effect size magnification or 'truth inflation' is a phenomenon that can result in exaggerated estimates of odds ratios, relative risks or rate ratios in those instances in which these effect measures

are derived from underpowered studies in which statistical or other thresholds need to be met in order for effects to be 'discovered'. The phenomenon is not specific to epidemiology or epidemiological studies, but rather to any science in which studies tend to be small and predetermined thresholds such as those relating to effect sizes or statistical significance are used to determine whether an effect exists. As such, it is important that users of epidemiological studies recognise this issue and its potential interpretational consequences. Specifically, any discovered associations from an underpowered study that are highlighted or focused upon on the basis of passing a statistical or other similar threshold are systematically biased away from the null. While we cannot know if any specific observed effect size from a specific study is biased away from the null as a result of being a 'discovered' association that passes a statistical threshold (just as we can't say that a specific study showing non-differential misclassification will necessarily be biased towards the null), we do know that that chance favours such a bias to some degree as illustrated by the explications presented and simulations performed here. Said another way: by choosing to focus on, report, or act upon effect sizes on the basis of those effect sizes passing a statistical or other threshold, a bias is introduced since it is inevitably more likely to select those associations that are helped by chance rather than hurt by it (Yarkoni, 2009). Again, this is an issue related to how studies are interpreted by users, not one that is intrinsic to the study design nor one that is related to good scientific principles or practices.

One (partial) solution to the above issue is for the reader to cautiously interpret effect sizes in epidemiological studies that pass a prestated threshold or are statistically significant if they arise from an underpowered study, recognising that the observed effect sizes can be systematically biased away from the null. Such an approach would require that either the authors report the power of the study or that the authors provide sufficient information for the reader to do so. Effects sizes from studies with powers substantially less than 80% should be interpreted with an appropriate degree of scepticism, recognising that these may be inflated – perhaps substantially so (particularly if the power is less than 50%). The potential degree of this inflation will depend on a number of issues including background rate of the health outcome of interest, the sample size of the study and the effect size of interest. More specifically, when (a) the smaller the background rate of the health outcome of interest is low, (b) the sample size of the study is small and (c) the effect size of interest is weak, then the power of the study (to detect that effect size) will be low and the tendency towards inflated effect sizes in statistically significant results will be high. Low power studies investigating small or weak effects in populations that have a low background rate of the health outcome of interest will tend towards the greatest degree of effect size inflation. As a result, the PPR Panel recommends that epidemiological publications either incorporate such calculations or include key information such that those calculations can be performed by the reader. Specifically:

When the association between a given pesticide exposure and a disease is found to be statistically significant, particularly in (presumed) low powered studies, data user should perform various power calculations (or a power analysis) to determine the degree to which the statistically significant effect size estimate (OR or RR) may be artificially inflated or magnified. This requires three values to be clearly reported by epidemiological studies: (i) the number of subjects in the non-exposed group (including diseased and non-diseased individuals); (ii) the number of subjects in the exposed group (including diseased and non-diseased individuals); and (iii) the number of diseased subjects in the non-exposed group. Risk managers can then select the target value of interest (typically an OR or RR) to detect a difference of a given (predetermined) effect size between the exposed and non-exposed subjects, and evaluate the degree to which effect size magnification could potentially explain the effect size that was estimated in the study of interest.

Since it appears that (i) many epidemiological studies are frequently underpowered; (ii) it is not common for authors to provide either power calculations or (sometimes) the information in publications required to do them, and (iii) the phenomenon of effect size magnification generally appears to be little recognised in the epidemiological field, the above PPR Panel recommendation will require effort on the part of researchers/grantees, publishers, and study sponsors to implement. While the above suggests that the current state of practice in this area may leave one pessimistic, an opinion piece on this topic by researcher Kate Button (Button, 2013) describing her work in Nature Reviews Neuroscience (Button et al., 2013) offered guarded reasons for optimism:

'Awareness of these issues is growing and acknowledging the problem is the first step to improving current practices and identifying solutions. Although issues of publication bias are difficult to solve overnight, researchers can improve the reliability of their research by adopting well-established (but

often ignored) scientific principles: Also, researchers can improve the usefulness/reliability of their research by adopting well-established (but often ignored) scientific principles:

- 1) Consider statistical power in the design of our studies, and in the interpretation of our results;
- 2) Increase the honesty with which we disclose our methods and results.
- 3) Make our study protocols, and analysis plans, and even our data, publically available; and
- 4) Work collaboratively to pool resources and increase our sample sizes and power to replicate findings.'

Although the above set of recommendations and thoughts were set in the context of sample size and neurotoxicology, they have broad applicability to any discovery science, including epidemiology. In sum, while there is much room for improvement in the conduct and reporting of epidemiological studies for them to be useful to regulatory bodies in making public health-based choices, the issues are beginning to be better defined and recognised and – going forward – there is reason for optimism.

#### 抄録

2013年にEFSAは、2006年から2012年までに発表された疫学研究の包括的なシステマティックレビューを発表 し、農薬ばく露と多くの健康影響との関連性を調査した。かなりの量の疫学的情報が得られたにもかかわらず、これらの エビデンスの多くはかなり質が低く、多くの制限が結果に影響している可能性が高いため、確固たる結論を出すことは できなかった。このように、規則(EU)No 1107/2009 に記載されている「認可基準」を満たしていない研究は、リスク評 価には適していない。この科学的意見書では、植物保護製剤(農薬)とその残留物に関するEFSAパネル(PPRパネ ル)は、農薬疫学研究の方法論的限界を評価するよう求められており、その主な限界はばく露の特徴付けが不十分で あることが原因であることが判明した。また、前向き研究ではなく症例対照研究を頻繁に使用していることも限界と考え られた。健康影響の不適切な定義や不正確さは避ける必要があり、結果の報告はいくつかのケースで改善される可能 性がある。PPRパネルは、これらの限界を克服し、リスク評価への適切な利用を促進するために、農薬疫学研究の質と 信頼性を向上させる方法についての勧告を提案した。パネルは、農薬の潜在的な有害性、ばく露シナリオ、ばく露評 価の方法、ばく露一反応特性、リスク特性を理解するための有用な方法として、農薬観察研究のシステマティックレビュ ーとメタアナリシスの実施(必要に応じて)を推奨した。最後に、PPRパネルは、農薬のリスク評価のために疫学的デー タを含む複数のエビデンスを統合し、重み付けする方法論的アプローチを提案した。生物学的妥当性は因果関係の 立証に寄与することができる。

#### 概要

欧州食品安全機関(EFSA)は、植物保護製剤(農薬)とその残留物に関するパネル(PPR パネル)に、外部科学報 告書「農薬へのばく露と健康影響を関連付ける疫学研究の文献レビュー」(Ntzani ら、2013 年)の結果のフォローアッ プ(追跡調査)に関する科学的意見書の作成を依頼した。この報告書は、2006 年から 2012 年の間に発表された疫学 研究のシステマティックレビューとメタアナリシスに基づいており、農薬ばく露と 23 の主要なカテゴリーのヒト健康影響と の間に見出された関連性をまとめたものである。最も関連性が高いのは、肝臓がん、乳がん、胃がん、筋萎縮性側索硬 化症、喘息、II型糖尿病、小児白血病、パーキンソン病であった。評価された疫学研究に内在する弱点があるため、因 果関係についての結論を導き出すことはできないが、システマティックレビューでは、特定の複雑なヒトの健康に関する 影響について情報を提供するための規制研究の適合性についての懸念が提起された。

PPR パネルは、農薬に関する疫学研究の質に影響を与える方法論的限界に対処するために、科学的意見書を作成した。この意見書は、規制(EC)1107/2009 の下での農薬の更新時のピアレビュープロセスを支援することのみを目的としており、あらゆる種類のヒトばく露による臨床例や中毒事故(入手可能であれば)を加えた疫学的研究の評価データが必要である。欧州における農薬へのばく露に関する疫学的データは、有効成分の最初の認可前には入手できないため、評価報告書草案(DAR)に提供することは期待できない。しかし、他の管轄区域では有効成分の使用について先行して認可されている可能性があり、その地域の疫学的データが適切だと考えられる。規則(EC)No 1107/2009 では、既存の疫学研究を含む学術的に査読された公表文献を検索することを要求している。このタイプのデータは、「更新のために提出された書類には、有効成分に関連する新しいデータと新しいリスク評価を含めるべきである」という規則(EC)1141/2010にも準拠しており、有効成分の更新プロセスに適している。

本意見書では、疫学データをリスク評価に適切に活用するための農薬有効成分に特化した方法論的アプローチを 提案し、農薬の疫学研究の質と信頼性を向上させるための提言を行った。さらに、PPR パネルは、農薬のリスク評価プ ロセスを改善するために、疫学的と実験毒性学のデータを統合するための方法論を議論し、提案した。

まず、本意見書では、観察による疫学研究1の基本的な要素を紹介し、因果関係を推論するための条件が通常満た されていることから、疫学研究において最も信頼性の高いエビデンスを提供すると考えられている介入研究との対比を 行っている。主な観察による研究の計画については、農薬ばく露の詳細な記述の重要性、有効な健康影響の使用及 びばく露と健康影響の関係をモデル化するための適切な統計解析の重要性が説明されている。また、外部及び内部 研究の妥当性については、結果における偶然の役割を説明し、ばく露以外の要因が発見された関連性を歪めないか どうかを確認するために取り上げられてもいる。いくつかの種類のヒトのデータは、農薬のリスク評価プロセス、特にハザ ードの特定をサポートするのに貢献することができる。正式な疫学研究以外にも、症例集積、疾病登録、毒物管理セン ター情報、労働衛生監視データ、市販後の監視プログラムなどのヒトのデータの他の情報源は、特に急性の特定の健 康影響の場合には、ハザードの特定に有用な情報を提供することができる。

しかし、農薬ばく露と健康影響に関する既存の疫学研究の多くは、さまざまな方法論の限界や不完全性に悩まされ ている(Terms of Reference(ToR)1)。パネルは、ヒトの観察環境における農薬ばく露と健康影響との関連を研究する ことは複雑で、疫学の他の多くの分野よりも困難であると指摘している。この複雑さは、市場に出回っている有効成分の 数の多さ(欧州連合 EU で使用が認可されているものは約 480 種類)、ばく露の測定の難しさ、個々の農薬へのばく露 に関する定量的及び定性的データが頻繁に欠如していることなど、農薬疫学の分野におけるいくつかの特殊な特徴に 起因する。EFSA の外部科学報告書(Ntzani ら、2013 年)で実施された疫学的証拠の系統的評価では、多くの方法 論的限界が指摘されている。特定の農薬に対する直接かつ詳細なばく露評価が行われていない(例えば、ジェネリック 農薬の使用に対して情報不足)ため、主にばく露の特徴付けが不十分であることが、ほとんどの既存の研究の主な限 界となっている。前向き研究ではなくて症例対照研究を頻繁に使用していることも限界となっている。健康影響の不十 分な定義、統計解析がないこと、研究結果の質の低い報告が、いくつかの農薬疫学研究の他の限界として確認されて いる。これらの限界は、因果関係に関する強固な結論を導き出すことを困難にするデータの不均一性や矛盾の原因と

<sup>&</sup>lt;sup>1</sup>本意見書は、観察研究(疫学研究ともいう)と警戒データのみを扱う。これに対し、介入研究(無作為化臨床試験などの実験研究とも呼ばれる)は本意見書の対象外である。

なっている。Ntzaniら、(2013年)が取り上げたほとんどの健康影響の効果量が小さいことを考えると、研究デザインにおけるバイアスの寄与が一役買っている可能性がある。

PPR パネルはまた、リスク評価に有益な将来の農薬疫学研究を改善するための多くの再修正(ToR 2)と勧告(ToR 3)も提供している。疫学研究の質と妥当性は、以下によって高められる。(a)ばく露の適切な評価、好ましくは個人のば く露モニタリングや特定の農薬(または農薬の組み合わせ)のバイオマーカー濃度を個人レベルで使用し、ばく露の誤 分類を最小化し、用量反応評価を可能にする方法で報告すること、(b)十分に有効で信頼性の高い健康影響(アウトカ ム)の評価(十分に定義された臨床データまたは有効な代替物)、(c)交絡変数(健康影響(アウトカム)に影響を与える 他の既知のばく露を含む)を適切に考慮すること、(d)サブグループ解析(例:性別、年齢などによる層別解析)を実施 し、報告すること、環境疫学の研究のために特別に開発された多くの報告ガイドラインとチェックリストは、農薬ばく露を 評価する疫学研究にとっても有用なものである。これは、修正された STROBE(STrengthening the Reporting of OBservational studies in Epidemiology)基準の拡張版が特に該当し、観察による研究の正確で完全な報告書に 何を含めるべきかについての推奨事項が含まれている。

ばく露評価は、個人レベル(バイオモニタリングのような他の直接的な手段で補足することができる信頼性の高い線 量計を目的とする農薬に使用することにより、特定の農薬に対する直接かつ詳細なばく露評価を行う)で改善すること ができる。さらに、登録されたデータを電子カルテにリンクさせることにより集団レベルでのばく露を評価することができ る。これにより、これまでにないサンプルサイズの研究が可能となり、ばく露とその後の疾患に関する情報を得ることがで きるようになる。地理情報システム(GIS)や小規模地域調査も、住居ばく露の推定値を提供するための追加的な方法と して役立つかもしれない。これらのより一般的なばく露評価は、一般的なリスク因子を特定する可能性があり、規制政策 全体への情報提供と、さらなる疫学研究の対象を特定することの両方で重要になる可能性がある。オミクス技術の開発 はまた、生物学的マトリックス中の外来物質や代謝物(メタボロミクス)からDNAやタンパク質との複合体(アダクトミクス) まで、幅広い分子の測定を通じてばく露評価を改善するための興味深い可能性を提示している。オミクスは、複雑な化 学物質の混合物への累積ばく露に対する生物学的反応の特性やシグネチャーを測定する可能性があり、生物学的経 路の理解を深めることができる。つまり、ばく露レベルに関連して、健康障害に関連する生化学的、生理学的、またはそ の他の変化を定量化できるバイオマーカーを使用することで、健康影響を再発見することができ、また、病気の発生の メカニズムを理解するのに役立つ。

規制リスク評価(ToR 4)に疫学的研究を組み込むことは、科学者、リスク評価者、リスク管理者にとって大きな課題で ある。様々な疫学研究の知見は、潜在的な健康被害と有害な健康影響との関連性を評価するために使用することがで き、その結果、リスク評価のプロセスに貢献することができる。農薬ばく露とヒト健康影響との関連性に関する利用可能 なデータが大量にあるが、それにもかかわらず、規制上のリスク評価へのこのような研究の影響はまだ限られている。ヒ トのデータはリスク評価の多くの段階で利用できるが、同じ農薬有効成分に関する他の研究がない場合には、単一の (反複されていない)疫学研究は、質が高く、規則(EU)No 1107/2009 に記載されている「認可基準」を満たしていな い限り、ハザードの特性評価に利用すべきではない。これらの「認可基準」は同規則には詳述されていないため、農薬 の規制評価を支援するための疫学的研究の最適な計画と報告のために、多くの勧告が考慮されるべきである。さらなる 特定のガイダンスが有用であるが、これは本意見書の ToR の範囲を超えている。システマティックレビューやメタアナリ シス(必要に応じて)などのエビデンス統合技術が有用なアプローチを提供する。これらのツールは、選択基準を満た すすべての個々の研究の結果を組み合わせることで、要約データを生成し、統計検出力を高め、リスク推定の精度を 向上させることができるが、個々の研究の方法論的な欠陥やバイアスを克服することはできない。観察による研究のシ ステマティックレビューやメタアナリシスは、これらのツールが農薬の潜在的なハザード、ばく露シナリオ、ばく露評価の 方法、ばく露-反応特性、リスク特性に関する理解を強化する情報を提供するため、リスク評価に大きな影響を与える 能力を持っている。システマティックレビューもまた、毒性学的な課題に答えるための潜在的なツールと考えられている が、その方法論は、異なるエビデンスの系統に合わせて対応させる必要がある。

研究の評価はベストエビデンス統合の枠組みの中で行われるべきであり、それによって各特定の研究が持つ可能性のあるバイアスの特性と疫学的データベースの全体的な整合性の評価が示される。本意見書は、単一の疫学研究で

4

評価すべき研究の質のパラメータと、各パラメータの関連する程度(低、中、高)を報告している。ヒトのデータをバイア スのリスクと品質に関して整理するための第一段階として、3つの基本的なカテゴリーが提案されている。(a)バイアスの リスクが低く、信頼性が高い/中程度、(b)バイアスのリスクが中程度で、信頼性が中程度、(c)バイアスのリスクが高く、 信頼性が低いのは、結果の妥当性を低下させたり、潜在的な因果関係をほとんど解釈できないような重大な方法論的 限界や欠陥があるためである。これらのカテゴリーは、EFSAの有効成分のピアレビューに基づく各エビデンスの信頼 性と妥当性の評価(受容可能、補足的、許容できない)と並行して行うことを意図している。規則(EU) No 1107/2009 ヒ トの健康リスクを適切に記載されている「認可基準」を満たすために、明確なデータ品質基準を満たさない疫学研究の 結果に基づいてリスク評価を行うべきではない。

疫学研究は補完的なデータを提供するものであり、農薬リスク評価のために in vivo の実験動物試験、in vitro のメ カニズムモデル及び in silico 技術から得られるデータと統合することができる(ToR 4)。これらすべてのエビデンスを 組み合わせることで、判断の改善を目的としたヒトの健康リスクの特性評価におけるエビデンスの重み付け(WOE, Weight-of-Evidence)解析に貢献することができる。異なるデータセットは補完的であり、結論を出すことができ、その 結果、1 つのエビデンス系統の別のエビデンス系統との整合性を強化するのに役立つが、それらは個別には不十分で あり、ヒトの健康リスクを適切に特性評価するにあたっての課題となる可能性がある。したがって特にばく露されたヒト集 団で臨床的に発現するまでに数十年かかる可能性がある農薬の慢性的な健康影響については、4 つのエビデンス(疫 学、動物実験、in vitro、in silico)は強力な組み合わせとなる。

最初に検討すべき事項は、対象となる健康影響が、農薬に関する既存の毒性学的・疫学的研究でどれだけカバー されているかということである。既知の健康影響/エンドポイントについて両方のタイプの研究が利用可能な場合、リス ク評価に使用する前に、両方の研究の長所と短所を評価すべきである。利用可能なとトのエビデンス(観察疫学及び監 視データ)、実験的エビデンス(動物及び in vitro のデータ)、非試験データ(in silico 研究)の信頼性が評価されたら、 次のステップでは、これらのデータソースに重み付けを行う必要がある。この意見書では、リスク評価をより適切にサポ ートするために、すべてのエビデンスを全体的な WOE フレームワークの中で考慮する統合的なアプローチを提案して いる。このフレームワークは、ある系統が他の系統よりも優先されるべき時を強調するいくつかの原則に基づいている。 どのデータセットを優先すべきかを決定するために、ヒトのデータと実験データの一致や不一致を評価すべきである。 エビデンスの全体性を評価すべきであるが、データがヒトと実験のどちらから来たものであるかに関わらず、より信頼性 の高いデータがより重要視されるべきである。より困難な状況は、研究結果が一致しない場合である。このような場合に は、相違の理由を検討し、矛盾の生物学的根拠の理解をより深く理解する努力をすべきである。

農薬に関するとトのデータは、標的臓器、用量反応関係、毒性影響の可逆性に関する完全な毒性学的データベースからの外挿に基づいて行われた推定値の妥当性を検証するのに役立ち、基準値の定義に直接的な影響を与えることなく、外挿の過程を再確認するのに役立つ。このように、農薬疫学的データは、根本的な因果関係の可能性を高めるための組織的なツールとして、改訂 Bradford Hill 基準を使用して、利用可能なデータの全体である WOE の一部を形成することができる。

#### 1. 序章

#### 1.1. 農薬リスク評価におけるとトの健康に関する規制データ要求

先進国の規制当局は、指定された試験プロトコールに基づいて実施される義務づけられた毒性学的研究と、ヒトへのばく露の可能性の推定値に基づいて、登録された各農薬について正式なヒトのリスク評価を行っている。

欧州連合(EU)では、植物保護剤(農薬)(PPP)の上市手続きは、欧州委員会規則第 1107/2009 号<sup>2</sup>で規定されて いる。欧州委員会規則第 283/2013 号<sup>3</sup>及び第 284/2013 号<sup>4</sup>では、有効成分及びその製剤の評価及び再評価のため のデータ要求が定められている。

有効成分の哺乳類毒性に関するデータ要求は、化学有効成分については欧州委員会規則(EU)No 283/2013 の Part A に、ウイルスを含む微生物については Part B に記載されている。農薬有効成分の要求事項に関しては、ヒトの データ使用に関する言及は、異なるエンドポイントに関連する第5章の異なる章で見られる。例えば、ヒト由来物質(ミク ロソームまたは無処置の細胞システム)を対象とした in vitro 代謝試験を含む毒物動態及び代謝に関するデータは、 哺乳類における吸収、分布、代謝及び排泄に関する研究を扱う第5.1章に属し、ヒト由来物質を対象とした in vitro 遺 伝毒性試験は、遺伝毒性試験に関する第5.4章に、ヒトのボランティアにおけるアセチルコリンエステラーゼ阻害などの 特殊な研究は、神経毒性試験に関する第5.7章に記載されている。5.8章では、有効成分に関する補足的な試験や、 薬理学的、免疫学的な試験などのいくつかの特殊な試験について言及している。

農薬の評価プロセスは主に実験研究に基づいているが、ヒトのデータはそのプロセスに関連する情報を追加すること ができる。ヒトのデータに関する要求は、主に規則(EU) No 283/2013 の第 5.9 章「医療データ」にある。これには、偶 発的な職業上のばく露や自傷/自殺の後の医学的報告書や、製造工場の従業員の監視などのモニタリング調査が含 まれる。情報は、国の毒物管理センターからの報告書や、公表文献に掲載されている疫学的研究によって生成され、 報告される。同規則は、ヒトへのばく露の影響に関する「意味のある」情報が入手可能な場合には、ばく露に関する外 挿法の妥当性や、標的臓器、用量反応関係、毒性影響の可逆性に関する結論を導き出すために使用することを要求 している。

規則(EU) No 1107/2009も同様に、「入手可能で、ばく露レベルとばく露期間に関するデータが裏付けされており、 公認の基準に従って実施されている場合、疫学的研究は特に価値があり、提出しなければならない」としている。しかし、 承認または更新プロセス中の有効成分に特化した疫学的研究を実施する義務が申請者にはないことは明らかである。 むしろ、規則(EC) No 1107/2009 によると、有効成分の承認のための書類(ドシエ)を提出する申請者は、「科学的な ピアレビューを受けた公的に利用可能な文献[......]」を提出しなければならない。これは、健康への副作用を扱った有 効成分及びその関連代謝物に関するものであり、書類(ドシエ)提出日前の過去 10 年以内に発表されたものでなけれ ばならない[......]。

特に、農薬に関する疫学的研究は、「規則(EC) No 1107/2009 の下での農薬有効成分の承認のための科学的根拠に基づいた公表文献の提出」(EFSA、2011 年 a)と題する EFSA ガイダンス「政策決定を支援するための食品・飼料安全性評価へのシステマティックレビュー方法論の適用」(EFSA、2010 年 a)の原則に沿って、文献から検索する必要がある。EFSA ガイダンスに示されているように、「有効成分、その代謝物、または植物保護製剤(農薬)のための科学的に査読された公表文献を特定し、選択するプロセス」は、アプローチが体系的な文献レビューに基づいている。

ヨーロッパにおける申請者による疫学研究やより一般的なヒトデータの提出は、特にこれまでに、不完全であったり、 現行の EFSA ガイダンス(EFSA、2011 年 a)に準拠していなかったりすることがあった。これは、特定の EFSA ガイダ ンスに従って(疫学的)文献検索を行うことを義務付けることが比較的最近になって導入(例えば AIR-3 物質に対し)さ

<sup>&</sup>lt;sup>2</sup> 植物保護製剤(農薬)の上市と理事会指令 79/117/EEC 及び 91/414/EEC の廃止に関する 2009 年 10 月 21 日の欧州議会及び理事会の規則(EC)No 1107/2009。OJL 309, 24.11.2009, p. 1-50.

<sup>&</sup>lt;sup>3</sup> 活性物質のデータ要求を定めた 2013 年 3 月 1 日の欧州委員会規則(EU) No 283/2013。 植物保護製剤(農薬)の上市に関する欧州議会の規則(EC) No 1107/2009 に基づく。OJ L 93, 3.4.2013, p. 1-84.

 <sup>&</sup>lt;sup>4</sup> 植物保護製剤(農薬)のデータ要求を定めた 2013 年 3 月 1 日の欧州委員会規則(EU) No 284/2013。
 植物保護製剤(農薬)の上市に関する欧州議会及び理事会の規則(EC) No 1107/2009 に基づく。OJ L 93, 3.4.2013, p. 85-152

れたことによるものであろう(規則 AIR-3: Reg. (EU) No 844/2012;ガイダンス文書 SANCO/2012/11251-rev.4)。

EU における農薬のピアレビュープロセスにおける疫学的データと毒性学的結果の統合評価は奨励されるべきであ るが、まだ不足している。最近の大きな議論となった例としては、グリホサートの評価に関連したものがあり、リスク評価 に疫学的研究を含めるために多大な努力がなされたが、結論としては、これらの研究はグリホサートと健康影響との間 の関連性を示す非常に限定的なエビデンスを提供したに過ぎず、十分なエビデンスは得られなかった。

2,4-D のピアレビューの場合、疫学的データのほとんどはリスク評価には使用されなかった。結論として、欧州の規制 システムの中では、疫学的データが農薬有効成分の承認に影響を与えた例はない。

疫学研究を含む文献検索が義務化され、ガイダンスが整備された現在(EFSA、2011 年 a)、より一貫したアプロー チにより、リスク評価が容易になると考えられる。しかし、規制プロセスにおいて、このような疫学的情報をどのように評価 するかについての枠組みは確立されていない。特に、これらの研究の評価に用いられる古典的な基準は、現在の規制 の枠組みには含まれていない(例:研究デザイン、オッズ比と相対リスクの使用、潜在的な交絡因子、多重比較、因果 関係の評価)。評価報告書草案(DAR)や更新評価報告書(RAR)の作成とピアレビューの過程で、疫学的知見を適 切に使用するための特定の基準や指針が必要である。EFSA ステークホルダーワークショップ(EFSA、2015 年 a)で は、ばく露に関する正確な情報を提供する上で、より強固で方法論的に健全な研究が利用可能になれば、EU におけ る農薬規制の向上が図れると予想している。

もう一つの潜在的な課題は、有効成分の更新プロセスと疫学研究の成果との同期化である。実際、疫学研究の計画、 実施、解析には多くの場合、特にデータの解釈が複雑な場合には相当な時間を必要とする。

#### 1.2. 依頼者から提供された背景と委託条件

2013 年、欧州食品安全機関(EFSA)は、イオアニナ大学医学部が実施した外部科学報告書「農薬へのばく露と健 康影響に関連する疫学的研究に関する文献レビュー」を発表した(Ntzani ら、2013 年)。この報告書は、2006 年から 2012 年の間に発表された疫学研究のシステマティックレビューに基づき、農薬ばく露と調査したあらゆる健康影響(ヒト の健康影響の 23 の主要カテゴリー)との関連性をまとめたものである。特に、農薬ばく露と以下の健康影響(肝臓がん、 乳がん、胃がん、筋萎縮性側索硬化症、喘息、II 型糖尿病、小児白血病、パーキンソン病)との間の統計学的に有意 な関連性が、固定効果及びランダム効果のメタアナリシスによって観察された。

膨大な数の研究論文と解析(6,000 件以上)が利用可能であるにもかかわらず、報告書の著者は、大部分の健康影響については何ら確かな結論を見出すことができなかった。この観察結果は、農薬の使用ととト健康への悪影響の発生との関連性を評価したこれまでの研究と一致しており、そのような疫学研究は多くの限界とデータの大きな不均一性が問題となっていることを認めている。著者らは特に、疫学研究における農薬の広範な定義がメタアナリシスの結果の価値を制限していることを指摘している。また、本報告書の範囲では、農薬ばく露と特定の健康影響との間の詳細な関連付けを行うことができなかった。しかし、報告書では、農薬ばく露との関連性の可能性について、より詳細な結論を出すためにさらなる研究が必要とされる多くの健康影響を強調している。

とはいえ、外部科学報告書の結果は、ヨーロッパで発表された他の同様の研究<sup>5.6</sup>と一致しており、農薬ばく露とヒト 健康影響との関連性について、多くの疑問や懸念を投げかけている。さらに、本報告書の結果は、疫学研究の結果を どのように農薬リスク評価に統合するかについての議論の道を開くものである。このことは、EU 規則 No 283/2013 に 従って疫学的結果を評価する必要がある植物保護製剤(農薬)の承認評価を扱う EFSA のピアレビューチームにとっ て特に重要である。同規則では、申請者は、利用可能な場合には「意味のある」疫学的研究を提出しなければならない とされている。

この科学的意見書では、PPR パネルは、外部科学報告書(Ntzani ら、2013 年)で観察された農薬ばく露とヒト健康

<sup>5</sup> フランス。INSERM レポート 2013。 農薬 – 人に及ぼす影響

<sup>6</sup> 英国。COTレポート2011年。農薬への准職業上ばく露とがん以外の健康影響に関する疫学的文献のシステマティックレビューに関する声明及び COT 報告書 2006。農薬散布と住民や居合わせただけの者 (bystanders)の健康に関する環境汚染に関する王立委員会報告書に関する共同声明。

影響との関連性と、これらの結果が規制上の農薬リスク評価の背景でどのように解釈されるかを議論する。したがって、 PPR パネルは、報告書で収集された疫学研究を体系的に評価し、研究の主要なデータギャップと限界に対処し、関連 する勧告を提言する。

PPR パネルは特に以下を行う。

- 1)利用可能な疫学研究の質と妥当性に関して外部科学報告書で明らかにされたものに基づいて(必ずしもこれに 限定されないが)、ギャップと限界のすべての情報源を収集し、レビューする。
- 2)上記 1)項で特定されたギャップと限界に基づき、調査結果の質、妥当性、信頼性を向上させ、それが農薬リス ク評価にどのように影響を与えるかについて、将来の疫学調査のための潜在的な改善点を提案する。これには、 研究デザイン、ばく露評価、データの質と評価、健康影響の診断分類、統計解析が含まれる。
- 3) 情報及び/または基準が不十分または不足している分野を特定し、リスク評価への適用を改善し最適化するために、農薬疫学的研究をどのように実施するかについての提言を行う。これらの推奨事項には、第1)項で明らかになったギャップと限界に基づいて、ばく露評価(バイオモニタリングデータの利用を含む)、脆弱な集団のサブグループ及び/または対象となる健康影響(生化学的、機能的、形態学的、臨床的レベルでの)の調和を含む。
- 4)評価報告書草案のピアレビューの過程で、疫学的知見を実験毒性学、有害転帰経路(AOP)、作用機序などのデータと統合するとともに、WOEなど、農薬のリスク評価に疫学的知見を適切に利用する方法を議論する。

PRAS ユニットは、リスク評価における疫学的研究の統合を含む EFSA の包括的な科学的分野7への合意に基づく アプローチについて、科学技術委員会に諮る。

#### 1.3. 委託条件の解釈

EFSA は、検討事項(ToR)の中で、2006 年から 2012 年の間に発表された農薬へのばく露ととトの健康影響を関連 付ける疫学的研究のシステマティックレビューの結果のフォローアップについて、PPR パネルに科学的意見書を作成 するよう要請している(Ntzani ら、2013 年)。EU 規則 No 283/2013 によると、疫学的データを農薬リスク評価に統合 することは、EU 承認のための有効成分の DAR と RAR 及び植物保護製剤(農薬)としての使用を目的とした有効成 分のピアレビュープロセスにとって重要であるとされている。

PPRパネルは、委託条件の解釈において、農薬の疫学的研究で明らかになった方法論的限界に対処し、規制上の 農薬リスク評価、特に承認後の物質のリスク評価への利用を容易にするためにどのように改善するかについて、そのよ うな研究のスポンサーに勧告を行うための科学的意見書を作成することになっている。PPRパネルは、実験的な毒性 試験にもその方法論と報告の質に関連した限界があることに留意しているが、これらの限界の評価は本意見書のToR の範囲を超えている。

この科学的意見書は、規制 1107/2009 に基づく農薬の更新時のピアレビュープロセスを支援することを目的として おり、疫学的研究の評価に加えて、なんらかのヒトばく露後の臨床症例や中毒事例(入手可能な場合)がデータ要求と なっている。欧州における農薬へのばく露に関する疫学的データは、有効成分の最初の承認前には入手できない(製 造過程で発生した事故を除いて、その可能性は非常に低いと予想される)ため、DAR に貢献することは期待できない だろう。しかし、他の管轄で有効成分の使用について先行承認を受けている可能性があり、その分野の疫学的データ が有用であると考えられる。EC 規則: (EC) No 1107/2009 では、既存の疫学的研究を検索することが期待される学術 的に査読された公表文献を検索することを要求している。したがって、疫学的研究が有効成分の更新プロセスにおい てより適していることが認識されており、「更新のために提出された書類には、有効成分が指令 91/414/EEC の付録 I に最初に含まれた時から、データ要求の変更や科学的・技術的知識の変化を再確認するために、有効成分に関連す る新しいデータと新しいリスク評価を含めるべきである」という EC 規則 1141/2010 の規定にも準拠している。

PPR パネルは具体的に以下のトピックに取り組む。

<sup>7</sup> 規則(EC)No 178/2002の第28条による。

- 1) 疫学研究の質に影響を与える固有の弱点(利用可能な農薬疫学研究のギャップと限界を含む)と、規制上の農 薬リスク評価との関連性を検討する。これらの弱点にはどのように対処できるか?
- 2)実験動物を用いた古典的な毒性学的研究を補完する疫学的研究は、農薬リスク評価の分野でどのような貢献 が期待できるか?
- 3) 農薬有効成分に特化した方法論的アプローチとして、疫学的研究をどのように適切に活用するかについて、指摘されたギャップや限界をどのように改善するかを中心に議論し、提案する。
- 4)リスク評価の目的で利用可能な疫学的証拠をより良く利用するための実践への再提案と推奨を提案する。疫学的情報と実験毒性学のデータを統合するための方法論を議論し、提案する。

本意見書、特にセクション 2-4 は、科学としての疫学の基礎を論じることを意図したものではない。疫学の科学的側面を深めたいと考えている読者には、疫学の一般的な教科書(例:Rothman ら、2008 年)を読むことを勧める。

本意見書は、EU 規制の背景における農薬疫学研究にのみ焦点を当てており、一般的な科学的観点からではない ことを考慮に入れるべきである。したがって、実験的な毒性試験の実際の限界と弱点については、ここでは触れていな い。

#### 1.4. 追加情報

上記のトピック 1-4(第 1.3 節)に完全に対応するために、疫学的研究の多くの関連するレビュー及び疫学の知識を 持つ他の国内外の機関の経験に注意を払い、疫学を農薬のリスク評価に特に適用した。付録 A ではこれらの研究に 詳細な注意を払い、この分野の理解に建設的に貢献してきた著者の経験に基づいている。また、付録 A では、いくつ かの公表された研究がどれほど役に立たないかを示すために、厳密さに欠けていると批判された公表情報を記録して いる。このような優れた(そしてあまり良くない)実践から得られた教訓は、附属書 A を相互に参照することで本文に組 み込まれている。このようにして、この科学的意見書(Scientific Opinion)は、それにもかかわらずアクセス可能なすべ ての裏付けとなるデータで読者を圧倒することなく、本文の議論を明確に抽出し、効果的に伝えることを目的としている。

さらに、付属書 B には、疫学研究におけるばく露評価のためのツールとしての労働安全衛生戦略におけるヒト生物 学的モニタリング(HBM)の役割をさらに調査し、農薬への職業上ばく露による潜在的な健康リスクの評価に貢献する ために、2015年に EFSA が委託したプロジェクトの主な成果の要約が含まれている(Bevan ら、2017年)。

### 2. 農薬に関する疫学研究の一般的枠組み

ここでは、農薬に関する疫学研究の基本的な要素を紹介し、他のタイプの研究との対比を行う。詳細については、疫 学の一般的な教科書を勧める(Rothman ら、2009 年)。

#### 2.1. 研究デザイン

疫学は、いつ、どこで、どのようにして疾患が発生したかを確認するために、ヒトまたは他の標的種の集団における健 康影響の分布と決定要因を研究する。これは観察による研究や介入研究(すなわち臨床試験)®によって行うことができ、 潜在的なリスク因子へのばく露が異なる研究グループを比較する。どちらのタイプの研究も、実験室よりも管理の行き届 いていない自然環境で実施される。

<sup>&</sup>lt;sup>8</sup> この見解では、「ヒトデータ」には、疫学研究とも呼ばれる観察研究が含まれ、研究者は研究参加者に影響を与えることなく、因子と健康影響との 間の自然な関係を観察している。警戒データもまた、この概念に該当する。これに対して、介入研究(実験研究ともいう)は本意見の対象外であ り、研究者が研究デザインの一部として介入することが大きな特徴である。

自然環境で発生した疾病の事例に関する情報は、ばく露者のみを対象とした症例報告や症例シリーズという形で体系的に記録することも可能である。症例報告や症例シリーズは、ばく露の違いによって研究グループを比較するものではないが、有用な情報、特に高濃度ばく露後の急性影響に関する情報を提供することができ、ハザードの特定に役立つ可能性がある。

無作為化臨床試験では、対象となるばく露が被験者に無作為に割り付けられ、可能な限り被験者は治療法を盲検 化し、それによって特定の治療法へのばく露に関する知識に起因する潜在的なバイアスを排除する。これが介入研究 と呼ばれる理由である。観察による疫学研究は臨床介入研究とは異なり、対象となるばく露が登録された被験者にラン ダムに割り付けられておらず、参加者はばく露について盲検化されていないことが多い。これが観察的研究と呼ばれる 理由である。その結果、無作為化臨床試験は平均的な治療効果のバイアスのない推定値を提供するため、計画の点 で上位にランクされている。

観察による研究におけるばく露の無作為割り付けがないことは、疾患の発生に関連する他のリスク因子がばく露者と 非ばく露者の間で不均等に分布している可能性があるため、重要な課題となる。これは、既知の交絡因子を測定して 説明する必要があることを意味する。しかし、未知の交絡因子は対処できないが、未知の交絡因子または測定されてい ない交絡因子が考慮されずに放置されている可能性が常にある。さらに、観察による研究で研究参加者が現在または 過去のばく露を知らないことが多い、またはこれらを正確に記憶していないことがある(例えば、副流煙、食事摂取量、 または職業上のハザード)という事実は、自己報告に基づいている場合、ばく露の推定値に偏りが生じる可能性がある。 例えば、がん症例と対照者が過去に農薬にばく露されたことがあるかどうかを尋ねられたとき、過去のばく露が両群間 で差がなかった場合でも、がん症例は対照者とは異なるばく露を報告する可能性は低くない。

伝統的に、観察による疫学研究計画は、生態学的研究、横断研究、症例対照研究、コホート研究のいずれかに分類される。このアプローチは、ばく露評価の質とばく露から結果への方向性を評価する能力に基づいている。これらの違いは、研究の質を大きく左右する(Rothman 及び Greenland、1998年; Pearce、2012年)。

- ・生態学的研究は観察研究であり、ばく露、影響(結果)、またはその両方を個人レベルではなく集団レベルで測定し、両者の相関関係を調べるものである。多くの場合、ばく露は集団レベルで測定されるが、健康登録を利用することで、個人レベルでの健康影響(がん、死亡率)を抽出することができる。これらの研究は、直接のばく露評価が困難な場合や、ばく露量の大きな対照が必要な場合(異なる国や職業間のレベルの比較)によく利用される。個人レベルでのばく露及び/または影響がないことを考えると、これらの研究は仮説を立てるのに有用であるが、一般的には、ヒトまたは実験動物を用いたより厳密な計画で結果をフォローアップ(追跡調査)する必要がある。
- ・横断研究では、ばく露と健康状態が同時に評価され、ばく露の程度が異なる群における有病率(または最近の限られた時間における罹患率)が比較される。このような研究では、現在のばく露が疾患の発症につながる関連時間枠ではないかもしれないので、ばく露と疾患の間の時間的関係は確立できない。有病率の高い症例を含めることは、(ほとんどの)横断研究の大きな欠点であり、特に慢性的な長期疾患の場合には注意が必要である。それでも、ばく露と影響が多かれ少なかれ同時に発生している場合や、ばく露が経時的に変化しない場合には、横断研究はリスク評価に有用であるかもしれない。
- ・症例対照研究では、すでに対象となる疾患(例:症例)と診断されている個人の過去のばく露の推定値と、そのような疾患のない同一集団の対照との間の関連を調べるものである。集団ベースの症例対照研究では、症例は十分に整備された集団から得られ、対照は症例が発生した時点で病気にかかっていない集団のメンバーから選ばれる。症例対照研究の利点は、前向き研究に比べてサンプル数、時間、供給源が少なくて済むことであり、ある種のがんのようなまれな疾患を研究する場合には、症例対照研究が唯一の実行可能な選択肢となることが多い。症例対照研究では、ほとんどの場合、過去のばく露は「直接的な」測定に基づいて評価されるのではなく、質問者または自己記入式のアンケートや職務記述書の肩書きや職務歴などの代用手段によって得られた想起など、より確実性の低い測定を介して評価される。症例対照研究は適切なばく露評価を可能にするかもしれないが、これらの研究はばく露を推定する際に想起バイアスに陥りやすい。その他の課題としては、適切な対照の

選択及び適切な交絡因子管理の必要性が挙げられる。

 コホート研究では、調査対象となる集団は、将来のある時点で特定の疾患や健康影響を発症するリスクがある 個人で構成されている。ベースライン時及びその後の追跡調査(前向きコホート研究)では、関連するばく露、 交絡因子及び健康影響が評価される。適切な追跡期間の後、以前に評価された対象となるリスク因子に異なる ばく露を受けた人々の間で、疾患の発生頻度が比較される。したがって、コホート研究は計画としては前向きで あり、対象となるリスク因子や共変量へのばく露の評価は健康影響が発生する前に測定される。したがって、コ ホート研究は、上記の他の計画と比較して、因果関係のより良いエビデンスを提供することができる。場合によっ ては、コホート研究が過去のばく露の推定値に基づいていることもある。このような回顧的ばく露評価は、直接測 定に比べて精度が低く、想起バイアスがかかりやすい。その結果、コホート研究から得られるエビデンスの質は、 ばく露を評価するために実際に使用された方法や共変量に関する情報が収集された詳細のレベルによって異 なる。コホート研究は、比較的一般的な健康影響に関する研究に特に有用である。規模の点で十分な検出力 があれば、比較的まれなばく露と健康影響に適切に対処するためにも利用できる。前向きコホート研究は、異な る臨界ばく露枠を研究するためにも不可欠である。その例として、成人になるまで一定間隔で子供を追跡する 縦断的出生コホート研究がある。コホート研究では、疾患発症前の潜伏期間が長い場合、長い観察期間を必要 とすることがある。このような研究は、実施するには複雑で費用がかかり、追跡調査の損失が生じやすい。

#### 2.2. 母集団とサンプルサイズ

疫学研究の主な強みは、代理種ではなく、結論を出すべき集団の中で病気を研究することである。しかし、全集団を 調査できることは稀であり、その代わりに研究の目的のために参照母集団からサンプルが引き出される。その結果、前 者が後者を正確に反映していない場合、研究母集団で観察された効果量は、母集団で観察された効果量と異なる可 能性がある。しかし、非代表的なサンプルで行われた観察は、そのサンプル内ではまだ有効であるかもしれないが、結 果を一般集団に外挿する際には注意が必要である。

研究のために対象個人をどのように選択するかを決定した後、最小で何人の参加者を登録すべきかを決定することも必要である。研究のサンプルサイズは、十分な統計的検出力を保証するのに十分な大きさでなければならない。標準検出力(感度とも呼ばれる)は80%で、これは、ある研究が、その効果が対象集団に実際に存在するときに、ある大きさの効果を検出する能力を意味する。言い換えれば、解析の結果から正しい結論を導き出せる確率は80%で、それに対応する確率は20%で、間違った結論を導き出して真の効果を見逃してしまう確率である。検出力解析は、与えられたサイズの効果を検出するのに必要な最小サンプルサイズを計算するためによく使用される。小規模サンプルは、非代表的サンプルを構成する可能性が高い。統計的検出力はリスク・インフレーション(risk inflation)と密接に関係しており、小規模または検出力不足の研究から統計的に有意な結果を解釈する際には特別な注意を払う必要がある(付属書Dを参照)。

疫学研究は、実験動物を用いた毒性学的研究と同様に、多くの場合は複数のエンドポイントを調査するように計画さ れているが、臨床試験は単一の仮説、例えば治療の有効性などを検証するために計画され、実施される。この点では、 実験動物の毒性試験プロトコールについては、OECDの農薬に関するガイダンスでは、各投与群に登録する動物の 最小数が規定されているので、同じ研究で試験される他の多数のエンドポイントのいずれに対しても、十分な検出力を 保証することはできない。したがって、疫学研究と実験室研究の両方を実施する際には、研究の検出力を適切に考慮 することが重要である。

#### 2.3. ばく露

ばく露測定の質は、ばく露(用量)と特定の毒性影響との間の因果関係を正確に確認する研究の能力に影響を与える。

実験動物を用いた毒性学的試験では、用量、頻度、期間、経路などの「試験実施計画」が事前に十分に定められており、その実施状況を確認することができる。これにより、例えば90日間の研究では、飼料中に存在する化学物質の目

13

標とする(そして確認された)濃度と、試験動物が毎日摂取した飼料の量を掛け合わせることで、経口経路を介して毎日投与された外部ばく露量を把握することが可能になる。また、将来的には、重要な試験で内部ばく露量を決定しなければならない。

農薬の場合、ヒトの観察環境においてはばく露濃度、ばく露経路、ばく露期間が管理されておらず曖昧のため正確 なばく露量を推定することは困難である。

意味のある関連性を調べるためには、ばく露の強度、頻度、期間を測定することが必要であることが多い。ばく露に は、比較的短期間の高濃度ばく露もあれば、数週間から数年にわたる低レベルの長期ばく露もある。急性の高用量の 農薬ばく露の影響は数時間から数日以内に現れるかもしれないが、慢性の低用量ばく露の影響は数年後にならないと 現れないかもしれない。また、病気によっては最小限のばく露で発現することもあろうが、ばく露期間が長くなればその 確率は高くなる。

異なるばく露経路(経皮、吸入、経口)では、吸収と代謝に違いが生じる可能性がある。経皮または吸入が職業上の 環境でばく露される経路であることが多いが、一般集団では経口摂取(食品、水)が農薬ばく露の主要な経路である。ヒ トにおける薬物動態には個人差が存在するため、吸収された外部ばく露量が類似している場合でも、異なる全身ばく 露または組織/器官ばく露をもたらす可能性がある。

#### 2.4. 健康影響

健康影響という用語は、調査中の健康に関連する疾病状態、事象、行動、または状態を指す。健康影響とは、研究 の焦点となる臨床事象(通常は診断コード、すなわち国際疾病分類(ICD)10)または健康影響(すなわち死亡)として 表現されるものである。健康影響データを使用する際には、十分に詳細な症例定義、症例を報告し記録するシステム、 そしてこれらの事象の頻度を示す尺度が必要である。

明確な症例の定義は、どこで、いつ、誰によって診断されたかを問わず、一貫して診断されることを保証し、誤分類を 避けるのに必要である。症例定義には標準的な基準が必要であり、それは臨床症状や徴候の組み合わせであり、時に は感度と特異性が知られている診断検査によって補完されることもある。真の有病率または罹患率を推定するためには、 検査手順全体の検出感度(すなわち、健康状態の悪い人が本当に不健康と診断される確率)を認識する必要がある。

また、臨床基準には、疾患リスクの増加と関連する他の特性(例えば、年齢、職業)も含まれている。同時に、適切に 測定・定義された表現型あるいは困難な臨床結果は、調査結果の妥当性を高める。

疾患登録には、診断、治療、結果に関する患者の臨床情報が含まれている。これらの登録は定期的に患者情報を 更新しているため、疫学研究に有用なデータを提供することができる。死亡率、がん、その他の全国的な健康登録は、 一般的に症例定義の要件を満たしており、母集団内の偶発的な症例に関する(ほぼ)網羅的なデータを提供している。 これらの健康影響は、国民健康統計データベースに記録され、分類されているものの、内容的にまだ改善の余地が 多々あり、また、国ごとに異なる許容診断基準に依存していることも問題である。これは、社会的利益のために有効なデ ータを集積する試みを混乱させる可能性がある。登録データは有意義な解析を可能にするが、データの完全性と妥当 性の程度によっては、適切な推論を行うことを困難にするかもしれない。また、データベースの存続期間中におけるコ ーディング規約の変更は、後ろ向きデータベース研究に影響を与える可能性がある。

疾患状態は一般的に二分変数として表現されるが、順序変数(例えば、重度、中等度、軽度、無疾患)あるいは定量 的変数(例えば、標的臓器における毒性反応の分子バイオマーカーや血圧、脂質、特定タンパク質血清濃度などの生 理学的測定値)として測定されることもある。

データ収集の完全性とその一貫性は、研究の信頼性に大きく寄与する。診断基準、データ保存、有用性の調和は、 疫学研究の質に利益をもたらすであろう。

代替エンドポイント(surrogate endpoint)は、十分に定義された疾患エンドポイント、健康影響指標、一般的な臨床 検査値(反応のバイオマーカー)等の代替として使用される。これらの指標は、臨床事象の原因経路上にあると考えら れる。明白な臨床疾患とは対照的に、このような健康状態の生物学的マーカーは、微妙な不顕性の毒性力学的プロセ スを検出することができるかもしれない。このような健康影響のために、詳細な定量分析プロトコールは、研究室間での 比較や再現を可能にするために特定されるべきである。AOP の使用は、症例定義における違いを強調することができる。

代替健康影響(surrogate outcomes)は付加的な情報を提供するかもしれないが、検査された代替健康影響の適 合性は慎重に評価される必要がある。特に、代替健康影響の妥当性は、その主な使用制限となりうる(la Cour ら、 2010年)。したがって、妥当性が確認されていない代替エンドポイントの採択は避けるべきである。

健康状態が他の方法により、例えば自己記入式のアンケートや電話インタビュー、地域の記録(医療や行政のデー タベース)から得られた場合、あるいは臨床検査のみで収集された場合、これらは基礎となる症例の定義を正確に反映 していることを実証するために検証されるべきである。

#### 2.5. 統計的解析と報告

疫学研究の質を保証するためには、資料、方法、結果を詳細に報告し、適切な統計解析を行うことが重要である。統 計解析については、記述的統計及びばく露ー健康影響の関係のモデル化に分けることができる。

#### 2.5.1. 記述的統計

記述的統計は、ばく露尺度、健康影響、可能性のある交絡因子やその他の関連因子など、研究対象グループの重要な特徴を要約することを目的としている。記述的統計には、しばしば頻度表と調査したパラメータまたは変数の中心傾向(平均値や中央値など)及びばらつき度(分散や四分位数範囲など)の測定が含まれる。

#### 2.5.2. ばく露ー健康影響の関係のモデル化

ばく露ー健康の関係のモデル化は、検討中のばく露と健康影響との間に考えられる関係を評価することを目的としている。特に、この関係によってばく露の量や様式、その他の介入因子にどのように依存しているかを評価することができる。

統計的検定は、科学的研究で発見された結果が偶然の結果として起こった可能性があるかどうかを判定する。これは、個々の所見からの結果を要約し、データのランダムエラーを考慮した後、これらの要約推定値が、例えば、ばく露 群と非ばく露群の間で有意に異なるかどうかを評価することによって行われる。

二分された調査結果については、統計解析によりばく露群と対照群との間で疾患頻度に差があるかどうかを検索する。これは通常、相対的な尺度を用いて行われる。コホート研究における相対リスク(RR)は、ばく露群(または高ばく露 群)と非ばく露群(または低ばく露群)を比較して、ばく露と疾患との関連性の相対的な大きさを推定する。これは、ばく 露群では、非ばく露群(または低ばく露群)と比較して、病気を発症する可能性が高いことを示唆している。オッズ比 (OR)は、一般的に症例対照研究や横断研究における健康影響の指標であり、症例と対照(または横断研究では罹患 者と非罹患者)の間のばく露のオッズ比を表し、しばしば統計的検査で使用される相対的な尺度である。用量反応関 係については、異なるレベルまたは用量のばく露を比較することによって確認できる。連続的な健康影響測定の場合、 結果の平均値や中央値の変化は、分散分析やその他のパラメトリック統計を用いて、異なるばく露レベルにまたがって 検討されることが多い。

統計解析は、観察された変化に統計学的有意差があるか否かを確認することであるが、いずれの結果においても慎重な再検討が必要である(Greenland ら、2016年)。

統計的に有意差がないことの解釈。帰無仮説を棄却できなかったからといって、必ずしも関連性がないということで はなく、関連性の有無はその研究の検出力が十分か否かに起因する。検出力は以下の要因に依存する。

- ・ 標本サイズ:標本サイズが小さいと、たとえ真であっても統計的な有意差を検出するのは困難である。
- ・ 偶然性または非ランダムな要因による個々の反応や特性のばらつき: ばらつきが大きいほど、統計的な有意性 を示すのは難しい。
- 効果の大きさ、またはグループ間の観察された差の大きさ:効果の大きさが小さければ小さいほど、統計的有意 性を示すのは困難である。

統計的に有意な差の解釈。統計的有意差とは、観察された差が偶然性だけによるものではないことを意味する。しかし、そのような結果はまだ慎重に検討する必要性がある。

- ・ 生物学的関連性:帰無仮説の否定は、必ずしも関連が生物学的に意味のあるものであることを意味するわけではなく、関連が因果関係にあることを意味するわけでもない(Skelly、2011年)。重要な問題は、観察された差の大きさ(または「効果の大きさ」)が、生物学的に関連性があると考えられるほど大きいかどうかということである。このように、統計的に有意な関連性は、生物学的に関連性があるかもしれないし、ないかもしれないし、その逆もある。統計的に有意な疫学的結果は「生物学的に関連性がない」として却下されるかもしれないが、統計的に有意でない結果が「生物学的に関連性がある」と判断されることはめったにない。研究者や規制当局は、一般的に使用されている健康影響の指標について、統計的有意性を超えて「生物学的に重要な差が最小である」というエビデンスを求めているケースが増えている。生物学的有意性の関連性を研究デザインや検出力の計算に配慮した上で、統計的有意性と同様に生物学的有意性の観点から結果を報告することは、リスク評価においてますます重要になってくるであろう(Skelly、2011年)。これは、生物学的関連性を考慮する際に考慮すべき一般的な問題と基準を概説した EFSA Scientific Committee のガイダンス文書の対象となっている(EFSA Scientific Committee、2017年a);また、エビデンスを扱うプロセスに関連した三つの主要な段階で生物学的関連性を考慮するためのフレームワークが開発されている(EFSA Scientific Committee、2017年b)。
- ・偶発誤差(ランダムエラー):統計的精度の評価には、研究内の偶然誤差を考慮する必要がある。偶発誤差とは、研究における予見できない部分であり、その部分が偶然性に起因する。統計的検定は、科学的研究で発見された結果が偶然性の結果として発生した確率を決定する。一般的に、研究参加者の数が増えると、中心傾向(例えば 平均値)の推定値の精度(標準誤差として表現されることが多い)が上がり、研究グループ間に実際の差がある場 合、統計的に有意な差を検出する能力が向上する。しかし、少なくとも理論的には、観察された結果が偶然に起因 するものであり、比較されたグループ間に真の違いが存在しないという可能性が常にある(Skelly、2011 年)。多く の場合、この値は 5%(有意水準)に設定される。
- ・ 多重検定:サンプルサイズについて議論する際に前述したように、ばく露ー健康影響の関係のモデル化は、原則として仮説主導型であり、予め何を検索するかを研究目的に明記しておく必要がある。しかしながら、実際には、疫学的研究(及び実験動物を用いた毒性学的研究)では、多くの場合、同じばく露に関連して多くの異なる健康影響を調査している。多くの統計的検定が実施された場合、そのうちの 5%程度は偶然にも統計的に有意な結果が得られることがある。このような複数のエンドポイント(仮説)の検定は、偽陽性結果のリスクを高めるが、これはBonferroni、Sidak、あるいは Benjamini-Hochberg の補正や、他の適切な方法を使用することでコントロールすることができる。しかし、これはしばしば省略される。このように、研究者が同じデータセットを対象に多くの統計的検定を行った場合、実際には何も変化はないのにも拘わらず差があるように結論づけられてしまうことがある。したがって、多くの統計結果は、さらなる検証を必要とする予備的な指標と考えることが重要である。統計的有意性と生物学的有意性に関する EFSA の見解は、統計解析から導き出される仮定は、研究デザインに関連して採択すべきであることに注意を促している(EFSA、2011年b)。
- ・ 効果量の拡大:あまり知られていないとはいえ、バイアス追加の原因は、サンプルサイズが小さく、結果として統計 的検出力が低いことに起因する可能性がある。このあまり知られていないバイアスの種類として知られているのは、 低検出力研究から生じる「効果量の拡大」である。小規模で低検出力の研究では、研究の検出力が意味のある効 果量を確実に検出するには不十分であるため、偽陰性が生じる可能性があることは一般的に知られているが、推 定された効果が統計的閾値(例えば、統計的有意性の判定に使用される一般的な p<0.05 閾値)を通過した場合 に、これらの研究が効果量の誇張(インフレ)をもたらす可能性があることはあまり知られていない。この効果は、効 果量の拡大としても知られているが、これは、「発見された」関連性(すなわち、統計的有意性のある閾値を通過し たもの)を有効化することを目的とした最適下限の検出力を伴う研究から得られる現象であり、観察された効果量が、 人工的かつ系統的に誇張されることを意味する。これは、小規模で検出力の低い研究は、大規模な研究よりも個 人間のランダムな変動(ばらつき)の影響を受けやすいからである。数学的には、結果が統計的に有意であるという

あらかじめ決められた閾値を通過することを条件に、推定された効果量は真の効果量の偏った推定値となり、この 偏りの大きさは研究の検出力に反比例している。例えば、ある試験を何千回も実施した場合、観察された効果量に は広い分布があり、小規模な試験では大規模な試験よりも観察された効果量のばらつきが大きくなるが、これらの 推定効果量の中央値は真の効果量に近いものになる。しかし、小規模で低検出力の研究では、観察された効果 のうち、任意の(高い)統計的閾値を通過するのはごく一部であり、これらは最大の効果量を持つものだけである。 したがって、ランダム変動が大きい小規模で検出力の低い研究では、与えられた統計的閾値を通過した場合、実 際に有意性を重視することにより引き起こされる関連性については、その効果量を過大評価する可能性が高くなる。 このことが意味するものは、小規模研究における有意な研究結果は、効果を誇張して発見することに有利になるよ うに偏っているということである。一般的に、バックグラウンド(または対照または無処置)の割合が低く、対象となる 効果量が小さく、研究の検出力が低いほど、誇張効果量の増大傾向がみられる。

しかし、この現象は、統計的有意性のための「事前スクリーニング」が行われた場合にのみ存在することに注意する ことが重要である。要するに、オッズ比(OR)や相対リスク(RR)のような与えられた量を推定したい場合、統計的有 意性のために一連の効果量を「事前スクリーニング」すると、無効値から系統的に偏った(真の効果量よりも大きい) 効果量が得られるということである。規制当局、政策決定者、その他の人々がこの方法で行動している範囲では、 限りない比較と考えられるものの中から統計的に有意な結果を探し、効果の大きさを評価し判断するために統計的 有意性のある閾値を超えたものを使用しているため、仮定された関連の大きさを誇張した感覚になる可能性が高 い。追加の詳細といくつかの効果量のシミュレーションは、本書の付属書 D で提供されている。

**交絡**は、ばく露と疾病との関係が他のリスク因子の影響、すなわち交絡因子の影響にある程度起因している場合に 発生する。リスク因子が実際に交絡因子として作用するためには、McNamee(2003年)により提示(以下に図示)され、 従来から認識されているいくつかの要件がある。その因子は次のようなものでなければならない。

- ・ 被曝していない人に疾患を引き起こす原因、または原因の代替指標となること。この条件を満たす因子は「リスク 因子」と呼ばれる。
- 病気の存在とは無関係に、調査集団のばく露と正または負の相関があること。調査集団がばく露群と非ばく露群に 分類されている場合、その因子が2つの群で異なる分布(有病率)を持っていることを意味する。
- ・ ばく露と疾患の間の因果関係の経路に中間段階はない。

交絡は、ばく露と疾病の関係を過大または過小に評価する結果となり、2 つのリスク因子の影響が分離されていなかったり、「解放」されていなかったりするために起こる。実際には、十分に強固な場合、交絡はまた、見かけ上の関連性を逆転させることもある。例えば、農業上ばく露は多くの異なるばく露カテゴリーがあるため、農業従事者は、生物学的要因(土壌生物、家畜、農場動物)、花粉、粉塵、日光、オゾンなど、潜在的な交絡因子として作用する可能性のあるものを含む、多種多様なリスク因子に一般集団よりも多くばく露されている可能性が高い。

交絡を制御するために、研究の計画段階または解析段階の両方で、多くの手順が利用可能である。大規模な研究 では、計画段階でのコントロールが好ましいことが多い。計画段階では、疫学研究者は、研究者がコントロールしたい 特徴を共有する個人に研究集団を限定することができる。これは「限定」として知られており、実際には、その特性によ って引き起こされる交絡の潜在的な影響を取り除くことができる。研究者が交絡をコントロールするための計画段階での 2つ目の方法は、「マッチング」によるものである。ここでは、研究者は交絡変数に基づいて個人をマッチングさせ、交絡 変数が2つの比較グループ間で均等に分布するようにする。

計画段階を超えて、解析段階では、層別化または統計的モデリングのいずれかの方法で交絡をコントロールすること ができる。コントロールの1つの手段は、交絡変数(例えば、男性と女性、民族、または年齢グループ)のそれぞれの下 で、関連性が別々に測定される層別化によるものである。別々の推定値は、各層で測定された推定値を重み付けする ことによって、共通のオッズ比(OR)、相対リスク(RR)、または他の効果量を生成するために(必要に応じて)統計学的 に「集積する」ことができる(例えば、Mantel-Haenszel アプローチを使用する)。これは、分析のサンプルサイズを小さ くする代償として行うことができる。比較的簡単に実行できるが、この層別化が複数の交絡因子を同時に扱うことができ ないことに起因する困難が生ずるかもしれない。このような状況では、統計的なモデル化(例えば、多重ロジスティック 回帰)によってコントロールを達成することができる。

上述の研究の計画と解析の段階で交絡をコントロールするために利用可能なアプローチにかかわらず、研究者が計 画で考慮しなかった変数や、データを収集しなかった変数をコントロールすることができないため、この分野で疫学研 究を開始する前に、交絡因子を慎重に考慮することが重要である。

疫学研究は、公表されているかどうかにかかわらず、特定のリスク因子を誤って暗示したり、不適切に否定したりする 可能性のある潜在的な交絡因子を無視しているとして、しばしば批判される。このような批判にもかかわらず、そのよう な可能性のある交絡因子によるバイアスの影響の大きさについての議論が提示されることはほとんどない。交絡因子は、 リスク推定値に実質的な歪みを生じさせるためには、対象となるばく露に強く関連した疾患の比較的強いリスク因子で なければならないことを強調しなければならない。単に交絡の可能性を提起するだけでは十分ではなく、リスク因子が なぜ交絡因子になりやすいのか、その影響がどのようなものなのか、そしてその影響が結果の解釈にとってどれほど重 要なのかを説明する説得力のある議論をしなければならない。強い相対リスクは測定されていない交絡因子によるもの である可能性が低いのに対し、弱い交絡因子は、研究者が解析で測定または管理していない変数による残存交絡因 子によるものである可能性があるため、相対リスク(RR)、オッズ比(OR)、リスク比、回帰係数などで測定される交絡の 大きさを考慮することが重要である(US-EPA、2010年b)。

効果修飾。
とトの健康に対する農薬及びその他の化学物質の影響は、すべての個人で同一であるとは考えにくい。 例えば、ある特定の有効成分が成人の健康な被験者に及ぼす影響は、乳児、高齢者、妊婦に及ぼす影響と同じでは ない可能性がある。このように、ある化学物質にばく露された場合、ある集団の一部(サブセット)が感受性が高いことか ら疾患を発症する可能性が高くなる。このため、「脆弱な小集団」という用語が使用されているが、これは子供、妊婦、高 齢者、重病歴のある人に加え、環境化学物質へのばく露による特別な健康リスク(薬物代謝酵素、トランスポーター、ま たは生物学的標的の遺伝的多型のため)の対象となると同定された小集団を含む。平均効果とは、あるばく露の影響 をすべての小集団で平均化したものである。しかし、様々な小集団間の関連の強さには不均一性があるかもしれない。 例えば、化学物質 A へのばく露と健康影響 B との間の関連の程度は、健康な成人よりも子供の方が強く、また、ばく露 時に防護服を着用している人や遺伝子型の異なる人には同様な影響は見られないかもしれない。もし不均一性が本当 に存在するのであれば、全体的な関連性を示す単一の要約尺度は意味をなさず、誤解を招く可能性がある。不均質 性の存在は、様々な小集団における因子と効果の間に統計的に有意な相互作用があるかどうかを検定することによっ て評価される。しかし、実際には、これは大きな標本サイズを必要とする。

関連因子によって定義された小集団での効果を調査することは、対象となるリスク因子のヒトの健康への影響についての知識を前進させるかもしれない。

#### 2.6. 研究の妥当性

例えば、農薬ばく露と健康影響の間に統計的に有意な関連が観察された場合、またはそのような有意な関連が観察 されなかった場合には、真の関連を歪めたり、その解釈に影響を及ぼす可能性のある要因を評価して、調査研究の妥 当性も評価する必要がある。これらの不完全性は、ばく露と疾病の間の関連性を(系統的に)誤って推定することになる 系統的な誤差の原因に関係している。さらに、単一の研究から得られた結果は、病気を発症するリスクのある他の集団 で実施された独立した調査で再現された場合、より高い妥当性を持つことになる。

時間的シーケンス(順序)。因果関係の断定は、推定される効果に先行する原因を時間的に関与させなければならない。Rothman(2002年)は、時間性を真に因果関係がある唯一の基準と考え、時間性の欠如は因果関係を排除する。疫学的関連の時間的順序は、時間的にはばく露が結果(効果)に先行する必要性を示唆しているが、ばく露の測定が結果の測定に先行する必要はない。この要件は、ばく露が後ろ向きに評価される場合(症例対照研究)や、結果と同時に評価される場合(横断研究)よりも、前向き研究の計画(すなわちコホート研究)では容易に満たされる。しかし、前向き研究においても、疾患の発症が遅かったり、初期の疾患形態が測定しにくかったりすると、原因と結果の時間的な順序や時間的な方向性を確認することが困難になることがある(Höfler、2005年)。

研究の妥当性については、研究対象集団からより広い集団への結果の一般化可能性も考慮しなければならない。

前述したランダムエラーは精度の問題と考えられ、サンプリング変動の影響を受けるが、バイアスは妥当性の問題と考 えられている。より具体的には、バイアスの問題は一般的に、正しい母集団パラメータが推定されているかどうかに影響 を与える研究デザインまたは研究分析における方法論的な不完全性を伴う。バイアスの主なタイプには、選択バイアス、 情報バイアス(想起バイアス、質問者/オブザーバーバイアスを含む)、交絡因子がある。追加の潜在的なバイアスの 発生源は、すでに述べた効果量の規模である。

選択バイアスは、被験者を研究に参加させるために使用された手順や方法、被験者が研究から外れる方法や、そう でなければ研究への継続的な参加に影響を与える結果として発生する妥当性に関する系統的な誤差に関係している。

典型的には、このようなバイアスは、症例対照研究において、疾患に基づいて被験者を含める(または除外する)こと が、研究対象となる前のばく露状態と何らかの形で関連している場合に発生する。一例としては、ばく露と健康影響との 間に関連性が疑われることに対する初期の広報やメディアの注目が、ばく露を受けた人はばく露を受けていない人に 比べて優先的に診断される傾向があるかもしれない。選択バイアスはまた、コホート研究においても、例えば、研究から 外れた人(追跡調査に参加できなくなった人、離脱した人、無回答の人)と残された人の状態が異なる場合のように、ば く露群と非ばく露群が真に比較可能でない場合に発生しうる。また、横断研究では、生存者のみを研究対象とする選択 的生存により、選択バイアスが生じることがある。このようなタイプのバイアスは、一般的に研究の慎重な計画と実施によ って対処できる(第4節、第8節も参照)。

「健康労働者効果」(HWE)は、一般的に認識されている選択バイアスであり、職域疫学研究で起こりうる特定のバイ アスを示すものである:労働者は、労働力として雇用される必要があるため、一般集団からの個人よりも健康である傾向 があり、そのため、一般集団から得られた集団ベースのサンプルよりも好ましい健康状態を持つことが多い。このような HWE バイアスは、観察された関連性が真の効果に比べて隠されたり、軽減されたりすることがあり、その結果、化学物 質やその他の有害物質にばく露された労働者の死亡率や罹患率が低く見えることがある。

**情報バイアス**とは、ばく露または健康影響に関する情報が異なる研究グループから得られる方法に系統的な違いがあり、その結果、研究で測定される1つ以上の共変量に関して不正確な情報が得られたり、測定されたりする場合の系統的な誤差のことである。情報のバイアスは、結果として、ばく露または疾病状態のいずれかに関して誤った分類につながり、ORやRRのような疫学的効果の大きさの尺度にバイアスが生じる可能性がある。

ばく露状態の誤分類は、不正確、不十分、または不正確な測定値、被験者の不正確な自己申告、またはばく露デー タの不正確なコーディングに起因する可能性がある。

疾患状態の誤分類は、例えば、検査室のエラー、検出バイアス、データベース内の疾患状態の不正確な、または一 貫性のないコーディング、あるいは不正確な想起から生じることがある。想起バイアスは情報バイアスの一種であり、ば く露状態(またはその逆)に応じて疾患状態の報告が異なる場合の系統的な誤りに関係している。質問者・バイアスは、 質問者が個人のばく露状況を認識している場合に発生するもう一つの情報バイアスで、ばく露グループ間で意図して いるかどうかに関わらず、ばく露グループ間で異なる疾患状況に関する回答を求めてしまうことがある。なぜなら、病気 の被験者は、病気ではない被験者に比べて、より早い時期に発生したばく露を思い出す可能性が高いからである。こ れは、何らかの効果測定において帰無値(ばく露と疾病の間に関係がないという)から遠ざかるバイアスにつながる。

重要なことに、上述のような誤分類は、「差がある(differential)」場合と「差がない(non-differential)」場合があることである。これらは、(i)真にばく露されている(または病気にかかっている)人が、真にばく露されている、または病気にかかっていると正しく分類される度合いと、(ii)真にばく露されていない(または病気にかかっていない)人が、そのように正しく分類される度合いに関係している。前者は「感度」として知られているが、後者は「特異性」と呼ばれ、これらの両方がバイアスの存在と可能性のある方向性を決定する役割を果たしている。差異的誤分類とは、他の変数の値に依存しない誤分類を意味する。

疫学的観点から重要なことは、誤分類バイアス(差異的か非差異的か)は、そのようなばく露を分類するために使用された研究方法の感度と特異性に依存し、特定の(限定された)条件の下でバイアスの方向に予測可能な影響を及ぼすことができるということである。すなわち、研究の方法や解析の知識に基づくバイアスの方向性を特性評価する能力は、考慮される疫学的効果量(OR、RR など)が真の効果量の過小評価か過大評価かを政策決定者が判断することができ

るから、規制当局の政策決定に有用である。非差異的な誤分類バイアスが帰無値への予測可能なバイアスをもたらす (したがって、体系的に効果量を過小予測する)と一般的に想定されていますが、これは必ずしもそうではない。また、 誤分類は非差異的であるという疫学研究で時々みられる一般的な仮定(これは、非差異的な誤分類バイアスが常に帰 無(null)に向かっているという仮定と対になっていることもある)は、必ずしも正当化されているわけではない(例えば、 Jurekら、2005 年を参照)。

測定されていない交絡因子が結果に影響を与えると考えられる場合、研究者は感度分析を実施して、影響の範囲と その結果として生じる調整された効果測定値の範囲を推定すべきである(US-EPA、2010 年 b)。しかし、定量的感度 (またはバイアス)分析は、多くの疫学研究では一般的には行われておらず、ほとんどの研究者は、論文の考察で様々 な潜在的なバイアスを定性的に記述している。

疫学研究者は既知ではあるが測定されていないリスク因子によるばく露の誤分類や選択バイアスなどのバイアスの 影響を推定したり、見落としや考慮されていない交絡因子が観察された効果の大きさに及ぼす影響を示すために感度 分析を実施することが推奨されている(Lash ら、2009 年;Gustafson 及び McCandless、2010 年)。感度分析は、リ スク評価目的で疫学データをレビューする際の基準リストに組み込まれるべきである。

#### 3. 農薬に関する利用可能な疫学研究の主な限界事項

#### 3.1. EFSA 外部科学研究報告書の著者が指摘した限界

EFSA 外部科学報告書(Ntzani ら、2013 年;付属書 A に要約)では、多様な健康影響を調査する疫学的研究が 多数報告されている。疫学的証拠を体系的に評価する努力の中で、多くの方法論的限界が強調された。これらの限界 の存在下では、確固たる結論を導き出すことはできなかったが、疫学からの裏付けとなるエビデンスが存在する結果は、 今後の調査のために強調された。識別された主な限界は以下の通りである(Ntzani ら、2013 年)。

- 前向き研究の欠如と、バイアスがかかりやすい研究デザイン(症例対照研究と横断研究)の頻繁な使用。さらに、評価された研究の多くは、十分な検出力を持っていないようにみえる。
- 少なくとも疫学の他の多くの分野の疫学と比較して、詳細なばく露評価が欠如している。特定の農薬ばく露と混合ばく露に関する情報は、多くの場合、不足しており、適切なバイオマーカーはほとんど使用されていない。代わりに、多くの研究では、アンケート調査(多くの場合、妥当性が確認されていない)によって評価されたばく露の大まかな定義に頼っていた。
- ・結果評価の不備(おおまかな結果の定義、自己申告性の健康影響または代替健康影響の使用)。
- ・報告と解析の不備(効果推定値の解釈、交絡因子のコントロール、多重検定)。
- ・ 選択的な報告・出版バイアスと、その他のバイアス(例:利害の対立)。

各研究結果の中で観察された結果の不均一性は、しばしば大きなものであった。しかし、不均一性は常にバイアスの結果であるとは限らず、本物である可能性があり、先験的に定義されたサブグループ解析やメタ回帰を考慮することは、エビデンス統合の努力の一環であるべきである。農薬ばく露に関して特に重要な職域研究もまた、健康労働者効果の影響を受けやすく、このバイアスによって労働者の罹患率と死亡率が一般集団よりも低くなっている。健康労働者効果は、雇用期間と追跡調査の期間が長くなるにつれて低下する傾向がある。

+分な統計力を持ち、農薬ばく露の詳細な定義、多くの健康影響に関するデータ及び明白性な報告を備えている 研究は、農業健康調査(Agricultural Health Study:AHS)や他の同様の研究を除けば、稀である。これらの方法論 的限界のいくつかは、農薬ばく露研究に限定されたものではなく、最も重要なことは、疫学的には特異的なものではな く、動物試験を含む他の特異的な研究分野でも観察されていることに注意することが重要である(Tsilidisら、2013年)。

EFSA の外部科学報告書には様々に定義された広範囲の農薬が記載されているが、この情報を研究間で調和させることは困難である。研究間での結果の不均一性は、同質性と同じくらい有益な情報になるが、情報は、反復を評価したり、要約効果量を計算したりできるように調和されている必要がある。これは、真の不均一性がある場合、異なる研究をプールすることができないことを意味するものではない。単一の研究からは限られた結論を導き出すことができるのみである。それにもかかわらず、報告書では、さらなる検討と調査に値する農薬と健康影響との間の多くの関連性が強調

されている。興味深いのは、公表されている文献のかなりの割合が EU 及びほとんどの先進国で使用が認可されてい ない農薬に焦点を当てているという事実である(例えば、DDTとその代謝物のみに焦点を当てた研究は、対象となる研 究の10%近くを占めている(Ntzaniら、2013年)。これらの研究は、残留農薬として残留している可能性があることや、 開発途上国で使用され続けていることから、まだ適切であるかもしれない。また、報告書では、約5年の期間にわたる あらゆる健康影響に関連した疫学的証拠に焦点を当てている。この報告書は、農薬ー健康影響の関連性の疫学的評 価の分野を記述する上で有用なものではあるが、特定の疾患と農薬の問題に完全に答えることはできない。農薬ばく 露に関連する疾患エンドポイントのより詳細な解析が必要であり、そのような情報が入手できる場合には、EFSAの外 部科学研究報告書でカバーされている期間よりも前に発表された研究も含めるべきである。

#### 3.2. 研究デザインの限界

倫理的な理由から、EU では低用量の農薬ばく露の安全性を試験するための無作為化比較試験は認められていない。したがって、ヒトにおける潜在的な有害健康影響に関する情報は、観察による研究を用いて抽出する必要がある。

潜伏期間の長い疾患では、ある時点でのばく露量を測定しても、そのような疾患の発症に必要な長期ばく露量を正確に再現できない可能性がある。これは、生物学的サンプル中の濃度が一定ではなく、頻繁に変動する非持続性農薬の場合に特に重要である。したがって、尿サンプル中の単一の測定値と長期の潜伏期間の結果との間に関連性があると断定する研究は、慎重に解釈されるべきである。

Ntzani の報告書で検討された 795 件の研究のうち、38%が症例対照研究であり、32%が横断研究であった。その 結果、農薬ばく露による潜在的な有害健康影響のエビデンスは、少なくとも潜伏期間が長い結果については、前向き な計画を欠いた研究に大部分が基づいている。横断研究では方向性を評価することができず、観察された関連性はし ばしば逆因果関係(病気はばく露によって引き起こされたのか、それとも病気がばく露に影響を与えたのか)をもたらす 可能性がある。逆因果関係は多くの疫学の分野で横断研究の潜在的な問題であるが、農薬疫学では、ほとんどの場 合、病気が農薬へのばく露を引き起こすことはほとんどないため、問題にはならない。

いくつかのがんなどのまれな転帰に対しては症例対照研究が頻繁に用いられるが、その主な限界は、想起バイアス がかかりやすく、ばく露の後ろ向き評価に頼らなければならないことである。しかしながら、特にまれな転帰に対しては 有用な情報を提供することはできる。症例対照研究と前向き研究の結果が一致するかどうかを調べることが重要である。 例えば、トランス脂肪酸の摂取量と心血管疾患との関連を調べるために実施された研究(EFSA、2004 年)では、症例 対照研究と前向き研究の両方で一貫して正の関連が報告されている。2 つの研究デザイン間の効果推定値は控えめ な効果量が報告された前向き研究とは系統的に異なるが、どちらの研究デザインも同様の結論に達した。農薬に関し ては、研究デザインにかかわらず、パーキンソン病と農薬ばく露との間の関連の大きさについては、同様の値が観察さ れている(レビューは Hernández ら、2016 年)。

#### **3.3.** 研究対象の妥当性

個人がばく露される農薬の環境的に適切な用量は、動物モデルで観察された毒性を誘発するのに必要な用量よりも 低いため、関連する毒性影響は、小集団の感受性の違いとの関連で理解する必要がある。潜在的に脆弱な集団は、 健康な個人よりも低用量の農薬へのばく露に対してリスクが高く、時にはばく露の敏感な時期にばく露されることもある。 これは遺伝的感受性の場合であり、これはリスク評価のために説明されるべき重要な要因である(Gómez-Martín ら、 2015 年)。遺伝的感受性は、毒物動態に影響を与える機能的な遺伝的多型(例えば、異物代謝酵素及び膜トランスポ ーターをコードする遺伝子)及び/または毒力学に影響を与える機能的な遺伝的多型(例えば、異なる受容体遺伝子 多型)に大きく依存する。この遺伝的多様性は、妥当な科学的仮説に基づいて考慮されるべきである。

さまざまな障害、特に神経変性疾患(パーキンソン病、アルツハイマー病、筋萎縮性側索硬化症)は、環境因子(例 えば農薬)へのばく露と結び付けられてきたが、多くの場合、病気の遺伝子構造は考慮されていない。特定の集団では、 特定の遺伝子変異の有病率は5-10%に達し、時には症例の20%を超えることもある(Gibsonら、2017年)ので、農薬 ばく露とこれらの疾患の関連性は、研究対象となる集団内の遺伝的構造によって大きく影響を受ける可能性がある。こ れらの疾患の多くの効果量が小さいことを考えると、研究デザインでは考慮されていない特定の遺伝子の根本的な効果が、疾患リスクの推定値を修正する可能性がある。したがって、農薬ばく露との関連は、一連の神経変性疾患に関連することが知られている一般的な遺伝的変異に照らして評価する必要があるかもしれない。しかし、遺伝的変異はそれ自体が人々を農薬ばく露の増加に向かわせるものではない。

特に注目すべきサブグループは子供であり、彼らの代謝、生理、食生活、環境化学物質へのばく露パターンは成人 とは異なり、有害な影響を受けやすくなるからである。生物学的感受性の窓口はほとんどの場合不明のままであり、メカ ニズムによって異なると予想される。性別に基づく感受性は、農薬に関連した生殖毒性や内分泌かく乱の場合にも考 慮する必要がある。これらのサブグループは現在リスクアセスメントの過程で考慮されているが、追加的な保護を提供 するためには、より注意を払う必要があるかもしれない。

#### 3.4. ばく露評価における課題

農薬に関する疫学研究の主な限界は、ばく露評価の不確実性に由来する。現在認可されているほとんどの農薬は、 消失半減期が短い傾向があり、作物や季節に応じて様々な製剤を散布しなければならないという事実もその限界に含 まれている。その結果、正確な評価には、これらの非難分解性化学物質の間欠的な長期ばく露を把握し、個々の農薬 へのばく露を定量化する必要がある。

多くの研究では、大規模な農薬群に共通する尿中の非活性代謝物(例えば、有機リン酸塩の場合はジアルキルリン酸塩、ピレスロイドの場合は 3-フェノキシ安息香酸、ネオニコチノイドの場合は 6-クロロニコチン酸)を測定することで内部ばく露を評価している。これらのデータを、以下の理由からリスクを推測するために利用すべきではない。(a)これらの代謝物の一部は、親化合物を摂取するのではなく、食品やその他の供給源から事前に生成された代謝物を摂取することで直接ばく露を反映する可能性があり、(b)異なる親化合物農薬の効果は桁違いに異なる可能性があるからである。そのため、これらの尿中代謝物に基づく HBM データは、実際の農薬ばく露量を示す他のデータと組み合わせない限り、役に立たない可能性がある。

理想的には、内部ばく露量を示すバイオマーカーを使用して個人レベルでばく露量を定量化する必要がある。利用 可能なバイオマーカーのほとんどは短期間(数時間または数日)のばく露を対象としており、長期にわたって複数のサ ンプルを収集するコストと困難さを考えると、多くの研究では外部ばく露量として定量化されている。外部ばく露量の定 量的な推定には、ばく露の頻度と期間の両方を考慮する必要があり、グループレベルではなく個人レベルで行うことが 望ましい。多くの場合、外部ばく露は以下のような代理指標を用いて定量化される。

- 一般的な農薬への潜在的ばく露または実際の使用に関連する、対象者または親族が報告した仕事、職種、作業、 その他のライフスタイルの習慣。
- 特定の製品または製品群の取り扱いと、既存の農薬の記録や日誌を通じて文書化された、または栽培された作物 から推定された、これらへの潜在的なばく露。
- ・環境データ:環境農薬モニタリング、例えば水中、ばく露場所と考えられる特定の地理学上の地域からの距離及び /または居住期間。

多くの場合、これらの代理指標測定は、質問者によるものでも、自己申告に基づくものでもよいアンケート調査を用い て記録される。しかし、アンケートデータはしばしば個人の想起と知識に依存しており、想起バイアスや質問者や被験者 によってもたらされるバイアスの影響を受ける可能性がある。これらのバイアスの原因は、アンケートがバイオマーカーに 対して検証されていれば、ある程度定量化することができる(つまり、個々の質問が参加者のサンプルにおけるバイオマ ーカー濃度をどの程度予測しているか)。ばく露が後ろ向きに評価された場合、明らかな理由により、想起の精度が損 なわれ、検証が不可能になる可能性が高くなる。ばく露が記録に基づいて評価される場合も、例えば記録が不完全で あったり、不正確であったりすることで、同様の困難が生じる可能性がある。

これまでの多くの研究では、ばく露の持続時間が累積ばく露の代用として使用されることが多く、ばく露は時間的に 均一で連続的であると仮定している(例えば、雇用期間)が、農薬の場合はこの仮定に疑問を呈しなければならない。 一部の化学物質ではばく露パターンはかなり一定であるかもしれないが、市場に出回っている多数の農薬のばく露は、 季節や個人用保護具(PPE)、作業習慣によって異なり、多くの場合、使用の反復性は高くない。個人のレベルでは、 ばく露量は日ごと、時間ごとに異なることがあり、多くの場合、複数の農薬が関与している。この時間的変動性は、生物 学的半減期が短い農薬の全身ばく露において特に高い変動性をもたらし、長期にわたって個人のばく露に単一または 少数の測定値を外挿する際にかなりの不確実性をもたらす可能性がある。したがって、ばく露の推定値を改善するため には、時間をかけて多くの測定を繰り返すことが必要になるかもしれない。

#### 3.5. 不適切な、あるいは検証されていない健康影響のサロゲート

疫学研究では自己申告による健康影響が頻繁に用いられているが、その理由は、大規模なサンプルや限られた資金を用いた研究では、回答を検証することが困難であることなどが挙げられる。多くの研究では、自己報告された影響と医療記録との一致について調べられているが、このような指標の検証が不足しているために、特に大規模な集団ベースの研究では、誤分類につながる可能性があり、発見された関連性の信頼性を損なう可能性がある。

臨床的に明らかになった結果に依存すると、ばく露から疾患への毒力学的連続して進行したが、まだ明らかな臨床 的疾患状態に達していない人が、疾患を持っていないと誤分類される可能性が高くなる可能性がある(Nachman ら、 2011 年)。そのため、ばく露後の臨床症状の発現が遅れると、不適切な時期に臨床評価だけが用いられた場合、過小 申告の原因となることがある。

発がん性の場合、無症状であるが、腫瘍性状態に進行する可能性のある前腫瘍性病変として評価されている例があ る。これは、AHS における農薬ばく露と関連している有効性が未決定である単クローン性ガンマグロブリン血症 (MGUS)の例であり(Landgren ら、2009 年)、この状態は悪性多発性骨髄腫に進行するリスクが年平均 1%である (Zingone 及び Kuehl、2011)。しかし、MGUS が悪性多発性骨髄腫に進行するかどうか、いつ、どのように進行する かを予測することは困難である。動物実験では、農薬ばく露が前がん病変のリスクと関連している可能性があることを示 す研究があるので、前がん病変とがん病変の両方の転帰を組み合わせた疫学的解析を行うことで、そのような解析の 検出力を高めることができるかもしれない。

代替健康影響は、臨床的に関連する転帰に代わる注目される選択肢である。なぜならば、同じ疾患の様々な代替健 康影響が存在し、それらの健康影響はより早く発生したり、評価が容易であったりして、診断までの時間を短縮できるか らである。しかし、有効な代替エンドポイントは、因果関係を予測し、対象となる健康影響を正確に予測するものでなけ ればならない。さらに、これらの代替指標は農薬の作用機序に関連していなければならず、その予測性を裏付けるため に、確立された毒物学的エンドポイントに固定されていなければならない。代替指標は健康影響と相関があるかもしれ ないが、健康影響に対する要因の効果を捉えていないかもしれない。これは、代替指標が臨床健康影響の因果関係ま たは強く関連しているのではなく、付随する要因に過ぎないため、臨床健康影響の予測にはならない可能性があるから である。このように、代替健康影響の妥当性は、サロゲートを使用する上での大きな制限となりうる(la Cour ら、2010 年)。

しかし、有害健康影響を直接測定したのではなく、代わりに有効な代替指標を用いた疫学研究に基づいて、規制上の政策決定を下すことができるかどうかについては、懸念がある。代替エンドポイントとしての代替指標の使用は、臨床的に意味のある影響を予測する上での信頼性を立証する十分なエビデンスがある場合にのみ検討されるべきである。

#### 3.6. 統計解析と結果の解釈

農薬と健康影響との関係に関する疫学的文献にみられる統計解析と科学的知見の解釈は、他の分野で報告された 疫学研究と大きく異なるものではない。したがって、2.5節で示した疫学研究の利点と限界は、農薬に関する疫学研究 にも適用される。

農薬の疫学研究のいくつかの特徴は以下の通りである。(a) 農薬へのばく露を評価する際の測定誤差の存在下での適切な統計解析を行うことが少ないこと、(b) ばく露ー健康影響の関係に影響を及ぼす可能性のある他の重要な因子に関する情報が不十分なことである。これらの特徴については、次の段落で詳しく説明する。

a) 測定誤差のある統計解析

ばく露量を正確に測定するための困難さは、栄養疫学や環境疫学などの疫学研究の多くの分野で頻繁にみられる。 制御された実験室での実験環境の外で、短期及び長期のばく露を評価することが容易ではない。大規模集団では、個 人は様々な期間、様々な強度で様々な形で様々な薬剤にばく露されている。

しかし、栄養疫学や環境疫学とは異なり、農薬疫学では、測定誤差を適切に考慮した統計解析が広く利用可能であ り、このテーマに関する膨大な文献があるにもかかわらず、これまでのところほとんど利用されていない。その直接的な 結果として、これらの統計的手法が利用されていたとしても、推論的結論が正確で、精密なものではなかった (Bengtson ら、2016年; Dionisio ら、2016年; Spiegelman、2016年)。

b)その他の重要な関係因子に関する情報

対象となる結果に影響を与える可能性のある他の関連因子を特定して測定することは、科学のすべての分野で繰り 返し起こる重要な問題である。例えば、ある薬が平均的に病気を効果的に治すということを知っていても、その薬が子 供や妊婦に有害であるかもしれない。年齢、妊娠、その他の特性が薬の有効性に影響を与えるかどうかは、医師、患者、 製薬会社、医薬品承認機関にとって重要な情報である。

農薬疫学は、可能性のある関連因子を慎重に特定し、正確に測定し、徹底的に評価し、ばく露と健康結果の関係に おけるそれらの役割を評価する機会を提供している。最も多くの場合、関連因子は潜在的な交絡因子としてスクリーニ ングされている。交絡因子の影響が検出された場合には、統計解析で補正する必要があった。このことは、すでに収集 されたデータや今後の研究で収集される可能性のあるデータを再検討することで、この重要な問題を明らかにするため の更なる調査の余地を残している。農薬の文献における統計的手法は、主に二項確率やハザード回帰モデルなどの 基本的な回帰分析の標準的な応用に限定されてきた。潜在的に有用な解析アプローチ、例えば、傾向スコアマッチン グ、媒介分析、因果推論などは、農薬疫学に役立つであろう(Imbens 及び Rubin、2015 年)。

#### 4. 農薬リスク評価のための将来の疫学研究への再検討案

このセクションでは、利用可能な農薬の疫学的研究の評価方法と、規制目的に役立つようにそのような研究を改善 するための提案を取り上げることを目的としている。

疫学的データの潜在的な規制上の利用の可能性を検討する際に、農薬ばく露と健康影響に関する既存の疫学的 研究の多くは、個々の有効成分の評価においてその価値を制限する様々な方法論的限界や不完全性に悩まされてい る。農薬ばく露と健康影響に関する疫学研究は、半定量的なデータを生成するか、予測モデルのアウトプットに関して 定量的なリスク評価との関連性を高めることが理想的である。これにより、疫学的な結果は、農薬のリスク評価に一般的 に用いられる定量的なリスク評価に匹敵する言葉で表現できるようになる。このような疫学データを予測モデルと比較し てリスク評価を行う際に、どのように考えればよいのかという疑問が生じる。現行の農薬疫学研究の結果では、正確に測 定された定量的な用量反応関係はほとんど達成されていない。

農薬ばく露と健康影響に関連した疫学的証拠の質、信頼性、妥当性は、(a)個々の研究の質及び(b)利用可能な すべての研究から得られた複合的なエビデンスの評価を改善させることによって向上させることができる。

#### 4.1 疫学研究の質の評価と報告

リスク評価に使用するために文献から疫学研究を選択する際には、疫学研究の質と関連性を考慮する必要がある。 この研究の質は、次のようにして高めることができる(US-EPA、2012年;Hernándezら、2016年)。

- a) ばく露の適切な評価、特に個人レベルでのバイオマーカー濃度が用量反応評価を可能にする方法で報告されて いること。
- b)合理的に有効で信頼性の高い健康影響評価(よく観察された臨床症状または有効な代替指標)。
- c)交絡変数(複数の化学物質へのばく露を含む)を適切に考慮していること。
- d)サブグループ解析の実施と報告(例えば、性別、年齢、民族による層別化)。

生物医学的研究が多様な限界の対象となり、その限界に苦しむことは広く受け入れられている。農薬に関する疫学

研究の計画、実施、解析における弱点の評価は、誤解を招く可能性のある結果を特定し、信頼性の高いデータを特定 するために不可欠である。

ガイドラインやチェックリストは、特定の分野での最良の行動に向けて導く一連のルールや原則を提供することで、個 人が特定の基準を満たすのを助けるものである。疫学的証拠の評価を助けとなるためにいくつかのツールやガイドライ ンが開発されているが、農薬に関する研究を評価するための特定のツールは存在しない。これらの研究には、特定の 注意を必要とするばく露評価に関する特別な考慮事項があるが、既存の研究を批判的に評価するための標準的な疫 学的手法を適用できる可能性がある。現行の報告ガイドラインは通常、研究にバイアスをもたらした可能性のある側面 に焦点を当て、調査研究中に何が行われ、何が発見されたかを完全かつ明確に説明するために必要な最低限の情報 を規定している(Simera6、2010年)。

観察による疫学研究の品質評価のために、Newcastle-Ottawa スケール(NOS)や Research Triangle Institute (RTI)のアイテムバンクなど、多くのツールが特別に計画されている。後者は、化学物質ばく露の疫学研究のバイアスのリスクと精度を評価するための 29 の質問のチェックリストからなる実用的で検証済みのツールである。また、バイオモニタリング、環境疫学、短命化学物質(BEES-C)は、バイオモニタリングを用いて短命化学物質を評価する疫学研究の質を評価するために開発されたが(LaKind ら、2015 年)、主な要素が横断であり、より広範囲に適用可能であるため、難分解性化学物質や環境対策にも利用できる。評価スキームの開発に向けた 2 つの先行研究は、環境化学物質ばく露と神経発達に関する疫学研究に焦点を当てたものである(Amler ら、2006 年; Youngstrom ら、2011 年)。

報告の質に関しては、2008 年 6 月に発足した EQUATOR ネットワーク(Enhancing the QUAlity and Transparency Of health Research (EQUATOR) Network)は、健康調査研究の明白性と正確な報告を促進する 国際的な取り組みである。現在、90 以上の報告ガイドラインがリストアップされており、その中には観察による疫学研究 に特化したものもある(例:Strengthening the Reporting of OBservational studies in Epidemiology (STROBE))。STROBE ステートメントには、論文のタイトル、要約、緒言、方法、結果、考察のセクションに関連する 22 項目のチェックリストを使用して、横断、症例対照、コホート研究を含む観察による研究の正確で完全な報告に何を 含めるべきかについての勧告が含まれている(von Elm ら、2007 年)。STROBE ステートメントは、著者への指示書の 中で言及されている生物医学雑誌の数が増えてきており、支持されている。表 1 は、疫学研究の報告の質を評価する 際に STROBE が考慮すべき主な特徴をまとめたものである。STROBE の拡張機能として、STROBE Extension to Genetic Association studies(STREGA)や分子疫学研究の評価のための STROBE-ME ステートメントがある。 STROBE チェックリストではばく露と健康の影響について一般的にしか言及されていないため、PPR パネルは、農薬 ばく露と健康影響の分野に特化した EQUATOR ネットワークライブラリに含めるための STROBE ステートメントの拡張 版を開発することを推奨する。これは、研究者や規制機関が研究の質を批判的に評価する際に大いに役立つであろう。

\*:症例対照研究では症例と対照について、また、コホート研究及び横断研究では、該当する場合には、ばく露群と非ばく露群について、別々に情報を提供する。

選択的報告は、有意性のない結果や注目されない有意な結果が公表されないことで起こる可能性がある。研究者は、 有意な結果やリスクの高い推定値の選択的報告を避けるべきである。この点では、疫学研究の報告の標準化は、選択 的な報告を減らすか回避するのに役立つであろう。STROBE 声明や同様の取り組みは、この目的のための有用なツ ールである。疫学研究の中には探索的でその場限りの性質を持つ研究もあるだろうが、これは出版物に明記されるべ きであり、選択的報告は最小限に抑えられるべきであり、そうすれば疫学研究の結果は最も適切な観点から解釈される (Kavvoura ら、2007 年)。

研究の事前登録とプロトコールの事前発表は、医薬品の臨床試験における報告バイアスと出版バイアスを減らすた めに、いくつかの雑誌の編集者と倫理委員会によって取られている措置である。観察による疫学研究についても、でき るだけ明白性をもって報告バイアスや出版バイアスを減らすことを実施するために、同様の提案がなされているが、疫 学者の間ではコンセンサスが得られていない(Pearce、2011年;Rushton、2011年)。これとは対照的に、優れた疫学 的実践を促進するための多くの取り組みが専門学会によって実施されてきた。例えば、国際疫学協会(IEA、2007年) やオランダ疫学協会の responsible epidemiologic Research Practice (DSE、2017年)などがその例である。

正式な疫学研究のデータの質の評価は、ばく露/影響の関連性についてのエビデンスを提供するか否かに関わらず、結果よりも個々の研究の方法論的特徴のみに基づいている。しかし、リスク評価においては、研究方法の質だけでなく、研究が提供する情報の質も評価することが重要である。実際、優れた研究であっても、正式な品質評価の際に、 情報の報告が不十分なために却下されてしまうことがある。

## 4.2. 研究デザイン

適切なばく露評価を行い、十分に実施された前向き研究は、最も信頼性の高い情報を提供し、バイアスがかかりにくい。前向き研究が利用可能な場合には、計画があまり強固でない研究の結果が追加的な裏付けとなることがある。前向き研究がない場合は、横断研究や症例対照研究の結果を考慮すべきであるが、慎重に解釈すべきである。しかし、 適切に計画された症例対照研究は、あまり適切に計画されていないコホート研究よりも優れている可能性があることは 認められている。解析的アプローチは研究デザインに合致したものでなければならず、必要とされる統計的手法の仮 定は慎重に評価されるべきである。

長期疾患の観察による研究は前向きであることが理想的であり、ばく露と健康影響との間の時間区分は、疾患の発症に要する時間に関して適切であるように計画されるべきである。がんや心血管疾患のように潜伏期間が長い(10年以上)ことが多い健康影響については、健康影響の評価に先立って複数回のばく露評価を行うべきである。免疫機能障害のような潜伏期間の短い他の健康影響では、適切な時間区分は数日から数週間の範囲であり、1回のばく露評価で十分であろう。要するに、研究の理想的な計画は、検討されている健康影響の潜伏期間に依存する。予測される潜伏期間は、追跡調査の長さとばく露量が定量化されなければならない頻度の両方を決定する。

## 4.3. 研究対象集団

EU の人口は 5 億人を超えており、かなり雑多であるため、低用量の農薬ばく露で影響を受ける可能性のある、より 感受性の高い個人が多数含まれていることが予想される。これに対処するために、層別サンプリングでは、いくつかの 主要な集団特性(性別、年齢、地理的分布、民族性、遺伝的変動など)に従って対象集団をサブグループに分割し、 各サブグループ内で無作為にサンプルを採取する。これにより、調査母集団の中でサブグループをバランスよく表現す ることができる。

次に、脆弱な集団は、小集団解析または感度分析のいずれかを用いて疫学研究で調査されるべきである。しかし、 そのような解析は事前に行う必要がある。事後的なサブグループ感度分析の場合、統計的閾値はそれに応じて調整さ れるべきで、結果の再現性はそれに従うべきである。脆弱な小集団のエビデンスは、理想的には、ばく露のバイオマー カー、前駆症状、経時的な疾患発生率の評価を含む前向き研究を必要とする。

多くの人が前臨床状態にあり、用量反応曲線の下端に敏感に反応してしまうため、集団における毒性による疾病の 増加の閾値を特定することは不可能かもしれない。このことを明らかにするためには、疫学データが、集団の広範な横 断面における化学物質ばく露と疾病リスクの関係を特徴づけ(あるいは前兆病変や重要事象を調べ)、低用量の傾きを しっかりと検討する必要がある。

脆弱な小集団に関連するエビデンスの程度に基づいて、用量反応評価が集団全体に焦点を当てるのか、一般集団 と影響を受けやすいサブグループに分けて評価するのかを検討すべきである。集団全体を対象とする場合、従来のア プローチでは、不確実性因子を用いて変動性に対処することになるが、毒性物質に反応して疾患のリスク分布がどのよ うに変化するかを評価することで、変動性のリスクへの影響を解析することも可能である。要するに、不顕性バイオマー カーに基づくリスク分布は、用量反応評価で捉えることができる毒力学的変動の表現である。

別のアプローチとしては、脆弱な小集団を一般集団とは別個のものとして扱い、その集団の実際の用量反応データ、 特定の薬物動態または毒物動態学的要因の調整、またはより一般的な補正や不確実性の要因に基づいた用量反応 モデルを用いて、その集団に固有の効果を割り当てることである。農薬については、特定の年齢層、疾患(または疾患 関連のエンドポイント)、遺伝的変異、または共ばく露が独特の脆弱性を生んでいることが分かっている場合には、一般 集団に対する効果の差を推定するよう努めるべきであり、それに基づいて、別個の効果を開発するか、または最も感受 性の高い集団または脆弱性のある集団に対する補正を加えた全体の集団に対する単一の効果をベースにすることを 検討すべきである。

## 4.4. ばく露評価の改善

疫学研究における農薬ばく露評価の困難さは、上記したように強調されている。農薬ばく露の記述(特に個々の農薬 へのばく露に関する定量的な情報)は、一般的に規制目的のためには十分な詳細が報告されておらず、特に潜伏期 間の長い疾患(多くのがんや神経変性疾患など)では、この限界を克服するのは困難である。

ばく露モニタリングを実施するために必要な方法は、申請者が申請書類の中で提出しなければならないことは注目 に値する。この規則の要求事項は、ばく露量の判定に使用できる有効な方法を要求している。欧州議会及び理事会の PPPの上市に関する規則(EC)No 1107/2009に基づき、有効成分のデータ要求を定めた欧州委員会規則(EU)No 283/2013 では、承認前の試験と承認後のモニタリングの両方をサポートするために必要な分析方法に関する情報が 記載されている。この文脈では、承認後の要求が最も有用性が高く、規則には実際に次の通りに記載されている。

'4.2. 承認後の管理及びモニタリング目的のための方法-方法は、以下の目的で提出されなければならない。

- a) 加盟国が確立された最大残留レベル(MRL) への準拠を決定できるようにするために、6.7.1 項の規定に従って 提出されたモニタリング残留物の定義に含まれるすべての成分の決定;これは、植物及び動物由来の食品及び飼料に含まれる、または上述の残留物を対象とする。
- b)7.4.2項の規定に従って提出された土壌及び水の残留基準をモニタリングする目的のための含有全成分の測定。
- c)申請者が、作業者、労働者、住民または居合わせただけの者(bystanders)のばく露が無視できる程度であること を示さない場合には、散布中または散布後に生成された有効成分及び関連する分解生成物の大気中の分析。

d) 体液中及び組織中の有効成分及び関連代謝物の分析。

これらの方法は、可能な限り、最も簡単な方法を採用し、最小限のコストで、一般的に利用可能な機器を必要とする ものとする。分析の特異性を確認し、報告されなければならない。それにより、モニタリング残留物の定義に含まれるす べての成分を測定できるようにしなければならない。必要に応じて、検証された測定法を提出しなければならない。方 法の直線性、回収率、精度(再現性)が測定され、報告されなければならない。

データは、LOQと残留可能性の高いレベル、またはLOQの10倍のいずれかで生成されなければならない。LOQ は、モニタリング残留物の定義に含まれる各成分について決定され、報告されなければならない。植物や動物由来の 食品や飼料中の残留物や飲料水中の残留物については、方法の再現性は、独立した試験施設のバリデーション(ILV) によって確認され、報告されなければならない。

このことから、要求事項は存在するが、食品や飼料中の残留物のモニタリングよりもとトのバイオモニタリングの方が やや厳しくないと結論づけることができる。

これらの既存の方法を使用しないと、特定の農薬の規制における疫学的証拠の使用の可能性が制限される。したが って、今後の研究を検討する際には、ばく露の誤分類を避けるために使用する手法を慎重に検討することが重要であ り、当該農薬について適切で詳細なばく露評価を行い、適切な用量反応分析を可能にし、使用された方法の妥当性を 証明することが重要である。

ばく露は、ばく露される生涯の期間に応じて、異なる健康影響を及ぼす可能性がある。ばく露評価がそのような重要 な時期に適切に対応していることを確実にすることで、疾患発症の可能性がある時期のばく露には、より大きな注意を 払う必要がある。これは、神経発達、肥満、アレルギー反応など、出生前または出生後早期に発生する複雑な多段階 の発達過程を伴う研究に特に関連していると考えられる。このため、単一の期間におけるばく露の測定では、環境因子 のすべての健康影響に対する関連ばく露を適切に特徴付けることができない可能性があり、したがって、環境因子に 対するいくつかの重要な生物学的に脆弱な期間におけるばく露を測定する必要がある可能性が生じてくる。化学物質 の範囲とばく露の強度及び研究範囲ではない他の物質とのばく露も含めた中で、現在のばく露とは異なる可能性があ る過去のばく露の評価を構築することは、特に困難である。

農薬ばく露を測定するすべての方法には長所と短所があり、特定の研究計画と目的は、特定の最適なアプローチを 通知するために慎重に考慮されるべきである。

観察による研究では、個人レベルのばく露評価は以下の方法を用いて改善することができる。

a)個人のばく露モニタリング:これは、測定装置を接触時での農薬濃度を記録するために使用することができる。個人用ばく露モニターは、研究参加者にとって高価で負担が大きいものであった。しかし、技術の進歩により、最近では大気中の浮遊物質ばく露のための個人ばく露モニターが安価で使いやすい装置になり、これらは集団研究に適している。農薬ばく露に特化した個人ばく露モニターには、空気中の濃度を測定するためのセンサー、経皮濃度を測定するための「皮膚」パッチ、他のばく露手段を測定するための塵埃を捕らえる屋内家庭用モニターなどがある。これらのモバイル技術の進歩は、詳細で強固なばく露評価がなされた観察による研究を提供するために利用することができる。このような機器は現在、大規模な集団研究や大規模なコホート研究からのデータを収集するために、ますます適応が増えている。これらは、ライフスタイルやその他の習慣を捉えるための携帯電話や携帯電話アプリケーションを介したリアルタイムのデータ転送などの他の技術的進歩と相まって、次世代の観察による研究では、現在のエビデンスと比較して、はるかに詳細で強固なばく露評価が可能になるだろう。しかし、膨大な量のデータを生成することは、組織的、統計的、技術的な課題、特に追跡調査時間の延長をもたらす可能性がある。倫理や個人データ保護の問題を考慮しなければならず、地域の規制により、このような技術の大規模な使用が妨げられる可能性がある。しかし、このような個人モニターの使用は、異なる潜在的なばく露経路のうちの1つの情報を提供するにすぎない。

b) ばく露のバイオマーカー(ヒト・バイオモニタリング(HBM))。代替的及び/または補完的なアプローチとして、異なる経路(経皮、吸入及び経口のばく露)を介したばく露の結果である内部ばく露量の確認がある。これらのバイオマーカーは、農薬への総体的なばく露を評価し、累積的なリスク評価に情報を提供する上で重要な役割を果たす可能性がある。バイオモニタリングには、検討対象の化学物質(親化合物または代謝物)またはその病態生理学的影響のマーカー(付加生成物など)の生体試料中の濃度を測定することが必要である。しかし、課題としては、生体試料中の濃度測

定値を関連する用量に外挿することに伴う不確実性が含まれる場合がある。

バイオモニタリングは異物の吸収量を確実に推定できる可能性があるが、現代の農薬とその代謝物は比較的迅速に 体内から排泄され、排泄半減期は通常数日で測定される(Oulhote 及び Bouchard、2013 年)。そのため、バイオマ ーカーの使用はそのため、バイオマーカーの使用は、資源を必要とし、かつ煩わしいものとなります。長期にわたるばく 露を監視するために、多数の人を対象に繰り返し実施しなければならない場合には、このプロセスはさらに煩わしいも のとなる。

とはいえ、吸収量の正確な積算値を提供できる可能性があるため、農薬とその代謝物の生物学的モニタリングは、ば く露評価の他のアプローチを調整するために有効に利用できる。このようなアプローチの例は、農業健康調査 (Agricultural Health Study)で使用されているものである(Thomas ら、2010 年;Coble ら、2011 年;Hines ら、 2011 年)。また、長いばく露履歴を構築するために、他の形態のばく露評価と組み合わせて HBM の手法を使用する こともできる。

バイオモニタリングは、ばく露の特性評価の精度を向上させ、環境に関連するばく露濃度で発生するばく露の変化を 調査することを可能にする。大規模なバイオモニタリング研究で収集されたデータは、今後の疫学研究におけるばく露 の分類を支援するための基準範囲を設定するのに有用である。また、バイオモニタリングデータは、リスク評価の改訂を 実施するための重要な情報を提供し、有害な健康影響に対して特別なリスクのある小集団を特定するのに役立つ。

生体試料他(Biobanks)は、生物試料の保管場所として、早期ばく露と遅発影響の関係を調査する目的で、ばく露のバイオマーカーを評価するために利用することができる。すなわち、生涯初期に発生したばく露が、生涯後期における疾患(神経行動障害、小児腫瘍、免疫毒性障害など)の発症に重要であるかどうかを調べ、現在の健康ガイドラインに沿って健康リスクを後ろ向きに評価することができる。

尿、血液、毛髪などのとトの試料中の代謝物レベルの測定結果だけは、実際に受けたばく露量を完全に把握できない。全身または組織・器官の総ばく露量を推定するためには、場合によっては生理学的毒物動態学(PBTK)アプロー チを用いた追加評価が必要となる。PBTK モデルは、化学物質の毒物動態を特徴づけるために使用される生理学的 なコンパートメントモデルであり、特にとトにおける化学物質の運命を予測するために使用される。各コンパートメント内 で化学物質が受ける血流速度、代謝及びその他のプロセスに関するデータは、PBTK モデルのマス-バランス・フレ ームワークを構築するために使用される。PBTK モデルは、外部ばく露を体内の内部(標的)ばく露量に変換するだけ でなく、バイオモニタリングデータから外部ばく露を推測するためにも使用することができる。さらに、PBTK モデルは検 証される必要がある。

毒物動態プロセス(ADME)は、標的に到達した有効成分の「内部濃度」を決定し、この濃度/用量を観察された毒 性効果と関連付けるのに役立つ。現行の規制でも試験実施が規定されているが、in vitro 試験、動物試験、ヒト試験な ど、有効成分の毒物動態に関するすべてのエビデンスを調査することは有益であろう。品質保証の問題や HBM 試験 に関連して考慮すべき要素についての更なる議論は、EFSA が委託したプロジェクトの報告書(Bevan ら、2017年)に 記載されている。

ばく露評価は、観察による研究における集団レベルでも、以下のような方法で改善することができる。

a)健康影響や農薬使用に関する登録データや大規模データベース(行政データベースを含む)から得られたデー タなど、新しい技術やビッグデータを利用した大規模な疫学研究は、より確かな知見が得られ、最終的には情報に基づ いた政策決定や規制に利用できる可能性がある。このようなデータは、維持管理が義務付けられている農家やその他 の専門的ユーザーなど、異なる集団による農薬使用の記録が含まれている可能性がある登録データの利用を中心に、 多くの努力が必要である%。このようなデータは、電子的健康記録(上記参照)にさらにリンクされ、これまでにないサンプ ルサイズ及びばく露とその後の病気に関する情報を持つ研究を提供し、最終的にはこれまで回答のなかった強固な問

<sup>9</sup> 規則 1107/2009 第 67 条は次のように述べている。記録の保持 1. 植物保護製剤(農薬)の生産者、供給者、流通業者、輸入業者及び輸出業者 は、自らが生産、輸入、輸出、保管又は市場に出した植物保護製剤(農薬)の記録を少なくとも5年間保管しなければならない。植物保護製剤(農 薬)の専門的使用者は、使用した植物防疫製品(農薬)の記録を少なくとも3年間、植物保護製剤(農薬)の名称、適用時間及び適用量、植物保 護製剤(農薬)が使用された地域及び作物を記載して保管しなければならない。これらの記録に含まれる関連情報は、要求があれば所轄官庁に 提供しなければならない。飲料水製造業界、小売業者又は住民などの第三者は、所轄官庁に連絡することにより、この情報へのアクセスを要求す ることができる。所轄官庁は、適用される国内法または共同体法に従って、当該情報へのアクセスを提供するものとする。

題に答えることができるようになるだろう。同時に、これらの登録や大規模なデータベースでは、有効成分に関する情報 をよりよく把握する必要がある。食品中の残留農薬ばく露は、監督下の残留試験と組み合わせて散布日誌データを使 用することで、より正確に推定することができる。この方法は、より包括的で強固な源データを含み、使用された農薬を より完全にカバーし、標準的な定量限界(LOQ)以下の残留物のより信頼性が高く正確な推定値を得ることができると いう利点がある(Larssonら、2017年)。

b) 地理的情報システム(GIS)や小地域調査への新しい高度なアプローチも、住居ばく露の推定値を提供する追加 的な方法として役立つかもしれない。GIS に基づくばく露指標(すなわち、農業用地への住居の近接性や住居周辺へ の影響のある農地面積)は、検証された場合、バイオモニタリングを補完する有用なツールとなる可能性があり、生物学 的半減期の短い農薬へのばく露を評価するために使用されてきた(Cornelis ら、2009 年)。このようなばく露の中には、 他の要因の中でも特に風向によって影響を受けるものがあるため、このアプローチを最大限に活用するためには、結 果の特別な分析を通じて、この点を考慮に入れる必要がある。また、これらの指標は、特定の指標ではないにせよ、生 物モニタリングデータよりも、長期にわたる非残留性農薬への累積ばく露のより代表的な指標となり得る(González-Alzaga ら、2015 年)。

すでに議論したように、個々の化合物の規制リスク評価に有用であるためには、疫学的ばく露評価は特定の農薬に 関する情報を提供すべきである。しかし、より一般的なばく露評価を含む疫学的研究は、一般的なリスク因子を特定し、 関連するとト集団における因果関係の推論を示唆する可能性もある。このような観察結果は、全体的な規制政策の情 報提供と、さらなる疫学的研究のための事項の特定の両方に重要であるかもしれない。

現代技術の最近の進歩により、新しい分析方法を用いて農薬ばく露を前例のない範囲で推定することが可能になった。

a)メタボロミクス(metabolomics)やアダクトミクス(adductomics)などのいわゆるオミクス技術の発展は、生物学的 マトリックス(血液、唾液、尿、毛髪、爪など)中に経時的に記録された異物や代謝物から、DNA やタンパク質との共有 結合体(アダクトミクス)や生物学的経路の理解に至るまで、幅広い分子の測定を通じてばく露評価を改善するための 魅力のある可能性を提示している。これらの方法論は、他のツールと組み合わせて使用することができる。また、このよ うな技術を規制毒性学に応用するには、さらなる研究が必要であるという認識と関心がある。エクスポソーム(exposome) (一生の間に個人が受けたばく露の全体)の利用は、「オミックス」技術とヒトのバイオモニタリングに適したバイオマーカ ーを使用することで、より良い結果を得ることができるかもしれない。それにもかかわらず、これらの方法論の検証が不 足していることと、大規模での使用を制限するコストのため、重要な制限が認められなければならない。

b)環境ばく露は従来「一回のばく露に一回の健康影響」というアプローチで評価されてきた。これに対して、エクスポ ソームは、受胎以降のヒト環境ばく露の全体を網羅しており、遺伝学の知識を補完することで、疾患の病因における環 境要因をよりよく特徴づけることができる。このように、エクスポソームには、生涯にわたる化学的ばく露だけでなく、感染 症、身体活動、食事、ストレス、内部生物学的因子(代謝因子、腸内フローラ、炎症、酸化ストレス)などの外部環境因 子や内部環境因子も含まれている。完全なエクスポソームを構築するためには、生涯にわたって継続的に異なる源か らの多くの外部ばく露と内部ばく露を統合しなければならない。しかし、真に完全なエクスポソームを測定することは不 可能である。エクスポソームのこれらすべての領域を従来のものとは異なるアプローチで捉える必要があるが、この目的 のためには単一のツールでは十分ではないと考えられている。

ばく露のより総合的なアプローチは、現在の疫学研究における従来の「一回のばく露-一回の健康影響」アプロー チに取って代わることを意図したものではない。しかし、それは複雑で多因子性の慢性疾患の予測因子、リスク因子、 保護因子についての理解を向上させるものである。エクスポソームは、生涯にわたる環境の影響やばく露を総合的に 記述し、統合する枠組みを提供している(Nieuwenhuijsen、2015年)。

これらの潜在的なバイオマーカーを検証し、最終的にはばく露評価の改善につなげるためには、共同研究や、大規 模なコンソーシアムを形成する疫学研究や探索的研究の統合が必要である。エクスポソームパラダイムを従来のバイオ モニタリング手法に組み込むことは、ばく露評価を改善する手段となる。エクスポソーム拡大関連研究(EWAS)は、健 康な人と病気の人の血液中の何千もの化学物質を測定し、病気との関連性を検査し、ばく露源を特定し、作用機序を 確立し、因果関係を明らかにするために、その後の調査で対象とすることができるばく露の有用なバイオマーカーを特 定することを可能にする(Rappaport、2012 年)。これらの主要な化学物質を特定し、症例と対照の独立したサンプル で疾患との関連性を検証した後、これらの化学物質は、大規模な集団からの血液を対象とした分析において、ばく露ま たは疾患進行のバイオマーカーとして使用することができる。

エクスポソームの概念に関連して、オミクス技術は複雑な化学物質の混合物への累積ばく露に対する生物学的反応 の特性やシグネチャーを測定する可能性を持っている。重要な進歩は、特定の生物学的試料中の個々のばく露を個 別に評価することなく、エクスポソームを特徴づけることができるユニークな生物学的マトリックスを特定することであろう。 オミクスデータの非標的特性は、ばく露に対する生物学的反応をより全体的な方法で捉え、ばく露に関連した健康影 響を裏付けるメカニズム論的な情報を提供することになる。重要なことは、オミクスツールは、多様なばく露がどのように して共通の経路で作用し、同じ健康影響を引き起こす仕組みを明らかにすることができるということである。

改良されたばく露評価は関連性を検出する力を高めるが、どのような個々の研究においても、各被験者のばく露評価を実施するために使用する供給源と被験者の総数のバランスを最適化することにより、研究の全体的な力を最大化することが必要である。

## 4.5. 健康影響

農薬については、これらの化学物質が単一の疾患領域に関連して特定の効果を示していないため、健康影響は広範囲にわたる。それぞれの健康影響について、文献には複数の定義が存在していて、程度の差こそあれ異なるデータベース間での再現性は不明であり、一般化できないという制限がある。健康影響の適切な定義は、観察による疫学研究の妥当性と再現性にとって非常に重要であり、これらの定義の一貫性と明確さは研究間で考慮する必要がある。前向きな観察研究では、明確な健康影響の定義、包含基準と除外基準、標準化されたデータ収集があるが、後ろ向き研究では通常、主にコード化されたデータに基づいた健康影響の同定に頼っており、疾患の分類とコード化は時間の経過とともに変化する可能性がある。主要な健康影響を定義するために使用された実際のコードの詳細な記述と検証作業の結果は、今後の研究活動にとって貴重なものである(Stang 6、2012 年; Reich 6、2013 年)。コード化された疾患の例としては、例えば ICD-10 があり、これは広範囲の悪性疾患を標準化するためのツールとして使用することができる。

いくつかのサーベイランス研究では、すべての潜在的な症例を特定するために感度の高いより広い定義を使用し、 その後、偽陽性の数を減らし、結果としてより正確な症例を得るために、高い陽性予測値のより狭く、より正確な定義を 適用することが望ましいとされている。対照的に、正式な疫学研究では、特定のイベントの定義が使用され、その精度 を決定するために検証される。しかしながら、「検証」では新たな定義をテストしないので、感度や特異度を測定できな いでだろう。

代替エンドポイントは、有効性が確認されていない限り避けるべきである。代替健康影響の妥当性を評価する基準に は、以下のようなものがある。

- ・代替指標が疾患の原因経路内にあることが示されていること。これは以下のエビデンスによって裏付けられる:バイオマーカーの反応が病理学と相関しており、他のバイオマーカーと比較して性能が向上していること;生物学的な理解と毒性との関連性(反応のメカニズム);メカニズム的に異なる化合物に対する一貫した反応と性、系統、種の違いによる類似した反応;用量反応の存在と反応の大きさと時間的関係;毒性に対する反応の特異性;すなわち、バイオマーカーは他の組織の毒性に対する反応や、標的臓器の毒性を伴わない生理学的効果を伴わない生理的効果を反映してはならない。
- ・代替健康影響と真の健康影響の両方を使用した少なくとも 1 つのよく実施された試験があること(Grimes 及び Schulz、2005年; la Cour ら、2010年)。これらの基準を評価するために、いくつかの統計的手法が使用されて、 それらが満たされていれば、代替指標の妥当性が高まる。しかし、多くの場合、不確実性が残っているため、疫学 研究に代替指標を適用することは困難である(la Cour ら、2010年)。

EU 全体の健康影響に関するデータは非常に広範囲に及ぶ可能性がある。これを効果的に管理することができれば、非常に大規模なサンプルサイズを用いて悪影響を評価する疫学研究において、より大きな統計力を発揮できる可能性がある。これらの研究に必要な前提条件は、新たな軽微な影響、慢性的な影響、または層別化した場合の小集団

への影響を検出する可能性があるが、リスク評価の範囲を超えている。これらの研究には、調和のとれた診断、データ 保存及び社会的利益のための匿名化された個人データへの法的に承認されたアクセスと相まって、健康情報学への 国境を越えたアプローチが含まれている。健康記録には、適切な中毒症候群の分類が含まれていなければならない。 後者は、入力データの品質を保証するために、医療と医療補助のトレーニングの改善を必要とするかもしれない。

生物学的モニタリングが採用されるもう一つの機会は、調査がいわゆる影響のバイオマーカーを含む場合である。こ れは、定量化可能な生化学的、生理学的、またはその他の変化であり、その大きさに応じて、確立された、または可能 性のある健康障害や病気に関連している。影響のバイオマーカーは、機能的または構造的損傷に先行する初期の生 化学的変化を反映している必要がある。このように、最終的に毒性につながるメカニズムの知識は、特定の有用なバイ オマーカーを開発するために必要であり、その逆もまた然りで、影響のバイオマーカーは、疾患の発生のメカニズムの 経路を説明するのに役立つかもしれない。このようなバイオマーカーは、生物学的システムにおける初期の可逆的な事 象を特定するものであり、後の反応を予測するものでなければならず、その性質上、前臨床的なものと考えられる。実 験的ーオミクス技術の進歩は有望であり、リスク評価戦略、すなわち作用機序、反応バイオマーカー、内部ばく露量の 推定、用量一反応関係に関する確かな情報を提供するだろう(DeBord ら、2015 年)。これらの技術は、その妥当性と 信頼性を評価するために検証されなければならない。妥当性が確認されれば、それらの技術は規制目的で利用できる ようになる。

## 5. 農薬リスク評価への警戒データの貢献

第2・4節で議論した正式な疫学調査に加えて、その他のヒトの健康データは、その場限りの報告書から、あるいは計画的なプロセスとして、すなわち公衆衛生当局や認可者によって国家レベルで実施されているモニタリングシステムを通じて、生成することができる。第2・4節に沿って、本節ではまず、このようなモニタリングシステムがどのように運用されるべきか、農薬のモニタリングに関する現状はどうなっているのか、そして改善のためにどのような勧告ができるのかをレビューする。

## 5.1. ケースインシデント研究の一般的な枠組み

有害事象の収集、報告、評価を継続的に行うことは、同じ有害事象が後から別の場所で発生する可能性を減らすことで、利用者やその他の人々の健康と安全の保護を向上させ、また、そのような事象の結果を緩和する可能性がある。 そのためには、当然ながら、収集した情報をタイムリーに発信する必要がある。このようなプロセスを警戒(vigilance)と呼んでいる<sup>10</sup>。

例えば、EU では、医薬品の安全性監視は医薬品安全性監視 (pharmacovigilance)して知られており、医薬品安 全性監視システムは、加盟国の規制当局、欧州委員会、欧州医薬品庁 (EMA)の間で運営されている。一部の加盟国 では、国内の管轄当局の調整の下に地域センターが設置されている。製造業者や医療従事者は、国レベルの管轄当 局に事件を報告する。これにより、有害事象に関するあらゆる情報が記録され、一元的に評価され、その後の対応につ いて他の当局に通知することができる。記録は EMA によって一元化され、欧州の医薬品安全性監視システムの調整 をサポートし、医薬品の安全で効果的な使用に関するアドバイスを提供する。

## 5.2. ケースインシデント報告の現在の枠組みの主な限界

いくつかの EU の規制では、ヒトに農薬が原因で発生した有害事象(職業環境での急性または慢性ばく露後に発生 したもの、偶発的または故意の中毒など)の通知及び/または収集及び/または報告を義務付けている。これらには 以下のものが含まれる。

・ EC 規則 1107/2009 の第 56 条は、「植物保護製剤(農薬)の認可を受けた者は、直ちに加盟国に通知しなけれ

<sup>10</sup> 調査という概念は、何かを測定し記録するための単一の努力を意味し、サーベイランスとは、疾病の不在を証明したり、疾病の存在や分布を特定して情報を適時に発信できるようにするために、集団の傾向を検出するために、標準化された調査を繰り返すことを意味する。モニタリングとは、集団の環境や健康状態の変化を検出するために、日常的な測定や観察を断続的に分析することを意味するが、反応を引き出すことはない。監視は、綿密かつ継続的に注意を払うプロセスを意味するため、監視や単なるモニタリングとは異なり、この背景では特に化学物質の使用に関連した販売後の事象を扱う。

ばならない」と規定している。この目的のために、認可保有者は、植物保護製剤(農薬)の使用に関連して、ヒト、動物及び環境におけるすべての疑われる有害な反応を記録し、報告しなければならない。通知義務には、国際機関や第三国の植物保護製剤(農薬)や有効成分を認可する公的機関による決定や評価に関する関連情報も含まれていなければならない。

・農薬の持続可能な使用を達成するための共同体行動の枠組みを確立した EC 指令 128/2009の第7条は、次のように要求している。加盟国は、作業者、農業労働者、農薬散布地域の近くに住む人など、定期的に農薬にばく露される可能性のある集団の間で、農薬による急性中毒事故や慢性中毒の発生状況に関する情報を収集するシステムを設置しなければならない。3.3.情報の類似性を高めるために、欧州委員会は加盟国と協力して、2012年12月14日までに「農薬使用がとトの健康と環境に与える影響のモニタリングと調査に関する戦略的ガイダンス文書」を作成する。しかし、この意見書を発表した時点では、この文書はまだ公表されていない。

間接的ではあるが、農薬と報告に適用される追加の規制が3つある。

- ・ 農薬の統計に関する EC 規則 1185/2009 は、加盟国が調和のとれたフォーマットに従って農薬の販売と使用に 関するデータを収集することを要求している。上市に関する統計は毎年欧州委員会に、農業利用に関する統計は 5年ごとに送信されなければならない。
- ・ 食品法の一般原則と要件を定めた規則(EC)178/2002 の第 50 条では、食品と飼料を対象とした改良・拡大され た迅速警報システム(RASFF)が設定されている。このシステムは欧州委員会によって管理されており、ネットワー ク加盟国、欧州委員会、当局が加盟している。それは残留農薬の認可されていない事例や食中毒の事例を報告 する。
- ・ EC 規則 1272/2008 (CLP 規則)第45条(4): EU 加盟国の市場に危険な化学物質の混合物を市場に出す輸入 業者と顧客ユーザーは、その加盟国の任命機関/毒物センターに通知書を提出しなければならない。通知書に は、化学成分や毒物学的情報、混合物が属する製品カテゴリーなど、混合物に関する特定の情報を記載する必 要がある。通知書に製品分類に関する情報を含めることで、指定団体/毒物取締センターは、同等の統計解析 (例えば、リスク管理措置の実施)を行い、報告義務を果たし、MS 間で情報交換を行うことができる。したがって、 製品カテゴリーは実際の緊急時の医療対応には使用されないが、ばく露や中毒の傾向を特定し、将来の中毒事 例を防ぐための対策をとることができる。正式に採択された場合、新規則は2020年1月1日から適用される。

実質的な立法規定がある一方で、今日までのところ、医薬品安全性監視システムに類似した単一の EU「植物薬理 監視」<sup>11</sup>システムは PPP には存在しない。むしろ、加盟国の公衆衛生にリスクをもたらす可能性のある化学物質のハザ ードについて警告、通知、報告、情報共有を行うための多くの警告システムが EU 内で開発されている。これらのシステ ムは、医薬品、食品、消費者製品、労働災害、国際保健規則(IHR)に基づく通知、EU 毒物センターや公衆衛生当局 によって検知した事象など、さまざまな分野をカバーしている。これらのシステムのそれぞれは、管轄官庁、公的機関、 政府、規制当局、公衆衛生当局にタイムリーな警告を通知し、配布して、公衆衛生へのリスクを最小限に抑え、管理す るための効果的な行動をとることを可能にしている(Orford ら、2014 年)。

EU では、急性農薬ばく露・事故に関する情報は、主に毒物管理センター(PCC)によって収集・報告されたデータに 基づいている。PCC は、一般集団や職業環境において、自分たちが知っている急性と慢性のばく露/中毒の両方の 事例を収集している。通常、症例は十分に文書化されており、情報にはばく露・事故の状況、原因物質と疑われるもの の説明、ばく露のレベルと期間、臨床経過と治療、因果関係の評価が含まれている。重症の場合は、通常、血液や尿 中の毒素や代謝物の測定が行われる。しかし、センターに報告された症例の追跡調査は、長期化する可能性のある影 響を特定するために、さらに注意を払う必要がある。

毒物センターのデータを使用するには、2 つの重要な障害がある:各国の毒物センターからの報告書は常に公表さ

<sup>&</sup>lt;sup>11</sup>「フィトビジランス(phytovigilance)」は植物に対する警戒システムを意味し、農薬は作物の「薬」であることを意図しているため、ここでは「フィト ファーマコビジランス(phytopharmacovigilance)」という用語がより適切であると考えられている。さらに、フランスでは、土壌、水、大気、環 境、動物のデータなどをカバーする広い用語として使われている。

れているわけではなく、公表されている場合でも、データ収集の形式やコーディング、因果関係の評価には大きな不均 一性がある。実際、各加盟国は独自の収集活動のためのツールを開発しており、ばく露データの比較や交換には困難 が伴う。2012 年、欧州委員会は、新たな化学物質事象への欧州の対応を支援するための共同研究開発プロジェクト 「化学物質健康脅威のための警告・報告システムフェーズ III(ASHTIII)プロジェクト」に資金を提供した。検討された 様々なツールや方法論の中で、欧州の PCC からのばく露データを交換・比較する方法が開発された。実現可能な研 究として、ワークパッケージ 5 には、加盟国が農薬ばく露データを比較できるようにするための、調和のとれた強固なコ ード化システムの開発が含まれていた。しかし、PCC コミュニティとの協議の結果、データのコーディングと収集活動の さらなる調整が必要であることが示された。その結果、ばく露データを加盟国間で比較できるようにするためには、EUと 加盟国レベルでの更なる支援と調整が必要であると結論づけられた(Orford ら、2015 年)。

PCC が収集したデータに加えて、いくつかの加盟国は、労働衛生監視に特化したプログラムを立ち上げた<sup>12</sup>。これら は、業務上の農薬による傷害や病気、中毒が疑われる症例について、医師による自発的なイベント通知(使用者による 自己申告の場合もある)に基づいている。医療データに加えて、収集された情報には、作物の種類、散布方法、温度、 風速、個人用保護具の着用状況などに関するデータが含まれる。一度収集されたこれらのデータは調査され、定期的 に報告書が発行され、再登録中の製品の安全性を評価するための有用な情報となる。これらのデータはまた、新たな 問題を浮き彫りにし、政策立案者のためのエビデンスに基づく予防措置を策定することを可能にする。EU レベルでは、 欧州労働安全衛生庁(EU-OSHA)<sup>13</sup>は、職業上の農薬関連疾病データのモニタリング方法をほとんど持っていない。 米国では、国立労働安全衛生研究所(NIOSH)が資金を提供し、農薬に特化したプログラムがいくつかの州で実施さ れている<sup>14</sup>。

要約すると、現在、ヒトのデータは、症例報告書や症例集積、毒物センターの情報、検視官の裁判結果、労働衛生 監視プログラムや市販後の監視プログラムの形で収集されている。しかし、申請者が提出した医療データには、このよう な情報がすべて含まれているわけではない。これは、さまざまな情報源が多様で異質な性質を持っているため、アクセ スできないものもあるためである。

- ・工場生産労働者の労働衛生監視を通じて収集されたデータ、あるいはそれが行われたとしても、医療データは非常に限られており、一般的には基本的な臨床血液測定、身体検査、潜在的にはどこでどのようにばく露されたかという単純な指標であり、通常は長期的なフォローアップは行われていない。さらに、最新の工場(特に EU)での労働者のばく露は一般的に非常に低く、多くの場合、潜在的なばく露は(特定の化学物質に特化した施設でない限り)様々な農薬へのばく露である。
- ・さらに、製造中の有効成分への職業上ばく露からのデータの報告は、しばしば調合された植物保護製剤(農薬)との接触から生じる観察結果と組み合わされる。実際、植物保護製剤(農薬)中の共配合剤の存在は、急性毒性学的プロフィルを変更することができる。したがって、適切な評価を容易にするために、ヒトで収集した結果を報告する際には、それ自体が有効成分なのか PPP なのかを明確に特定しなければならない。

EC 規則 283/2013 の第 5.9 章の一部でもある有効成分や配合された植物保護製剤(農薬)や提案された治療法に よる中毒の診断に関する特定のデータの要求に関しては、情報が欠落していたり、毒性作用のモードがとトで起こること が知られていて特定の解毒剤が特定されている場合に限定されていたりすることがよくある。

### 5.3. ケースインシデント報告の現行枠組みの改善提案

重複と努力の無駄を避けるために、論理的な次のステップは、すべての関係する公的部門と民間部門の関係者と一 緒に、医薬品のために実施されているものと同様の化学物質のための EU の「植物薬理監視」システムを開発すること であろう。このネットワークは、献身的で特別な訓練を受けた地方の産業保健医や開業医を基盤とすることができ、シス テムを確立し、成功裏に維持するために加盟国が供給源を配分すべきである。実際、このようなネットワークは急性の 影響を検出するのに有用であろう。また、特定の健康影響(喘息、感作など)や新たな職業関連疾患の検出のためのセ ンチネルサーベイランスネットワークとしても機能するであろう。実際、このようなシステムを段階的に構築する方法につ いては、すでに多くの経験が得られているが、それにもかかわらず、これが実施されるまでには何年もかかることが想定 されている。収集されるデータの特性(情報源は多様である可能性がある)、収集された情報の質と完全性(特に状況)、 観察された効果の重症度と説明責任(観察された効果と製品との間のリンク)など、いくつかの困難が生じる。ルールは、 ある「評価者」から別の「評価者」まで同一であるように定義されなければならない。植物薬理監視システムが目的に完 全に適合していることを保証するために、ネットワークは長期的に安定していなければならない(例えば、関与する国の 組織の継続性、採用された一貫した方法論など)。植物薬剤モニタリングデータの使用は、リスク評価の目的に限定さ れることはなく、リスク管理上の政策決定(例えば、製品認可の条件の改定や最終的には製品の取り下げなど)に影響 を及ぼす可能性があるが、これは最初からすべての利害関係者に明確でなければならない。

このようなシステムは、(主に)農薬として使用されている化学物質のみを対象としたものでは意味がないかもしれない。しかし、すでに農薬に関する法律の規定があることを考えると、このシステムの開発は農薬に優先して行われる必要があるかもしれない。

結論として、欧州委員会は加盟国とともに、EU 全体の農薬の警戒枠組みの開発に着手すべきである。これには以下が含まれるべきである。

- ・EUレベルでのヒトでの健康影響データ収集活動の調和
- ・ EU 全体のデータベースの編集の調整
- ・各加盟国で発生したすべての PPP 中毒を収集するために、各国レベルでのポイズンセンターと規制当局との連携を改善すること
- ・因果関係のデータ評価の整合化を伴う農薬使用がとトの健康に及ぼす影響のモニタリングに関するガイダンス文書
- ・ EU 全体を対象とした定期的な報告書

## 6. 農薬のリスク評価を支援するための疫学研究と監視データの利用の提案

本節では、実験的研究に基づくリスク評価プロセス(第 6.1 節)を概説し、そのプロセスに疫学的研究がどのような情報を付加しうるかを論じる。次に、第 6.2 節では、疫学研究の信頼性の評価について述べる。6.3 節では、信頼性があると認められた1つ以上の研究の関連性を評価する。

#### 6.1. リスク評価プロセス

リスクアセスメントとは、健康に悪影響を及ぼす可能性のある化学物質やその他の汚染物質、薬剤によるヒトや環境 へのリスクを評価するプロセスである。規制目的のために、リスク管理者に情報を提供するために使用されるプロセスは、 4 つのステップで構成されている(EFSA、2012 年 a)。一方では、毒性影響の特性(ハザード同定)と、農薬と毒性影 響の間に考えられる用量反応関係(ハザード特性評価)に関する情報が収集される。一方で、ヒト(消費者、散布者、労 働者、居合わせただけの者、住民)と環境へばく露可能性についての情報が求められる(ばく露評価)。これら2つの要 素は、集団が基準ばく露量を超える量にばく露される可能性があることを推定するために、リスク特性評価の中で考慮 される。通常、これは規制目的のためのリスク管理者への情報提供に用いられる。

#### a) ステップ 1. ハザードの同定

疫学的研究と監視データは、農薬ばく露と健康影響とが関連する可能性を示すことができるため、ハザードの特定 に関連している。この背景では、疫学的データは、実験モデルでは検出されなかった影響を「ホライズン・スキャニング」 する上で、非常に貴重な情報を提供することができる。重要なことは、これらの研究はまた、脆弱な集団のサブグループ、生涯における感受性の高い時期、性別による選択的影響など、リスクが高まる可能性についての情報を提供することである。

b) ステップ 2. ハザードの特性評価(用量反応評価)

前述したように、通常、疫学的データを使用する場合には、ばく露量が割り当てられることはほとんどないため、古典 的な用量反応の枠組みは考慮されない。質の高い疫学研究が利用可能な場合の課題は、それらを数値入力としてス キームに統合するのが最善かどうかを見極めることである。農薬のリスク評価に疫学的データを使用する場合、用量反 応フレームワークが考慮されることはほとんどない。しかし、EFSA CONTAMパネルのこれまでの科学的見解では、基 準ばく露量を設定するための基礎として疫学を使用してきた、特にカドミウム、鉛、ヒ素、水銀の場合は、最もよく知られ ていてデータが豊富である(EFSA、2009年 a,b、2010年 b、2012年 b)。これらが用量反応評価の基礎とならない場 合でも、監視と疫学的データは、実験動物を用いた用量反応研究の妥当性を検証したり、無効にしたりするための裏 付けとなるエビデンスを提供することがある。化学物質の様々な用量とばく露された集団における有害な影響の発生率 との間の関係を特性評価するためには、ばく露または用量の特性評価、反応の評価、無影響量を特定するために観察 されたデータが適合する用量反応モデルの選択が必要である。2 つの課題が提起される。すなわち、無影響量を特定 するために、疫学的データから用量反応を導き出すことができるのか、ということである。もしそうでない場合、疫学的情 報はハザードの特性評価に貢献できるのか、ということである。

用量反応関係を理解することは、EU の優れた植物保護対策が予想されるよりも高いばく露量の使用による有害な 健康影響が関連していることが証明されるが、低いばく露量の使用では関連性が観察されない。この背景では、RR ま たは OR を明らかにした疫学研究の統計的要約は、研究デザインが必要な基準を満たしている場合には、ハザード特 性評価プロセスに投入するための有用な定量的情報となる可能性があることは明らかである。

c) ステップ 3. ばく露評価

ばく露の評価に関するデータは、制御されていない様々な「実社会」の要因が解析を混乱させる複雑な状況では、 推定が困難なことが多い。前述したように、現代の生物学的モニタリングは、コストの高さ、実施可能性、ロジスティック スなどの実際的な理由から、一般のヒト集団ではほとんど実施されていない。しかし、近い将来、農薬への定量的ばく 露に関する生物学的モニタリング研究やデータが増加することが予想されている。

ステップ 4. リスクの特性評価。この最後のステップでは、ばく露に関するデータを健康ベースの基準値と比較し、ば く露された集団における健康障害のリスクを推定する。ヒトのデータは、標的臓器、用量反応関係、毒性影響の可逆性 に関する完全な毒性学的データベースからの外挿に基づいて行われた推定の妥当性を検証するのに役立ち、基準値 の定義に直接影響を与えずに外挿のプロセスを再確認するのに役立つ(London ら、2010 年)。

疫学的データは、不確実性因子(UF)との関連で考慮されることもある。一般的に動物データでは、影響の種間変 動を考慮するために 10 の UF が使用され、これにさらに 10 の係数を加えてヒト集団の異なる部分の感受性の変動を 考慮する。しかし、ヒトのデータのみを考慮する場合(動物のデータよりも重要な場合)もあり、種族間のばらつきを考慮 した 10 の係数が適用される。現時点では、規則(EC)No 1107/2009 の第4条(6)が次のように規定していることに留 意する。「ヒトの健康に関連して、ヒトから収集したデータがない場合、動物試験に由来する安全マージンを低下させて はならない」と規定している。このことの意味するところは、リスク評価において疫学的データはリスク評価で使用される 警戒レベルを高めるためにのみ使用され、関連するヒトのデータが入手可能であっても UF を低下させるために使用さ れてはならないということである。

#### 6.2. 個々の疫学研究の信頼性の評価

WOE 評価のために疫学をどのように考慮すべきかを決定する際に考慮すべき因子は以下に記載されており、観察 疫学的研究のためのバイアスのリスクツールで広く概説されている<sup>15</sup>。以下の例は、網羅的なリストではないが注目すべ

<sup>&</sup>lt;sup>15</sup> 介入またはばく露の観察研究におけるバイアスと交絡因子のリスクの評価。RTI アイテムバンクのさらなる発展 (https://www.ncbi.nlm.nih.gov/books/NBK154464/)とコクランハンドブック。

き因子を示している。

- ・研究デザインと実施。研究デザインは、ばく露と健康影響及びリスクのある集団の予想される分布を考慮して適切 なものであったか?その研究は主に仮説生成モードまたは仮説検証モードで実施されたか?
- ・集団。研究は、十分に定義された集団から目的の個人をサンプリングしたか?研究は、ばく露群と非ばく露群の健 康影響について有意な差を検出するのに十分な統計力と精度を有していたか。
- ・ ばく露の評価。ばく露の評価に使用された方法は有効で、信頼性があり、適切であったか? 広範囲のばく露が調 査されたか? ばく露は定量的レベルで評価されたのか、それともカテゴリカルまたは二分法(例:経験対未経験)で 評価されたのか? ばく露は前向きに評価されたか、あるいは後ろ向きに評価されたか?
- ・健康影響の評価。健康影響の評価に使用された方法は有効で、信頼性が高く、適切であったか?健康影響に関 するデータ収集には標準化された手順が用いられていたか。情報の偏りを避けるために、健康影響はばく露状態 とは独立して把握されていたか?
- ・交絡因子の管理:潜在的な交絡因子が適切に特定され、考慮されていたか?それらはどのように管理されていた か?これらの因子を記録するために使用された方法は有効で、信頼性があり、適切であったか?
- ・統計解析。研究は、対象となる健康影響に対するばく露の独立した影響を定量的に推定したか?データの解析に おいて交絡因子が適切に管理されていたか。

・研究の報告は適切であり、透明性の原則とSTROBE 声明(または同様のツール)のガイドラインに従っているか。

研究の評価は、それぞれの研究が持つ可能性のある潜在的な限界の特性と、疫学的データベースの全体的な整合 性の評価を示すものでなければならない。

さらに、他の既知のリスク因子に関する健康影響の特性と特異性は、リスク評価目的のためのヒトデータの評価に影響を与える可能性があり、特に誘発期間や潜伏期間の長い慢性的な影響のような複雑な健康エンドポイントの場合には、その評価に影響を与える可能性がある。

表 2 は、単一の疫学研究で評価すべき主なパラメータと、各パラメータの関連する程度(低、中、高)を示している。 特定の科学的考察はケースバイケースで適用されるべきであるが、これらの基準を厳格かつ明確な方法で実施するこ とは非現実的である。

パラメータ	高	中	低
試験のデザ インと実施	前向き研究 特定の仮説(化合物と 健康影響の特定)	症例対照研究。ばく露または 健康影響評価を十分にカバー していない前向き研究	横断、生態学的研究 症例対照研究では、ばく露や健康 影響評価が十分にカバーされて いない
集団	ランダムサンプリング。十分な検出 力を保証するのに十分な大きさの サンプルサイズ	疑わしい研究検出力、詳細に 正当化されていない	研究集団の選定方法についての 詳細な情報がない
	母集団の特性が十分に把握されて いる(脆弱なサブグループを含む)	標的集団の代表的なサンプル ではない 母集団の特性が十分に解明さ れていない	母集団の特徴が十分に解明され ていない
ばく露評価	検証された方法を用いた正確かつ 精密な定量的ばく露評価(ヒトのバ イオモニタリングまたは外部ばく 露) 被験者が回答した化学物質ばく露 に関する有効なアンケート及び/ま たはインタビュー	特定のマトリックス中の非有 効なサロゲートまたはバイオ マーカーと外部ばく露 被験者または代理人が回答し た化学物質ばく露に関するア ンケート及び/またはインタ ビュー	乏しいサロゲート 質の低いアンケート及び/また はインタビュー;化学物質のグル ープについて収集された情報 化学物質に特化したばく露情報 は収集されていない;農薬の使用 の有無の一般的な評価
健康影響評 価	有効で信頼性の高い健康影響評価 研究集団において標準化され、妥当 性が確認されていること カルテまたは診断結果が記載され	標準化された健康影響、母集 団で有効性が確認されていな い、またはスクリーニングツ ール、またはカルテが不明確	標準化されていない、検証されて いない健康影響 不適切な健康影響、または自己報 告された健康影響

(a):パラメータ全体の総合的な評価に基づく総合的な研究品質ランキング。

(b): Muñoz-Quezadaら(2013)とLaKindら(2014)を順に引用したUS-EPA(2016)からの引用。

上記の評価が、疫学研究が評価され定量的にまとめられているエビデンス総合演習の一部である場合、農薬ばく露 に関連する絶対的リスクをより正確に推定し、さらに定量的なリスク評価を行うことが可能となる。

農薬疫学データの場合には、バイアスのリスクと信頼性に関してヒトデータを整理するための第一段階として、3 つの 基本的なカテゴリーが提案されている<sup>16</sup>。(a)バイアスのリスクが低く、信頼性が高い(上記の品質要因のすべて、また は大部分が軽微な方法論的限界で対処されている);(b)バイアスのリスクが中程度で信頼性が中程度(上記の品質要 因の多くが中程度の方法論的限界で対処されている);(c)バイアスのリスクが高く、信頼性が低い(結果の妥当性を低 下させる、または潜在的な因果関係をほとんど解釈できない、といった重大な方法論的限界や欠陥があるため)。後者 の研究は、主にばく露評価の不備、ばく露及び/または健康影響の誤分類、または関連する交絡因子の統計的調整 の欠如により、リスク評価には受け入れられないと考えられている。リスク評価は、十分に定義されたデータ品質基準を 満たしていない疫学研究の結果に基づくべきではない。さらに、予備的研究の結果は、リスク評価に使用する前に、将 来の研究で確認する必要がある。

### 6.3. 疫学研究のエビデンスの強さの評価

このセクションでは、農薬ととト健康影響との関連性に関する様々な疫学研究から得られた結果を組み合わせて要約 することに関連したいくつかの重要な問題について簡潔に論じている。

疫学研究の重み付けのアプローチは、主に修正された Bradford Hill 基準に基づいている。これは、事象と起こりえる結果(強さ、一貫性、特異性、時間性、生物学的勾配、妥当性、統一性、実験と類推)との間の潜在的な因果関係を示すエビデンスを提供する条件のグループである(表 3)。明らかに、これらの基準を満たせば満たすほど、意味のある

<sup>16</sup> これらのカテゴリーは、現在 EFSA が農薬有効成分のピアレビューに使用している、許容可能、補助的、非許容のカテゴリーに準拠している。www.efsa.europa.eu/efsajournaEFSA Journal 2017;15(10):5007

関連性の証拠としてその関連性を提起する根拠が強くなる。しかし、Bradford Hill は、因果関係とは何かを明確にすることを目的とせず、基準を十分に、あるいは絶対的に必要なものとしてかんがえず、単に常識的な評価の中で考慮することが重要であると考えている。

表 3:エビデンス統合のための修正された Bradford Hill 基準に基づく WOE	解析の考察
---	-------

カテゴリー	考察事項
関連性の強さ	関連性の強さ(関連性の大きさだけでなく、統計的有意性も)の評価には、基礎となる方法の 検討、文献の WOE との比較及びここで議論されている他の基準を含む他の背景的要因の考慮 が必要である。
関連性の一貫性	関連性は、複数の独立した研究、特に異なる計画で、異なる状況下で異なる集団で実施された 研究において一貫性があるべきである。この基準は、現代のデータ統合に照らして、すべての エビデンス系統(疫学、動物実験、in vitro システムなど)にまたがって一貫性のある結果に も適用される。
特異性	特定の結果をばく露に結びつけるエビデンスの独自の基準は、因果関係についての強力な議 論を提供できるようになり、データ統合の背景の中で新たな興味深い意味合いを持つように なったかもしれない。データの統合は、複雑なばく露に関連した様々な結果の中から、いくつ かのメカニズム論的な特定性を明らかにするかもしれない。特異性の欠如は、疾患に関連する 特異的な薬剤を絞り込むのに役立つかもしれない。
時間性	薬剤へのばく露と適切な時間枠内での影響の出現との間の時間的順序のエビデンスは、因果 関係を支持する最良の論拠の一つを構成する。このように、2つの尺度間の時間的進行を確実 にする研究デザインは、因果関係の推論においてより説得力がある。
生物学的勾配(用量反 応)	より大きなばく露またはばく露の持続時間に関連した影響の増加は、因果関係を強く示唆し ている。しかし、その不在は因果関係を排除するものではない。
生物学的妥当性	実験的エビデンスに基づいた生物学的に信憑性のあるメカニズムによって説明され、支持されたデータは、関連性が因果関係にある可能性を強化する。しかし、メカニズム論的データの 欠如は因果関係に反するエビデンスとして捉えられるべきではない。
統一性	エビデンスの解釈は理にかなったものでなければならず、ばく露-疾病パラダイムの下で問題となっている健康影響の生物学について知られていることと矛盾するものであってはならない。もしそうであれば、ヒトに最も近い種の方がヒトとの関連性が高いと考えるべきである。
実験的エビデンス	無作為化実験の結果は、他の研究デザインに基づく結果よりも因果関係の強いエビデンスを 提供する。あるいは、非実験的研究からの関連は、関連から導き出された無作為化予防が結論 を導く場合には、因果関係があると考えられる。
重要事象の結果	特定の健康影響について確立された MOA/AOP の基礎となる重要事象(すなわち、in vitro、 in vivo、またはヒトのデータ源を組み合わせた測定可能なパラメータ)をそれぞれ明確に説明 する。完全に解明された MOA/AOP は、ヒト健康リスク評価に疫学研究を使用するための要 件ではない。

Höfler (2005)、Fedak ら (2015) 及び US-EPA (2016) からの引用。

予測的因果関係については、「事象 Y が事象 X の後に続いたので、事象 Y は事象 X によって引き起こされたに違いない」という論理的誤謬を避けるために注意を払わなければならない。Höfler (2005 年) は、より正確な「反事実」の定義を次のように引用している:「しかし、E があれば、D は発生しないか、発生しなかっただろうが、E があれば発生するだろう/しただろう」。しかし、記号論理を用いたより詳細な記述もある (Maldonado 及び Greenland、2002 年)。Rothman 及び Greenland (2008 年) は、「反事実効果の唯一の必須条件は、原因が効果に先行しなければならないという状態である」と述べている。結果または「影響」として提案された事象がその原因に先行している場合、事象間の関連性はあるかもしれないが、因果関係は確かにない」と述べている。

## 6.3.1. 疫学的証拠の統合

観察による研究のシステマティックレビューとメタアナリシスは、農薬の潜在的なハザード、ばく露反応の特徴、ばく露 シナリオとばく露評価の方法、そして最終的にはリスクの特性評価の理解を強化する情報を提供することができる(van den Brandt、2002 年)。システマティックレビューは、特定のトピックに関するすべての関連研究を特定し、評価し、統 合することでバイアスを低減することを目的とした、詳細で包括的な計画と事前に定められた検索戦略を伴う。システマ ティックレビューの主なステップは以下の通りである:研究課題の策定、包含基準と除外基準の定義、異なるデータベ ースにまたがる研究の検索戦略、事前に定めた戦略に従った研究の選択、データ抽出とエビデンス表の作成、選択した研究の方法論的品質の評価、バイアスのリスクを含めた評価、データの統合(研究が許せばメタアナリシスを行うこともできる)、結果の解釈と結論の導き出し(EFSA、2010 年 a)。しかし、農薬疫学の分野では、標準化と調和が困難であるため、エビデンスの統合は困難である。それにもかかわらず、疫学研究の強固性と妥当性を評価する上で、エビデンス統合は極めて重要な役割を果たすべきである。

このエビデンスの評価に役立つ統計ツールが開発されている。ほぼ同一のばく露と転帰に関する複数の研究が利 用可能な場合、これらの研究は重要な科学的証拠を提供することができる。ばく露と転帰が研究間で定量化され、調 和されている場合には、類似した計画の個々の疫学研究からのデータを組み合わせることで、より正確なリスク推定値 を得るのに十分な検出力を得ることができ、不均一性の評価を容易にすることができる。適切なシステマティックレビュ ー及びエビデンスの定量的な統合を定期的に行う必要がある(例えば、世界がん研究基金のがんリスク因子のメタアナ リシスの継続的な更新のためのアプローチ<sup>17</sup>)。研究は、以前に発表された観察による研究の基準に従って評価され、 可能性のある選択バイアス、測定誤差、サンプリング誤差、異質性、研究デザイン及び結果の報告と提示について慎 重に検討されるべきである。

メタアナリシスとは、一般的に、異なる研究で報告された結果を組み合わせて比較するための統計的手法の集積を 示すために使用される用語である(Greenland 及び O'Rourke、2008 年)。メタアナリシスの技術は、小さな研究効果 や過剰な有意性バイアスなど、研究分野における多様なバイアスの存在を調べるために使用されることがある。しかし、 メタアナリシスは、各研究デザインに関連している可能性のある根本的なバイアスを克服するものではない(すなわち、 交絡、想起バイアス、または他のバイアスの原因が排除されない)。システマティックレビューやメタアナリシスが農薬の 影響について結論を導き出すことができる範囲は、含まれた研究から得られたデータや結果が有効かどうか、つまり検 討された研究の質に大きく依存する。特に、一貫したバイアスの結果として、オリジナルの研究間で一貫した結論が得 られれば、システマティックレビューでは偏った結論が得られることになる。同様に、無効な研究のメタアナリシスでは、 誤った影響推定値に狭い信頼性間隔が生じるなど、誤解を招く結果になる可能性がある。

レビューされた文献の基本的な研究の特徴を要約することに加えて、典型的なメタアナリシスには以下の要素が含まれるべきである。(a)対象となる各健康影響の平均影響量と影響量分布及び影響量分布の不均一性の検討(b)影響 量分布に存在する変動性を系統的に解析し、効果量の大小に関連する研究の特徴を特定するサブグループ解析(c) 引き出された結論の妥当性を評価するための出版バイアス解析及びその他の感度分析(Wilson 及び Tanner-Smith、 2014 年)。

メタアナリシスでは、基礎となる研究集団の影響量分布を適切に記述するモデルを指定することが重要である。意味のある影響量分布を用いたメタアナリシスは、定量的リスクをリスク評価モデルに統合するのに役立つ。従来の正規の固定影響モデル及びランダム影響モデルは、パラメータと共変量に条件付きで正規の影響量母集団分布を仮定している。このようなモデルは、全体的な影響量を推定するのには適切かもしれないが、影響量分布が非正規の形状を示す場合には予測には確実に適していない(Karabatsos 6、2015 年)。

## 6.3.2. 研究間の異質性を探索するツールとしてのメタアナリシス

異なる研究の結果を評価する際には、多くの側面を慎重に評価すべきである。メタアナリシスを行う研究者は、調査 の範囲を、考慮した研究を平均した関連性の大きさの結果に限定する傾向があります。その動機は、多くの場合、考慮 した研究を平均した関連性の強さの決定に限定する傾向がある。影響の個々の推定値は偶然性によって変化するた め、ある程度のばらつきは予想される。しかし、推定値は意味のある場合にのみ要約されなければならない。見落とさ れがちな重要な側面として、サブグループを超えた個人間の関連の強さの不均一性がある。研究間の不均一性は評 価され、存在する場合には定量化される必要がある(Higgins、2008 年)。メタアナリシスでは、異なる研究からの結果 の間の不均一性は、同質性と同じくらい有益であるかもしれない。観察された結果の矛盾の根底にある理由を探ること

#### は、一般的に大きな理解につながる。

図1は、3つの農薬(A、B、C)のそれぞれが2つの研究のメタアナリシスで評価されている仮想例の3つのフォレストプロットを示している。各農薬の両方の研究が、最高の品質と科学的な厳密さを持っていると仮定している。バイアスが疑われない。

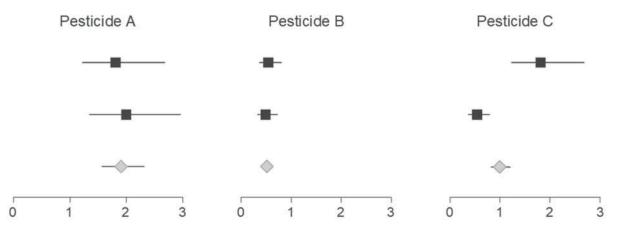

図 1:3 つの農薬(A、B、C)のそれぞれが 2 つの研究のメタアナリシスで評価されている仮想例のフォレストプロット。 各プロットの x 軸は、ばく露した個体とばく露していない個体を比較した、対象疾患の推定リスク比を表している。 四角は各研究における推定リスク比を示し、灰色のダイヤモンドは要約されたリスク比を示している。横線は 95%信頼区間を示す。

以下の文章には、図1の結果の解釈について、農薬を1つずつ、短くコメントしている。

- ・ 農薬 A へのばく露は、病気のリスクを2倍にするようである。結果は2つの研究の間で一致しており、信頼区間には帰無値である1が含まれていない。しかし、これらの結果は、(a)同じばく露と疾患について実施された他の研究では、リスク比が約2であること、または(b)個人のどのグループ(例えば、男性か女性か、若年者か高齢者)でもリスク比が2であることを暗示するものではない。
- ・ 農薬 B へのばく露は、病気のリスクを半減させるようである。結果は2つの研究の間で一致しており、信頼区間 には帰無値である1は含まれていない。しかし、これらの結果は、(a)同じばく露と疾患について実施された他 の研究では、(a)リスク比が約半分になること、または(b)個人のどのグループ(例えば、男性か女性か、若年者 か高齢者か)でもリスク比が約半分になることを暗示するものではない。
- ・ 農薬 C へのばく露は、一方の研究では病気のリスクが2 倍になり、他方の研究ではリスクが2 分の1 になるよう である。結果は2 つの研究の間で矛盾しており、また、信頼区間には帰無値である1 が含まれていない。しか し、これらの結果は、(a)同じばく露と疾患について実施された他の研究では、リスク比が約1 であること、また は(b) 個人のどのグループ(例えば、男性か女性か、若年者か高齢者か)でもリスク比が約1 であることを暗示 するものではない。

図1に示された結果は、どのようなエビデンスを提供できるか?

どのような研究で報告されたリスク比も、すべての関連因子がコントロールされている場合にのみ、他の集団に一般 化することができる(Bottai、2014年;Santacatterina及びBottai、2015年)。この背景では、関連因子とは、対象と なる健康影響に確率的に依存する変数のことである。例えば、心血管疾患は、若年者よりも高齢者の方が多い。したが って、年齢は心血管疾患の関連因子である。図1に示された結果から得られるエビデンスは、検討した各研究でこのス テップを踏んだ場合にのみ有効となる可能性がある。もしそうであれば、2つの研究のそれぞれで考慮された個人の特 定のグループでは、農薬Aへのばく露がリスクを2倍にするというエビデンスがある。リスク比がそれぞれの研究集団の 要約測定値であるならば、どの結論も一般化されるべきではない。しかし、農薬Aのリスク比がいかなる因子でも調整さ れておらず、基礎となる母集団が2つの研究で大きく異なっていた場合、関連因子が存在せず、農薬Aはどのサブグ ループの個人においてもリスクを2倍にするというエビデンスが残っている。 農薬 B はリスクを半減させるようであり、推定された信頼区間は農薬 A よりも農薬 B の方が狭い。しかしながら、農薬 A についての上記の条件のもとでは結果を一般化できる可能性は農薬 B についても維持されている。 農薬 C に関しては、フォレストプロットから、この農薬へのばく露が、一方の研究では個人のグループで病気のリスクを上げ、他方の研究ではリスクを下げるというエビデンスが得られた。 繰り返しになるが、リスク比がそれぞれの研究集団の要約測定値であるならば、どの結果も一般化されるべきではない。 農薬 C に関する2 つの研究間の矛盾の背後にある理由を調査することは、 農薬 A または農薬 B に関する研究間の類似性の背後にある理由を調査するのと同じくらい多くの科学的予測を提供することができる。

一般的に、図1の3つのパネルのそれぞれにある銀色のダイヤモンドのようなフォレストプロットによって提供される 全体的な要約評価尺度は、ほとんど科学的な関係を持たない。異なる研究の結果を評価する際には、多くの側面を慎 重に評価しなければならない。見落とされがちな重要な側面は、サブグループを超えた個人間の関連の強さの不均一 性である。研究を記述した出版物でサブグループ解析に関する情報が提供されている場合、これは慎重に評価される べきである。感度分析は、異なる研究で得られた結果を補完すべきである。これらの解析は、異質性と、情報とサンプリ ング誤差とともに、関連する因子を制御していない場合の影響を評価することを目的とすべきである。図2 に総観図を 示す。

## 6.3.3. ハザード同定のためのメタアナリシスの有用性

ヒトのデータはリスク評価の多くの段階で利用できる。単一の疫学研究(同じ農薬に関する追加研究が入手できない 場合)は、質の高い研究(表 2 に示す基準による)でない限り、単独のハザード同定のための情報源として使用すべき ではない。代わりに、システマティックレビューやメタアナリシス(必要に応じて)など、多くの研究をまとめたエビデンス統 合技術を利用すべきである。慢性疾患に関連するデータの定量的な統合のために多くのメタアナリシスが実施されて いるが、リスク評価モデリングへの応用はまだ限られている。

重要なことは、エビデンス統合は、現在のエビデンスの方法論的評価とバイアスのリスク評価を提供し、不確実性の 領域を強調し、強固で信頼性の高いエビデンスとの関連を特定することである。

図 3 は、疫学研究をリスク評価に適用するために提案された簡単な方法論を示している。最初の考慮事項は、同じ 健康影響を扱う異なる疫学研究を組み合わせる必要性である。これは、EFSA のシステマティックレビューのためのガ イダンス(EFSA、2010 年 a)で提案されている基準に従って行うことができる。次に、研究デザインと実施、母集団、ば く露評価、健康影響評価、交絡因子の管理、統計解析、結果の報告など、WOE 評価のための 6.2 節に記載されてい

43

る要素に基づいてバイアスのリスクを評価する。信頼性が低いと分類された研究は、リスク評価のために受け入れられないと考えられる。残りの研究は重み付けを行い、ハザードの特定に使用する。

定量的データが利用可能な場合、メタアナリシスを実施して要約データを作成し、利用可能な、あるいは選択基準を 満たすすべての個々の研究の結果を組み合わせることで、統計的な検出力とリスク推定値(OR、RR)の精度を向上さ せることができる。メタアナリシスは、関連の大きさが検討した研究の平均値に決定するので、ハザード同定のためのよ り強力な基盤を提供する。さらに、特定の状況下では、健康影響におけるこれらの測定された差(OR、RR)を用量反応 関係に変換できるため、リスク特性の測定基準に移行する可能性がある(Nachman ら、2011 年)。実際には非常に珍 しいことではあるが、これにより、動物からの外挿法を使用することなく、ヒトにおける重大影響の同定や基準値の設定 が可能になる。

メタアナリシスでは不均一性が一般的であるため、どの研究を定量的に組み合わせることができるかを評価する必要 がある。異質性は、異なるサブグループにおける多様な影響を表す真正なものである場合もあれば、バイアスの存在を 表す場合もある。異質性が高い場合(I<sup>2</sup>が50%を超える場合)は、異なる情報源からのバイアスを集約するリスクが高い ため、要約尺度を得るために個々の研究を組み合わせるべきではない。感度分析及び/またはメタ回帰によって異質 性の原因を探るべきである。さらに、メタアナリシスにおける多様なバイアスの存在、例えば、小規模な研究効果、出版 バイアス、過剰な有意性バイアスなどを調べるべきである。基礎となる研究集団の影響量分布を適切に記述するモデ ルをみつけることが重要である。

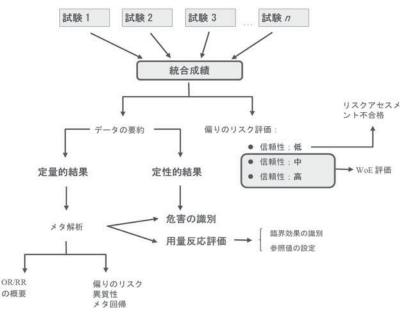

図3:疫学研究をリスク評価に活用するための方法論

#### 6.3.4. 潜在的な用量反応モデル化のための類似の疫学研究からのデータの蓄積

他の研究と同様に、単一の疫学研究から得られた結果は、複製によって検証する価値がある。複製の数が豊富な場合には、メタアナリシスによって複製された疫学研究の全セットを評価し、主要な健康影響事象について、研究間で結果が一貫しているかどうかを確認することについては価値があるかもしれない。このようなアプローチにより、因果関係の存在についてより強固な結論が得られるであろう。

ハザードが同定されると、リスク評価の次のステップは、異なるばく露レベルでの有害な影響のリスクを推定するための用量反応評価を実施することであり、特定の集団に対して健康への有害な影響が認められない濃度以下のばく露レベルを推定する。しかし、このステップでは、個人レベルでの完全に定量的な(または少なくとも半定量的な)ばく露データが必要である。定量的統合から得られた要約推定値は、研究間の相対比較が可能となるようなばく露の連続変数の変化(またはばく露のある一定割合の変化)に対する OR を示すものであれば、リスク評価にとってより有益であり、研

44

究間の相対比較が可能となり、健康に基づく基準値を導き出すのに役立つ。このような枠組みの中でのみ、類似した計画のヒト研究からのデータを統合して、適切な用量反応曲線をモデル化するのに十分な力を得ることができる (Greenland 及び Longnecker、1992年; Orsini ら、2012年)。

逆に、メタアナリシス的アプローチは、すべての研究で同じ割合で含まれる有効成分へのばく露が必ずしも必要では ないため、ばく露を「はい」または「いいえ」(これまでにあり、または決してない)と解釈するメタアナリシスに基づいて複 合 OR が計算された場合には、限られた価値しかないかもしれない。これらのケースでは、メタアナリシスは一貫して農 薬ばく露に関連したリスクの増加を示しているが、リスク評価のためには、ばく露は特定の農薬クラスの影響を特性評価 する必要があり、同じクラス内でも効力が異なる可能性があるため、個々の農薬の影響を特性評価する必要がある (Hernándezら、2016 年)。

このアプローチは、Point of Departure を特定することを可能にし(例えば、ベンチマーク用量(BMD))、疫学研究 を定量的リスク評価に統合することに関連するであろう。現在、BMD モデリングは実験研究からの用量反応データの 解析に使用されているが、観察による疫学研究からのデータにも同様のアプローチを適用することが可能である (Budtz-Jørgensonら、2004年)。EFSA 科学委員会は、BMD アプローチは、実験研究や疫学研究からの用量反応 データを利用して潜在的なリスクをよりよく特徴付け、定量化するために、Reference Point を得るための NOAEL(no observed-adverse-effect level)アプローチと比較して、より科学的に進んだ方法であると結論づけている。このアプロ ーチは、原則としてヒトのデータにも適用可能である(EFSA Scientific Committee、2017年 b)が、対応するガイドラ インはまだ作成されていない。

観察による疫学研究からの用量反応データは、いくつかの点で典型的な動物試験の毒性データとは異なる可能性 があり、これらの違いは BMD の計算に関連する。ばく露データは、多くの場合、少数の十分に定義された用量群に当 てはまらないことが多い。ほとんどの実験研究とは異なり、観察による研究には完全に未ばく露の対照群が含まれてい ない場合がある。この場合、用量反応曲線を作成することは必ずしもばく露量ゼロでの観察を必要としないため、BMD アプローチが適用される。しかし、ばく露量ゼロでの反応は低用量外挿法で推定する必要がある。したがって、疫学デ ータから得られる BMD はモデル依存性が強い(Budtz-Jørgensen 6、2001 年)。

疫学データは、BMD アプローチを適用するためには、特に特定の農薬とそのばく露に影響を与えるという点で、十 分な品質のものでなければならない。このような BMD アプローチについては、明確なルールとガイダンス、モデルパラ メータの定義を考慮する必要があり、制御された実験環境からの BMD アプローチとは異なる可能性がある。BMD モ デリングアプローチは重金属やアルコールに関する疫学データに適用されているが(Lachenmeier ら、2011 年)、現 在のところ、農薬に関する個別の研究は、用量反応モデリングに使用するのに適しているものはほとんどなく、他の研 究と組み合わせて使用することはあまりない。しかし、今後も研究は実施され、同様の報告がなされ、それらの研究を蓄 積して、より強固な評価を行うことができるようにすべきである。

## 7. 多様なエビデンスの統合:ヒト(疫学データと警戒データ)と実験の情報

本節では、まず第 7.1 節で、実験研究や疫学研究に由来する主なエビデンスの特性の違いについて考察する。使用したアプローチは、EFSA Scientific Committee Guidance on WOE(EFSA Scientific Committee、2017 年 b) で推奨されているもので、これらの異なる情報を評価し統合するために、信頼性、関連性、一貫性の 3 つの段階を区別している。最初の段階では、疫学的研究(セクション 6 で述べている)や実験的研究(この意見書の範囲を超えている) である個々の研究の信頼性の評価で構成されている。次に、信頼性があると判断された 1 件以上の研究の関連性(エビデンスの確実性)を疫学(第 6 節に記載)と毒物学の原則を用いて評価する。次に、第 7.2 節では、WOE アプローチで検討された疫学的及び実験的研究からの様々な関連情報を、ヒトに対する一貫性と生物学的妥当性を評価するために、どのようにしてまとめるかを検討する。

## 7.1. 異なるエビデンスの起源と特性 実験的アプローチと疫学的アプローチの比較

農薬の規制リスク評価では、毒性影響に関する情報は、規則(EC)283/2013 及び 284/2013 で要求され、OECD ガイドラインに従って実施された一連の実験結果に基づいている。これらの実験は in vivo または in vitro で実施され ているため、規則(EC)1107/2009 に基づき申請者が提供することが要求されているように、農薬については常に質の 高い実験データが存在している。EFSA の有効成分のピアレビューによると、各エビデンスの信頼性を評価するために、 許容範囲、補足範囲、不許容範囲といういくつかのカテゴリーが設定されている。 in vivo または in vitro 毒性試験の データの質及び信頼性は、ハザード及びリスク評価のための試験の妥当性を判断するためのより構造的な裏付けをよ り良く提供する評価方法を用いて評価されるべきである。農薬の健康リスク評価に使用できるように、実験的研究の実 施と報告のための基準が提案されている(Kaltenhäuser 6、2017 年)。

標準化された試験ガイドラインや優良試験所規範(GLP、例えば OECD 試験ガイドライン)に従って実施された農薬 有効成分の動物(in vivo)試験は、通常、他の研究よりも信頼性が高いとされている。しかし、このような枠組みの下で 実施された研究の方がバイアスのリスクが低いというエビデンスはないため(Vandenbergら、2016年)、GLPと非GLP の両方を問わず、関連するすべての研究から得られたエビデンスも考慮し、重み付けを行うべきである。このように、査 読された科学文献からのデータは、方法論的信頼性を評価した後に十分な品質のものであれば、農薬有効成分の規 制リスク評価のために考慮されるべきである。WOE 全体への貢献は、試験系、試験計画、統計的方法、試験項目の特 定、結果の文書化、報告などの要因によって左右される(Kaltenhäuser ら、2017 年)。

ハザード及びリスク評価のための試験の妥当性を判断するためのより良い補助とするために、in vitro 毒性試験の 内部妥当性も評価されるべきである。in silico モデルは、構造活性相関(SAR)を導出し、ヒトにおける有効成分の作 用様式や作用機序の同定や特性評価のための現行の毒性試験を補完するために使用することができる。これらの代 替毒性試験(及び非試験)アプローチは、動物データがない場合、例えば農薬の潜在的な神経発達や内分泌かく乱 作用をスクリーニングし、動物試験の信頼性を高めるのに役立つ可能性がある。規制目的のために動物試験の数を最 小限にすることが求められていることを考慮すると、動物試験以外の情報はWOE評価に使用できる適切な独立したエ ビデンスを提供することができる。

化学物質のビト健康への影響から特定の化学物質へのばく露に伴うリスク、化学物質の混合物の毒性、毒性反応の バイオマーカーの関連性、あるいは新しい毒性試験法の評価まで、多くの毒性学的問題がシステマティックレビューの 対象となっている(Hoffmann ら、2017 年)。例えば、以前の Scientific Opinion では、EFSA は AOP アプローチの 枠内で毒性学的メカニズムの決定にシステマティックレビューを使用した(Choi ら、2016 年; EFSA Scientific Committee、2017 年 c)。

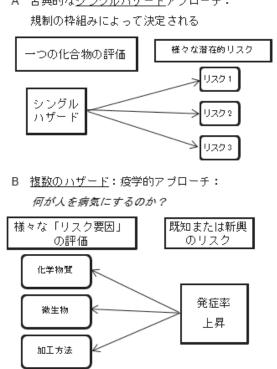

有効成分の毒性データの他に、食事や飲料水を通じてヒトにばく露された場合には、代謝物や残留物についてもデ ータが必要となる場合がある。これらの研究から得られた結果は、食品消費やその他のばく露源から推定される予想さ れるヒトばく露量との関連で検討される。このアプローチの長所は、動物の代謝経路が必ずしもヒトの代謝経路と類似し ているとは限らないにもかかわらず、in vivo 試験では潜在的な毒性代謝物を考慮していることである。

実験動物を用いた実験研究は、交絡因子が排除されるように計画された研究であるが、疫学研究では必ずしもそうと は限らない。しかし、規制研究に使用される動物は、一般的には近親交配されて遺伝的に同一であり、制御された環 境のために、定量的及び定性的な化学物質感受性のすべての特性を欠いている。それにもかかわらず、ヒト疾患の動 物代替は、その科学的妥当性とヒトへの外挿性が問われており、動物データとヒトの結果との間にしばしば見られる相 関性の欠如は、疾患経路や遺伝子発現プロフィルにおける疾患誘発性の変化における実質的な種間差に起因してい ると考えられている(Esch ら、2015 年)。そのため、多くの実験モデルは複雑な多因子疾患を捉えていないため、動物 からヒトへの外挿はかなりの不確実性を伴うものとなっている。したがって、現在のリスク評価はその特性上、予測的なも のであり、化学物質に特化したものであり、ヒトは環境、食事、職業上の源からの多数の化学物質にばく露されているた め、あるいは異なる毒物動態の違いのために、十分ではないかもしれない。動物からヒトへの外挿の不確実性を考慮し て、規制当局のリスク評価のアドバイスは、単に安全性が確認されている関連の Point of Departure (NOAEL、 LOAEL、または BMDL)を考慮するのではなく、不確実性因子(UF)を用いてこれらの値を下げ、急性毒性または慢性毒性の安全な参照用量値を提案するものである。

実験動物を用いた研究の限界を考えると、たとえそれ自体に限界があるとしても、「実社会」での疫学研究が必要で ある。疫学的研究では、集団のばく露の真の範囲(または推定された範囲)を組み入れているが、これは通常、一貫し た速度と用量の大きさで発生するのではなく、断続的で一貫性のない用量で発生する(Nachman ら、2011 年)。疫学 的研究は実社会のばく露に基づいているため、実際のヒトのばく露についての予測を提供し、それを疾病に結びつけ ることができ、種を超えた外挿に関連する不確実性を回避することができる。したがって、リスク評価は、優れた植物保 護対策 (Good Plant Protection Practice)と現実的な使用条件に基づいて行われるべきであると規定した規制 1107/2009の第4条の要件に対応していると言える。このように、疫学的研究は、高用量外挿の必要性を回避しつつ、 問題の定式化とハザード/リスクの特性評価を支援する(US-EPA、2010 年)。

したがって、疫学的研究は、(a)動物モデルでは検出が困難な特定のとトの健康影響との関連性を特定する。(b)動 物モデルで特定された影響のとトへの関連性を明らかにする(c)動物モデルが利用できない、または限定された、健康 影響を評価する能力を提供する(Raffaele ら、2011 年)。疫学的証拠は、十分に強固な農薬の疫学的研究が利用可 能な場合にのみ、動物実験によるエビデンスよりも考慮される。しかし、疫学研究では、健康影響に影響を与え、結果 を混乱させる様々な要因が常に存在する。例えば、疫学的データが農薬製剤へのばく露が有害であることを示唆して いても、通常、農薬へのとトばく露を正確に評価することの複雑さから、どの成分が原因であるかを特定することはでき ない。一部の製剤補助剤は本質的には毒性がないが、有効成分の毒物動態を変化させる場合には、毒性学的に関連 性がある可能性がある。さらに、ばく露に関連した測定されていない因子による交絡を完全に排除することはできない が、仮説的な交絡因子(まだ認識されていない)は実際の交絡因子ではない可能性があり、リスク(または効果量)の推 定値に意味のある影響を与えるためには、疾患やばく露と強く関連していなければならないが、必ずしもそうとは限らな い。

多くの病気は複数のリスク因子と関連していることが知られているが、脆弱なシステムに対する個々の農薬のハザードの影響を評価するためには、通常、ハザードごとのアプローチが考慮される(図 4A)。特に、単一リスク解析では、特定の条件下で発生する特定のハザードやプロセスに起因する個々のリスクを決定することができるが、異なる環境ストレス要因(自然現象または人為的要因のいずれか)によって引き起こされる複数のリスクを統合的に評価することはできない(図 4B)。リスク評価は、複数の有害な健康影響の同時発生のエビデンスを評価するための手順を開発することが有用である(Nachman ら、2011 年)が、これはよりヒトの環境で起こることと一致している。これらの理由から、適切に実施されれば、疫学研究はリスク評価プロセスとの関連性が高い。

# A 古典的な<u>シングルハザード</u>アブローチ:

#### 図 4:古典的な毒性学的研究と比較した場合の疫学的研究の役割

疫学的データと並行して、特に急性毒性については、警戒データが追加のエビデンスの流れを提供することができ る。通常、症例は十分に文書化されており、リスク評価のさまざまな段階で情報を利用することができる。これらの情報 には、ばく露のレベルと期間、臨床経過、因果関係の評価などが含まれる。重度のケースでは、毒素及び/または代 謝物が通常、血液または尿中で測定され、動物データとの比較が可能であり、場合によっては毒性値を設定することが できる。

要約すると、実験的研究、疫学的研究、及び警戒データは、エビデンスを収集し評価するための 2 つの異なるアプ ローチを表している。すなわち、実験的な研究計画と比較的均質な代理母集団を用いた(通常は単一物質に対する) 管理されたばく露から得られるものと、非実験的な研究デザインを用いた混合ばく露条件(及び変化する)から不均質 な対象集団で観察される変化を反映したものである(ECETOC、2009 年)。 疫学と毒物学は、それぞれがヒトへのハザ ードの特定に重要かつ異なる貢献をしている。このことは、両方のエビデンスの流れを補完的なものにしており、それら を組み合わせることで強力なアプローチが可能になる。動物実験は常に疫学的研究の解釈に情報を与えるものである べきであり、その逆もまた然りであるため、これらを独立して研究・解釈すべきではない。

## 7.2. ヒトの観察データと実験動物の実験データの重み付けの原則

信頼性の高いとト(疫学的または警戒研究)研究の特定し、プールされたとト研究の関連性の評価した後、関連性が あると判断された別個のエビデンスを、同様に関連性があると判断された他のエビデンスと統合する必要がある。

したがって、最初の検討事項は、検討対象の健康影響がどれだけ毒性学的及び疫学的研究でカバーされているか ということである。特定の健康影響/エンドポイントについて動物試験とヒト試験の両方が利用可能であると考えられる 場合、これは、様々なエビデンス源の重み付けに先立って、個々の試験が信頼性とエビデンスの強固さを評価されるこ とになる(疫学的研究については、それぞれ 6.2 項と 6.3 項)。異なるデータセットは補完的で確実なものであるが、個 別には不十分な場合があり、ヒトの健康リスクを適切に特定するための課題となる可能性がある。良好な観察データが 不足している場合は、実験データを使用しなければならない。逆に、実験データが利用できない場合や、既存の実験 データがヒトに関連していないことが判明した場合には、リスク評価は利用可能で適切な観察による研究に頼らなけれ ばならないかもしれない。

リスク評価のために、複数のエビデンス(特にヒト研究と実験研究)から得られたデータを体系的に統合するためのフレームワークが提案されている(図 5)。このような統合は、修正された Bradford Hill 基準(表 3)を用いて、関連性、一 貫性、生物学的妥当性を考慮した WOE 解析に基づいている。ヒトと動物のデータを比較解釈するためには、この枠組 みは以下の原則に依存すべきである(ECETOC、2009 年; Lavelle ら、2012 年)。

- エビデンスの全体を評価すべきであるが、信頼性があると判断された研究(許容可能なエビデンスまたは補足的エ ビデンスに分類された研究)のみがさらに検討される。とト研究または実験研究から得られたデータの信頼性が低い(許容できないと分類される)と考えられる場合は、リスク評価を行うことはできない。
- ・複数のエビデンスが関連していることが判明した場合には、WOE アプローチに従うべきである。農薬有効成分については、OECDの試験ガイドラインに従った実験研究は、それに反するエビデンスがない限り、信頼性が高いとみなされる。動物実験からのエビデンスの強固さは、代替的な農薬毒性試験または非試験方法(例えば、それぞれ in vitro 試験と in silico 試験)に高い信頼性がある場合に向上させることができる。疫学的証拠については、メタアナリシスを実施することで、個々の研究よりも効果の大きさをより正確に推定でき、また、研究間のばらつきを調べることができる(第6.3節参照)。
- 次に、評価されるステージに関連性が高いと判断された研究は、データがヒトまたは動物の研究からのものである かどうかに関わらず、より重要視されるべきである。ヒトのデータが最も関連性が高く、作用機序的な科学的根拠に 支えられている場合には、リスク評価の各段階で優先されるべきである。ヒトデータと実験データの関連性が同等ま たは類似している場合には、どのデータセットが優先されるかを判断するために、それらのデータの一致性(エビ デンス系統間の一貫性)を評価することが重要である。
  - ーヒトデータと実験データが一致している場合、リスク評価では、ハザードの特定(例:両方とも同じハザードを示す)またはハザードの特性評価(例:両方とも同じような安全用量を示唆する)のいずれにおいても類似した結果が得られるため、すべてのデータを使用すべきである。このように、両者は互いに補強し合うことができ、両方のケースで同様のメカニズムを想定することができる。
  - -不一致の場合、フレームワークはこの不確実性を考慮する必要がある。ハザードの特定については、一般的 にハザードの存在を示唆するデータが優先されるべきである。用量反応については、低い許容量のデータが 優先されるべきである。不一致が生じた場合には、この相違の理由を検討すべきである。その理由が基礎と なる生物学的メカニズム、またはヒトと動物モデル間の毒物動態学的差異に関連している場合は、リスク評価 の信頼性が高まる。逆に、その理由が理解できない、あるいは説明できない場合は、リスク評価の信頼性が 低下するかもしれない。このような場合には、生物学的エビデンスにおける矛盾に対する考察を行うべきであ る。

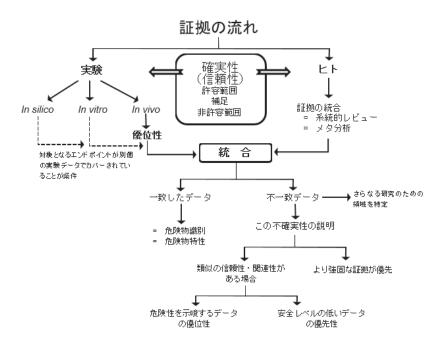

図 5:リスク評価のためのヒトと動物のデータ統合の方法論

疫学研究はリスクを解析するための補完的なデータを提供するものであり、十分に計画された毒物学的 in vivo 研 究やメカニズム研究と併せて文脈を考慮する必要がある。複数のエビデンスを統合して得られたエビデンスの総合的な 強度は、少なくとも単一のエビデンスで得られた最高のエビデンスと同程度になる。この統合的アプローチは、毒性学 的証拠と疫学的証拠をどのように重み付けして統合するかについての明確な指針を提供するものである。これは複雑 な作業であり、疫学的データが多因子性、多発性、慢性の疾患を対象としている場合には、毒物学的モデルや疾患特 異的動物モデルが限られているため、さらに困難な作業となる。

## 7.3. 異なる起源のエビデンスの重み付け

WHO/IPCS は、WOE アプローチをリスク評価に関連すると考えられるすべてのエビデンスが評価され、重み付けされるプロセスと定義している(WHO/IPCS、2009 年)。WOE アプローチは、化学物質のリスク評価を例にとると、異なる一連のエビデンス(in vivo、in vitro、in silico、母集団研究、モデル化されたばく露データや測定されたばく露データなど)の評価を必要とする。課題は、体系的で一貫性がある明確な方法で、これらのタイプのエビデンスを重み付けすることである(SCENIHR、2012 年)。重み付けは、形式的には定量的なものであってもよいし、リスクの基準を参照した分類に依存するものであってもよい。

EFSA のパネルと科学技術委員会による科学技術データの評価に WOE アプローチを使用するための明確な基準 を提供するために EFSA ワーキンググループが設立された(EFSA、2015 年 b)。このワーキンググループの目的は、 個々の研究がどのように選択され、どのように重み付けされるべきか、結論に到達するためにどのように知見を統合し、 結論に関する不確実性をどのように特定するかについて、利害関係者に支援を提供することであった。

WOE アプローチは、DAR や RAR のピアレビュープロセスにおける農薬のリスク評価において一貫して考慮されて いない。構造化された WOE アプローチを用いずに専門家の判断だけで行うことがより一般的になっている。いくつか の例を挙げると、グリホサートのピアレビュー(EFSA、2015 年 c)では、報告者である加盟国(RMS)は、疫学的データ を含む産業界または公的文献からのすべてのデータを考慮し、確立された事後基準と、探索された毒性の各エンドポ イントについて「全体的な」NOAELを提案するために利用可能なすべてのデータを考慮した特定の WOE アプローチ を採用している。

US-EPA は最近、「健康リスク評価にヒトの疫学的データと事象データを組み込むためのフレームワーク」に従って、

農薬のクロルピリホスのピアレビューに WOE アプローチのための特定の基準を適用した。この特定のケースでは、実験的毒性研究、疫学研究、生理学的ベースの薬物動態・薬力学(PBPK-PD)モデリングを含む多くのエビデンスを横断して、定量的・定性的な知見を統合するために WOE 解析が実施された。クロルピリホスは、規則(EC)No 1107/2009に基づく文献検索に関する EFSA ガイダンスの例としても使用されている。さらに、EFSA の結論(EFSA、2014年a)は、2011年に出された最初の結論を修正するために US-EPA のレビュー(2011年)を考慮に入れている。

まとめると、根本的な因果関係の可能性を高めるための組織的なツールとして、修正された Bradford Hill 基準を使用して、利用可能な科学的データを評価するために、より広範なWOEアプローチを適用することができる(表 3)。疫学は因果関係の立証にますます貢献しているが、この目的のための重要なステップは、生物学的妥当性の立証である(US-EPA、2010年; Adami ら、2011; Buonsante ら、2014年)。

## 7.4. 健康影響の基礎となる生物学的メカニズム

生物学的メカニズムとは、農薬とその生物学的標的との相互作用に続く健康影響につながる主要なステップを記述 したものである。毒性のメカニズムは、健康への悪影響につながる主要なステップとして記述されている。影響につなが るすべてのステップを理解する必要はないが、化学的相互作用に続く重要なイベントを特定することは、メカニズム(健 康に悪影響を及ぼす場合の毒性)を記述するために必要である。多くの疫学研究で農薬ばく露と慢性疾患との関連性 が示されているが、ヒトの疫学的観察にメカニズム的な裏付けと生物学的な妥当性を与えるためには、補完的な実験研 究が必要である。実験でのばく露は、実験動物の生物学的メカニズムがヒトで発生することを条件に、ヒトの集団に関連 するものでなければならない。

疫学研究の解釈の一部として生物学的妥当性を確立することは重要であり、最新の技術とアプローチを活用すべき である(7.6節)。この意味では、AOPの枠組みは、毒性結果の基礎となる生物学的メカニズムを調査し、実験研究と観 察による研究の両方で観察された関連性の因果関係を知るために、異なる情報源からの複雑な情報を体系的に整理 し、統合するためのツールとして利用できる(7.5節)。

農薬の潜在的な毒性作用の基礎となる生物学的メカニズムや経路について特定の情報を提供するためのデータの 利用は、特定の健康影響に関連した生物学的機能について調査された農薬化学物質のみであるため、限られたもの である。特に、同等の動物実験の結果の間に一致点がある場合や、異なる化学物質が同じ毒性パターンを示す場合 には、作用機序(MOA)仮説を立てることが可能な場合がある。毒物と標的臓器を特定することは、考えられる影響の 用量反応曲線とその時間的関係と同様に不可欠である。毒性につながるさまざまな主要事象と MOA 仮説を特定でき れば、ヒトに対するこれらの事象の妥当性を評価することが可能になることもある(ECETOC、2009年)。

農薬のスルホキサフロル (Sulfoxaflor) は、MOA が広範囲に研究されてきた例であり、2014 年 11 月に開催された ECHA/EFSA MOA/HRF ワークショップでも広く取り上げられている。スルホキサフロルはラットとマウスの両方で肝発 がん性を誘発した。これらの肝腫瘍に対する MOA を決定するための試験は、発がん性試験が終了する前または終了 するまでに MOA データが入手できるように、標準的な毒性試験のバッテリーの一部として、統合的かつ前向きな方法 で実施された。WOE アプローチで評価された MOA データは、スルホキサフロルの齧歯類での肝腫瘍の MOA がヒト では発生しないことを示している。この理由から、スルホキサフロルはヒトの潜在的な肝臓発がん性物質ではないと考え られている。

さらに、MOA データが影響の可能性がないことを示す場合もある。仮に、ヒトでは有害な影響が発生する可能性が ないことを示す生物学的データがある場合は、疫学研究の解釈に反映させる必要がある。それにもかかわらず、害虫と ヒトの間の一次標的部位選択性は農薬の安全性において重要な役割を果たしているが、哺乳類における二次標的も 考慮しなければならない。

複数の農薬にばく露した場合、リスクを組み合わせるかどうかの判断は、農薬が共通の毒性メカニズム(同じ標的組織で同じ分子標的に作用し、同じ生化学的作用機序で作用し、共通の毒性中間体を共有する)を共有しており、同じ重大影響を引き起こす可能性がある場合、あるいは単に同じ標的臓器を共有しているという観察に基づいて判断することができる(EFSA、2013年 a,b)。しかし、累積リスク評価は本意見書の範囲を超えている。

# 7.5. 有害転帰経路(AOPs)

AOP の解析法は、リスク評価に有用な方法で、関連する化学的、生物学的、毒物学的な情報を収集し、評価するた めの枠組みを提供している(OECD、2013 年)。AOP は、化学物質と生物学的標的との相互作用(標的分子への作用 (Molecular initiating event:MIE))から、ヒトの健康に関連する in vivo での有害な事象に至るまでの一連の重要 事象として定義することができる。これらの重要事象はすべて MOA の必要な要素であり、経験的に観察可能であるか、 またはそのような事象の生物学的ベースのマーカーを構成するものでなければならない。したがって、AOP は、リスク 評価に関連する生物学的組織のレベルで、1 つの MIE から 1 つの有害な事象に至る直線的な経路である。AOP の 目的は、因果関係の連鎖において、1 つの MIE から 1 つの有害な事象へとつながる重要事象の段階を記述するため の、柔軟なフレームワークを提供することである(EFSA PPR パネル、2017 年)。重要な事象は実験的に測定可能で なければならず、有害な事象は通常、in vivo での OECD 試験ガイドラインに関連している。しかし、場合によっては、 有害な事象が試験ガイドラインに記載されている先端エンドポイントよりも低いレベルの生物学的組織のレベルにあるこ ともある(OECD、2013 年)。

特定の MIE はいくつかの毒性影響につながる可能性があり、逆に、複数の MIE は同じ毒性影響に収束する可能 性がある。しかし、各 AOP は 1 つの MIE と 1 つの毒性影響象のみであるが、無制限の数の中間ステップを伴うことも ある(Vinken、2013 年)。生物学的組織の異なるレベルでの重要事象は、同じレベルの組織での複数の事象よりも大 きな WOE をもたらすことに留意すべきである(OECD、2013 年)。

毒性反応に関与する重要な生化学的ステップは、関連する科学文献の詳細な調査や実験研究から同定され、検索 される。構造データ、「オミクスベース」データ、in vitro、in vivo、あるいは in silico のデータなど、あらゆるタイプの情 報を AOP に組み込むことができる。しかし、in vitro データよりも in vivo データの方が優先され、対象となるエンドポ イントは代替エンドポイントよりも優先される(Vinken、2013 年)。特定された AOP は、生物学的に妥当性をもつ必要 があるため、正常な生物学的プロセスと両立しないものであってはならない。

定性的 AOP (AOP 開発のための OECD ガイダンスに従った WOE の組み立てと評価を含む AOP として意図され ている)は、経路に悪影響を与える農薬へのばく露と有害な影響との間の関連性の生物学的妥当性を裏付ける(また は裏付けがないことを特定する)ことによって、疫学研究をリスク評価に統合するプロセスの出発点であり、標準的なア プローチであるべきである。したがって、定性的な AOP は、メカニズム的知見に基づく疫学研究の生物学的妥当性を 裏付けるために、ハザード同定の目的のためだけに開発される可能性がある(EFSA PPR パネル、2017 年)。

AOP フレームワークは、異なる情報源から収集された複雑な情報のレビュー、整理、解釈を行うための柔軟で透明 性の高いツールである。このアプローチには、因果関係の推論に関連する不確実性を定性的に特徴づけ、不確実性 を低減するためには、追加のメカニズム的研究や疫学研究がより効果的であるかどうかを特定するという付加的な利点 がある。したがって、AOP フレームワークは、有害な影響が生物学的にもっともらしいかどうかを探るためのリスク評価に 有用なツールである。生物学的に妥当性を解析する目的では、AOP は重要なツールとなり得る。特に、規制上の動物 を用いた毒性試験が陰性であっても、疫学研究で観察された先端エンドポイント(または関連するバイオマーカー)の 評価が AOP に基づいて不十分であると考えられる場合には、AOP は重要なツールとなり得る。先端エンドポイントをメ カニズム的に記述することにより、AOP はリスク評価におけるハザードの特定と特性評価のステップに貢献する。AOP フレームワークは化学的には不明確な点があるため、MOA 及び/または試験・評価に関する統合的アプローチ (IATA)フレームワークで補完されれば化学物質特有のリスク評価をサポートすることになる(EFSA PPR パネル、 2017 年)。

AOPとMOAのデータは、疫学研究の結果を評価し、その結論に重み付けをするために使用できる。それらの結論 が生物学的メカニズムの深い理解と矛盾するものであろうと、あるいは単に経験的なものであろうと、一度確立された AOPや MOAの枠組みと一致する他の結論よりも、それらの結論の重要性は低く設定されるべきである。しかし、十分 に文書化された AOPの例は比較的少なく、完全な AOP/MOA の枠組みはリスク評価に疫学的研究を用いるための 要件ではない。

したがって、AOP は、動物実験で観察された末端の影響(apical effects)に大きく依存する現在の試験パラダイム

ではなく、メカニズムに基づくリスク評価への移行を促進するための重要な要素である。リスク評価のパラダイムをメカニズム的な理解へと移行させることで、単一の農薬のヒトへの健康影響を予測する上での動物データの限界を下げることになり、また、農薬ばく露の累積リスク評価に関する現在の取り組みを支援することにもなる(EFSA PPR パネル、2017年)。

#### 7.6. 毒性の基礎となる生物学的経路とメカニズムを特定するための新しいツール

毒性経路の解明は、特にバイオモニタリング、オミクス技術、システムバイオロジー(毒性学)の進歩から、顕在化した 疾患への毒性力学的進行における初期の生物学的摂動の新規バイオマーカーを特定する機会をもたらしている。疫 学におけるオミクスの革命は、早期効果の新しいバイオマーカーの可能性を秘めており、関連のメカニズム、生化学的 経路、因果関係を調査する機会を提供している。

疫学調査におけるバイオモニタリングデータの価値が認識されつつあることは、ばく露と転帰の客観的な尺度を提供 することで、誤分類を減らすのに役立つかもしれない。ばく露、転帰、感受性に関するバイオマーカーデータが増加し ている限り、疫学は農薬ばく露の関数としての毒性力学的進行の理解と最終的にはリスク評価に大きな影響を与えるこ とになるであろう。リスク評価者にとっての課題は、毒性力学的経路に沿った軽微で初期の変化が、下流への影響の可 能性の増大を示唆していることを認識することである(Nachman ら、2011 年)。オミクスデータは、農薬の影響を受ける 経路を特定することで MOA への理解を深め、リスク評価の第一段階であるハザードの特定を支援することができる。

生物学的サンプルのトランスクリプトーム(Transcriptomic,)、メタボローム(metabolomic)、エピゲノム (epigenomic)、プロテオミクス(proteomic)のプロファイリングは、環境化学物質の影響下での細胞の進化状態の詳 細な画像を、時には個々の分子レベルで提供し潜在的な健康影響との早期のメカニズム的な関連性を明らかにするこ とができる。今日では、オミクス技術の進歩が規制毒性学にもたらす課題と長所については、まだ研究が進められてい る(Marx-Stoelting ら、2015 年)。これらのバイオマーカーの特異性を評価するための明確なルールが必要である。

毒物学の文脈において、最も有用であり進歩しているオミクス技術は、MOAの解析とAOPの誘導、バイオマーカーの同定であり、これらはすべて疫学にも役立つ可能性がある。例えば、(a)トランスクリプトミクス:遺伝子発現(mRNA) プロファイルの比較は、バイオマーカーの発見、発現遺伝子の機能グループ(Gene Ontology カテゴリー)へのグループ化、または遺伝子セット分析に使用することができる。これらの手法により、生物学的メカニズムに関する様々な情報が得られる可能性がある。(b)プロテオミクス:試料のタンパク質プロファイリングを調べ、タンパク質の量や転写後の修飾を高度に分析し、ばく露後の生物学的経路の変化や疾患の発症に関連している可能性がある。(c)メタボロミクスは、核磁気共鳴分光法や質量分析法をベースにした技術を用いてデータを作成し、ソフトウェアやデータベースを介して分析することで、ばく露や疾患と相関のあるマーカー(分子シグネチャーや経路)を特定するものである。(d)エクスポソーム(個人が生活の中で受けたばく露の総量)の利用は、ヒトのバイオモニタリングに適したオミクス技術とバイオマーカーを使用することができるかもしれない。それにもかかわらず、これらの方法論の検証不足とそのコストの問題から、大規模な使用には限界がある。

オミクス技術を環境衛生研究に応用するには、研究デザイン、バリデーション、再現性、時間的分散、メタデータ分析 に特別な配慮が必要である(Vlaanderen ら、2010年)。大規模な研究では、生体サンプルで測定された分子プロファ イルの個人内変動は、時間の経過とともに大きく変動する遺伝子発現、タンパク質レベル、または代謝物のプロファイ ルの個人間変動よりも少ない変動を示す。これらの個人間変動がばく露変化に関連した変動よりも大きくならないことが 重要であるが、これが実現するかどうかは定かではない。

生物学的に意味のあるオミクスのシグネチャーは、オミクスーばく露及びオミクスー健康の関連性の研究を行うことに よって同定され、高度なリスク評価に有用なデータを提供する。このアプローチは、末端の毒性エンドポイントから、化 学物質によって誘発された分子/細胞応答の摂動に起因する毒性経路の初期の主要イベントへと移行することを支 持するものである(NRC、2007年)。

## 7.7. 疫学における新たなデータの機会

現在の技術的状況では、スマートフォン、テキストメッセージ、クレジットカードでの購入、オンラインでの行動、電子カ

ルテ、全地球測位システム(GPS)、スーパーマーケットの購買データなど、多くの情報源からの前例のない量のデータ のデジタル化と保存が可能になっている。これらのデータ源の中には、リスク評価のための貴重な情報を提供するもの もあるが、それらの多くには法的枠組みを超えて、科学的または規制上の目的のために使用することの倫理性につい て疑問が生じることもある。具体的な例としては、電子カルテ、職業や環境に関するアンケート、地理的な位置、健康や 社会保障番号など、機密性が高い、または特に保護されていると考えられる健康に関連する個人情報を含むデータが 挙げられる。これらの様々な形態の健康情報が容易に作成、保存、アクセスされている。ビッグデータは、研究者に多く のデータ源をまたいで記録を照合したり、リンクしたりする能力を提供する。健康情報と遺伝性情報のビッグデータ源の リンクは、病気の予測因子を理解するための大きな可能性を期待されている(Salerno ら、2017 年)。しかし、現在の方 法を用いてデータを体系的かつ効率的に処理、解析、解釈すること、あるいは大量データの中から関連するシグナル を特定することには課題がある(全米科学・工学・医学の環境研究・毒物学委員会が 2017 年の報告書で指摘している) <sup>18</sup>。

さらに、国民健康保険や退院データベースから抽出された薬剤費などの医療行政データは、農業人口調査や地理 的マッピングから抽出された農業活動に関するデータと相互にリンクさせることができる。このような情報が集団レベル でしか得られない場合もあることは認識されているが、個人レベル及び/または個人の習慣に関するデータを得ること が重要な課題である。

バイオバンクはまた、健康な集団や病気にかかった集団からの新たなデータ源を構成するものである。バイオバンク は、多様な研究目的のために保存されているとトの生物学的標本と関連情報の整理されたコレクションで構成されてい る。これらのバイオサンプルは、ばく露評価やばく露の再構成に有用なデータを生成する可能性のある新技術の応用 に利用可能である。研究の計画と実施が調和されていれば、データとサンプルはバイオバンク間で共有され、強力な 蓄積分析や反復研究を促進することができる(Burton ら、2010 年)。

深い表現型(deep phenotyping)を用いた大規模な疫学研究は、優れた表現型を持つ研究参加者と前述のデータ を結びつける前例のない機会を提供する。例えば、英国のバイオバンクでは、アンケート、病歴、身体測定データだけ でなく、50万人以上の参加者全員のゲノムワイドな関連データを持つ血液と尿のサンプルを保存し、病院の事例統計、 国の登録データ、プライマリーケアの記録とリンクさせている。大気汚染や騒音レベルに関する情報を得るために、参 加者の郵便番号を大気汚染や騒音の推定値にリンクさせている。さらに、これらのばく露に関する個人レベルのデータ を収集するために、個人ばく露モニタリングの試験的実施が行われる予定である。これらのアプローチは、地理的リンク、 購買・職業登録とのリンク、個人のばく露モニタリングのいずれかを通じて、農薬ばく露に関する情報を得るために拡張 される可能性がある。同様のバイオバンクは、他の多くのEU諸国にも存在する(http://www.bbmri-eric.eu/BBMRI-ERICは、ほとんどのEUの研究を収集している)。

# 8. 全体的な推奨事項

## 8.1. 単一の疫学的研究に関する勧告

疫学的研究を改善するための以下の勧告は、規制(EU)No 1107/2009 で言及されている「認知された基準」に準拠し、農薬のリスク評価に特に価値のあるものとすることを目的としている(「利用可能で、ばく露レベルとばく露期間に関するデータを裏付けとし、認識された基準に従って実施された場合、疫学的研究は特に価値があり、提出しなければならない」としている)。したがって、これらの勧告は、このような研究をどのように実施するかについての研究者のための実践的な指針としてではなく、農薬リスク評価にさらに活用するための研究を計画している研究者のためのものと考えることができる。

## **a)研究デザイン**(交絡を含む)

1)前向き疫学的デザインは因果関係推論のためのより強力なエビデンスを提供するので、農薬リスク評価のための 他の計画よりもこれらの研究が奨励される。

<sup>18</sup> 全米科学・工学・医学アカデミー、地球・生命研究部門、環境研究・毒物学委員会、リスクベースの評価に21世紀の科学を組み込む委員会。ワシントン(DC)。全米アカデミープレス(米国);2017年1月

- 2) 今後の疫学研究は、調査対象の課題に適切に答えるために、適切な標本数を用いて実施されるべきである。その ためには、研究デザインの段階で検出力解析を行う必要がある。
- 3)今後の研究では、異質性、小集団、ばく露方法、感受性の時期や条件(妊娠、発育、疾患など)を考慮する必要がある。
- 4)幅広い潜在的交絡変数(他の化学物質への共ばく露、ライフスタイル、社会経済的要因など)を研究の計画段階 (例:マッチング)で測定または考慮すべきである。
- 5) 毒性に影響を与え、効果を調節する宿主因子を考慮する。これらには、遺伝的多型データ(例:パラオキソナーゼ -1 遺伝子型)や栄養因子(例:ヨウ素の状態)などが含まれる。
- 6)研究者間の共同研究は、個々のコホートの有効性を高めるコンソーシアムを構築するために奨励される。

将来のばく露評価のために、新規技術の利用を含め、関連する生物学的試料の収集と適切な保管を行うべきである。 b) ばく露(測定、報告のためのデータ変換、統計解析)

- 1) ばく露に関する特定の情報の収集は、可能な限り、ばく露の広範な定義、非特定の農薬の記述及び「一度もない」 対「今までにあり」のような広範なばく露の分類を避けるべきである。それにもかかわらず、これらのカテゴリーは、 特定の状況下では、例えばクラス効果を予測するために価値があるかもしれない。
- 2) 農薬の幅広いクラス(無関係な物質の一般的なグループ)、または「殺虫剤」、「除草剤」など、あるいは一般的な 「農薬」だけを対象とした研究は、リスク評価にはあまり役に立たない(あるとすれば)。特定の名前のついた農薬や 共調合製剤を調査した研究の方がリスク評価には有用である。
- 3)同じ化学クラスに属する農薬、または同じ毒性作用モードや毒性学的効果をもたらす農薬は、同じカテゴリーにグ ループ化されている可能性がある。ばく露の頻度、持続時間、ばく露の強度などの情報を追加することで、ばく露 パターンの推定に役立てることができるかもしれない。
- 4) 職域疫学研究では、作業者や労働者の行動や PPE の適切な使用は、これらのばく露修飾がばく露を大幅に変 化させ、それによって潜在的な関連性を変化させる可能性があるため、適切に報告されなければならない。
- 5) ばく露測定の精度を向上させることは、特にコホート研究において、ますます重要になってきている。病因学的に 関連する期間をカバーする長期のコホート研究では、繰り返しの生物学的測定や自己報告されたばく露の繰り返 しの更新を使用することにより、ばく露の測定の精度を向上させるべきである。
- 6) 農薬の使用記録、登録データ、GIS、地理的マッピングなどを含むより広い集団の環境ばく露の間接的な尺度及び大規模なデータベース(行政データベースを含む)から得られたデータは、探索的研究には貴重であるかもしれない。これらのデータが利用できない場合は、記録・登録を開始すべきである。同様に、食品消費データベースからの農薬への食事ばく露の推定や、モニタリングプログラムからの残留農薬レベルの推定も利用できる。直接的なばく露評価と同様に、間接測定の各方法は、偏りや誤分類のリスクを検討し、適切な重み付けを行うべきである。
- 7)可能な限り、ばく露評価は、異なるばく露レベルを確立するために、指定された農薬へのばく露の直接測定を使用すべきである(例えば、個人的なばく露測定/生物学的モニタリング)。新しい研究では、個人ばく露モニタリングの新しい方法を探求すべきである。結果は、集団間のばく露を標準化するために、標準化された単位を用いて表現されるべきである。
- 8)長期にわたるばく露評価の特性評価は、より包括的なばく露モニタリング戦略を実施し、アンケートやバイオモニタリングデータに裏付けられた作業ばく露マトリックスから収集された長期にわたるばく露決定要因に関する情報と相まって、利益を得ることができる。ばく露評価モデルは、重要なばく露パラメータを特定することを可能にする HBM の研究によって包括的にサポートされることができる。そのような場合には、モデル内のパラメータの仮定を 調整することで、より現実的なばく露の評価につなげることができる。
- 9) エクスポソームの概念とメタボロミクスの使用は、特に、より良いばく露測定(ばく露のバイオマーカー)、脆弱な小 集団の特定、毒性経路の生物学的解釈(疾患のバイオマーカー)のための次世代の疫学研究に大きな可能性を 秘めている。

10) 農薬混合物へのばく露(及び毒性)に関する知識の向上は、包括的なリスク評価に有益である。共通の標的に作

用する複数の農薬への複合ばく露の共同作用を考慮すること、または類似の有害作用を誘発することは、累積リ スク評価に関連している。そのためには、混合物の全成分を把握し、MOA、用量反応特性、成分間の潜在的な 相互作用を理解しておく必要がある。ばく露の特性を把握することは、ばく露のパターンや大きさが時間の経過と ともに変化する複数の農薬への複合ばく露において重要な要素である。

- c) 有害な健康影響(測定、報告のためのデータ変換、統計解析)。
  - 1)自己申告による健康上の影響は、研究に指定された医療専門家による病状の独立した盲検評価により、回避するか、または結論を出すべきである。
  - 2)研究の対象となる健康影響は十分に定義されているべきであり、妥当性が確認されている場合を除き、代替エンド ポイントは避けるべきである。疾患や疾患のサブクラスの定義が時間の経過とともに変化する場合には注意が必要 である(がん、神経変性疾患など)。
  - 3) 早期の生物学的効果を示す生物学的マーカーを利用して、疾患の病態の理解を深めるべきである。これらの定量的な生物学的パラメータは、実験動物を用いた研究から得られた結果と比較して、研究の感度を向上させ、誤分類を減らし、ヒトへの関連性を高めることができるため、疫学の有用性を高めることができる。これらの再定義されたエンドポイントは、毒性力学的経路における初期のイベントであり、連続的なスケールで測定されることが多いため、よりあからさまな従来の健康影響よりも好ましいかもしれない。
  - 4)効果のバイオマーカーの使用は、農薬への総体的ばく露を評価し、累積的なリスク評価に役立てることができるか もしれない。
  - 5)健康影響を疫学研究を用いて特定し、急性・慢性の事故記録と実験結果を結びつけることを可能にするリードアク ロス手法(read across methods)を開発する。
- d)統計(記述的統計、ばく露と影響の関係のモデル化)。
  - 1) 統計解析は、事前に定められた解析(統計)プロトコールに基づき、探索的研究のための事後的な解析を避け、統計的に有意であるかどうかにかかわらず、すべての結果を報告すべきである。
  - 2) データは、適切な場合には、直接または間接的な測定法が使用されているかどうかにかかわらず、個人/集団の ばく露と用量反応評価を推定するための数学的モデル化を可能にするような方法で報告されなければならない。
  - 3)報告書には、関連因子やばく露の構造が異なる基礎となる集団に基づいた研究において、未調整と調整の両方の割合と、対象となる結果の割合と率を含めるべきである。
  - 4)考えられる関連因子及びばく露と健康転帰の関係におけるそれらの役割は、慎重に同定され、正確に測定され、 徹底的に評価されるべきである。ほとんどの場合、関連因子は潜在的な交絡因子としてスクリーニングされている。 交絡因子が検出された場合には、感度分析を含む適切な統計的手法を用いて、交絡因子を調整する必要がある。
  - 5) プロペンシティスコアマッチング (propensity score matching)、メディエーション解析 (mediation analyses)、因 果推論などの潜在的に有用な解析手法を農薬疫学に適用することが奨励されている。
  - 6)対象とした農薬ばく露と疾患との間の関連が統計的に有意であることが判明した場合、特に(推定される)検出力の低い研究では、統計的に有意な効果の大きさの推定値(例えば、オッズ比 OR または相対リスク RR)が人為的に増大するか、または拡大するかの程度を決定するために、検出力解析/設計計算を実行することが一般的に良い対応とされている<sup>19</sup>。

<sup>19</sup> 検出力とサンプルサイズの推奨事項及び効果量の算出とデザインの計算を含む関連問題に関する追加情報は、本報告書の附属書 D に記載されている。特に、検出力の計算では、疫学研究で明確に報告されるべき3つの値が必要である。(i)非ばく露群の被験者数(対象となる疾患の有無を含む)、(iii)非ばく露群の被験者数(対象となる疾患の有無を含む)、(iii)非ばく露群の福患者数。

#### e)結果の報告

- 1)結果報告は、STROBE 声明及び統計報告に関する EFSA ガイドライン(EFSA、2014 年 b)に概説されている疫 学研究の良好な報告の慣行に従うべきであり、効果量の推定値を含む本意見書で指摘されている更なる提案を 含むべきである。
- 2)いくつかの疫学研究は探索的で事後的な特性を持つものもあるがが、そのことを認識し、適切な統計解析によっ て裏付けられるべきである。
- 3) 疫学研究は、さらなる調査のために生データへのアクセスを提供し、その全結果と解析に使用したスクリプトやソフ トウェアパッケージを提供することが奨励されている。
- 4) 結果の再現性を検証するために使用したスクリプトや統計ツールとともに、すべての結果を報告するか、またはオ ンライン源を利用して寄託する。
- 5) すべての資金源を報告し、財務上の問題やその他の潜在的な利害関係者を適切に報告する。

一般的な勧告として、PPR パネルは、リスク評価における疫学研究の価値、透明性、説明責任を高めるために、疫 学研究のためのガイダンスの開発を奨励している<sup>20</sup>。疫学研究の質の向上は、責任ある研究の実施と科学的誠実さと ともに、リスク評価にこれらの研究を組み入れることに利益をもたらすであろう。

## 8.2. サーベイランス

- 1) EU 指令 2009/128 の第 7 条で要求されている市販後サーベイランスプログラム(産業用及び一般集団)を設定 することにより、急性及び慢性の事故の報告を増加させる。これは、産業保健医とのサーベイランスネットワークを 構築し、PPPを扱う国の当局と毒物管理情報センターとの連携を強化することにより達成すべきである。
- 2)急性・慢性事故の因果関係の程度/強度(「推定可能性」)を評価するための有効な方法を開発し、EU 加盟国間の整合化された報告を支援するための用語集と類義語集を開発する。
- 3) EU 加盟国からの整合化されたデータを EU レベルで収集し、欧州委員会/EFSA が定期的に検討し、最も関 連性の高い結果に焦点を当てた報告書を発表すべきである。
- 4) 農薬に関する EU 全体の警戒体制を構築する。
- 5)診断決定、データ入力、管理を担当する医療・救急スタッフのための毒物学コースにおいて、農薬のトキシドロームに関する研修を改善する余地がある。

## 8.3. 複数の疫学研究のメタアナリシス

- 1) 個々の研究の方法とバイアスの徹底的な評価、研究間の異質性の程度の評価、異質性の根底にある説明の展開、 エビデンスの定量的な要約(一貫性があれば)を考慮に入れて、疫学研究からのエビデンスを蓄積することができ る。
- 2) すべてのエビデンス統合作業において、関連するバイアスのリスクツールを用いて研究をレビューすべきである。 計画が異なる研究や計画の特徴が異なる研究では、バイアスのリスク評価のために(いくつかの)異なる課題が必要になるかもしれない。
- 3)エビデンス統合は、特定の期間に限定されるべきではなく、エビデンス全体を含めるべきである。これらの努力は、 特定の健康影響または疾患カテゴリーに焦点を当てれば、より適切である。
- 4) エビデンス統合の取り組みでは、効果量の定量的な統合に加えて、計算された予測間隔、小試験効果と非対称 性バイアス、対象となる対角線、交絡、過剰な有意性バイアス<sup>21</sup>及び不均一性の推定値についても考慮すべきで ある。

<sup>20</sup> 例として、オランダ疫学協会が責任ある疫学的研究実践に関するガイドラインを作成した(2017年)

<sup>&</sup>lt;sup>21</sup> 過剰シグニフィカンスバイアスとは、特定のアウトカムに関する公表されている文献の中に、統計的に有意な結果が得られた研究が多すぎる状況 を指す。このパターンは、出版バイアスを伴う文献の強いバイアスを示唆している。 選択的な結果報告、選択的な分析報告、または捏造されたデータが説明の対象となる可能性がある(Ioannidis and Trikalinos、2007 年)。

- 5) 不均質性が存在する場合、高度に選択された母集団を用いた研究は、それぞれの母集団を代表するものではないが、統計的な不均質性ではなく真の不均質性を示すものである可能性があるため、価値があることが証明され、 検討に値する。
- 6)年齢、人種、性別など、研究間での一貫性のある報告があれば、メタアナリシスがより充実すると思われる。
- 7) 個々の農薬の定量的データが疫学研究から得られる場合には、それらのデータを組み合わせたり、プールして用 量反応モデリングを行うことで、定量的なリスク推定値や Point of Departure(BMDL、NOAEL)の開発が可能 となる。
- 8) 個々のコホートでは十分な統計的力がない疾病ばく露関連を研究するために、コホート研究の国際的なコンソー シアムがデータプールを支援するよう奨励されるべきである(例:AGRICOH)。

#### 8.4. 疫学的証拠と他の情報源との統合

- 1) すべてのエビデンス(疫学、動物、試験管内データ)は、バイアスがなく、平等に精査されるべきである。
- 2)リスク評価のために、観察による研究、動物/基礎科学研究、その他のエビデンス源を組み合わせるために、有 効かつ調和のとれた方法を開発すべきである。
- 3)実験データとヒトデータの両方が、ハザードの特定と用量反応評価に寄与するべきである。
- 4) 複数のエビデンスから得られたデータを体系的に統合することは、Bradford Hill 基準を修正したものを用いて、 関連性、一貫性、生物学的妥当性を考慮した WOE 解析に基づくべきである。この枠組みの基礎となる原則は 7.2 節に記載され、図 5 に要約されている。
- 5) WOE アプローチを用いて、疫学的知見を他の情報源(実験毒性学からのデータ、作用機序/AOP)と統合すべ きである。統合された調和のとれたアプローチは、体系的かつ一貫した方法で WOE の全体的な枠組みの中で動 物、メカニズム、ヒトのデータをまとめることによって開発されなければならない。
- 6) AOP フレームワークは、様々な種類の研究成果を統合するための構造化されたプラットフォームを提供する。
- 7)動物データ、in vitro データ、ヒトデータは、それぞれのエンドポイントについて全体として評価されるべきである。 実験から得られた結果が各エンドポイントのヒトのデータと一致しているかどうかの結論を導き出すことができ、これ を RARs に含めることができる。

### 9. 結論

本意見書は、既存の疫学研究を含む科学的に査読された公表文献の検索を要求する規制 1107/2009 の下で、農 薬の認可更新時(可能であれば認可プロセス時)の査読プロセスを支援することを目的としている。これらは有効成分 の更新プロセスに適しており、更新のために提出される書類には有効成分に関連する新しいデータを含める必要があ ることを示す規則 1141/2010 にも準拠している。

以下では、参照条件の4つの重要な要素を繰り返し、個々の用語に対応する部分を順番に示している。それぞれの ToRs でグループ化された文章から導かれるように、それぞれのToR に関連する推奨事項も以下のように示す。

「PPR パネルは、外部科学報告書(Ntzani ら、2013 年)で観察された農薬ばく露ととトの健康影響との関連性と、これらの知見が規制上の農薬リスク評価の文脈でどのように解釈され得るかを検討する。したがって、PPR パネルは、報告書で収集された疫学研究を体系的に評価し、研究の主要なデータギャップと限界に対処し、その提言を行う」。

PPR パネルは特に以下を行う。

- 1)利用可能な疫学研究の質と妥当性に関して外部科学報告書で明らかにされたものに基づいて(必ずしもこれに限 定されないが)ギャップと限界のすべての情報源を収集し、レビューする。セクション 3、20・24 頁、セクション 5.2 33・35 頁:勧告は適切ではない。
- 2) ポイント1 で明らかになったギャップと限界に基づき、調査結果の質、妥当性、信頼性を向上させ、それが農薬リス ク評価にどのように影響を与えるかについて、将来の疫学的研究のための潜在的な改善点を提案する。これには、 研究デザイン、ばく露評価、データの質とアクセス、健康影響の診断分類、統計解析が含まれる。(セクション 4 の

回答 24-33 頁: セクション 8.1、8.2 及び 8.3 の推奨事項 54-58 頁。54-58)

- 3) 情報及び/または基準が不十分または不足している分野を特定し、リスク評価における適用を改善し最適化する ために、農薬疫学的研究をどのように実施するかについての提言を行う。これらの推奨事項には、第1項で特定 されたギャップと限界に基づいて、ばく露評価(バイオモニタリングデータの使用を含む)、脆弱な集団のサブグル ープ及び/または対象となる健康影響(生化学的、機能的、形態学的、臨床的レベルでの)の調和を含むべきで ある。(セクション 4.2-4.5 の回答 27-33 頁、セクション 5.3 36 頁:セクション 8.1 c) 1-4、56 頁の推奨事項)
- 4) WOE などの評価報告書草案のピアレビュープロセスにおいて、疫学的情報を実験毒性学、AOP、作用機序などのデータと統合しながら、農薬のリスク評価に疫学的知見を適切に活用する方法について議論する。(6.2 及び 6.3 節の回答 37-45 頁、7 節 45-54 頁:8.4 節の回答 58 頁)

上記で説明したように、適切な疫学的データと承認後のサーベイランスは、ハザードの特定や、方法論の改善により ハザードの特徴を明らかにすることで、リスク評価の枠組みに有用に貢献することができる。WOE 解析、不確実性分析、 バイアスの同定と推定により改善することができる。利用可能な関連文献を収集し、システマティックレビューを含む関 連する EFSA 基準を用いてその妥当性と質を検討し、EU 法で規定されている DAR、RAR、承認後の枠組みの中で 結果の議論を導入することは申請者の責任である。

適切な品質の定義には、サンプルサイズの解析、統計的手続き、効果の大きさの推定値の浮動、バイアスの評価、 導き出された結論への寄与が必要である。研究の特性は、リスク評価プロセスのすべての関連ポイントで考慮する必要 があり、例えば、生殖に関する疫学的データは、生殖影響を明らかにするために計画された実験動物研究と一緒に考 慮され、生殖毒性(ECHAの場合)のための表示勧告の背景で考慮される。

EU 域外の国での使用実績がない限り、関連する疫学的研究は、DAR への影響が制限されるが、RAR とサーベイ ランスの枠組みは、最初の承認後の時間が経つにつれて、また他の法域での原薬の先行使用がある場合には、段階 的に疫学から恩恵を受けることができる可能性がある。RAR とサーベイランスのプロトコールはこの違いを反映させるこ とが推奨される。

上記の提言は、リスク評価における疫学的データの利用に関連した現在及び将来の強み・弱み・機会・脅威の解析 に基づく詳細な論拠に基づくものである。大まかには以下の通りである。

#### 強み:

- ・その証拠は人間の特定のリスクに関するものであること。
- ・健康影響は、毒素へのすべてのばく露の影響を総合的に測定するものであること。
- ・影響を受ける可能性のある人々から主観的な経験を引き出すことができること。

#### 弱み:

- ・ 農薬へのばく露は通常複雑である;特定の有効成分の寄与は容易に解読されない。
- ・ばく露は、正確に管理された条件が不足している様々な設定で発生する。
- ほとんどのデータは混合集団の反応を再現している。
- 多くのデータは低レベルの関連性を示しており、再現性がなく、高度な解析を必要とする。

機会:本意見書に記載されている限界は、公表されている多くの疫学研究に適用されるが、農薬のリスク評価に利益 をもたらす機会がある。これには以下が含まれる。

- ・軽微な健康影響を明らかにし、敏感な小集団の経験を明らかにする可能性のある研究のために、非常に多くの潜 在的にばく露された個人にアクセスできること。
- ・ 潜在的な毒素とその残留物の組織負荷を確立するためのバイオモニタリングと新しい分子アプローチを用いたば く露推定の改善の見通し。
- ・実験動物の反応に基づく従来のリスク評価にとトのデータを完全に統合する可能性。
- WOE, AOP, Expert judgement, Expert Knowledge Elicitation (EEKE) 及び Uncertainty Analysis を利 用して、潜在的に関連性のあるデータの質の違いを評価する。
- ・ 専門の疫学者や統計学者と協力して、疫学的結果の解釈を再検討し、慢性ばく露リスクや複合ばく露リスク、用量

反応データなどの困難な分野に取り組むための改善案を提案する機会がある。

・ 様々な国の情報源からのデータを蓄積することには、大きな情報技術の機会が存在する。関連する法的、方法論 的、倫理的な問題が克服されれば、より多くの価値あるデータを収集することができる。このデータが社会的利益 のために「ビッグデータ」の設定で使用できる形で利用できるようになれば、疫学研究を大幅に改善できる可能性 がある。しかし、第一に、個人のプライバシーと本質的な商業的な機密性を守る必要がある。これらの障害が克服 されれば、疫学研究の統計的な力を向上させ、ハザードをより良く特定し、場合によっては特徴づけるために応用 することができる。これらの目的は、EU の高いレベルで合意された行動によって効果的に実現することができる。 データとインタラクティブなプラットフォームを提供するための相互間承認は、集団の健康情報、食品消費データ、 有効成分と共調合製剤の空間的・時間的な適用データの調和によって裏付けられる必要がある。このような豊富 なデータは、因果関係と信頼性のエビデンスを強化する基準である一貫性の向上を支援することが期待できる。そ れは、農薬毒性からの特別な保護を必要とするかもしれない脆弱なグループをよりよく特定できるようになる疫学研 究のためのより大きなサンプルサイズを約束している。

#### 脅威:

- ・ 非現実的であり、社会に否定的な結果をもたらすとト集団や野生生物、環境に対するリスクレベルの認識が広まっ ていること。
- 他の有効な情報源からのデータを損なうような、誤った陽性または誤った陰性の結論をもたらす不十分な実験計 画。
- 効果的なサーベイランスが行われていなかったり、匿名化された適切なデータを社会的利益のために利用できる。 ようにする気がなかったりした結果、新たなリスクに対応できなかったこと。
- ・登録(がんや先天性異常)やサーベイランスプログラムによるばく露(特に職業上ばく露)に関する適切な情報収集 の失敗によるデータの浪費。
- 診断基準の調和の失敗、統合解析のための十分に詳細な組み合わせ可能な形でデータを記録しなかったことに よるデータの浪費、健康統計データベースに入力されるデータの最適な品質を可能にするための関連するトキシ ドロームについての医療や救急医療スタッフのトレーニング不足。

## 用語集と略語

ADI	一日の許容摂取量。食品または飲料水に含まれる農薬の量の尺度で、相当な健康リスクを伴わず
	に生涯にわたって日常的に(経口的に)摂取することができる。
ADME	薬理学(及び毒物学)で使用される略語(体内動態)で、化学物質の吸収、分布、代謝及び排泄
	のために使用され、生物体内でのその処理を示す。
AOP Adverse O	utcome Pathway(有害性転帰経路)。リスク評価に関連する有害な影響につながる生物学的事象
	を構造的に表現したもの。
ARfD	急性参照用量(Acute Reference Dose)。食品または飲料水に含まれる農薬の量(通常は体重べ
	ースで表される)の推定値で、評価時に知られているすべての事実に基づいて、24時間以内に消
	費者が健康上のリスクを認めずに摂取できる量。
バイオマーカー	「生物学的マーカー」とも呼ばれる。正常な生物学的プロセス、病原性プロセス、または治療的介
	入に対する薬理学的反応の指標として客観的に測定され、評価される特性。
BMD	ベンチマークドーズ。バックグラウンドと比較して有害な影響の反応率(ベンチマーク反応または
	BMR)に所定の変化をもたらす閾値の用量または濃度。95%の下限値(BMDL)が計算され、健
	康に基づいた参照値を導き出すための出発点としてさらに使用される。
HBM	ヒューマンバイオモニタリング(Human biomonitoring)。ヒトの生物学的体液または組織におけ
	る化学物質及び/またはその代謝物の測定。また、すべてのばく露経路からの総合的なばく露か
	ら得られる化学物質の内部ばく露量とも呼ばれる。
ヒトデータ	研究者が研究参加者に働きかけることなく、要因と健康影響との間の自然な関係を観察する観察

による研究(疫学研究とも呼ばれる)が含まれる。警戒データもこの概念に該当する。対照的に、研 究者が研究デザインの一部として介入する介入研究(実験研究または無作為化臨床試験とも呼 ばれる)は、本意見書の範囲外である。

- IARC International Agency for Research on Cancer(国際がん研究機関)。世界のがんの原因と発生に関する 研究を実施し、調整することを役割とする世界保健機関(WHO)の機関。
- LOAEL(LOAEL) 最小中毒量(Lowestobserved-adverse-effect level)。毒性試験で評価され、有害な影響(対象生物の形態、生化学、機能、または生涯への有害な変化など)を示す化学的ストレス因子の最低濃度または用量。

NOAEL 無毒性量。毒性または毒性影響が観察されなかった最高用量。

- OR オッズ比。ばく露と結果との関連性を示す尺度。OR は、特定のばく露を受けた場合に転帰が起こ る確率を、ばく露がなかった場合に転帰が起こる確率と比較して表している。
- PBTK-TD Physiologically based toxicokinetic/toxicodynamic modelling (PBTK-TD) Physiologically based toxicokinetic/toxicodynamic modelling とは、生理学的プロセスに関する先端的な知識 を他の既知/観察された情報と統合して、ヒト、前臨床試験動物種及び/または他の生物の体内で の化合物の転帰と影響を模倣することを目的とした数学的モデル化手法である。
- PPP 植物防疫製品(農薬)。用語「pesticide(殺虫剤)」はしばしば「plant protection product(植物 防疫製品)」と互換的に使用されるが、pesticide(殺虫剤)は植物/作物以外の用途、例えば biocide(殺生物剤)などもカバーするより広い用語(農薬)である。
- RR 相対リスク(Relative risk)。ある事象(病気の発生など)がばく露したグループで発生する確率と、 比較対照の非ばく露グループで発生する確率との比。

RMS Rapporteur(ラポーター)の加盟国。農薬有効成分の毒性評価に関する書類の評価及び評価を 最初に担当する欧州連合の加盟国。

感度 ある検査で個人を正しく「疾病」と同定する能力。疾患が存在する場合に検査が陽性となる可能性。 特異性 個人を疾患無しと正しく同定する検査の能力。疾患がない場合に検査が陰性である可能性。

代替エンドポイント(surrogate endpoint)臨床エンドポイントの代わりとなることを目的としたバイオマーカー。

# 付属書 A-EFSA の外部科学報告書でレビューされた農薬疫学研究及びその他のレビュー

EFSA 外部科学報告書(Ntzani ら、2013 年)によって収集された広範なエビデンスは、疫学研究からの農薬ばく 露と健康影響に関するかなりの量の情報が利用可能であることを強調している。それにもかかわらず、このエビデンス の質は通常低く、多くのバイアスが結果に影響を与え、結論を出すことができない可能性が高い。特に、ばく露疫学は 長い間、測定と定義の貧弱さに悩まされてきたが、特に農薬に関しては、これは常に評価と定義が非常に難しいもので あった。

## A.1. EFSA の外部研究報告書

## A.1.1. 方法論的品質評価

外部研究報告書は、2006年1月1日から2012年9月30日までに発表されたすべての疫学研究の包括的なシ ステマティックレビューから構成されており、農薬ばく露ととト健康関連影響の発生との関連性を調査している。

対象となる研究の方法論的評価(各研究に関連するバイアスのリスクを評価する)は、研究デザイン、研究対象集団、 ばく露の定義の詳細度、ばく露の測定方法、測定の特殊性に焦点を当てた。マッチングモデルや多変量モデル、盲検 化されたばく露評価、十分に説明された有効な結果評価を通じた交絡因子の説明などの取り組みが検討された。

方法論的評価の要素は、Research Triangle Institute (RTI; Research Triangle Park, NC, USA)の項目バンク で検討されたもので、観察による研究の偏りのリスクと精度を評価するための実用的で検証済みのツールである。これ らの要素を以下に示す(表 A.1)。

# 表 A.1: Research Triangle Institute (RTI; Research Triangle Park, NC, USA)の疫学研究の方法論的評価のための項目バンクの要素

質問	- 高リスク	低リスク
研究デザイン(有望、回顧的、混合、断面的)	回顧的、混合、該当なし	有望
除外基準が明確に記載されている(はい、部分的に、いいえ)	いいえ	はい
著者は電力計算について言及しています(はい、いいえ)		はい
暴露の記述の詳細レベル(高、中、低)	低	高
暴露のロバストな測定(バイオマーカー(有);小面積生態学的尺度、職	いいえ	はい
種、アンケート(部分的);大面積生態学的尺度(無)に基づいている。)		
曝露の尺度は特定のものだったか? はい;より広範な化学的に関連した	いいえ	はい
グループに基づいて(部分的)、多様な化学的および毒性学的特性の広範		
なグループに基づいて(いいえ)。		
グループ間の配分のバランスを図る(層別化、マッチングなど)。	いいえ	はい
潜在的な交絡因子の調整を行った(はい、いくつか、いいえ)。	いいえ	はい
被ばく状態に盲検化された評価者(コホート研究の場合)	いいえ	はい
有効かつ信頼性の高い尺度を用いて評価された結果は、すべての研究参加	いいえ	はい
者に一貫して実施されているか?		
サンプルサイズ	低	最大
ラフな品質評価	6 以上の回答で高リスク	6以上の回答で低リスク

結果の定量的な統合は、対象となる結果ごとに 5 件以上の適格な研究があり、発表されたエビデンス間に実質的な 異質性がない場合に試みられた。出版バイアスは、10 件以上の研究がメタアナリシスに含まれている場合に、非対称 性を視覚的に確認できる漏斗プロットを用いて評価した。

毒性学的データは、外部科学研究報告書ではレビューまたは議論されなかった。

## A.1.2. 除外基準

レビューの時点で入手可能な疫学的証拠の総合的に評価するために、EU で禁止されているものを含むすべての 種類の農薬を検討した。

除外基準。

www.efsa.europa.	eu/efsajourna
------------------	---------------

474

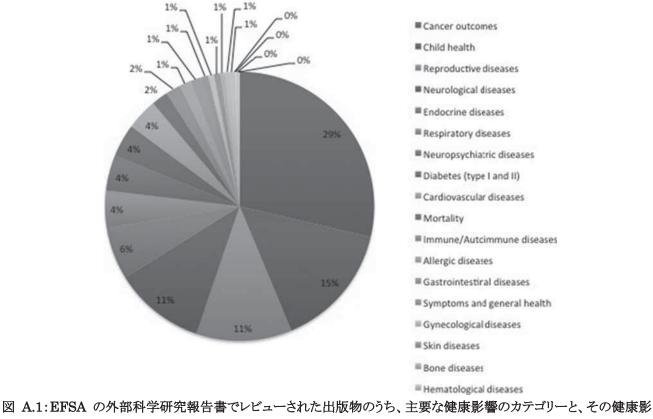

- ・ 対照集団のない研究(症例報告、症例シリーズ)及び生態学的研究
- ・農薬中毒または偶発的な高用量ばく露
- ・影響の推定に関する定量的な情報がない研究
- ・データの重複を避けるために、追跡期間が異なり、同じ健康影響(アウトカム)を調査している研究については、 追跡期間が最も長いもののみを残した。
- ・様々な病状の治療に使用される物質の有害影響について言及した研究(例:ワルファリンをベースとした抗凝固 薬)。
- ・農薬中の溶剤やその他の非有効成分(補助剤など)の研究
- ・ばく露とばく露のバイオマーカーとの関連性を検討した研究は、健康影響を調べないため対象外とされた。
- ・ 農薬へのばく露を調査した研究/解析:ヒ素、ヘキサクロロシクロヘキサン(HCH)aまたはb、鉛、ダイオキシン 類及びポリ塩化ビフェニル(PCB)を含むダイオキシン様化合物は考慮されなかった。
- ・ ナラティブレビューは除外したが、システマティックレビューやメタアナリシスは除外しなかった。

急性中毒または臨床症例のシリーズである出版物、健康影響とは無関係のバイオモニタリング研究、または動物また はヒトの細胞システムで実施された研究は含まれず、ヒトの健康影響を扱った疫学的研究のみが選ばれた。また、関連 性を測定するための定量的データを欠く出版物も除外した。

コホート研究、症例対照研究及び横断研究が含まれた。各研究は、研究デザイン、除外・包含基準の正確な記述、 ばく露の記述の詳細度、ばく露の測定の強固性、潜在的な交絡因子の調整、健康影響の評価方法、サンプルサイズ 等の12の基準を含む方法に基づいて適格性の評価を受けた。これら12の基準のうち、3つの基準はばく露の記述・ 測定の精度に関連しており、多くの疫学研究が選ばれなかった理由を説明することができるかもしれない。

# A.1.3. 結果

全体では、602の個別の論文が科学的レビューに含まれている。これら 602の出版物は、6,479の異なる解析に対応していた。エビデンスの圧倒的多数は後ろ向きまたは横断研究(それぞれ 38%と32%)であり、前向きな研究は 30%のみであった。ばく露評価は研究によって大きく異なり、全体の 46%が農薬ばく露のバイオマーカーを測定し、さらに 46%が農薬ばく露を推定するためにアンケートを使用していた。研究のほぼ半数(49%)がアメリカを拠点としていた。 ほとんどの研究では、農薬への職業性ばく露と健康影響との関連性が調査されていた。農薬に関連する疾患の全領域を対象とした研究はこれまで行われていなかった。報告書では、さまざまなアウトカムを調査している(図 A.1)。最も多いのは、がんのアウトカム(N=164)と子どもの健康に関するアウトカム(N=84)である。

# 図 A.1: EFSA の外部科学研究報告書でレビューされた出版物のうち、主要な健康影響のカテゴリーと、その健康影響を調査した研究の割合(Ntzaniら、2013 年)

利用可能な大量のデータと大量の分析(>6,000 件)にもかかわらず、研究されたアウトカムの大部分については確 固たる結論が出ていない。これは、収集したデータのいくつかの限界と、レビュー自体の固有の限界によるものである。 上述したように、レビューでは約5年間に農薬に関連して検討されたアウトカムの全範囲が調査された。したがって、最 近のエビデンスのみがレビューされ、実施されたメタアナリシスの結果は、利用可能なすべてのエビデンスを含んでい るわけではないため、慎重に解釈されるべきである。したがって、文献全体(5年以上)をみて、選択したエビデンスの 信頼性を評価することに焦点を当てることで、農薬に関連してさらに詳細な解析を行う価値のある結果を浮き彫りにす ることができる。研究自体の限界は、環境疫学の他の分野と一致しており、ばく露評価、研究デザイン、統計解析、報 告に焦点を当てている。特に以下の点が挙げられる:

a) ばく露評価: ばく露の評価は、おそらく ESR でレビューされた研究の中で最も重要な方法論的限界である。研究では、ばく露の評価と割り付けにさまざまな方法が用いられている。ほとんどの研究では、「これまでに使用したことがあるかないか」または「定期的に使用したことがあるかないか」という自己申告による農薬へのばく露に基づいていた。このような方法では、高い誤分類率に悩まされ、用量反応分析を行うことができない。これは特に後ろ向き研究の場合で、病気のある参加者で報告されるより高いばく露量の差が誤分類を生じる(想起バイアス)(Raphael、1987年)。アンケートは非常に高いばく露レベルと非常に低いばく露レベルの被験者を区別することができるかもしれないが、ばく露濃度による有効な分類を行うことはできず、その結果、用量反応関係の研究を行うことができない。また、ばく露評価のためのアンケートは、疫学研究で使用するために検証される必要がある。それにもかかわらず、多くの研究では検証されていないアンケートを使用しているが、これには内容(アンケートが対象とする有害なばく露源をすべて網羅していない)や基準妥当性(例えば、不正確な想起や質問の誤解)に問題があるかもしれない(Coggon、1995年)。

調査対象とした農薬のカテゴリーの範囲は広いが、研究では多くの場合、広く定義された農薬のカテゴリーに集中しているため、対象集団がどのような種類の農薬にばく露されているのかを知ることは困難である。

農薬へのばく露は、研究参加者による農薬の使用報告または政府の登録データとして定義された。これらのデータ

は、自己記入式アンケート、質問者が管理するアンケート、職業性ばく露マトリックス(JEM)、居住状況(農薬ばく露に 近接しているかどうか)、農薬ばく露に関連するバイオマーカーの検出、または各研究によって定められたその他の方 法から得られたものである。

- 研究では、欧米の集団や EU ですでに禁止されている農薬を調査することが多い。ばく露評価の手段としてバイオ マーカーを使用することはまれであるが、ほぼ半数の研究ではまだ利用可能である。
  - b)研究デザイン:上述したように、エビデンスの大部分は症例対照研究と横断研究から得られている。横断研究や一部の症例対照研究では、時間的関係を完全に評価することができないため、関連性の因果関係に関する裏付け を提供することができない。
  - c) 調査された健康影響:臨床健康影響の定義は、適格な疫学研究において大きなばらつきを示しており、これが結果のばらつきの原因となっている。おそらくこのような状況において最も重要なのは、調査された多数の代替健康 影響の使用である。代替健康影響とは、特定の臨床転帰の代替または予測因子として一般的に受け入れられているバイオマーカーまたは身体測定値のことである。しかし、多くの場合、これらの代替健康影響は検証されておらず、代替健康影響の厳密な定義を満たしていない。このような健康影響は、臨床健康影響の予測因子の可能性があるとされているが、代替健康影響の基準を満たしていない。これらの健康影響の暗黙の仮定を考慮に入れることにより、検証されていない代替健康影響に関するエビデンスを評価することが不可欠である。

広範囲の病態生理をカバーすると評価されたアウトカムは非常に多様だった。データベースに含まれる多くの代替 健康影響と同様に「ハード」な臨床健康影響は、評価された臨床研究の課題にアプローチするために支持された異な る方法論を反映している。さまざまな健康影響は 23 の主要な疾患カテゴリーに分類されており、がんと小児の健康影響を扱った研究が最も多くを占めている。

評価された健康への悪影響には以下のものが含まれる。

- a) がん、呼吸器(アレルギー)、生殖(受精率低下、先天性疾患)、神経変性(パーキンソン病)などの主要な臨床転 帰;
- b)神経発達障害(神経認知スケールで評価)などの臨床代替健康影響;
- c)検査での代替健康影響(例:肝酵素の変化)。

農薬ばく露に起因する多くの有害な健康影響については、矛盾した、あるいは曖昧な研究が存在する。この結果が 一貫性の欠如からくるものなのか、真の不均一性からくるものなのかは、さらなる解明が必要である。

d)統計的解析。

異なる供給源からの複数の物質(重金属、溶剤、浮遊粒子状物質など)への同時ばく露は一般的である。それらの すべてが有害な健康影響をもたらす可能性があるため、結果にさらなるバイアスがかかる可能性がある。したがって、 真の関連性を明らかにするためには、複数の物質へのばく露による交絡を考慮することが不可欠であるが、EFSAの 外部科学研究報告書で評価された圧倒的多数のエビデンスでは、これは不可能であった。

さらに、EFSA の外部科学研究報告書(Ntzani ら、2013 年)で収集・評価されたエビデンスは、都合の良い報告と 複数の試験に悩まされる可能性が高い。研究は非常に広範な解析を報告しており、602 の出版物で 6,000 の解析が 行われた。多重仮説検定の量は膨大である。これらの解析は、複数の仮説検定のために調整されていなければならず、 そうでなければ結果は高い偽陽性率に悩まされる。研究が 1 つの解析しか行われていない場合でも、他の疫学的研究 でも示されているように、都合の良い報告の可能性が常にある。さらに、結果を解釈する際には、特に特定の健康影響 (がんなど)については、エビデンスの大部分が単一の研究集団そして特に農業健康調査から得られていることも考慮 に入れるべきである。

#### A.1.4. EFSA 外部科学研究報告書の結論

上記で強調された限界にもかかわらず、外部科学研究報告書(Ntzani ら、2013 年)では農薬ばく露とパーキンソン病及び小児の白血病との関連、これらは先行するメタアナリシスでも裏付けられている、について首尾一貫したエビデンスを示した。さらに、肝臓がん、乳がん、II 型糖尿病など、これまであまり研究されてこなかった多様な健康影響につ

いてもリスクの増加が認められた。内分泌疾患、喘息、アレルギー、糖尿病、肥満などの他の健康影響への影響は、リ スクの増加を示しており、今後さらに調査が必要である。

小児白血病とパーキンソン病は、2006 年以降のメタアナリシスで一貫して農薬ばく露に関連したリスクの増加を示した2 つの健康影響である。それにもかかわらず、特定の農薬クラスや個々の農薬の影響を解きほどくためには、ばく露をよりよく研究する必要がある。他の健康影響についても、有意な要約推定値が報告されている(表 A.2 に要約)。しかし、これらは2006 年以降の研究であるため、結果は関連性を示唆するものとみなすべきであり、特にばく露の不均一性に関する限界は常に考慮されるべきである。存在しうるバイアスの量を定量化し、バイアスの推定値を考慮に入れても農薬との関連性が十分に支持される結果を分離するために、2006 年以前の出版物を含むように結果を更新した後、特定の健康影響に関連してこれらのデータにデータ統合と統計ツールを適用すべきである。同様に、結論を出すためにさらなるエビデンスが必要な健康影響は、強調される必要がある。

健康面での成果	N	メタアナリシスの	<sup>2</sup>
	studies	結果	
白血病	6	1.26 (0.93; 1.71)	59.40%
ホジキンリンパ腫	7	1.29 (0.81-2.06)	81.60%
小児白血病(妊娠中の農薬ばく露)	6	1.67 (1.25-2.23)	81.20%
小児白血病(妊娠中の殺虫剤ばく露)	5	1.55 (1.14–2.11)	65%
小児白血病(妊娠中に殺虫剤にばく露された場合-ターナー,2010 年の更新)	9	1.69 (1.35–2.11)	49.80%
小児白血病(妊娠中に不特定多数の農薬にばく露された場合	5	2.00 (1.73-2.30)	39.60%
小児白血病 (妊娠中の特定されていない農薬へのばく露 - ターナー、2010 年の更新)	11	1.30 (1.06–1.26)	26.50%
小児白血病(小児期の農薬ばく露)	7	1.27 (0.96-1.69)	61.10%

#### 表 A.2:報告書で実施されたメタアナリシスの概要

N=メタアナリシスのために検討された研究の数;メタアナリシス結果の列では、数字は効果の大きさ(オッズ比(OR)または相対リ スク(RR))の統計的推定値を、対応する 95%信頼区間(Cl)とともに表している。

l<sup>2</sup>は、研究間の総変動のうち、不均一性に起因する割合を示す。

Epidemiological studies and pesticides

#### A.2. INSERIM レポート

2013 年 9 月、フランス国立保健医療研究所(INSERM)は、農薬へのばく露によるとト健康影響について専門家グ ループと共に実施した文献レビューを発表した<sup>22</sup>。2012 年 6 月までの科学文献に発表された疫学的または実験的デ ータが解析された。報告書には、文献的解析を概説し、主要な結論と政策及び勧告を強調した要約が添付されている。

INSERM の報告書は4つの部分から構成されている。(1) ばく露評価、疫学研究におけるばく露を評価するための 直接的及び間接的な方法の詳細な説明、(2) 疫学、2012 年までの文献で利用可能な疫学研究のインベントリと解析 及び推定される関連性の強さを評価するためのスコアリングシステム、(3) 毒性学、いくつかの物質の毒性学的データ (代謝、作用機序、分子経路)のレビューと生物学的妥当性の評価、(4) 推奨事項。

健康影響の発生と推定される中等度または強い関連性を持つと INSERM の報告書で特定された物質の大部分は、 現在禁止されている化学物質である。これは主に、調査された疾患の大部分が高齢者の疾患であるという事実によっ て推進されている。したがって、これまでに実施された研究は、研究の時点で高齢であり、何年も前にばく露された人に 基づいている。結論から言うと、最近の製品の多くの潜在的な長期的影響を調査することはまだ可能ではない。

これらの物質は、DDT やトキサフェンのような有機塩素系殺虫剤や、テルブフォスやプロポキサーのようなコリンエス テラーゼ阻害作用を持つ殺虫剤のグループに属している。

INSERM の専門家評価報告書で確認された 7 つの承認された有効成分(除草剤 2,4-D、MCPA、メコプロップ、グ リホサート、殺虫剤クロルピリホス、葉の殺菌剤マンコゼブとマネブ)のうち、すべてが造血器がんとの中等度または弱い 関連性があると推定されていた。そのうち 2 つ(葉状殺菌剤マンコゼブとマネブ)はパーキンソン病との関連性が弱いと 推定され、2 つ(クロルピリホスとグリホサート)は専門家の評価で弱い、または中等度とされた発達障害との関連性があ ると推定された。

#### A.2.1. 疫学研究におけるばく露評価方法の説明

ばく露を評価するために、生物学的または環境モニタリングデータ、その場しのぎのアンケート、職業別または作物 別のばく露マトリクス、専門家のカレンダーの分析、販売データ、土地利用データなど、さまざまな方法(直接的及び間 接的)が開発されてきた。著者らによると、これらの様々なツールは互いに組み合わせることができるが、現在までのとこ ろ、職業性農薬ばく露評価の背景でばく露を推定するための基準となる方法として有効性が確認されていない。

#### A.2.2. 疫学

INSERMの専門家グループは、文献で入手可能な疫学研究の目録作成と解析を行い、農薬ばく露と健康影響との 関連性の可能性を検討した。8 つのがん部位(非ホジキンリンパ腫、白血病、リンパ腫、多発性骨髄腫、前立腺、精巣、 脳、メラノーマ)、3 つの神経変性疾患(パーキンソン病、アルツハイマー病、筋萎縮性側索硬化症)、認知・抑うつ障害、 生殖能への影響(受胎性、胎児と出生児の発生)、小児がんである。これらは、以前の研究で農薬ばく露に関連する可 能性があるとして同定されている健康影響である。

主に農家、農薬散布者、農薬製造業の労働者を対象とした疫学的研究と、関連性がある場合には一般集団を対象 とした研究が選ばれた。

INSERM の専門家グループは、研究の関連性における階層を設定し、メタアナリシスを最上位に置き、次にシステ マティックレビュー、コホート研究、そして最終的には症例対照研究とした。この階層に基づいて、研究結果の解析から、 ばく露と健康影響の発生との間の関連性の推定の強さを評価するためにスコアリングシステムが定義された;調査され た各疾患や病態について、このスコアは、例えば、利用可能な研究の質、種類、数によって異なる。

(++):強い推定:メタアナリシスの結果に基づく、または複数のコホート研究、または少なくとも1 つのコホート研究と2 つの症例対照研究、または2 つ以上の症例対照研究。

(+):中程度の推定:コホート研究または入れ子になった症例対照研究または2つの症例対照研究の結果に基づ

<sup>&</sup>lt;sup>22</sup> INSERM. 農薬。 sante への影響。 Collection expertise collective, Inserm, Paris, 2013.

く。

(±):弱い推定:1件の症例対照研究の結果に基づく。この統合により、この作業は単純なマッピング作業の状態を 超えたものとなった。

## A.2.3. 毒性学的データ

文献レビューで検討した毒性データは、主に代謝、作用機序、分子経路に関するものであった。製品を上市するための手続きの一部として提供された研究は、公表された文献で発表された場合を除き、考慮されなかった。

疫学研究で物質が明らかに同定された場合には、研究結果から生物学的に妥当であるかどうかを評価するためのス コアリングシステムを設定した:病態生理学的データとの整合性と健康影響の発生。

(++):3つの毒性メカニズムで支持された仮説。

(+):少なくとも1つの毒性メカニズムによって支持された仮説。

## A.2.4. 所見

INSERM 報告書の主な結果は、表 A.3-A.6 にまとめられている。

健康面での成果	リスク過剰が顕著な集団のタイプ	推定の強さ (a)
エヌエイチエル	農家、農薬散布者、製造工場関係者	++
前立腺がん	農家、農薬散布者、製造工場関係者	++
多発性骨髄腫	農家、農薬散布者	++

## A.2.5. 推奨事項

いくつかの有効成分に関する利用可能な疫学的・機序学的データを解析した結果、さらなる研究開発のためのいく つかの推奨事項が示唆された。

- a) 農薬への集団ばく露に関する知識は改善されるべきである。
  - 1) 農家の有効成分使用に関する情報収集
  - 2) 実際のばく露レベルを測定するための農地での研究の実施
  - 3) 生涯労働期間のばく露を監視すること
  - 4)空気(屋外・屋内)、水、食品、土壌中のばく露レベルの測定
  - 5) 急性中毒に関する情報収集
  - 6) バイオモニタリングや外部ばく露量測定のための解析方法の改善
  - 7)研究者が広範な製剤データ(溶剤、共配合製剤など)にアクセスできるようにする。
- b) ばく露と健康影響との間の潜在的な関連性を研究する。
  - 1)健康影響をもたらす物質または物質群の特性を把握する
  - 2)影響を受けやすい個人または集団に焦点を当てる(酵素の遺伝子多型など)
  - 3) ばく露枠と感受性(妊娠期間、発育期間)に焦点を当てた研究
  - 4) 疫学と毒物学のギャップを埋める(作用機序)
  - 5) 混合物の毒性に関する知識の向上

6)研究の新しいアプローチ(in vitroや in silicoモデル、オミクスなど)を育成する。

#### A.3. EFSA 外部科学研究報告書と INSERM 報告書の類似点と相違点

ここで議論されている2つの報告書は、異なる方法論を使用している。しかし、多くの場合、それらの結果と結論は一致している。INSERMの報告書は、事前に調査された結果に限定されており、毒物学的データもレビューすることで疫学研究の生物学的妥当性を調査しようとしているのに対し、EFSAの報告書は、約5年の期間に発表されたすべての利用可能な疫学研究の包括的なシステマティックレビューである。

両報告書の違いは表 A.7 に示されており、検索期間(すなわち、両報告書は同じ出版データを評価していない)、研究の適格性の基準の違い、健康影響全体と健康影響内のエビデンスを要約するアプローチの違いに関連している。

全体的に、INSERM の報告書は EFSA の報告書よりも多くの健康被害との関連を特定している。しかし、同じ健康 影響(小児白血病、パーキンソン病)については、両方の報告書で農薬ばく露との関連性が十分に証明されていると主 張されている。

# A.4. The Ontario College of Family Physicians の文献レビュー(OCFPLR)

2004 年、カナダの The Ontario College of Family Physicians は、1992 年から 2003 年の間に発表された、農 薬ばく露に関連した主要な健康影響に関する文献をレビューした。著者らは、表 A.8 に示すように充実性腫瘍と農薬 ばく露との間には正の関連が存在すると結論づけた。著者らは、よく計画された大規模コホート研究では、これらの関 連性は一貫して統計的に有意であり、その関係は高ばく露レベルで最も一貫していたと指摘している。また、用量反応 関係がしばしば観察され、研究の質は概ね良好であるとした。

+ve: positive; -ve: negative.

報告書は、農薬ばく露と非ホジキンリンパ腫(NHL)の発症との関連性を示す説得力のあるエビデンスがあり、また農 薬ばく露と白血病との間に正の関連性があるという明確なエビデンスがあると結論づけている。著者らはまた、様々な ばく露時間の経過から生じる多くの神経系への影響についても一貫した結果が得られたと主張している。

このような断定された結論は、非政府組織(NGO)の支持を得て、いくつかの規制当局の間で疑問が生じた。当時の

英国政府の独立諮問委員会である農薬諮問委員会(ACP)は、オンタリオ大学レビューの結果の評価を依頼された。 委員会のメンバーには1人の疫学者が含まれており、委員会は、他の政府の委員会に独立した助言を提供することに 関与している他の5人の疫学者に相談した。彼らはすべてのレビューが主要な欠点を持っていたことに同意した(例え ば、正確な検索戦略と特定されていない選択基準、結果の選択的な報告、不適切な理解と関連する毒性学の考慮、 ばく露のルートとレベルへの不十分な注意、正当化された結論、等)。全体的に、オンタリオ大学レビューの結論は、提 示された解析によってサポートされていないと考えられた。2012年には、オンタリオ大学レビューの著者は、彼らの評 価の更新を発表した;彼らの2番目の報告書では、彼らは非常に似たようなアプローチを使用したが、使用される包含 基準に関するより詳細を提供した。この例は、疫学研究の過剰解釈のリスクを思い起こさせるものである。特に、ばく露 と有害な性健康影響の発生との間の因果関係を推論することはよくあるが、これはさらに評価されるべき関連性を示し ている。 Epidemiological studies and pesticides

### 付属書 B-EFSA が委託したヒト・バイオモニタリング・プロジェクト23

2015 年、EFSA は、疫学研究におけるばく露評価のためのツールとして、また、農薬への職業上ばく露による潜在 的な健康リスク評価に貢献するために、労働安全衛生戦略における HBM の役割をさらに調査するためのプロジェクト を外部委託した。実際、ばく露評価はすべての疫学研究の重要な部分であり、ばく露の誤分類や単純な分類法の使用 は、接触と健康被害の結果との間に関連性があるかどうかを判断する研究の能力を弱めてしまうことが知られている。

Risk & Policy Analysts Limited (RPA)、IEH Consulting Limited (IEH)、Health & Safety Laboratory (HSL)からなるコンソーシアムは、1990 年から 2015 年までの期間、系統的な文献レビューを実施した。その目的は、 作業ばく露評価の再開発のためのツールとしての HBM の使用に関する概要を提供し、長所、短所、さらなる開発の 必要性を特定することであった(第一の目的)。検索では、農薬(またはその代謝物)への職業上ばく露を評価するため の HBM の使用に関連する 2096 の文献を特定した。検索の結果(Bevan ら、2017 年)は、過去 10~20 年の間に HBM の使用が拡大してきたこと、特に環境や消費者のばく露分析の分野にまで拡大してきたことを示している。しかし、 農薬ばく露評価のための HBM の使用については、特に、分析品質の向上や標準化のための戦略の開発、代謝物の ための標準物質の利用可能性の向上、数学的モデリングへの HBM データの統合、ばく露の再構築、分析機器の改善、ヒト毒性データの利用可能性の向上など、さらなる改善が必要とされている。

請負業者は、EU/米国の作業環境で実施された利用可能な HBM 研究/サーベイランスプログラムのレビューを 実施し、残留性のあるものと残留性のないものの両方の農薬(または代謝物)を特定した。最も関連性の高い研究を特 定するために、HBM、疫学的、毒性学的側面の品質スコアリングを含む 2 段階のスクリーニングプロセスを利用し、 178 件の研究をクリティカルレビューの対象とした。特定された研究のスクリーニングと並行して、これらの文献からのデ ータを照合するためにマスタースプレッドシートが計画され、その中には、研究タイプ、研究参加者、調査対象の化学 物質、バイオマーカーの品質チェック、分析方法、ばく露評価、健康影響/毒性エンドポイント、追跡期間、結果の説 明、バイアスのリスク、その他のコメントに関する情報が含まれている。

HBM は、様々な農薬への作業者のばく露を監視するために広く使用されている。職業上の農薬の使用に関する疫 学的研究では、不十分なばく露情報や後ろ向きなばく露情報が制限されていることが見受けられる。職業別または作 物別のばく露マトリックスの使用例も報告されている。しかし、実際のばく露データに対するこれらのマトリックス研究の 検証はほとんど行われていない。季節的なばく露と PPE の影響を調査したデータは非常に限られており、多くの研究 では、1 つまたは 2 つの特定化合物のみを評価するために HBM を使用している。現在、健康リスク評価には多種多 様なばく露モデルが採用されており、モデルによって予測されたばく露推定値を評価するためにバイオマーカーもしば しば使用されている。

関連性があると判断された 178 の出版物から、41 の個別研究が除草剤を含み、そのうち 34 の個別除草剤が同定され、そのうちの 15 が現在 EU での使用が承認されている。同様に、殺虫剤を含む 90 件の個別研究のうち、79 件の殺虫剤が同定され、そのうち 18 件は現在 EU での使用が承認されている。20 の個別研究には殺菌剤が含まれており、34 種類の殺菌剤が確認され、そのうち 22 種類が現在 EU での使用が承認されている。最も研究された除草剤は(順に)、2,4-D>アトラジン>メトラクロール=MCPA>アラクロール=グリホサートであることが示されている。同様に、最も研究された殺虫剤(順に)は、クロルピリホス>ペルメトリン>シペルメトリン=デルタメトリン>マラチオンであり、最も研究された殺菌剤は、キャプタン>マンコゼブ>フォルペットであった。

現在の限界は、特にとトを対象とした個々の農薬の ADME に関して、とトからの動特性データの数が限られているこ とに起因しており、これにより、すべてのばく露経路についてより正確な HBM サンプリングが可能になる。このことは、 毒物動態データに依存する農薬のリスク評価のための PBPK モデルの開発や、現在使用されているばく露評価モデ ルのバリデーションにも影響を及ぼす。現在、この分野での HBM の使用に影響を与えているさらなる限界は、現在使 用されている農薬への長期ばく露を評価するための大規模な前向きコホート研究が不足していることである。

特定されたエビデンスは、ヨーロッパにおける農薬の労働衛生サーベイランスの一環としての HBM の実施に関する

<sup>23</sup> Bevanら

推奨事項を策定するために使用されている。実施を可能にするために克服しなければならないいくつかの重要な問題 が検討された。その中には、新しいスペックや感度の高いバイオマーカーの開発の優先順位の設定、健康に基づいた ガイダンス値の導入と採用、研究間の計測値を検証するための QA スキームの開発、野外作業やアンケートの作成に おける良好な実施、バイオバンキングの使用範囲の拡大、農薬の安全性の承認後のモニタリングにおける HBM の使 用などが含まれている。

# 付属書 C-ハザードの特定のための疫学研究の統合に関する国際規制機関の経験 C.1. WHO-国際がん研究機関(IARC)

国際がん研究機関(IARC)の「ヒトに対する発がん性リスク評価に関する IARC モノグラフ」は、ヒトのがんリスクを増加させる可能性のある環境ばく露を評価するために 40 年前に設立されたプログラムである。これらには、個々の化学物質や化学物質の混合物、職業上ばく露、物理的要因、生物学的要因、生活様式の要因が含まれる。

IARC は、科学者からなる国際的な学際的作業部会を組織し、科学的出版物からのエビデンスの質と強度をレビューして評価し、懸念される物質がヒトに発がんリスクをもたらす可能性を評価するためのハザード評価を実施している。 特に、IARC ワーキンググループのメンバーの役割は、がんに関する疫学的研究やその他の実験的研究の結果の評価、発がんのメカニズムに関するデータの評価、ヒトへのばく露による発がん性の総合的な評価を行うことである。

モノグラフは、世界中の政府、組織、公衆衛生の予防・管理措置を設定するために広く利用され、参照されている。

IARC モノグラフの前文<sup>24</sup>は、プログラムの範囲、モノグラフの開発に使用される科学的原理と手順、考慮されるエビ デンスの種類、評価の指針となる科学的基準を説明している。モノグラフの範囲は、単一の化学物質だけでなく、関連 する化学物質のグループ、複雑な混合物、職業上ばく露、物理的・生物学的物質、生活様式の要因を含むように拡大 された。そのため、モノグラフのタイトルは「ヒトに対する発がん性リスクの評価」となっている。

関連する疫学研究、実験動物を用いた発がんバイオアッセイ、メカニズムデータ、ばく露データなどが批判的にレビューされている。公表されている科学文献に掲載された、または掲載が認められた報告書のみが含まれる。しかし、研究を含めることは、研究デザインの妥当性や結果の分析と解釈を受け入れることを意味するものではない。利用可能な研究の質的側面は慎重に精査されている。

モノグラフではハザードの特定を強調しているが、がんのハザードを評価するために用いられた疫学研究や実験研 究と同じものを、用量反応関係を推定するためにも用いることができる。モノグラフは、利用可能な疫学データの範囲内 で用量反応関係を推定することもあれば、実験研究と疫学研究の用量反応情報を比較することもある。

モノグラフの構成は以下のようになっている。

1)ばく露データ

2) ヒトにおけるがんの研究

3)実験動物を用いたがんの研究

4)メカニズム等の関連データ

6)評価と根拠

ヒトの疫学的データは、関連するすべての疫学的研究が評価されている 2)に記載されている。バイオマーカーの研究は、ヒトに対する発がん性の評価に関連する場合に含まれる。

疫学研究の IARC 評価には、以下の基準の評価が含まれる:検討された研究の種類(例:コホート研究、症例対照 研究、相関(または生態学的)研究及び介入研究、症例報告)、研究の質(例:バイアス、交絡、生物学的変動及び影 響の推定精度に対するサンプルサイズの影響)、メタアナリシス及びプール分析、時間的影響。例えば、最初のばく露 時の年齢、最初のばく露からの時間、ばく露の期間、累積ばく露、ピークばく露などの時間的変数)、疫学研究におけ るバイオマーカーの使用(例えば、ばく露のエビデンス、初期効果のエビデンス、細胞、組織または生物の反応のエビ デンス)、因果関係の基準。

因果関係に関する特定の基準では、問題の薬剤がとトに対して発がん性があるというエビデンスの強さに関して判断 がなされる。

判断を下す際に、作業部会は因果関係についていくつかの基準を考慮している(Hill、1965 年)。強い関連性(例 えば、大きな相対リスク)は因果関係を示す可能性が高い。しかし、疾患やばく露が一般的な場合には、弱い関連性が 重要であることが認識されている。異なるばく露条件で計画の異なる複数の研究で再現された関連性は、単一の研究

www.efsa.europa.eu/efsajourna

489

<sup>5)</sup>まとめ

<sup>&</sup>lt;sup>24</sup> http://monographs.iarc.fr/ENG/Preamble/CurrentPreamble.pdf

からの孤立した観察よりも因果関係を示す可能性が高い。異なる研究間で一貫性のない結果が得られた場合には、考 えられる理由(例えば、ばく露の違い)を探り、方法論的に健全でない研究よりも質の高い研究の方が重要視される。明 確な用量反応効果がないからといって必ずしも因果関係を否定するエビデンスにはならないが、ばく露に伴ってリスク が増加することは因果関係を示す強いエビデンスと考えられている。ばく露の停止または減少後にリスクが低下してい ることが示された場合も、結果の因果関係の解釈を支持するものである。時間性、影響の推定精度、生物学的妥当性、 全体的なデータの一貫性が考慮される。バイオマーカー情報は、疫学的観察の生物学的妥当性の評価に使用される ことがある。被験者と非被験者でがんの発生率が異なることを示している無作為試験は、特に因果関係を示す強力な エビデンスとなる。

疫学的研究でばく露とがんとの間の関連性がほとんど、または全く示されない場合には、発がん性がないと判断する ことができる。このような場合、研究は、バイアスの可能性、交絡の可能性、またはばく露の誤分類を含めて、上述の計 画と解析の基準を評価するために精査される。さらに、方法論的に健全な研究は、観察されたばく露レベルのどのよう なばく露についても、影響の推定値が一致していること、相対リスクのプール推定値がほぼ一致すること、そして狭い信 頼性間隔を持つことに一貫性があるべきである。さらに、個々の研究も、すべての研究のプール結果も、ばく露レベル の増加に伴うリスクの増加を示すべきではない。発がん性がないというエビデンスは、研究されたがんの種類、報告され たばく露量及びこれらの研究で観察された最初のばく露と疾患発症の間の期間にのみ適用できる。ヒトのがんの経験 から、最初のばく露から臨床症状のがんの発生までの期間が20年よりも長いことがあり、30年よりも実質的に短い潜伏 期間は、発がん性の欠如のエビデンスを提供できないことが示されている。

最後に、疫学研究の結果、標的臓器または組織、用量反応関連、ヒト及び動物のデータのエビデンスの強固さの評価、メカニズムのエビデンスの強固さをまとめた総合評価に到達するために、エビデンスの全体像を検討する。

総合評価の最後に、以下のいずれかのグループに分類される。グループ 1、その薬剤はヒトに対して発がん性がある;グループ 2A、その薬剤はおそらくヒトに対して発がん性がある;グループ 2B、その薬剤はヒトに対する発がん性に関して分類できない;グループ 4、その薬剤はおそらくヒトに対して発がん性がない。

薬剤の分類は、とト及び実験動物での研究、ならびにメカニズム及びその他の関連データから得られたエビデンスの 強固さを反映する科学的判断の問題である。これらの分類は、ばく露が発がん性であるというエビデンスの強固さにの み言及しており、発がん性(可能性)の程度には言及していない。

例えば、グループ 1:その薬剤はヒトに対して発がん性がある。このカテゴリーは、ヒトにおける発がん性の十分なエビ デンスがある場合に使用される。例外的に、ヒトにおける発がん性のエビデンスが十分ではないが、実験動物における 発がん性の十分なエビデンスがあり、ばく露されたヒトにおいて、その薬剤が発がん性の関連メカニズムを介して作用 するという強いエビデンスがある場合には、薬剤はこのカテゴリーに分類される。国際的に広く受け入れられているが、 過去には特定の薬剤の分類に対する批判があり、より最近の批判は、そのような評価のために IARC が採用した一般 的なアプローチに向けられており、反論の発表を動機づける可能性がある(Pearce ら、2015 年)。

#### C.2. リスク評価における疫学的研究の統合に関する US-EPA の経験

米国環境保護庁の農薬プログラム(OPP)は、農薬製品の登録と規制を担当する米国の政府機関である<sup>25</sup>。この活動の一環として、また農薬の使用が許可される前に、OPPは農薬がビト健康と環境に及ぼす影響を評価している。

EPAは、連邦殺虫剤・殺菌剤・殺鼠剤法(FIFRA)及び連邦食品・医薬品・化粧品法(FFDCA)を通じて、農薬製品のリスクを特性評価するための広範なハザード及びばく露情報を入手している。農薬の毒性影響に関する情報は、一般的に、農薬登録者が実施し、EPAに提出する実験動物を用いた研究から得られている。

これまでは、農薬へのばく露に関連する可能性のある潜在的なリスクを EPA が評価するための情報として、農薬に 関する十分に計画された疫学研究から得られた情報は一般的には得られていなかった。農薬へのばく露と健康影響と

www.efsa.europa.eu/efsajourna

490

<sup>&</sup>lt;sup>25</sup> 農薬科学及び農薬リスクの評価に関する一般的な情報については、https://www.epa.gov/pesticide-science-and-assessing-pesticide-risks を参照のこと。

の間に考えられる関連性を調査する疫学研究が文献に掲載されることが増えてきたため、EPA はこの情報源をさらに 重視している。これは、20 年以上にわたって 9 万人近くの個人を追跡した大規模でよく実施された前向きなコホート研 究である農業健康調査(Agricultural Health Study<sup>26</sup>(AHS)や、小児環境保健・疾病予防研究センターから得られ た豊富な研究に特に当てはまる。EPA<sup>27</sup>は、このような疫学的情報を最も科学的に強固で明白性の高い方法で利用す ることを目標に、ヒトの健康リスク評価においてこれらの疫学的研究をより多く利用することを意図している。

# C.2.1. OPP 疫学的フレームワーク文書

このプロセスの初期段階として、EPA-OPPは、2010年に「健康リスク評価にヒトの疫学的データ及びインシデントデ ータを組み込むためのフレームワーク(Framework for incorporated human Epidemiologic and Incident Data in Health Risk Assessment)」(US-EPA、2010 年 a)という疫学的枠組み文書案を作成した。2010 年のフレームワ ーク草案は、2010年2月にFIFRA科学諮問委員会(SAP)によって好意的にレビューされた(US-EPA、2010年b)。 この文書は最近、2016 年に「Office of Pesticide Programs' Framework Document for Incorporating Human Epidemiology and Incident Data in Risk Assessments for Pesticides」(US-EPA、2016年)に更新された。改訂 及び更新された2016年のフレームワーク文書は、疫学研究(ヒト事例データベース、バイオモニタリング研究に加えて) でみられるようなヒトの情報が、実験的な毒性学的情報とともに、実際の化学物質ばく露によって引き起こされる影響に ついての予測を提供することで、この新しいアプローチにおいて重要な役割を果たすことが提案されている。さらに、疫 学的/分子疫学的データは、追加解析の指針となり、潜在的に影響を受けやすい集団や新たな健康影響を特定し、 既存の毒物学的観測を補完する可能性がある。2016 年版フレームワークの概念は、専門家の査読を経た強固な原則 とツールに基づいており、疫学データのレビューと評価のための多くの既存のガイダンス文書とフレームワーク(表 C.1) に依存している。また、問題設定の重要性と生物学的組織の異なるレベルでの情報統合の必要性を強調した世界保 健機関/国際化学安全計画(MOA)/ヒト関連性フレームワークの更新とも一致している(Meek ら、2014 年)。さらに、 このフレームワークは、2009年の報告書「Science and Decisions (NRC、2009年)」の中で、複雑な科学的分析の最 初に問題の定式化を使用することの重要性を説明しているという点で、全米科学アカデミーの全米研究評議会(NAS /NRC)の勧告と一致している。問題の定式化の段階は、解析の目標と可能なリスク管理戦略を特定するためのリスク 管理者との計画的な対話から始まると想定されている。この最初の対話は、科学的解析のための規制の背景を提供し、 そのような解析の範囲を明確にするのに役立つ。問題設定の段階では、農薬の使用/使用、懸念される毒性学的影 響、ばく露経路、持続時間、データや科学的情報の主要なギャップに関する利用可能な情報を考慮することも含まれ ている。

表 C.1: OPP が使用している主なガイダンス文書とフレームワーク(US-EPA、2016 年より)

EPA フレームワーク文書は、このような疫学的研究及び科学的情報を農薬化学物質のリスク評価にどのように組み 込むことができるかを評価する際に、また、有害性転帰経路(または MOA)の理解との関連で複数の科学的エビデン スを評価するための基盤を提供する際に、EPA が考慮する科学的考察を記述している。このフレームワークは、疫学、 毒性学、リスク評価の標準的な手法に依存し、それを支持しているが、新しい情報源や追加の情報源からの情報を取り 入れることも可能である。この機関のフレームワークの重要な構成要素の一つは、実験研究と観察研究の両方で観察 された因果関係の特性を知るために、異なる情報源からの情報を整理して統合するためのツールとして、MOA フレー ムワーク/有害性転帰経路の概念を使用することである。MOA(Boobis ら、2008 年; Simon ら、2014 年; Meek ら、 2014 年)と有害性転帰経路の概念を使用することである。MOA(Boobis ら、2008 年; Simon ら、2014 年; Meek ら、 2014 年)と有害性転帰経路(Ankley ら、2010 年)は、フレームワーク文書で議論されている統合解析において重要な 概念を提供する。MOA と有害性転帰経路の両方とも、化合物へのばく露によって引き起こされる毒性影響は、ヒトの毒 性影響をもたらす一連の因果関係のある生物学的重要事象によって記述できるという前提に基づいており、その目的 は、環境物質へのばく露がこれらのパスウェイをどのようにかく乱させ、それによって毒性影響につながる後続の重要事 象のカスケードを引き起こすかを決定することである。

フレームワークの多くの概念は、全米科学アカデミー(National Academies, Science and Decisions)の2つの報告書:「リスクアセスメントの進展」(Advancing Risk Assessment: NAS 2009 年)と「21世紀の毒性試験」(Toxicity Testing on the 21st Century: NAS 2007 年)から引用されている。これら2つのNRC報告書は、毒性試験の実施方法、データの解釈方法、そして最終的に規制上の政策決定の方法を大幅に変更することを提唱している。特に、21世紀の毒性試験に関する2007年の報告書では、毒性試験、リスク評価、政策決定をより良く伝えるために、現在の先毒性エンドポイントの頂点の使用に焦点を当てたものから、毒性経路を使用することへの決定的な変化を提唱している。

MOA のフレームワークは、原因経路に沿って、そして用量反応、時間的一致、生物学的妥当性、一貫性、一貫性などの要素を考慮に入れ、Bradford Hill によって記述されたものに基づいた基準を使用して、エビデンスの重み付け

に基づいて確立された一連の重要事象を特定することから始まる。特に、修正された Bradford Hill 基準(Hill、1965年)は、MOA または有害な影響の現経路内の重要事象を立証する実験的支持を評価するために使用され、エビデンスの重み付け分析において、強度、一貫性、用量反応、時間的一致、生物学的妥当性などの概念を明示的に考慮している。この分析的アプローチを用いることで、疫学的結果は、報告された結果の一貫性、再現性、生物学的妥当性を評価し、不確実性の領域と将来の研究を特定するために、他のヒト情報との関連で評価することができる。以下の図C.1(NRC、2007年より引用)は、異なるタイプの情報が生物学的組織の複数のレベル(分子レベルから集団ベースのサーベイランスに至るまで)でどのように相互に関連しているかを示唆しており、遺伝子、タンパク質、低分子がヒトの細胞機能を維持する分子経路を形成するためにどのように相互作用するかという急速に発展している科学的理解に基づいている。

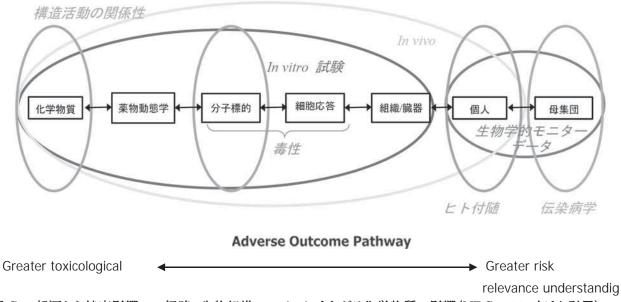

図 C.1:起源から健康影響への経路。生物組織のレベルにまたがる化学物質の影響(NRC、2007年より引用)

# C.2.2. システマティックレビュー:目的にかなった

全米アカデミーの全米研究評議会(NRC)は、EPA の IRIS プログラムのレビューにおいて、システマティックレビュ ーを「特定の問題に焦点を当て、明確かつ事前に特定された科学的方法を用いて、類似しているが別個の研究の結 果を特定、選択、評価、要約する科学的調査」と定義している<sup>28</sup>。近年、NRC は、規制上の政策決定に情報を提供す るために化学的特異性リスク評価をサポートする科学的な文献レビューの明白性を高めるシステマティックレビュープロ セスに移行することを EPA に勧めている<sup>6</sup>。

NRC の勧告に沿って、EPA-OPP は、政策決定を支える科学的データの収集、評価、統合のための明白性の高い 方法に依拠した、目的にかなったシステマティックレビューを採用している。そのため、各システマティックレビューの複 雑さと範囲はリスク評価ごとに異なる。EPA-OPP は、対象範囲/問題策定から始まり、データ収集、データ評価、デー タ統合及び重要なデータギャップが特定された結果の要約が行われる。

システマティックレビューでは、対象となる研究の結果をまとめるために統計的手法(メタアナリシスなど)やその他の 定量的手法を使用することが多く、利用可能なエビデンスのレベルや存在する可能性のあるバイアスの程度を評価す るために半定量的な採点システムを使用することができる。EPAの農薬プログラム管理局の場合、規制審査プロセスの 一環として実施されるこのような Tier III(システマティックレビュー)評価には、審査中の農薬化学物質と、(最初の Tier II 評価で示唆されたように)特定の関連する健康影響が疑われる農薬化学物質の審査が含まれることになる。

米国の多くの連邦政府やその他の組織が、このようなシステマティックレビューの実施方法を評価したり、ガイダンス

<sup>&</sup>lt;sup>28</sup> http://dels.nas.edu/Report/Review-Integrated-Risk/18764 www.efsa.europa.eu/efsajourna

文書を発行したりしており、多くのフレームワークが開発されている。これらには、EPA IRIS プログラムのアプローチ<sup>29</sup>、 National Toxicology Programs'Office of Health Assessment and Translation (NTP/OHAT) アプローチ<sup>30</sup>、 Cochran Collaboration のアプローチ<sup>31</sup>、Campbell Collaboration 及び Navigation Guide<sup>32</sup>が含まれ、後者については Environmental Health Perspectives 誌の一連の記事で説明されている。それぞれのアプローチは、データ収集、データ評価、データ統合、要約/更新という 4 つのステップを大まかに共有している。例えば、The Cochrane Collaboration は、The Cochrane Handbook for Systematic Reviews of Interventions for evidence-based medicine の中で、システマティックレビューの重要な主要特性の多くをリストアップしている(US-EPA、2016 年)。

- ・ 目的が明確に示されており、研究の適格性基準があらかじめ定義されていること
- ・明示的で再現性のある方法論
- ・ 適格性基準を満たすすべての研究を特定するための系統的な検索
- ・ 特定された研究から得られた知見の妥当性の評価
- ・収録された研究の特性と知見を体系的に提示し、総合的にまとめたもの。

この付属書の以下のセクションで説明・詳述されているように、農薬リスク評価への疫学的データのレビューと統合に 対する OPP のアプローチは、「作成された評価が必要な政策決定を報告するのに適しており有用であることを確認し (US-EPA、2012 年)、必要な供給源が、より詳細な研究から得られる予測または予測される情報と一致しているか、バ ランスが取れていることを確認する」という意味で、各段階が目的に応じて適切に実施される段階的なアプローチを採 用している。Tier I 評価は、調査及び評価が AHS に由来する研究に限定されている場合の、調査実施または調査実 施の更新のいずれかである。Tier II 評価では、疫学的文献の広範な検索、包括的なデータ収集、より深く、より関与し たデータ評価が行われ、より広範であるが、一般的には範囲が疫学に限定されており、疫学、ヒト中毒事例、動物毒物 学、有害な影響経路を横断した学際的な統合には至らない。Tier III 評価は、データ統合とより広範なデータ評価と抽 出を伴う完全なシステマティックレビューであり、メタアナリシスやメタ回帰、因果関係推論/因果関係図、定量的バイア ス解析や感度分析などのより高度な疫学的手法を含むことがある。

# C.2.3. 現在及び将来予想される EPA 疫学レビューの実施

## C.2.3.1. Tier I (scoping と問題の定式化)とTier II (より広範な文献検索)

現在 EPA では、農薬の疫学的レビューは、上述の通り、リスク評価の進展に応じて段階的なプロセスで実施されて いる。この初期段階の Tier I/scoping 疫学報告書の目的は、プロセスの問題の定式化/scoping 段階で関連性の高い 疫学研究が検討され、適切な場合には、プロセスの(後期の)リスク評価段階で十分に検討されるようにすることである。 Tier I 段階では、EPA-OPP は、農薬問題に焦点を当てた質の高い有名なコホート研究、特に農業健康調査 (Agricultural Health Study:AHS)に焦点を当てている。AHS は、農薬ばく露とがん及びその他の健康影響との関 連を評価する連邦政府出資の研究であり、米国国立がん研究所(NCI)、国立環境衛生科学研究所(NIEHS)、CDC の国立労働安全衛生研究所(NIOSH)及び米国環境保護庁との共同研究を代表するものである。AHS 参加者コホー トには、アイオワ州とノースカロライナ州の 89,000 人以上の免許を持つ商業及び民間の農薬散布者とその配偶者が含 まれている。登録は 1993 年から 1997 年まで行われ、データ収集は現在も継続中である。AHS は、AHS コホートに 関連した、またそれを利用した出版物のリストをウェブサイトに掲載している (https://aghealth.nih.gov/news/publications.htmlを参照)。

対象となる農薬がAHS(www.aghealth.org)の一部として調査されている場合、EPAの「scoping」解析の一環として内容摘要(または「調査資料」)が公表されるため、評価の早い段階でこれらの研究の予備的な(Tier I/scoping)レビ

<sup>&</sup>lt;sup>29</sup> <u>https://www.epa.gov/iris/advancing-systematic-review-workshop-December-2015</u>年を参照。

<sup>&</sup>lt;sup>30</sup> http://ntp.niehs.nih.gov/pubhealth/hat/noms/index-2.html 及び NTP の「系統的レビューとエビデンス統合のための OHAT アプローチを 用いた文献ベースのアセスメントを実施するためのハンドブック」https://ntp.niehs.nih.gov/ntp/ohat/pub s/handbookjan2015\_508.pdf を参 照。

<sup>&</sup>lt;sup>31</sup> http://handbook.cochrane.org/を参照。

<sup>&</sup>lt;sup>32</sup> http://ehp.niehs.nih.gov/1307175/を参照

www.efsa.europa.eu/efsajourna

ューが実施される。この初期の段階では、AHS研究の基本的な疫学的結果と結論は、審査中の農薬に関連するAHS 結果がある場合には、様々な AHS 研究の著者による適切な結論を簡潔に要約することを目的とした Tier I/scoping 文書に記載されている;この Tier I scoping レビューは詳細な内容、批判的な評価またはエビデンスの統合を提供す るようになっていなくて AHS に関連する学術論文の要約されたハイライトに触れる可能性があるだけである。子ども環 境保健・疾病予防研究センター(Children's Environmental Health and Disease Prevention Research Centres) の研究のように、AHS 以外の高品質な研究がある場合は、これらの研究も同様にこの Tier I/scoping 疫学レビューに 要約されているかもしれない。繰り返しになるが、文献の批評や統合は行われていない。場合によっては、Tier I/scoping レビューでは、利用可能なエビデンスの追加的な疫学的レビューはこれ以上必要ないと結論付けられること がある。あるいは、より詳細な Tier I/update または Tier II 評価の一部として、更なるレビューが必要であると勧告する 場合もある。

Tier I/update 評価は通常、Tier I/ scoping 評価の完了から1年から3年後に完了し、後述するTier II と同様に、 ヒト健康リスクアセスメント案(Draft Human Health Risk Assessment)と一緒に、またその一部として発行される。 Tier I/update アセスメントでは、AHS で利用可能な文献の徹底的なレビューが行われる。Tier I/update 評価では、 AHS のウェブサイトに掲載されている該当する研究を質的、叙述的な要約(報告された関連性の尺度を含む)でレビュ ーし、要約し、評価する<sup>33</sup>。レビューは一般的に叙述の形式で行われ、研究の主要な側面とその結論に焦点を当て、必 要に応じて EPA OPP の結論の要約及び更なる研究のための勧告に加えて EPA OPP の解説を含む。

# C.2.3.2. Tier II(より広範な文献検索)

Tier II 評価は、利用可能な疫学的証拠のより完全なレビューであり、一般的には、初期の Tier I/scoping 文書が特 定の懸念の可能性を示唆している場合にのみ実施される(例えば、特定で信頼できるばく露・疾病仮説が進められてお り、より詳細な評価の一部としてさらに評価する必要がある)。Tier II 疫学評価は、Tier I/update と同様に、一般的に Tier I 評価の完了から 1 年から 3 年後に完了し、OPP のヒトの健康リスク評価案 (Draft Human Health Risk Assessment)と一緒に、またその一部として発行される; Tier II 評価はシステマティックレビューの特定の要素を組み 込む定性的で叙述的なレビューだと考えられる。例えば、Tier II 評価では、AHS データベースだけでなく、PubMed、 Web of Science、Google Scholar、Science Direct などのデータベースや、場合によっては標準化された明白で再現 性のある照会言語を使用して、専門の図書館や情報科学の支援を得て、Tier I 評価よりも広範囲に及ぶ徹底した完全 な文献検索が含まれている<sup>34</sup>。EPA によるエビデンス統合 (一般的には定性的かつ叙述的な形式で行われるが)も Tier II 評価では行われ、疫学的文献に関する全体的な結論が出されている。さらに、Tier II 評価は、特別な仮説とし てばく露・健康影響に関する更なる疫学的データや研究が将来の研究のための興味深い分野を示す可能性がある。 Tier II 評価文書は一般的に、疫学的知見を、動物毒性試験や、リスク評価の一部としてある程度(別個にに)行われる MOAs/AOPs からの情報などの他のエビデンスと統合しようとはしない。特定の農薬に関連すると考えられる特定の健 康影響が特定される範囲までの Tier II 評価に対して、その後のより包括的な Tier III 評価では、分野を超えた更な る調査及び統合を行うことができる(下記参照)。

# C.2.3.3. Tier 3(データ統合を伴う完全なシステマティックレビュー)

Tier II 評価では、ある農薬化学物質との関連性があると仮説が立てられている疫学的文献に現れる広範な健康影響を検討するが、Tier III 評価では、より広範な(学際的な)疫学的根拠に基づく、時にはより定量的/統計学的な評

価を行い、これを動物毒性学や MOA/AOP 情報とより正式に統合しようとするものである。このような Tier III 評価は、 疫学的文献のシステマティックレビューの形をとり、毒性及び有害な転帰の経路の評価と併せて実施される。

AHS 由来の農薬化学物質については、Tier III 解析では、他の質の高い疫学調査の評価結果を取り入れ、より多 様な情報源を再調査するために「エビデンスの重み付け」をより多く取り入れることが理想的である。これらの調査の結 果は、AHS の結果との再現性と一貫性を評価するために使用される。多くのケースにおける初期の AHS の結果は、 特定の健康影響を示した少数の参加者、または参加者を追跡した年数が比較的少ない参加者に基づいている。AHS コホートの高齢化に伴い、AHS からのいくつかの化学物質の 2 回目の評価の発表は、さらなる追跡調査の年数と、ば く露と健康影響の間の正負の関連を解釈するためのより強固な根拠となると期待されるより多くの症例数に基づいて行 われることになるであろう。さらに、AHS では、疫学研究の結果の解釈を助けるために、かなりの量の生化学的、遺伝 的マーカー及び分子データの生成が増加している。このような結果は、AHS の結果をさらに明確にしたり、ばく露と健 康影響を結びつける生物学的基盤のエビデンスを提供したり、あるいは因果関係の経路の基礎となるメカニズムのエビ デンスを強化する可能性のある追加の実験研究や観察研究を示唆したりする可能性がある。さらに Tier III 解析では、 AHS がメンバーである国際農業コホートコンソーシアム(AgriCOH)の国際的なコホート研究からの情報と結果をまと める努力を利用することもできる。AgriCOH は、研究間のデータを蓄積するための機会と方法を特定するために積極 的に取り組んでおり、これらの他のコホートデータの利用可能性は、EPA が疫学的データを検討、評価、重み付けする 際に、ばく露ー健康影響の関係の再現性と反復を評価するのに役立つはずである。

## C.2.4. OPP の公表文献検索戦略及び研究の質の評価

システマティックレビューアプローチの重要な側面は、確立された適格基準を満たす多くの文献をみつけることがで きるように、公表されている疫学的文献を徹底的に、体系的に、再現可能に検索することである<sup>35</sup>。OPP は文献検索の 一部として特定のデータベースを使用しており、その実施に関する特定のガイダンスがある(例えば、ヒト健康リスク評価 に関する OPP の公表文献検索ガイダンス<sup>36</sup>)。すべての関連文献の評価、エビデンスの強固さを評価するための標準 化されたアプローチの適用、明確で一貫性のある総括的表現は、一般的に重要な要素となる(NRC、2011年)。さらに、 質の高いばく露評価は、環境疫学研究や職域疫学研究において特に重要である。

上記のシステマティックレビューのアプローチの第二の重要な要素は、同定された研究から得られた結果の妥当性 の評価である。一般的に言えば、疫学研究の質、研究の文書化の妥当性(研究の計画と結果)、リスク評価との関連性 は、政府機関のリスク評価に使用するために公表されている文献から疫学研究を評価する際に考慮される。個々の研 究の質を検討する際には、疫学研究の計画、実施、解析、解釈の様々な側面が重要である。これらには以下が含まれ る(US-EPA、2016年より)。

- 1) 仮説を明確に明示することで、たとえその研究が本質的に仮説生成的なものであったとしても、その仮説を明確に示されていること。
- 2)健康影響の関連する臨界期、リスク評価対象集団の関係あるばく露範囲、試験から得られる用量/ばく露反応の 傾向の入手可能性など、ばく露評価の資質の中で、適切なばく露評価が十分であること。
- 3) 合理的に有効で信頼性の高い結果の確認(研究集団における健康影響の有無を正しく識別されていること)。
- 4)対象集団を代表するサンプル集団となり、系統的な偏りがない適切な組み入れ基準と除外基準。
- 5)観察されたリスク推定値における複数の農薬ばく露、または混合物ばく露の役割の評価または考察を含む、潜在 的な交絡変数の適切な評価及び解析。

<sup>35</sup> 出版バイアスに関連する潜在的な問題を軽減するために、はっきりしない文献や未発表の文献を見ることを提唱する者もいる。

<sup>36</sup> 疫学的データに関する特別な注意事項については、

<sup>&</sup>lt;u>https://www.epa.gov/pesticide-science-and-assessing-pesticide-risks/guidance-identifying-selecting-and-evaluating-open</u>及び2012年 8月28日付けの文書「Guidance for Considering and Using Open Literature Toxicity Studies to Support Human Health Risk Assessment」の10ページを参照のこと。

- 6)参加者の選択や情報収集における誤りを含む、研究における潜在的な系統的な偏りの全体的な特性。これには、 提示されたリスク推定値に対する系統的誤差の潜在的な影響を調査するための感度分析の実施を含む。
- 7) ばく露・健康影響評価のための適切な統計的検出力、または観察された影響に対して検出力が不足している場合 の研究の統計的検出力の影響の評価及び検出力推定値の適切な考察及び/または提示。
- 8)研究デザインと対象となる結果の性質を考慮した適切な統計的モデル化技術の使用。

#### 付属書 D-影響量の拡大/膨張

この文書の本文で説明されているように、研究の検出力が低い場合には、バイアスの潜在的な原因が生じる可能性 がある。このあまり知られていないタイプのバイアスは、「影響量の規模」として知られています。一般的に、小規模で検 出力の低い研究では、研究の検出力が意味のある影響量を確実に検出するには不十分であるため、偽陰性が生じる 可能性があることは広く知られているが、推定された影響が重要、関連性がある、または「発見された」と判断されるため に、統計的閾値(例えば、統計的有意性に使用される一般的な p<0.05 の閾値)を通過する必要がある場合、これらの 研究が影響量の膨張をもたらす可能性があることはあまり知られていない。この影響は、影響量の拡大、「勝者の呪い」、 真実の膨張、または影響量の膨張として様々に知られているが、これは、「発見された」関連性(すなわち、意味がある と判断されるために統計的有意性の所定の閾値を通過した関連性)が、その発見を行うために最適ではない検出力を 持つ研究から得られる現象であり、その結果、意図的かつ体系的に膨張した影響量が生じることになる。

このような真偽の不明確化は、検出力の低い研究で統計的有意差を達成する研究では、帰無値から離れる(系統的 な)バイアスとして現れる(Reinhart、2015年)。これは、検出力の低い(したがって一般的には小さい)研究は、結果が 大きく変動する可能性が高く、大規模な研究よりも個人の間のランダムな変動の影響を受けやすいからである。より具 体的には、どのような研究でも観察されるかもしれない影響量の拡大の変化の程度は、研究の結果がどの程度広く変 化すると予想されるかに部分的に依存しており、これは研究の検出力に依存する;検出力の低い研究は影響量の拡大 の程度を大きくする傾向があり、その結果検出力の高い研究よりも統計的有意性(または他の閾値基準をパスする)を 見出す。

この「影響量の拡大」の概念とその理由の例として、可変のサンプルサイズで何千回も試験を実施した場合を想像す ると便利である。この場合、観察された影響量の広い分布がある。これらの推定影響量の観察された中央値は、真の影 響量に近いと予想されるが、小規模な試験では、大規模な試験に比べて、観察された影響量のばらつきが必然的に大 きくなる。しかし、低検出力の研究では、観察された影響のうち、統計的に有意な(高い) 閾値を通過するのはごく一部 であり、これらの影響は最大の影響量を持つものだけである。このように、一般的に小規模で、ランダム変動が大きい低 検出力の研究では、与えられた統計的閾値を通過した結果、実際に有意性起因の関連を発見した場合、その影響の 大きさを過大評価する可能性が高くなる。これが意味するのは、低検出力で統計的に有意な研究の結果は、膨張効果 となるように偏っているということである。Gelman 及び Carlin(2014 年)が要約しているように、「研究者が小さな影響 を研究するために小さな[検出力不足]<sup>37</sup>サンプルとノイズの多い測定を使用した場合、有意な結果はしばしば驚くほど 間違った方向に行き、影響を大幅に過大評価する可能性が高い」のである。一般的に、バックグラウンド(または対照ま たは無処置)率が低い、対象となる影響量が小さい、研究中のサンプルサイズが小さいと、研究の検出力が低下し、そ の結果、(あらゆる)膨張した影響量の傾向と規模が大きくなることが示されている。

影響量の膨張現象は、発見科学全般に適用される一般的な原則であり、疫学の特殊な現象や弊害ではないことに 注意することが重要である(Ioannidis、2005年;Lehrer、2010年;Button、2013年;Buttonら、2013年;Gelman 及び Carlin、2014年;Reinhart、2015年)。これは、薬理学の研究、遺伝子研究、心理学の研究、そして最もよく引 用される医学文献の多くでよくみられる。ほとんどの疫学研究のように、研究者がサンプルサイズを増加させる能力が限 られている場合、影響効果量の拡大は、研究や研究デザインの機能や欠陥ではなく、むしろ、その研究の結果がユー ザーコミュニティによってどのように解釈されるかという機能である。したがって、疫学研究における選択や情報バイアス のような他のバイアスの可能性とは異なり、バイアスは研究やその計画に内在するものではなく、むしろその研究がどの ように解釈されるかに特徴がある。

統計的に有意な結果をもたらす研究について、影響量の規模の潜在的な程度を決定(定量化)するために、査読者 は様々な検出力の計算を実行しなければならない。より具体的には、化学物質ばく露と疾患との間の関連が統計的に 有意であることが判明した場合、検出力解析は、統計的に有意な影響量の推定値(例えば、オッズ比、相対リスクまた は率比)がどの程度人工的に膨張しているかを決定するために行われる。

<sup>37 [</sup>斜体を付けた]

必要な検出力計算を行うために、査読者は以下の4つの値を知っているか、または得なければならない。

1) 非ばく露群の被験者数。

2) ばく露群の被験者数。

3) 非ばく露群の対象疾患を持つ個人の数(または症例数) 及び

4)2 つのグループ(例えば、ばく露群 vs.非ばく露群)の比較において、所定の(事前決定の)量の差を検出するための対象となる目標値。

最初の3 つの値は文献に記載されているか、文献から入手しなければならないが、対象となる目標値(一般的に疫 学研究ではORまたはRR)はリスク管理者によって選択される(最終的には政策決定である)38。本付属書では、シミュ レーションを用いて、この影響量の膨張現象を定量的に検討する。本付属書では、2 つの公表された研究例と数百件 の試験のシミュレーションを用いて、検出力が低いために偏った影響量(オッズ比、率比、相対リスクなど)を生み出す のに影響量の拡大がどの程度の役割を果たしているかを評価している。

最初の例では、ダイアジノンばく露と肺がんを調査した Agricultural Health Study の前向きコホート出版物からの データを使用し、計算された RR の影響量の偏りの問題を説明している。2番目の例は、マラチオンばく露とNHLを研 究した症例対照研究からの ever-never データを使用して、推定 OR の観点から影響量の拡大の概念を説明する。

#### 影響量の拡大の説明と相対リスクを説明する例(Jones ら、2015 年)

ダイアジノンにばく露されていないものと、最も高い三分位(T)でばく露されているものとの間の比較に関連した検出 力は、肺がんに対する Jones ら(2015 年)の AHS 研究発表「Incidence of solid tumours among pesticide applicators exposed to the organophosphate insecticide diazinon in the Agricultural Health Study - an updated analysis」で提供された情報から計算することができる。各ばく露量での被験者数は文献中に記載されてい た(非ばく露群。N=17710及びT(ertile)1、T2及びT3は、ばく露分布に基づいて分類された;具体的には、各三分 位の N=(2,350 + 2,770)/3=1,710文献の表1から。(a)2,350の値は最も低いばく露量を表し、(b)2,770の値は、 ばく露された被験者を二分法で分類したときの、2つの最も高いばく露量を表している。(i)参照非ばく露群の被験者数 =17,710; (ii) ばく露群(三分位)のそれぞれの被験者数=1710; (iii)参照非ばく露群の罹患者数(肺がん)=199人 (引用文献の表3より)とすると、真の率比=1.2、1.5、または2.0と仮定すると、文献に示されたT1対非ばく露群、T2 対非ばく露群、T3対非ばく露群の比較の検出力を計算することができる。

ここで、我々は、199/17710(=0.011237)の推定バックグラウンド率及び感度分析の形態として、このバックグラウン ド率の1/2(または0.005617)及びダイアジノンにばく露された個人の各三分位の被験者の間で1.2、1.5、2.0及び3.0 の(可能な規制関係の)相対率を検出するためのこの率の2倍(0.022473)に関連する検出力を評価することに注目し ている。この解析はStata統計ソフトウェアを使用して行われ、1.2、1.5、2.0及び3.0の真の率比について、199人の 罹患者/17,710人のバックグラウンド率に対して1/2x・、1x・(太字/網掛けで以下に示す)及び

<sup>&</sup>lt;sup>38</sup>この目標値は対象となる効果量であり、相対リスク(コホート研究の場合)またはオッズ率(症例対照研究の場合)のいずれかで表されることが多い。 すなわち、目標値は一般的に、リスク管理者が一定の確信度で検出したいと考えている一定の大きさの OR または RR である。OR または RR が 高ければ高いほど、ばく露と健康影響との間の推定関連性の規模が大きくなる。何が「弱い」関連性と「強い」関連性を構成するかについての厳密 なガイドラインはないが、約1以下(時には1.2以下)の値は「帰無」または「本質的に帰無」と考えられる(これは、いくつかの背景(例えば、ワクチ ン接種の有効性など)では考慮することが適切であるかもしれない保護効果の可能性を無視している)。2または3未満の値は、しばしば「弱い」と 考えられている。2(または3)より大きく約5までの値は「中等度」と考えられ、5より大きい値は「大」であると考えられている。Monson(1990)は、 関連性の強さの目安として、1.0~1.2を「なし」、1.2~1.5を「弱」、1.5~3.0を「中程度」、3.0~10.0を「強」としている。他の著者は疫学において は Cohenの基準を用いて、1.5を「小」、5を「大」、3.5を「中」と表現している(Cohen and Chen、2010)。また、1.5を「小」、2.5を「中」または「中 程度」、4を「大」または「強」、10を「非常に大きい」または「非常に強い」と表現する人もいる(Rosenthal、1996年)。Taube(1995年)は、弱い関 連性を検出する上での環境疫学の限界について議論している(Wynder(1997年)の反論を示す招待解説も参照のこと)。これらの境界線はどれ も「難しい」ものではなく、どこに線が引かれ、どのように考えられ、どのように解釈されるかについては、正当な意見の相違があり得ることを認識す べきである。それにもかかわらず、これらの境界線は背景に大きく依存するものであり、上記のような境界線は、いかなる意味でも、公式なものでも、 決定的なものでもあると考えるべきではない。

N <sub>control</sub>	$N_{exposed}$	Proportion control <sup>(b)</sup>	Proportion exposed	Relative risk	Power

2x-(観察された)を表形式及びグラフ形式の両方で以下に示す39。

上記の検出力計算結果を生成するために使用される Stata コード:検出力2比例('=0.5\*199/17710'=199/17710'=2\*199/17710), test(chi2) RR (1.2 1.5 2.0 3.0) n1(17710) n2

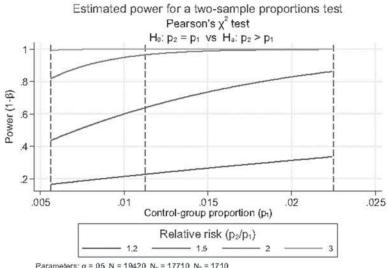

(1710)片側表(N1:"N コントロール" N2:"N エクスポージャー" p1:"割合コントロール" p2:"割合エクスポージャー" RR:"相対リスク" power:"検出力')。

(a):片側検定 a=0.05 Ho:p2=p1 vs Ha:p2>p1; Ncontrols=17,710、Nexposed=1,710;反復回数=1,000回(データセッ ト)。

(b): Jones ら(2015)の199/17710の肺がんの観察されたバックグラウンド率を1/2倍-、1倍-、2倍-を表す。

上表の強調表示/太字の領域は、引用研究における肺がんのこの 1x 観測されたバックグラウンド率に関連した検出力を表してい る。

これらの値は以下のようにグラフ化することができる40。

Parameters: a = .05, N = 19420, N<sub>1</sub> = 17710, N<sub>2</sub> = 1710

<sup>&</sup>lt;sup>39</sup> 1.2、1.5、2.0、3.0のRRは、リスク管理者や意思決定者が関心を持ちそうな一連の相対リスクに関連する検出力検出力を示すために、やや恣意 的に選択されたものである。RR または OR=2.0 と 3.0 の値は、弱い影響量の大きさと強い影響量の間の境界線であると考えられている。RR 値 1.2は、一部の人が「帰無に近い、または本質的に帰無」と考えるものであり、RR値1.5はこれらの間の中間値である。疫学的証拠がばく露と健康 影響との間の関係を示唆しているかどうかを判断する際に、リスク管理者は、許容可能な統計力(一般的には 80-90%と考えられている)を持つ強 固な研究から得られた「本質的には帰無」RR1.2 を、関連性を見いだせなかったことを示す十分なエビデンスであり、事実上、ばく露と健康影響と の間に観察可能な関連性がないという結論を支持するエビデンスを提供していると判断されることがあるかもしれない。

<sup>40</sup> 上のグラフを生成するための Stata コード:乗 2 比例(' = 0.5 \* 199/17710'(0.0001) '= 2 \* 199/17710'), test(chi2) rrisk(1.2 1.5 2.0 3.0) n1(17710) 0) n1(17710) n2(1710)グラフ(recast(line) xline(= 0.5 \* 199/17710" '= 199/17710" '= 2 \* 199/17710', lpattern(dash)) legend(rows(1)size(small)) ylabel(0.2(0.2)1.0))片側グラフである。

1.2-、1.5-、2.0-及び 3.0 の真の RR における制御群比率の関数としての検出力を評価する(片側)2 標本比率検定 の推定検出力を示すグラフ。検定では、1.2-1.5-2.0、2.0-3.0 の真の RR でのコントロールグループ比率の関数として の検出力を評価している。

上の表とグラフからわかるように、本研究では、バックグラウンド率(対照比率、199人の罹患者/17,710人=0.011237) の1倍で約23%の検出力でRR1.2を検出することができた。約64%の検出力が1.5のRRを検出する。真のバック グラウンド率が実際には観測されたバックグラウンド率の2倍(290.011237=0.022473)であれば、RR1.5を検出でき る検出力は約86%、RR2.0を検出できる検出力は実質的に100%となる<sup>41</sup>。

上記を考えると、真の相対リスクを1.2、1.5、2.0、3.0とした場合に、どの程度の影響量の拡大(別名、影響量の膨張) があるかをシミュレーションするために SAS が使用された。下の表は、ダイアジノンと肺がんの検出力解析を示しており、 シミュレーション結果から影響量の拡大の程度を示している。下の表に示された解析は、Ioannidis(2008 年)によって 行われたものと類似していて、彼の表2に示された、影響量の拡大の概念を説明するための正式な統計的有意性の閾 値を通過した仮説的な結果のセットである。

真値		解析した

	1.5	1,000	0.87	871	1.3	1.5 (0)	1.8			
	2	1,000	1	1,000	1.7	2.0 (0)	2.3			
	3	1,000	1	1,000	2.6	3.0 (0)	3.4			

ポアソン回帰モデルが、グループ間の(相対リスク)率を比較するために使用された. EXACT 検定は、一般化ヘシアン行列が正のデフィニートでない場合(グループの1つでゼロのケースがあるため)、いくつかのデータセットの解析に使用された。

(a):片側検定、a=0.05、N コントロール=17,710、N ダイアジノンばく露者=1,710、反復回数=1,000回(データセット)。

(b):このシミュレーションから得られた検出力は、SAS (PROC POWER)や Stata (power two-proportion)のような統計ソフトの組み 込まれた手順から計算された検出力に近いかもしれないが、正確には一致しないかもしれない。これは、シミュレーションされたデ ータセットの数が十分でないためかもしれない。しかし、1,000回の反復は、検出力を適切に推定し、統計的に有意な結果(ここで は、≤0.05)を与えられた影響量の拡大の程度を説明するのに十分である。

p<0.05 で統計的に有意な結果が得られた場合、統計的に有意な結果の中央値での影響量の拡大の変化率は、ダイアジノンにばく露されていない個人の肺がんの割合(すなわち、非ばく露グループの罹患者の割合)と真の相対リスク(1.2 から 3.0 までの範囲)の両方に応じて 0%から 42%まで変化することに注意する。例えば、ばく露対非ばく露の三分位の真の RR が 1.2 であった場合、非ばく露グループの肺がんの割合は 0.011237(上記の表の太字の行)で、観察された統計的に有意な RR の半分は 1.6 の中央値を超えており、半分は 1.6 以下になるだろう;これは、シミュレーションで使用される 1.2 の真の RR の上に 33%の膨張があることを表している。

Jones ら(2015 年)の研究(0.011237)でみつかったバックグラウンド率については、統計的に有意であることが判明

<sup>&</sup>lt;sup>41</sup> 別の言い方をすると、真の(しかし未知の)バックグラウンド率が実際に観測されたバックグラウンド率の2倍であった場合、統計的に有意な関係 がみつからなかった場合、我々は合理的に(86%の信憑性で)真のOR が1.5を超えていないと結論付けることができる。

した真の RR の 1.2 は、前述の中央値 1.6 の代わりに 1.4(10%のパーセンタイルで)から 1.8(90%のパーセンタイル で)に変化することが観察される研究が繰り返されるだろう。 真の RR が 2 または 3 のときには、検出力は 80%以上(上 記の表に見られるように)であり、観測された RR の中央値は真の RR に近く、観測された RR の範囲は狭い。 真の RR が 3 になると、影響量の膨張がなくなり、シミュレーションの中央値が真の RR に回帰するように検出力が増加する。

エバー/ネバー解析における影響量の拡大とオッズ比を示す例(Waddellら、2001 年)

ばく露群と非ばく露群の比較は、三分位や四分位などの他の分類やグループ分けに基づいた比較とは対照的に、 「これまでありと、決してない」の比較で示されることがある。このようなばく露カテゴリーベースの解析は、ばく露カテゴリ ーを小さな(より均質な)ばく露分類やグループに分けるには十分な数の症例数がないため、あるいはばく露の測定値 が利用できないか、あるいは信頼性が低いため(症例対照研究のような)に行われるかもしれない。これらの状況では、 (i)非ばく露群の被験者の総数、(ii)ばく露群の被験者の数、(iii)ばく露群と非ばく露群の間の比較の検出力を計算 するために、非ばく露群の罹患者の数、(iv)与えられた、または事前に選択されたオッズ比が同様に必要となる。

エバー/ネバー分類を用いた症例対照研究において、検出力と影響量の拡大の解析がどのように行われるかを説明するために、マラチオンとNHLの関連性を調査した研究(Waddellら、2001)を選択した。ここでは、(i)基準非ばく 露群の被験者数=1,018人(表1より:非農家=243人の罹患者+775人の非罹患者)、(ii)ばく露群の被験者数=238 人(表4より:マラチオンばく露者=91人の非ばく露者+147人の非ばく露コントロール)、(iii)参照非ばく露群の罹患 者数=243人(表1より:非農家または非ばく露群の243人の罹患者)とすると、真の率比=1.2、1.5、または2.0と仮定 すると、「ばく露ありと、ばく露なし」の比較の検出力が計算できた。

肺がんとダイアジノンについて上述したように、非農家(非ばく露者)では、以下の表に示すように、研究で推定され	/
た NHL の割合が 0.2387 で 1.2 の OR を検出する検出力を 30.5%と推定した。	

片側 2 標本の比率検定の検出力解析の結果 $(a=0.05)^{(a)}$

ロジスティック回帰モデルが、2 つのグループのオッズ比を計算するために使用された。最尤推定値が存在しない場合(おそらくいずれ かのグループの症例がゼロであったため)、EXACT 検定をいくつかのデータセットの解析に使用した。

(a):片側検定、a = 0.05、非ばく露群=1,018、マラチオンばく露群=238、反復 N=1,000 (データセット)。(b):このシミュレーション から得られた検出力は近いかもしれないが、組み込みの SAS (PROC POWER)や Stata (power 2-proportion)のような統計ソフトウェア のプロシージャを使用している。これは、シミュレーションされたデータセットの数が十分でないためかもしれない。しかし、1,000 回 の反復は、検出力を十分に推定し、統計的に有意な結果(ここでは、≤0.05)が得られた場合の影響量の拡大を説明するのに十分である

EFSA Journal 2017;15(10):5007

p<0.05 で統計的に有意な結果が得られた場合、影響量の中央値は、非ばく露群の NHL の割合と真のオッズ比 (1.2 から 3.0 まで)によって、1.4 から 3 まで変化することに注意する。例えば、非農家の NHL の割合が 0.2387 の場 合、真の OR が 1.2(表中の太字の行)とすると、統計的に有意な OR の半分は中央値 1.4 を超え、半分は下回ってい ることになる。さらに、統計的に有意な OR の大部分(90%)は 1.3 以上であることが観察され、少数(10%)は 1.6 以上 であることさえ観察された。

まとめると、疫学研究の検出力は、規制当局や他の人がそのような研究を評価する際に考慮すべき重要な要素であ る。十分な検出力を持つ研究は、与えられた規模の真の効果が実際に存在する場合に検出する可能性が高くなるだ けでなく(検出力の古典的な定義は、II型エラーや偽陰性の問題に関連している)、影響が存在しないが(偶然にも) 事前に選択された閾値(統計的有意性の0.05レベルなど)を超えた場合に、影響を拡大したり誇張したりする可能性 が低くなるだろう。研究が適切な検出力を持っている場合(例えば、80%以上)、観察された影響量は真の影響量を再 現する可能性が高く、この影響量の観察された偶然の変動は、未知の真の値を中心に対称的に分布を再現する。これ らのシミュレーションと Ioannidis によるオリジナルの研究及び Gelman と Carlin(2014年)による拡張研究から得ら れるメッセージは、研究は偽陰性(タイプ II エラー)を回避するために適切な検出力が必要であるだけでなく、統計的 に有意な(または他の閾値を通過した)影響量のために影響量の拡大を回避するために適切な検出力が必要であると いうことである。Gelman と Carlin(2014年)はさらに進んで、そのような「後ろ向き計画の計算は、統計的に有意でな い影響量よりも統計的に有意な影響量に関連しているかもしれない。統計的に有意な結果の解釈は、基礎となる影響 のもっともらしい規模によって大きく変わる可能性がある」と述べている。研究が適切な検出力を持っていれば体系的な リスクの膨張は皆無であるが、統計的に有意な効果をもたらす検出力不足の研究の影響推定値は、実質的なリスク膨 張の可能性があり、その解釈は真の(基礎となる)影響の現実的な推定値に依存することに注意することである。

理想的には、公表されている文献研究は、検出力解析を実施し、文書化するべきである。それ以外にも、公表されて いる文献は、読者がこのような検出力計算(あるいは Gelman と Carlin(2014 年)が言うところの(後ろ向き)デザイン 計算)を行うのに十分な情報を提供すべきである。上記の2つの例では、著者は読者に検出力と影響量の拡大を計算 することができる十分な情報を提供していた。これは常にそうとは限らない。検出力の計算に使用された情報が文献に 部分的にしか提供されていなかったり、提供された情報がそのような計算ができない方法で構成されていたりすること がある<sup>43,44</sup>。例えば、著者が三分位または四分位を決定するためにばく露量の代わりに症例数を使用している場合(こ れはグループ間での症例数が一定であることから証明される)、または著者が複数のがん症例をまとめてグループ化し、 その数を使用して三分位を決定している場合、必要な入力が得られないため、ここに示されている検出力(またはデザ イン)の計算は不可能である。集積及び報告される数値及びデータは、著者及び文献の間で必ずしも標準化されてい るわけではないので、一つの強い推奨事項は、文献が(補足的またはオンラインデータであっても)検出力を推定する ために必要な情報を報告することを義務付けることであり、このような評価を査読者及び関心のある読者の両方ができ るようにすることであろう。

以上の解析から、影響量の膨張現象の潜在的な意味合いは、疫学研究を評価する上で重要な考慮事項であること が示唆されたが、この現象に関するいくつかの注意点を覚えておくことが重要であり、疫学研究の解釈にどのように考

<sup>&</sup>lt;sup>43</sup> 例えば、Stella Koutros ら(2012年)の出版物「Risk of Total and Aggressive Prostate Cancer and Pesticide Use in the Agricultural Health Study」で発表されたマラチオンばく露と侵攻性前立腺がんの関連性のレビューでは、発表された論文に重要な情報が提供されていなか ったため、パネルはマラチオンばく露群と非ばく露群の比較の力を算出できなかった。文献及び文献の補足文書から、非ばく露群の症例数を容 易に把握することができたが(本文中の表 2)、非ばく露群または各ばく露量(四分位)の被験者数は入手できなかったようである。我々は、文献の 補足文書の表 1 の情報から非ばく露者群の被験者数及び各四分位の被験者数を導入しようとしたが、表 1 の情報は、ばく露者を症例数の四分 位に基づいてグループに分類するという他の多くの AHS の出版物と一致しない方法で示されていたため、それを行うことができなかった。

<sup>&</sup>lt;sup>44</sup> 検出力の計算に使用された情報は、文献では部分的にしか提供されていないことがある。例えば、我々は Laura Beane-Freeman ら(2011)に よる AHS 研究文献「Atrazine and Cancer Incidence Among Pesticide Applicators in the Agricultural Health Study(1994-2007)」に記 載されている情報から、様々な甲状腺がんの比較に関連した検出力を計算した。この文献では、著者らは被験者をばく露に基づいて四分位に分 類するのではなく、その代わりに、すべてのがん症例を合わせた総症例数に基づいて被験者を分類またはグループ化した。このようにして、すべ てのタイプのがんの症例数は、分類されたグループ間で同じであり、したがって、対象となる任意の特定のがん(例えば、甲状腺、ここでは)の症例 数は、グループ間で同じではなく、被験者の数は、グループ間で同じではなかった。この例では、文献は、(i)参照 Q1:N=9,523、(ii)Q2、Q3 及 び Q4 の総被験者数を提供した。N=26,834 人(表 1)及び(iii)参考 Q1 の甲状腺がん症例数=3 人(表 2)を提供した。しかし、比較群(Q2、Q3 または Q4)のそれぞれの正確な被験者数は得られなかった。

慮すべきであるかについても留意すべきである。

- -第一に、この現象は、対象となる影響が統計的(またはその他の)閾値を通過するような検出力不足の研究では影響量が膨張する傾向があるが、他にも推定値を帰無に向かって逆方向に偏らせるバイアスが存在する可能性がある。このバイアスは、影響量抑制と呼ばれることがある。おそらく、これらのバイアスの中で最もよく知られているのは、本文で議論されている非差異的誤分類バイアスである。これは、一般的に(常にではないが)帰無値に向かって予測可能なバイアスを生じさせ、それによって影響量を体系的に過小予測する。これが常に正しいとは限らず、(少なくとも小規模の低い検出力の研究については)影響量の拡大のような対抗要因や相殺要因が存在する可能性があることを認識することは、重要な前進である。特に、検出力不足の研究では、例えば、非差異的誤分類バイアスから生じるかもしれない帰無値へのバイアスを潜在的に相殺する(そして、多分相殺以上に)ことができる程度に、帰無値から離れた方向に偏った推定値をもたらすことがある。いずれにしても、重要なことは、統計的に有意な結果を得るための影響量の推定値に少なくともいくつかの最低限の一致度を持たせることができるようにするためには、十分な検出力のある研究が必要であるということを認識することである。
- -第二に、そして本文で述べられているように、影響量の拡大は、研究者(またはそのような研究を解釈する規制者)の側で、その研究が検出力不足の場合に、与えられた有意性の閾値(例:p<0.05)を通過するか、または一定の大きさ(例:OR>3)を達成する影響を特定することに焦点を当てた努力に関連している。この現象は、統計的有意性(または影響量)の「事前スクリーニング」を行う際に最も懸念される現象である。規制者や政策決定者などが、事前に決められた統計的閾値を「通過」した関連性のみに焦点を当てて行動することを避け、研究が検出力不足の場合に効果量の拡大を評価して判断するためにその影響量を使用する場合、この現象はあまり懸念されない。影響量の拡大の決定は、研究や研究デザインの機能や欠陥ではなく、むしろその研究がユーザーコミュニティによってどのように解釈されるかの機能であることに注意する。

残念なことに、与えられた量よりも大きい、またはある統計的閾値を通過して「発見された」影響量に注目が集まる 傾向が時々ある。これらの「発見」がどのように考慮されるべきかに関しては Ioannidis によって推奨されている (Ioannidis、2008年)。

「最初に仮定された発見の時点では、影響量を判断することはおろか、関連性が全く存在するかどうかもわからないのが普通である。最初の原則として、影響量については慎重にならなければならない。不確実性は、単に CI (95%、99%、99.9%であるかどうかは関係ありません)だけでは伝わらない。

新たに提案された関連性については、提案された影響の信頼性と正確性はケースによって異なる。とトは次のよう な質問をするだろう:この分野の研究コミュニティは、研究成果を主張するために、広く統計的な有意性や同様の選 択の閾値を採用しているのか?発見は小規模な研究から生まれたのか?分析に大きな変動の余地があるか?選択 的な報告から保護されていないか(例:プロトコールが前もって完全に利用可能ではなかったか)?特定の「ポジティ ブな」結果を発見し、促進することに興味を持っている人や組織はあるか?最後に、影響を相殺する力は最小限に 抑えられているか?

- 第三に、影響量の膨張現象は、発見科学全般に適用可能な一般的な原則であり、疫学の特異的悩みや弊害で はないことを覚えておくべきである(Ioannidis、2005年;Lehrer、2010年;Button、2013年;Buttonら、2013 年;Reinhart、2015年)。先に示したように、これは薬理学、遺伝子研究、心理学研究、そして最も頻繁に引用さ れる医学文献の多くでしばしば見られる。このような真実性の膨張は、研究の規模が小さく、検出力が不足してい る場合に起こり、そのような研究では結果に大きなばらつきがあるからである。これは、多くの研究者が同様の研究 を行っており、「新しい」または「刺激的な」結果を発表するために競争している場合には特に問題となる (Reinhart、2015年)。

# まとめと結論

影響量の拡大または「真実の膨張」とは、影響を「発見」するために統計的またはその他の閾値を満たす必要がある

検出力不足の研究から得られた効果測定値の場合に、オッズ比、相対リスク、または率比の推定値が誇張されることが ある現象である。この現象は、疫学や疫学研究に特有のものではなく、むしろ、影響が存在するかどうかを判断するた めに、影響量や統計的有意性に関連するような、研究の規模が小さく、事前に設定された閾値が使用される傾向にあ るあらゆる科学に見られる。このように、疫学研究の利用者がこの問題とその潜在的な解釈の結果を認識することが重 要である。特に、検出力不足の研究から発見された関連性は、統計的または他の同様の閾値を通過したことに基づい て強調されたり、注目されたりするが、それは帰無値から系統的にバイアスがかかっている。統計的閾値を通過した「発 見された」」関連性の結果として、特定の研究で観測された影響量が帰無値から遠ざかるかどうかはわからないが(非差 異的な誤分類を示す特定の研究が必ずしも帰無値に向かって偏るとは言えないのと同じように)、ここで提示された説 明と実行されたシミュレーションによって説明されているように、偶然がそのような偏りをある程度有利にすることはわか っている。別の言い方をすると、統計的またはその他の閾値を通過した影響量に基づいて影響量に注目したり、報告し たり、行動したりすることを選択することで、バイアスが導入される(Yarkoni、2009 年)。繰り返しになるが、これは研究 がユーザーによってどのように解釈されるかに関連する問題であり、研究デザインに内在するものでもなければ、優れ た科学技術の原則や実践に関連するものでもない。

上記の問題に対する(部分的な)解決策の 1 つは、観察された影響量が帰無値から系統的に偏ってしまう可能性が あることを認識した上で、事前に定められた閾値を通過した疫学研究の影響量または検出力不足の研究から生じた場 合の統計的に有意な影響量を慎重に解釈することである。このようなアプローチでは、著者が研究の検出力を報告す るか、著者が読者に十分な情報を提供する必要がある。検出力が実質的に 80%未満の研究から得られた影響量は、 おそらく実質的に(特に検出力が 50%未満の場合)誇張する可能性があることを認識した上で、適切な程度の疑いを 持って解釈する必要がある。この誇張の潜在的な程度は、対象となる健康影響のバックグラウンド率、研究のサンプル サイズ、対象となる影響量など、多くの問題に依存する。より具体的には、(a)対象となる健康影響のバックグラウンド率 が低い場合、(b)研究のサンプルサイズが小さい場合、(c)対象となる影響量が弱い場合、研究の検出力(その影響量 を検出するための)は低く、統計的に有意な結果において影響量が誇張される傾向が高くなる。対象とする健康影響 のバックグラウンド率が低い集団で、小さな、または弱い影響を調査する低検出力研究では、影響量の誇張が最も大き くなる傾向がある。その結果、PPRパネルは、疫学的文献にこのような計算を組み込むか、または読者が計算を実行で きるような重要な情報を含めることを推奨している。具体的には以下の通り。

特定の農薬ばく露と疾病との間の関連が統計的に有意であることが判明した場合、特に(推定される)検出力の低い 研究では、データ利用者は、統計的に有意な影響量推定値(OR または RR)がどの程度人工的に拡大、または誇張さ れているかを判断するために、様々な検出力計算(または検出力解析)を実行すべきである。これは、疫学研究で明確 に報告される3つの値を必要とする。(i)非ばく露群の被験者数(罹患者と非罹患者を含む)、(ii)ばく露群の被験者数 (罹患者と非罹患者を含む)、(iii)非ばく露群の罹患者数である。リスク管理者は、次に、ばく露群と非ばく露群の間の 所定の(予め決められた)影響量の差を検出するために、対象となる目標値(典型的には、OR または RR)を選択でき、 影響量の規模が、対象となる研究で推定された影響量をどの程度説明できるかを評価することができる。

(i)多くの疫学研究はしばしば検出力不足であり、(ii)著者が検出力の計算や(場合によっては)計算に必要な情報 を文献の中で提供することは一般的ではなく、(iii)影響量の拡大の現象は一般的に疫学分野ではほとんど認識され ていないようであるため、上記の PPR パネルの勧告を実施するためには、研究者/助成機関、出版社、研究資金提 供者の側での努力が必要である。上記のように、この分野での実践の現状は悲観的になるかもしれないことを示唆して いるが、研究者である Kate Button (Button、2013 年)が Nature Reviews Neuroscience 誌に掲載したこのトピック に関するオピニオン・ピース(Button ら、2013 年)で、楽観について慎重な理由を提供した。

これらの問題に対する認識は高まっており、問題を認識することは、現在の実践を改善し、解決策を特定するための 第一歩である。出版バイアスの問題を一朝一夕に解決するのは難しいが、研究者は確立された(しかし、しばしば無視 される)科学技術の原則を採用することで、研究の信頼性を向上させることができる。また、研究者は、確立された(しか し無視されることが多い)科学技術の原則を採用することで、研究の有用性/信頼性を向上させることができる。

1)研究の計画や結果の解釈において、統計的な検出力を考慮する。

2)研究方法と結果の開示には誠実さを高める。

3)研究計画書、解析計画、さらにはデータまでもが公表されるようにする。

4)供給源を共有し、サンプルサイズと再現力を向上させるために協力して作業する

上記の一連の推奨事項と考えは、サンプルサイズと神経毒性学の背景で設定されているが、疫学を含むあらゆる発 見科学に広く適用可能である。まとめると、疫学研究の実施と報告が公衆衛生に基づいた選択をする際に規制機関に とって有用なものとなるためには、改善の余地が大いにあるが、問題点はより明確にされ、認識され始めており、今後も 楽観的に考えられる理由がある。

# Scientific Opinion of the PPR Panel on the follow-up of the findings of the External Scientific Report 'Literature review of epidemiological studies linking exposure to pesticides and health effects'

EFSA Panel on Plant Protection Products and their Residues (PPR), Colin Ockleford, Paulien Adriaanse, Philippe Berny, Theodorus Brock, Sabine Duquesne, Sandro Grilli, Susanne Hougaard, Michael Klein, Thomas Kuhl, Ryszard Laskowski, Kyriaki Machera, Olavi Pelkonen, Silvia Pieper, Rob Smith, Michael Stemmer, Ingvar Sundh, Ivana Teodorovic, Aaldrik Tiktak, Chris J. Topping, Gerrit Wolterink, Matteo Bottai, Thorhallur Halldorsson, Paul Hamey, Marie-Odile Rambourg, Ioanna Tzoulaki, Daniele Court Marques, Federica Crivellente, Hubert Deluyker and Antonio F. Hernandez-Jerez

# Abstract

In 2013, EFSA published a comprehensive systematic review of epidemiological studies published from 2006 to 2012 investigating the association between pesticide exposure and many health outcomes. Despite the considerable amount of epidemiological information available, the quality of much of this evidence was rather low and many limitations likely affect the results so firm conclusions cannot be drawn. Studies that do not meet the 'recognised standards' mentioned in the Regulation (EU) No 1107/2009 are thus not suited for risk assessment. In this Scientific Opinion, the EFSA Panel on Plant Protection Products and their residues (PPR Panel) was requested to assess the methodological limitations of pesticide epidemiology studies and found that poor exposure characterisation primarily defined the major limitation. Frequent use of case-control studies as opposed to prospective studies was considered another limitation. Inadequate definition or deficiencies in health outcomes need to be avoided and reporting of findings could be improved in some cases. The PPR Panel proposed recommendations on how to improve the quality and reliability of pesticide epidemiology studies to overcome these limitations and to facilitate an appropriate use for risk assessment. The Panel recommended the conduct of systematic reviews and meta-analysis, where appropriate, of pesticide observational studies as useful methodology to understand the potential hazards of pesticides, exposure scenarios and methods for assessing exposure, exposure-response characterisation and risk characterisation. Finally, the PPR Panel proposed a methodological approach to integrate and weight multiple lines of evidence, including epidemiological data, for pesticide risk assessment. Biological plausibility can contribute to establishing causation.

#### Summary

The European Food Safety Authority (EFSA) asked the Panel on Plant Protection Products and their Residues (PPR Panel) to develop a Scientific Opinion on the follow-up of the findings of the External Scientific Report 'Literature review of epidemiological studies linking exposure to pesticides and health effects' (Ntzani et al., 2013). This report was based on a systematic review and meta-analysis of epidemiological studies published between 2006 and 2012 and summarised the associations found between pesticide exposure and 23 major categories of human health outcomes. Most relevant significant associations were found for liver cancer, breast cancer, stomach cancer, amyotrophic lateral sclerosis, asthma, type II diabetes, childhood leukaemia and Parkinson's disease. While the inherent weaknesses of the epidemiological studies assessed do not allow firm conclusions to be drawn on causal relationships, the systematic review raised a concern about the suitability of regulatory studies to inform on specific and complex human health outcomes.

The PPR Panel developed a Scientific Opinion to address the methodological limitations affecting the quality of epidemiological studies on pesticides. This Scientific Opinion is intended only to assist the peer review process during the renewal of pesticides under Regulation (EC) 1107/2009 where the evaluation of epidemiological studies, along with clinical cases and poisoning incidents following any kind of human exposure, if available, is a data requirement. Epidemiological data concerning exposures to pesticides in Europe will not be available before first approval of an active substance and so will not be expected to contribute to a draft assessment report (DAR). However, there is the possibility that earlier prior approval has been granted for use of an active substance in another jurisdiction and epidemiological data from that area may be considered relevant. Regulation (EC) No 1107/2009 requires a search of the scientific peer-reviewed open literature, which includes existing epidemiological studies. This type of data is more suited for the renewal process of active substances, also in compliance with Regulation (EC) 1141/2010 which indicates that 'The dossiers submitted for renewal should include new data relevant to the active substance and new risk assessments'.

In this Opinion, the PPR Panel proposed a methodological approach specific for pesticide active substances to make appropriate use of epidemiological data for risk assessment purposes, and proposed recommendations on how to improve the quality and reliability of epidemiological studies on pesticides. In addition, the PPR Panel discussed and proposed a methodology for the integration of epidemiological evidence with data from experimental toxicology as both lines of evidence can complement each other for an improved pesticide risk assessment process.

First, the opinion introduces the basic elements of observational epidemiological studies<sup>1</sup> and contrasts them with interventional studies which are considered to provide the most reliable evidence in epidemiological research as the conditions for causal inference are usually met. The major observational study designs are described together with the importance of a detailed description of pesticide exposure, the use of validated health outcomes and appropriate statistical analysis to model exposure-health relationships. The external and internal study validity is also addressed to account for the role of chance in the results and to ascertain whether factors other than exposure can distort the associations found. Several types of human data can contribute to the risk assessment process of pesticides, particularly to support hazard identification. Besides formal epidemiological studies, other sources of human data such as case series, disease registries, poison control centre information, occupational health surveillance data and post-marketing surveillance programmes, can provide useful information for hazard identification, particularly in the context of acute, specific health effects.

However, many of the existing epidemiological studies on pesticides exposure and health effects suffer from a range of methodological limitations or deficiencies (Terms of Reference (ToR) 1). The Panel notes that the complexity of studying associations between exposure to pesticides and health outcomes in observational settings among humans is more challenging than in many other disciplines of epidemiology. This complexity lies in some specific characteristics in the field of pesticide epidemiology such as the large number of active substances in the market (around 480 approved for use in the European Union (EU)), the difficulties to measure exposure, and the frequent lack of quantitative (and qualitative) data on exposure to individual pesticides. The systematic appraisal of epidemiological evidence carried out in an EFSA external scientific report (Ntzani et al., 2013) identified a number of methodological limitations. Poor exposure characterisation primarily defines the major limitation of most existing studies because of the lack of direct and detailed exposure assessment to specific pesticides (e.g. use of generic pesticide definitions). Frequent use of case-control studies as

Epidemiological studies and pesticides

#### 概要

欧州食品安全機関(EFSA)は、植物保護製剤(農薬)とその残留物に関するパネル(PPR,パネル)に、外部科学報 告書「農薬へのばく露と健康影響を関連付ける疫学研究の文献レビュー」(Ntzani ら、2013 年)の結果のフォローアッ プ(追跡調査)に関する科学的意見書の作成を依頼した。この報告書は、2006年から2012年の間に発表された疫学 研究のシステマティックレビューとメタアナリシスに基づいており、農薬ばく露と 23 の主要なカテゴリーのヒト健康影響と の間に見出された関連性をまとめたものである。最も関連性が高いのは、肝臓がん、乳がん、胃がん、筋萎縮性側索硬 化症、喘息、II型糖尿病、小児白血病、パーキンソン病であった。評価された疫学研究に内在する弱点があるため、因 果関係についての結論を導き出すことはできないが、システマティックレビューでは、特定の複雑なとトの健康に関する 影響について情報を提供するための規制研究の適合性についての懸念が提起された。

PPR パネルは、農薬に関する疫学研究の質に影響を与える方法論的限界に対処するために、科学的意見書を作 成した。この意見書は、規制(EC)1107/2009の下での農薬の更新時のピアレビュープロセスを支援することのみを目 的としており、あらゆる種類のヒトばく露による臨床例や中毒事故(入手可能であれば)を加えた疫学的研究の評価デ ータが必要である。欧州における農薬へのばく露に関する疫学的データは、有効成分の最初の認可前には入手でき ないため、評価報告書草案(DAR)に提供することは期待できない。しかし、他の管轄区域では有効成分の使用につ いて先行して認可されている可能性があり、その地域の疫学的データが適切だと考えられる。規則(EC)No 1107/2009 では、既存の疫学研究を含む学術的に査読された公表文献を検索することを要求している。このタイプの データは、「更新のために提出された書類には、有効成分に関連する新しいデータと新しいリスク評価を含めるべきで ある」という規則(EC)1141/2010にも準拠しており、有効成分の更新プロセスに適している。

本意見書では、疫学データをリスク評価に適切に活用するための農薬有効成分に特化した方法論的アプローチを 提案し、農薬の疫学研究の質と信頼性を向上させるための提言を行った。さらに、PPR パネルは、農薬のリスク評価プ ロセスを改善するために、疫学的と実験毒性学のデータを統合するための方法論を議論し、提案した。

まず、本意見書では、観察による疫学研究1の基本的な要素を紹介し、因果関係を推論するための条件が通常満た されていることから、疫学研究において最も信頼性の高いエビデンスを提供すると考えられている介入研究との対比を 行っている。主な観察による研究の計画については、農薬ばく露の詳細な記述の重要性、有効な健康影響の使用及 びばく露と健康影響の関係をモデル化するための適切な統計解析の重要性が説明されている。また、外部及び内部 研究の妥当性については、結果における偶然の役割を説明し、ばく露以外の要因が発見された関連性を歪めないか どうかを確認するために取り上げられてもいる。いくつかの種類のヒトのデータは、農薬のリスク評価プロセス、特にハザ ードの特定をサポートするのに貢献することができる。正式な疫学研究以外にも、症例集積、疾病登録、毒物管理セン ター情報、労働衛生監視データ、市販後の監視プログラムなどのヒトのデータの他の情報源は、特に急性の特定の健 康影響の場合には、ハザードの特定に有用な情報を提供することができる。

しかし、農薬ばく露と健康影響に関する既存の疫学研究の多くは、さまざまな方法論の限界や不完全性に悩まされ ている(Terms of Reference(ToR)1)。パネルは、ヒトの観察環境における農薬ばく露と健康影響との関連を研究する ことは複雑で、疫学の他の多くの分野よりも困難であると指摘している。この複雑さは、市場に出回っている有効成分の 数の多さ(欧州連合 EU で使用が認可されているものは約 480 種類)、ばく露の測定の難しさ、個々の農薬へのばく露 に関する定量的及び定性的データが頻繁に欠如していることなど、農薬疫学の分野におけるいくつかの特殊な特徴に 起因する。EFSA の外部科学報告書(Ntzani ら、2013 年)で実施された疫学的証拠の系統的評価では、多くの方法 論的限界が指摘されている。特定の農薬に対する直接かつ詳細なばく露評価が行われていない(例えば、ジェネリック 農薬の使用に対して情報不足)ため、主にばく露の特徴付けが不十分であることが、ほとんどの既存の研究の主な限 界となっている。前向き研究ではなくて症例対照研究を頻繁に使用していることも限界となっている。健康影響の不十 分な定義、統計解析がないこと、研究結果の質の低い報告が、いくつかの農薬疫学研究の他の限界として確認されて いる。これらの限界は、因果関係に関する強固な結論を導き出すことを困難にするデータの不均一性や矛盾の原因と

3

EFSA Journal 2017:15(10):5007

<sup>&</sup>lt;sup>1</sup> This Opinion deals only with observational studies (also called epidemiological studies) and vigilance data. In contrast, interventional studies (also called experimental studies, such as randomised clinical trials) are outside the scope of this Opinion. 3

<sup>1</sup> 本意見書は、観察研究(疫学研究ともいう)と警戒データのみを扱う。これに対し、介入研究(無作為化臨床試験などの実験研究とも呼ばれる)は 本意見書の対象外である。

opposed to prospective studies is also a limitation. Inadequate definition or deficiencies in health outcomes, deficiencies in statistical analysis and poor quality reporting of research findings were identified as other limitations of some pesticide epidemiological studies. These limitations are to some extent responsible for heterogeneity or inconsistency of data that challenge drawing robust conclusions on causality. Given the small effect sizes for most of the outcomes addressed by Ntzani et al. (2013), the contribution of bias in the study design can play a role.

The PPR Panel also provides a number of refinements (ToR 2) and recommendations (ToR 3) to improve future pesticide epidemiological studies that will benefit the risk assessment. The quality and relevance of epidemiological research can be enhanced by (a) an adequate assessment of exposure, preferentially by using personal exposure monitoring or biomarker concentrations of specific pesticides (or combination of pesticides) at an individual level, reported in a way that minimises misclassification of exposure and allows for dose-response assessment; (b) a sufficiently valid and reliable outcome assessment (well defined clinical entities or validated surrogates); (c) adequately accounting for potentially confounding variables (including other known exposures affecting the outcomes); (d) conducting and reporting subgroup analysis (e.g. stratification by gender, age, etc.). A number of reporting guidelines and checklists developed specifically for studies on environmental epidemiology are of interest for epidemiological studies assessing pesticide exposures. This is the case for extensions of the modified STROBE (STrengthening the Reporting of OBservational studies in Epidemiology) criteria, among others, which includes recommendations on what should be included in an accurate and complete report of an observational study.

Exposure assessment can be improved at the individual level (direct and detailed exposure assessment to specific pesticides in order to provide a reliable dosimeter for the pesticide of concern that can be supplemented with other direct measures such as biomonitoring). Besides, exposure can be assessed at population level by using registered data that can then be linked to electronic health records. This will provide studies with unprecedented sample size and information on exposure and subsequent disease. Geographical information systems (GIS) and small area studies might also serve as an additional way to provide estimates of residential exposures. These more generic exposure assessments have the potential to identify general risk factors and may be important both informing overall regulatory policies, and for identification of matters for further epidemiological research. The development of -omic technologies also presents intriguing possibilities for improving exposure assessment through measurement of a wide range of molecules, from xenobiotics and metabolites in biological matrices (metabolomics) to complexes with DNA and proteins (adductomics). Omics have the potential to measure profiles or signatures of the biological response to the cumulative exposure to complex chemical mixtures and allows a better understanding of biological pathways. Health outcomes can be refined by using validated biomarkers of effect, that is, a guantifiable biochemical, physiological or any other change that, is related to level of exposure, is associated with a health impairment and also helps to understand a mechanistic pathway of the development of a disease.

The incorporation of epidemiological studies into regulatory risk assessment (ToR 4) represents a major challenge for scientists, risk assessors and risk managers. The findings of the different epidemiological studies can be used to assess associations between potential health hazards and adverse health effects, thus contributing to the risk assessment process. Nevertheless, and despite the large amount of available data on associations between pesticide exposure and human health outcomes, the impact of such studies in regulatory risk assessment is still limited. Human data can be used for many stages of risk assessment; however, a single (not replicated) epidemiological study, in the absence of other studies on the same pesticide active substance, should not be used for hazard characterisation unless it is of high quality and meets the 'recognised standards' mentioned in the Regulation (EU) No 1107/2009. As these 'recognised standards' are not detailed in the Regulation, a number of recommendations should be considered for optimal design and reporting of epidemiological studies to support regulatory assessment of pesticides. Although further specific guidance will be helpful, this is beyond the ToR of this Opinion. Evidence synthesis techniques, such as systematic reviews and meta-analysis (where appropriate) offer a useful approach. While these tools allow generation of summary data, increased statistical power and precision of risk estimates by combining the results of all individual studies meeting the selection criteria, they cannot overcome methodological flaws or bias of individual studies. Systematic reviews and meta-analysis of observational studies have the capacity of large impact on risk assessment as these tools provide information that strengthens the understanding of the potential hazards of pesticides, exposure scenarios and methods for assessing exposure, exposure–response characterisation and risk characterisation. Although systematic reviews

なっている。Ntzaniら、(2013年)が取り上げたほとんどの健康影響の効果量が小さいことを考えると、研究デザインに おけるバイアスの寄与が一役買っている可能性がある。

PPR パネルはまた、リスク評価に有益な将来の農薬疫学研究を改善するための多くの再修正(ToR 2)と勧告(ToR 3)も提供している。疫学研究の質と妥当性は、以下によって高められる。(a) ばく露の適切な評価、好ましくは個人のば く露モニタリングや特定の農薬(または農薬の組み合わせ)のバイオマーカー濃度を個人レベルで使用し、ばく露の誤 分類を最小化し、用量反応評価を可能にする方法で報告すること、(b) 十分に有効で信頼性の高い健康影響(アウトカ ム)の評価(十分に定義された臨床データまたは有効な代替物)、(c) 交絡変数(健康影響(アウトカム)に影響を与える 他の既知のばく露を含む)を適切に考慮すること、(d) サブグループ解析(例:性別、年齢などによる層別解析)を実施 し、報告すること、環境疫学の研究のために特別に開発された多くの報告ガイドラインとチェックリストは、農薬ばく露を 評価する疫学研究にとっても有用なものである。これは、修正された STROBE(STrengthening the Reporting of OBservational studies in Epidemiology)基準の拡張版が特に該当し、観察による研究の正確で完全な報告書に 何を含めるべきかについての推奨事項が含まれている。

ばく露評価は、個人レベル(バイオモニタリングのような他の直接的な手段で補足することができる信頼性の高い線 量計を目的とする農薬に使用することにより、特定の農薬に対する直接かつ詳細なばく露評価を行う)で改善すること ができる。さらに、登録されたデータを電子カルテにリンクさせることにより集団レベルでのばく露を評価することができ る。これにより、これまでにないサンプルサイズの研究が可能となり、ばく露とその後の疾患に関する情報を得ることがで きるようになる。地理情報システム(GIS)や小規模地域調査も、住居ばく露の推定値を提供するための追加的な方法と して役立つかもしれない。これらのより一般的なばく露評価は、一般的なリスク因子を特定する可能性があり、規制政策 全体への情報提供と、さらなる疫学研究の対象を特定することの両方で重要になる可能性がある。オミクス技術の開発 はまた、生物学的マトリックス中の外来物質や代謝物(メタボロミクス)から DNA やタンパク質との複合体(アダクトミクス) まで、幅広い分子の測定を通じてばく露評価を改善するための興味深い可能性を提示している。オミクスは、複雑な化 学物質の混合物への累積ばく露に対する生物学的反応の特性やシグネチャーを測定する可能性があり、生物学的経 路の理解を深めることができる。つまり、ばく露レベルに関連して、健康障害に関連する生化学的、生理学的、またはそ の他の変化を定量化できるバイオマーカーを使用することで、健康影響を再発見することができ、また、病気の発生の メカニズムを理解するのに役立つ。

規制リスク評価(ToR 4)に疫学的研究を組み込むことは、科学者、リスク評価者、リスク管理者にとって大きな課題で ある。様々な疫学研究の知見は、潜在的な健康被害と有害な健康影響との関連性を評価するために使用することがで き、その結果、リスク評価のプロセスに貢献することができる。農薬ばく露ととト健康影響との関連性に関する利用可能 なデータが大量にあるが、それにもかかわらず、規制上のリスク評価へのこのような研究の影響はまだ限られている。ヒ トのデータはリスク評価の多くの段階で利用できるが、同じ農薬有効成分に関する他の研究がない場合には、単一の (反複されていない)疫学研究は、質が高く、規則(EU)No 1107/2009 に記載されている「認可基準」を満たしていな い限り、ハザードの特性評価に利用すべきではない。これらの「認可基準」は同規則には詳述されていないため、農薬 の規制評価を支援するための疫学的研究の最適な計画と報告のために、多くの勧告が考慮されるべきである。さらなる 特定のガイダンスが有用であるが、これは本意見書の ToR の範囲を超えている。システマティックレビューやメタアナリ シス(必要に応じて)などのエビデンス統合技術が有用なアプローチを提供する。これらのツールは、選択基準を満た すすべての個々の研究の結果を組み合わせることで、要約データを生成し、統計検出力を高め、リスク推定の精度を 向上させることができるが、個々の研究の方法論的な欠陥やバイアスを克服することはできない。観察による研究のシ ステマティックレビューやメタアナリシスは、これらのツールが農薬の潜在的なハザード、ばく露シナリオ、ばく露評価の 方法、ばく露一反応特性、リスク特性に関する理解を強化する情報を提供するため、リスク評価に大きな影響を与える 能力を持っている。システマティックレビューもまた、毒性学的な課題に答えるための潜在的なツールと考えられている が、その方法論は、異なるエビデンスの系統に合わせて対応させる必要がある。

研究の評価はベストエビデンス統合の枠組みの中で行われるべきであり、それによって各特定の研究が持つ可能性のあるバイアスの特性と疫学的データベースの全体的な整合性の評価が示される。本意見書は、単一の疫学研究で www.efsa.europa.eu/efsajourna EFSA Journal 2017:15(10):5007

are also considered a potential tool for answering toxicological questions, their methodology would need to be adapted to the different lines of evidence.

Study evaluation should be performed within a best evidence synthesis framework as it provides an indication on the nature of the potential biases each specific study may have and an assessment of overall confidence in the epidemiological database. This Opinion reports the study quality parameters to be evaluated in single epidemiological studies and the associated weight (low, medium and high) for each parameter. Three basic categories are proposed as a first tier to organise human data with respect to risk of bias and quality; (a) low risk of bias and high/medium reliability; (b) medium risk of bias and medium reliability; (c) high risk of bias and low reliability because of serious methodological limitations or flaws that reduce the validity of results or make them largely uninterpretable for a potential causal association. These categories are intended to parallel the reliability and relevance rating of each stream of evidence according to the EFSA peer review of active substances: acceptable, supplementary and unacceptable. Risk assessment should not be based on results of epidemiological studies that do not meet well-defined data quality standards in order to meet the 'recognised standards' mentioned in the Regulation (EU) No 1107/2009.

Epidemiological studies provide complementary data that can be integrated together with data from *in vivo* laboratory animal studies, mechanistic *in vitro* models and ultimately *in silico* technology for pesticide risk assessment (ToR 4). The combination of all these lines of evidence can contribute to a Weight-of-Evidence (WoE) analysis in the characterisation of human health risks with the aim of improving decision-making. Although the different sets of data can be complementary and confirmatory, and thus serve to strengthen the confidence of one line of evidence on another, they may individually be insufficient and pose challenges for characterising properly human health risks. Hence, all four lines of evidence (epidemiology, animal, *in vitro*, *in silico*) make a powerful combination, particularly for chronic health effects of pesticides, which may take decades to be clinically manifested in an exposed human population.

The first consideration is how well the health outcome under consideration is covered by existing toxicological and epidemiological studies on pesticides. When both types of studies are available for a given outcome/endpoint, both should be assessed for strengths and weaknesses before being used for risk assessment. Once the reliability of available human evidence (observational epidemiology and vigilance data), experimental evidence (animal and *in vitro* data) and non-testing data (*in silico* studies) has been evaluated, the next step involves weighting these sources of data. This opinion proposed an integrated approach where all lines of evidence are considered in an overall WoE framework to better support the risk assessment. This framework relies on a number of principles highlighting when one line should take precedence over another. The concordance or discordance between human and experimental data should be assessed in order to determine which data set should be given precedence. Although the totality of evidence should be assessed, the more reliable data should be given more weight, regardless of whether the data comes from human or experimental studies. The more challenging situation is when study results are not concordant. In such cases, the reasons for the difference should be considered and efforts should be made to develop a better understanding of the biological basis for the contradiction.

Human data on pesticides can help verify the validity of estimations made based on extrapolation from the full toxicological database regarding target organs, dose–response relationships and the reversibility of toxic effects, and to provide reassurance on the extrapolation process without direct effects on the definition of reference values. Thus, pesticide epidemiological data can form part of the overall WoE of available data using modified Bradford Hill criteria as an organisational tool to increase the likelihood of an underlying causal relationship.

#### Epidemiological studies and pesticides

評価すべき研究の質のパラメータと、各パラメータの関連する程度(低、中、高)を報告している。ヒトのデータをパイア スのリスクと品質に関して整理するための第一段階として、3 つの基本的なカテゴリーが提案されている。(a)パイアスの リスクが低く、信頼性が高い/中程度、(b)パイアスのリスクが中程度で、信頼性が中程度、(c)パイアスのリスクが高く、 信頼性が低いのは、結果の妥当性を低下させたり、潜在的な因果関係をほとんど解釈できないような重大な方法論的 限界や欠陥があるためである。これらのカテゴリーは、EFSAの有効成分のビアレビューに基づく各エビデンスの信頼 性と妥当性の評価(受容可能、補足的、許容できない)と並行して行うことを意図している。規則(EU)No 1107/2009 ヒ トの健康リスクを適切に記載されている「認可基準」を満たすために、明確なデータ品質基準を満たさない疫学研究の 結果に基づいてリスク評価を行うべきではない。

疫学研究は補完的なデータを提供するものであり、農薬リスク評価のために in vivo の実験動物試験、in vitro のメ カニズムモデル及び in silico 技術から得られるデータと統合することができる(ToR 4)。これらすべてのエビデンスを 組み合わせることで、判断の改善を目的としたヒトの健康リスクの特性評価におけるエビデンスの重み付け(WOE, Weight-of-Evidence)解析に貢献することができる。異なるデータセットは補完的であり、結論を出すことができ、その 結果、1 つのエビデンス系統の別のエビデンス系統との整合性を強化するのに役立つが、それらは個別には不十分で あり、ヒトの健康リスクを適切に特性評価するにあたっての課題となる可能性がある。したがって特にばく露されたヒト集 団で臨床的に発現するまでに数十年かかる可能性がある農薬の慢性的な健康影響については、4 つのエビデンス(疫 学、動物実験、in vitro、in silico)は強力な組み合わせとなる。

最初に検討すべき事項は、対象となる健康影響が、農薬に関する既存の毒性学的・疫学的研究でどれだけカバー されているかということである。既知の健康影響/エンドポイントについて両方のタイプの研究が利用可能な場合、リス ク評価に使用する前に、両方の研究の長所と短所を評価すべきである。利用可能な比のエビデンス(観察疫学及び監 視データ)、実験的エビデンス(動物及び in vitro のデータ)、非試験データ(in silico 研究)の信頼性が評価されたら、 次のステップでは、これらのデータソースに重み付けを行う必要がある。この意見書では、リスク評価をより適切にサポ ートするために、すべてのエビデンスを全体的な WOE フレームワークの中で考慮する統合的なアプローチを提案して いる。このフレームワークは、ある系統が他の系統よりも優先されるべき時を強調するいくつかの原則に基づいている。 どのデータセットを優先すべきかを決定するために、ヒトのデータと実験データの一致や不一致を評価すべきである。 エビデンスの全体性を評価すべきであるが、データがヒトと実験のどちらから来たものであるかに関わらず、より信頼性 の高いデータがより重要視されるべきである。より困難な状況は、研究結果が一致しない場合である。このような場合に は、相違の理由を検討し、矛盾の生物学的根拠の理解をより深く理解する努力をすべきである。

農薬に関するとトのデータは、標的臓器、用量反応関係、毒性影響の可逆性に関する完全な毒性学的データベー スからの外挿に基づいて行われた推定値の妥当性を検証するのに役立ち、基準値の定義に直接的な影響を与えるこ となく、外挿の過程を再確認するのに役立つ。このように、農薬疫学的データは、根本的な因果関係の可能性を高める ための組織的なツールとして、改訂 Bradford Hill 基準を使用して、利用可能なデータの全体である WOE の一部を 形成することができる。

# 1. Introduction

# 1.1. Regulatory data requirements regarding human health in pesticide risk assessment

Regulatory authorities in developed countries conduct a formal human risk assessment for each registered pesticide based on mandated toxicological studies, done according to specific study protocols, and estimates of likely human exposure.

In the European Union (EU), the procedure for the placing of plant protection products (PPP) on the market is laid down by Commission Regulation No 1107/2009<sup>2</sup>. Commission Regulations No 283/2013<sup>3</sup> and 284/2013<sup>4</sup> set the data requirements for the evaluation and re-evaluation of active substances and their formulations.

The data requirements regarding mammalian toxicity of the active substance are described in part A of Commission Regulation (EU) No 283/2013 for chemical active substances and in part B for microorganisms including viruses. With regard to the requirements for pesticide active substances, reference to the use of human data may be found in different chapters of Section 5 related to different end-points. For instance, data on toxicokinetics and metabolism that include *in vitro* metabolism studies on human material (microsomes or intact cell systems) belong to Chapter 5.1 that deals with studies of absorption, distribution, metabolism and excretion in mammals; *in vitro* genotoxicity studies performed on human material are described in Chapter 5.4 on genotoxicity testing and specific studies such as acetylcholinesterase inhibition in human volunteers are found in Chapter 5.7 on neurotoxicity studies. Chapter 5.8 refers to supplementary studies on the active substance, and some specific studies, such as pharmacological or immunological investigations.

Although the process of pesticide evaluation is mainly based on experimental studies, human data could add relevant information to that process. The requirements relating to human data are mainly found in Chapter 5.9 'Medical data' of Regulation (EU) No 283/2013. It includes medical reports following accidental, occupational exposure or incidents of intentional self-poisoning as well as monitoring studies such as on surveillance of manufacturing plant personnel and others. The information may be generated and reported through official reports from national poison control centres as well as epidemiological studies published in the open literature. The Regulation requires that 'relevant' information on the effects of human exposure, where available, shall be used to confirm the validity of extrapolations regarding exposure and conclusions with respect to target organs, dose-response relationships, and the reversibility of adverse effects.

Regulation (EU) No 1107/2009 equally states that, 'where available, and supported with data on levels and duration of exposure, and conducted in accordance with recognised standards, epidemiological studies are of particular value and must be submitted'. However, it is clear that there is no obligation for the petitioners to conduct epidemiological studies specific for the active substance undergoing the approval or renewal process. Rather, according to Regulation (EC) No 1107/2009, applicants submitting dossiers for approval of active substances shall provide 'scientific peer-reviewed public available literature [...]. This should be on the active substance and its relevant metabolites dealing with side-effects on health [...] and published within the last ten years before the date of submission of the dossier'.

In particular, epidemiological studies on pesticides should be retrieved from the literature according to the EFSA Guidance entitled 'Submission of scientific-peer reviewed open literature for the approval of pesticide active substances under Regulation (EC) No 1107/2009' (EFSA, 2011a), which follows the principles of the Guidance 'Application of systematic review methodology to food and feed safety assessments to support decision-making' (EFSA, 2010a). As indicated in the EFSA Guidance, 'the process of identifying and selecting scientific peer-reviewed open literature for active substances, their metabolites, or plant protection products' is based on a literature review which is systematic in the approach.

The submission of epidemiological studies and more generally of human data by the applicants in Europe has especially previously sometimes been incomplete and/or has not been performed in

<sup>3</sup> Commission Regulation (EU) No 283/2013, of 1 March 2013, setting out the data requirements for active substances, in accordance with Regulation (EC) No 1107/2009 of the European Parliament of the Council concerning the placing of plant protection products on the market. Epidemiological studies and pesticides

# 1. 序章

# 1.1. 農薬リスク評価におけるとトの健康に関する規制データ要求

先進国の規制当局は、指定された試験プロトコールに基づいて実施される義務づけられた毒性学的研究と、ヒトへ のばく露の可能性の推定値に基づいて、登録された各農薬について正式なヒトのリスク評価を行っている。

欧州連合(EU)では、植物保護剤(農薬)(PPP)の上市手続きは、欧州委員会規則第 1107/2009 号<sup>2</sup>で規定されて いる。欧州委員会規則第 283/2013 号<sup>3</sup>及び第 284/2013 号<sup>4</sup>では、有効成分及びその製剤の評価及び再評価のため のデータ要求が定められている。

有効成分の哺乳類毒性に関するデータ要求は、化学有効成分については欧州委員会規則(EU)No 283/2013 の Part A に、ウイルスを含む微生物については Part B に記載されている。農薬有効成分の要求事項に関しては、ヒトの データ使用に関する言及は、異なるエンドボイントに関連する第5章の異なる章で見られる。例えば、ヒト由来物質(シク ロソームまたは無処置の細胞システム)を対象とした in vitro 代謝試験を含む毒物動態及び代謝に関するデータは、 哺乳類における吸収、分布、代謝及び排泄に関する研究を扱う第5.1章に属し、ヒト由来物質を対象とした in vitro 遺 伝毒性試験は、遺伝毒性試験に関する第5.4章に、ヒトのボランティアにおけるアセチルコリンエステラーゼ阻害などの 特殊な研究は、神経毒性試験に関する第5.7章に記載されている。5.8章では、有効成分に関する補足的な試験や、 薬理学的、免疫学的な試験などのいくつかの特殊な試験について言及している。

農薬の評価プロセスは主に実験研究に基づいているが、ヒトのデータはそのプロセスに関連する情報を追加すること ができる。ヒトのデータに関する要求は、主に規則(EU)No 283/2013 の第 5.9 章「医療データ」にある。これには、偶 発的な職業上のばく露や自傷/自殺の後の医学的報告書や、製造工場の従業員の監視などのモニタリング調査が含 まれる。情報は、国の毒物管理センターからの報告書や、公表文献に掲載されている疫学的研究によって生成され、 報告される。同規則は、ヒトへのばく露の影響に関する「意味のある」情報が入手可能な場合には、ばく露に関する外 挿法の妥当性や、標的臓器、用量反応関係、毒性影響の可逆性に関する結論を導き出すために使用することを要求 している。

規則(EU)No 1107/2009 も同様に、「入手可能で、ばく露レベルとばく露期間に関するデータが裏付けされており、 公認の基準に従って実施されている場合、疫学的研究は特に価値があり、提出しなければならない」としている。しかし、 承認または更新プロセス中の有効成分に特化した疫学的研究を実施する義務が申請者にはないことは明らかである。 むしろ、規則(EC)No 1107/2009 によると、有効成分の承認のための書類(ドシエ)を提出する申請者は、「科学的な ピアレビューを受けた公的に利用可能な文献[.....]」を提出しなければならない。これは、健康への副作用を扱った有 効成分及びその関連代謝物に関するものであり、書類(ドシエ)提出日前の過去 10 年以内に発表されたものでなけれ ばならない[.....]。

特に、農薬に関する疫学的研究は、「規則(EC)No 1107/2009 の下での農薬有効成分の承認のための科学的根拠に基づいた公表文献の提出」(EFSA、2011 年 a)と題する EFSA ガイダンス「政策決定を支援するための食品・飼料安全性評価へのシステマティックレビュー方法論の適用」(EFSA、2010 年 a)の原則に沿って、文献から検索する必要がある。EFSA ガイダンスに示されているように、「有効成分、その代謝物、または植物保護製剤(農薬)のための科学的に査読された公表文献を特定し、選択するプロセス」は、アプローチが体系的な文献レビューに基づいている。

ヨーロッパにおける申請者による疫学研究やより一般的なヒトデータの提出は、特にこれまでに、不完全であったり、 現行の EFSA ガイダンス(EFSA、2011 年 a)に準拠していなかったりすることがあった。これは、特定の EFSA ガイダ ンスに従って(疫学的)文献検索を行うことを義務付けることが比較的最近になって導入(例えば AIR・3 物質に対し)さ

compliance with current EFSA Guidance (EFSA, 2011a). This is probably owing to the fact that a mandatory requirement to perform an (epidemiological) literature search according to specific EFSA Guidance is relatively recent, e.g. introduced for AIR-3 substances (Regulation AIR-3: Reg. (EU) No 844/2012; Guidance Document SANCO/2012/11251 – rev.4).

The integration of epidemiological data with toxicological findings in the peer review process of pesticides in the EU should be encouraged but is still lacking. A recent and controversial example is the one related to the evaluation of glyphosate in which significant efforts were made to include epidemiological studies in the risk assessment, but the conclusion was that these studies provided very limited evidence of an association between glyphosate and health outcomes.

In the case of the peer review of 2,4-D, most of epidemiological data were not used in the risk assessment because it was critical to know the impurity profile of the active substance and this information was not available in the publications (as happens frequently in epidemiological studies). In conclusion, within the European regulatory system there is no example of a pesticide active substance approval being influenced by epidemiological data.

Now that a literature search including epidemiological studies is mandatory and guidance is in place (EFSA, 2011a), a more consistent approach can facilitate risk assessment. However, no framework has been established on how to assess such epidemiological information in the regulatory process. In particular, none of the classical criteria used for the evaluation of these studies is included in the current regulatory framework (e.g. study design, use of odd ratios and relative risks, potential confounders, multiple comparisons, assessment of causality). It follows that specific criteria or guidance for the appropriate use of epidemiological findings in the process of writing and peer reviewing Draft Assessment Reports (DARs) or Renewal Assessment Reports (RAR) is warranted. The EFSA Stakeholder Workshop (EFSA, 2015a) anticipated that the availability of more robust and methodologically sound studies presenting accurate information on exposure would bolster the regulation of pesticides in the EU.

Another potential challenge is synchronisation between the process of renewal of active substances and the output of epidemiological studies. Indeed, the planning, conduct, and analysis of epidemiological studies often require a substantial amount of time, especially where interpretation of data is complex.

#### **1.2.** Background and Terms of Reference as provided by the requestor

In 2013, the European Food Safety Authority (EFSA) published an External scientific report 'Literature review on epidemiological studies linking exposure to pesticides and health effects' carried out by the University of Ioannia Medical School (Ntzani et al., 2013). The report is based on a systematic review of epidemiological studies published between 2006 and 2012 and summarises the association between pesticide exposure and any health outcome examined (23 major categories of human health outcomes). In particular, a statistically significant association was observed through fixed and random effect meta-analyses between pesticide exposure and the following health outcomes: liver cancer, breast cancer, stomach cancer, amyotrophic lateral sclerosis, asthma, type II diabetes, childhood leukaemia and Parkinson's disease.

Despite the large number of research articles and analyses (> 6,000) available, the authors of the report could not draw any firm conclusions for the majority of the health outcomes. This observation is in line with previous studies assessing the association between the use of pesticides and the occurrence of human health adverse effects which all acknowledge that such epidemiological studies suffer from a number of limitations and large heterogeneity of data. The authors especially noted that broad pesticides definitions in the epidemiological studies limited the value of the results of meta-analyses. Also, the scope of the report did not allow the in-depth associations between pesticide exposure and specific health outcomes. Nonetheless, the report highlights a number of health outcomes where further research is needed to draw firmer conclusions regarding their possible association with pesticide exposures.

Nevertheless, the outcomes of the External scientific report are in line with other similar studies published in Europe,<sup>5,6</sup> and raise a number of questions and concerns, with regard to pesticide exposure and the associations with human health outcomes. Furthermore, the results of the report

#### Epidemiological studies and pesticides

れたことによるものであろう(規則 AIR-3: Reg. (EU) No 844/2012;ガイダンス文書 SANCO/2012/11251-rev.4)。

EU における農薬のピアレビュープロセスにおける疫学的データと毒性学的結果の統合評価は奨励されるべきであ るが、まだ不足している。最近の大きな議論となった例としては、グリホサートの評価に関連したものがあり、リスク評価 に疫学的研究を含めるために多大な努力がなされたが、結論としては、これらの研究はグリホサートと健康影響との間 の関連性を示す非常に限定的なエビデンスを提供したに過ぎず、十分なエビデンスは得られなかった。

2,4-D のピアレビューの場合、疫学的データのほとんどはリスク評価には使用されなかった。結論として、欧州の規制 システムの中では、疫学的データが農薬有効成分の承認に影響を与えた例はない。

疫学研究を含む文献検索が義務化され、ガイダンスが整備された現在(EFSA、2011 年 a)、より一貫したアプロー チにより、リスク評価が容易になると考えられる。しかし、規制プロセスにおいて、このような疫学的情報をどのように評価 するかについての枠組みは確立されていない。特に、これらの研究の評価に用いられる古典的な基準は、現在の規制 の枠組みには含まれていない(例:研究デザイン、オッズ比と相対リスクの使用、潜在的な交絡因子、多重比較、因果 関係の評価)。評価報告書草案(DAR)や更新評価報告書(RAR)の作成とピアレビューの過程で、疫学的知見を適 切に使用するための特定の基準や指針が必要である。EFSA ステークホルダーワークショップ(EFSA、2015 年 a)で は、ばく露に関する正確な情報を提供する上で、より強固で方法論的に健全な研究が利用可能になれば、EU におけ る農薬規制の向上が図れると予想している。

もう一つの潜在的な課題は、有効成分の更新プロセスと疫学研究の成果との同期化である。実際、疫学研究の計画、 実施、解析には多くの場合、特にデータの解釈が複雑な場合には相当な時間を必要とする。

# 1.2. 依頼者から提供された背景と委託条件

2013 年、欧州食品安全機関(EFSA)は、イオアニナ大学医学部が実施した外部科学報告書「農薬へのばく露と健 康影響に関連する疫学的研究に関する文献レビュー」を発表した(Ntzani 6、2013 年)。この報告書は、2006 年から 2012 年の間に発表された疫学研究のシステマティックレビューに基づき、農薬ばく露と調査したあらゆる健康影響(ヒト の健康影響の 23 の主要カテゴリー)との関連性をまとめたものである。特に、農薬ばく露と以下の健康影響(肝臓がん、 乳がん、胃がん、筋萎縮性側索硬化症、喘息、II 型糖尿病、小児白血病、パーキンソン病)との間の統計学的に有意 な関連性が、固定効果及びランダム効果のメタアナリシスによって観察された。

膨大な数の研究論文と解析(6,000 件以上)が利用可能であるにもかかわらず、報告書の著者は、大部分の健康影響については何ら確かな結論を見出すことができなかった。この観察結果は、農薬の使用ととト健康への悪影響の発生との関連性を評価したこれまでの研究と一致しており、そのような疫学研究は多くの限界とデータの大きな不均一性が問題となっていることを認めている。著者らは特に、疫学研究における農薬の広範な定義がメタアナリシスの結果の価値を制限していることを指摘している。また、本報告書の範囲では、農薬ばく露と特定の健康影響との間の詳細な関連付けを行うことができなかった。しかし、報告書では、農薬ばく露との関連性の可能性について、より詳細な結論を出すためにさらなる研究が必要とされる多くの健康影響を強調している。

とはいえ、外部科学報告書の結果は、ヨーロッパで発表された他の同様の研究5・6と一致しており、農薬ばく露ととト 健康影響との関連性について、多くの疑問や懸念を投げかけている。さらに、本報告書の結果は、疫学研究の結果を どのように農薬リスク評価に統合するかについての議論の道を開くものである。このことは、EU 規則 No 283/2013 に 従って疫学的結果を評価する必要がある植物保護製剤(農薬)の承認評価を扱う EFSA のピアレビューチームにとっ て特に重要である。同規則では、申請者は、利用可能な場合には「意味のある」疫学的研究を提出しなければならない とされている。

この科学的意見書では、PPRパネルは、外部科学報告書(Ntzaniら、2013年)で観察された農薬ばく露ととト健康

<sup>5</sup> フランス。INSERM レポート 2013。農薬-人に及ぼす影響

<sup>6</sup> 英国。COTレポート2011年。農薬への准職業上ばく露とがん以外の健康影響に関する疫学的文献のシステマティックレビューに関する声明及びCOT報告書2006。農薬散布と住民や居合わせただけの者(bystanders)の健康に関する環境汚染に関する王立委員会報告書に関する共同声明。

open the way for discussion on how to integrate results from epidemiological studies into pesticide risk assessments. This is particularly important for the peer-review team at EFSA dealing with the evaluation of approval of plant protection products for which the peer-review needs to evaluate epidemiological findings according to EU Regulation No 283/2013. The regulation states that applicants must submit 'relevant' epidemiological studies, where available.

For the Scientific Opinion, the PPR Panel will discuss the associations between pesticide exposure and human health effects observed in the External scientific report (Ntzani et al., 2013) and how these findings could be interpreted in a regulatory pesticide risk assessment context. Hence, the PPR Panel will systematically assess the epidemiological studies collected in the report by addressing major data gaps and limitations of the studies and provide related recommendations.

The PPR Panel will specifically:

- collect and review all sources of gaps and limitations, based on (but not necessarily limited to) those identified in the External scientific report in regard to the quality and relevance of the available epidemiological studies.
- 2) based on the gaps and limitations identified in point 1, propose potential refinements for future epidemiological studies to increase the quality, relevance and reliability of the findings and how they may impact pesticide risk assessment. This may include study design, exposure assessment, data quality and access, diagnostic classification of health outcomes, and statistical analysis.
- 3) identify areas in which information and/or criteria are insufficient or lacking and propose recommendations for how to conduct pesticide epidemiological studies in order to improve and optimise the application in risk assessment. These recommendations should include harmonisation of exposure assessment (including use of biomonitoring data), vulnerable population subgroups and/or health outcomes of interest (at biochemical, functional, morphological and clinical level) based on the gaps and limitations identified in point 1.
- 4) discuss how to make appropriate use of epidemiological findings in risk assessment of pesticides during the peer review process of draft assessment reports, e.g. weight-ofevidence (WoE) as well as integrating the epidemiological information with data from experimental toxicology, adverse outcome pathways (AOP), mechanism of actions, etc.

The PRAS Unit will consult the Scientific Committee on the consensual approach to EFSA's overarching scientific areas,<sup>7</sup> including the integration of epidemiological studies in risk assessment.

#### **1.3.** Interpretation of the Terms of Reference

In the Terms of Reference (ToR), EFSA requested the PPR Panel to write a scientific Opinion on the follow up of the results from the External Scientific Report on a systematic review of epidemiological studies published between 2006 and 2012 linking exposure to pesticides and human health effects (Ntzani et al., 2013). According to EU Regulation No 283/2013, the integration of epidemiological data into pesticide risk assessment is important for the peer review process of DAR and RAR of active substances for EU approval and their intended use as plant protection products.

In its interpretation of the terms of reference, the PPR Panel will then develop a Scientific Opinion to address the methodological limitations identified in epidemiological studies on pesticides and to make recommendations to the sponsors of such studies on how to improve them in order to facilitate their use for regulatory pesticide risk assessment, particularly for substances in the post-approval period. The PPR Panel notes that experimental toxicology studies also present limitations related to their methodology and quality of reporting; however, the assessment of these limitations is beyond the ToR of this Opinion.

This Scientific Opinion is intended to assist the peer review process during the renewal of pesticides under Regulation 1107/2009 where the evaluation of epidemiological studies, along with clinical cases and poisoning incidents following any kind of human exposure, if available, represent a data requirement. Epidemiological data concerning exposures to pesticides in Europe will not be available before first approval of an active substance (with the exception of incidents produced during the manufacturing process, which are expected to be very unlikely) and so will not be expected to contribute to a DAR. However, there is the possibility that earlier prior approval has been granted for use of an active substance in another jurisdiction and epidemiological data from that area may be considered relevant. Regulation (EC) No 1107/2009 requires a search of the scientific peer-reviewed

10

www.efsa.europa.eu/efsajournal

EFSA Journal 2017;15(10):5007

el usa muni

影響との関連性と、これらの結果が規制上の農薬リスク評価の背景でどのように解釈されるかを議論する。したがって、 PPR パネルは、報告書で収集された疫学研究を体系的に評価し、研究の主要なデータギャップと限界に対処し、関連 する勧告を提言する。

PPR パネルは特に以下を行う。

- 1)利用可能な疫学研究の質と妥当性に関して外部科学報告書で明らかにされたものに基づいて(必ずしもこれに 限定されないが)、ギャップと限界のすべての情報源を収集し、レビューする。
- 2)上記 1)項で特定されたギャップと限界に基づき、調査結果の質、妥当性、信頼性を向上させ、それが農薬リス ク評価にどのように影響を与えるかについて、将来の疫学調査のための潜在的な改善点を提案する。これには、 研究デザイン、ばく露評価、データの質と評価、健康影響の診断分類、統計解析が含まれる。
- 3)情報及び/または基準が不十分または不足している分野を特定し、リスク評価への適用を改善し最適化するために、農薬疫学的研究をどのように実施するかについての提言を行う。これらの推奨事項には、第1)項で明らかになったギャップと限界に基づいて、ばく露評価(バイオモニタリングデータの利用を含む)、脆弱な集団のサブグループ及び/または対象となる健康影響(生化学的、機能的、形態学的、臨床的レベルでの)の調和を含む。
- 4)評価報告書草案のピアレビューの過程で、疫学的知見を実験毒性学、有害転帰経路(AOP)、作用機序などのデータと統合するとともに、WOEなど、農薬のリスク評価に疫学的知見を適切に利用する方法を議論する。

PRAS ユニットは、リスク評価における疫学的研究の統合を含む EFSA の包括的な科学的分野<sup>7</sup>への合意に基づく アプローチについて、科学技術委員会に諮る。

# 1.3. 委託条件の解釈

EFSAは、検討事項(ToR)の中で、2006年から2012年の間に発表された農薬へのばく露ととトの健康影響を関連 付ける疫学的研究のシステマティックレビューの結果のフォローアップについて、PPR パネルに科学的意見書を作成 するよう要請している(Ntzani 6、2013年)。EU 規則 No 283/2013によると、疫学的データを農薬リスク評価に統合 することは、EU 承認のための有効成分の DAR と RAR 及び植物保護製剤(農薬)としての使用を目的とした有効成 分のピアレビュープロセスにとって重要であるとされている。

PPR パネルは、委託条件の解釈において、農薬の疫学的研究で明らかになった方法論的限界に対処し、規制上の 農薬リスク評価、特に承認後の物質のリスク評価への利用を容易にするためにどのように改善するかについて、そのような研究のスポンサーに勧告を行うための科学的意見書を作成することになっている。PPR パネルは、実験的な毒性 試験にもその方法論と報告の質に関連した限界があることに留意しているが、これらの限界の評価は本意見書の ToR の範囲を超えている。

この科学的意見書は、規制 1107/2009 に基づく農薬の更新時のピアレビュープロセスを支援することを目的として おり、疫学的研究の評価に加えて、なんらかのヒトばく露後の臨床症例や中毒事例(入手可能な場合)がデータ要求と なっている。欧州における農薬へのばく露に関する疫学的データは、有効成分の最初の承認前には入手できない(製 造過程で発生した事故を除いて、その可能性は非常に低いと予想される)ため、DAR に貢献することは期待できない だろう。しかし、他の管轄で有効成分の使用について先行承認を受けている可能性があり、その分野の疫学的データ が有用であると考えられる。EC 規則: (EC) No 1107/2009 では、既存の疫学的研究が有効成分の更新プロセスにおい てより適していることが認識されており、「更新のために提出された書類には、有効成分が指令 91/414/EEC の付録 I に最初に含まれた時から、データ要求の変更や科学的・技術的知識の変化を再確認するために、有効成分に関連す る新しいデータと新しいリスク評価を含めるべきである」という EC 規則 1141/2010 の規定にも準拠している。 PPR パネルは具体的に以下のトピックに取り組む。

10

EFSA Journal 2017;15(10):5007

<sup>&</sup>lt;sup>7</sup> According to article 28 of Regulation (EC) No 178/2002.

<sup>&</sup>lt;sup>7</sup> 規則(EC)No 178/2002の第28条による。

open literature, where it is expected to retrieve existing epidemiological studies. It is therefore recognised that epidemiological studies are more suitable for the renewal process of active substances, also in compliance with the provision of the EC regulation 1141/2010 indicating that 'The dossiers submitted for renewal should include new data relevant to the active substance and new risk assessments to reflect any changes in data requirements and any changes in scientific or technical knowledge since the active substance was first included in Annex I to Directive 91/414/EEC'.

The PPR Panel will specifically address the following topics:

- Review inherent weaknesses affecting the quality of epidemiological studies (including gaps and limitations of the available pesticide epidemiological studies) and their relevance in the context of regulatory pesticide risk assessment. How can these weaknesses be addressed?
- 2) What are potential contributions of epidemiological studies that complement classical toxicological studies conducted in laboratory animal species in the area of pesticide risk assessment?
- 3) Discuss and propose a methodological approach specific for pesticide active substances on how to make appropriate use of epidemiological studies, focusing on how to improve the gaps and limitations identified.
- 4) Propose refinements to practice and recommendations for better use of the available epidemiological evidence for risk assessment purposes. Discuss and propose a methodology for the integration of epidemiological information with data from experimental toxicology.

This Scientific Opinion, particularly Section 2–4, is not intended to address the bases of epidemiology as a science. Those readers willing to deepen into specific aspects of this science are encouraged to read general textbook of epidemiology (e.g. Rothman et al., 2008).

It should be taken into account that this Opinion is focussed only on pesticide epidemiology studies in the EU regulatory context and not from a general scientific perspective. Therefore, the actual limitations and weaknesses of experimental toxicology studies will not be addressed herein.

#### **1.4.** Additional information

In order to fully address topics 1–4 above (Section 1.3), attention has been paid to a number of relevant reviews of epidemiological studies and the experience of other National and International bodies with knowledge of epidemiology in general and in applying epidemiology to pesticide risk assessment specifically. Detailed attention has been given to these studies in Annex A and drawn from the experience of the authors that have constructively to understanding in this area. Also Annex A records published information that has been criticised for its lack of rigour showing how unhelpful some published studies may be. The lessons learned from such good (and less-good) practice have been incorporated into the main text by cross-referring to Annex A. In this way, this Scientific Opinion has the aim of clearly distilling and effectively communicating the arguments in the main text without overwhelming the reader with all the supporting data which is nevertheless accessible.

In addition, Annex B contains a summary of the main findings of a project that EFSA outsourced in 2015 to further investigate the role of human biological monitoring (HBM) in occupational health and safety strategies as a tool for refined exposure assessment in epidemiological studies and to contribute to the evaluation of potential health risks from occupational exposure to pesticides (Bevan et al., 2017).

#### 2. General framework of epidemiological studies on pesticides

This section introduces the basic elements of epidemiological studies on pesticides and contrasts them with other types of studies. For more details general textbook on epidemiology are recommended (Rothman et al., 2008; Thomas, 2009).

#### 2.1. Study design

Epidemiology studies the distribution and determinants of health outcomes in human or other target species populations, to ascertain how, when and where diseases occur. This can be done through observational studies and intervention studies (i.e. clinical trials),<sup>8</sup> which compare study

- 1)疫学研究の質に影響を与える固有の弱点(利用可能な農薬疫学研究のギャップと限界を含む)と、規制上の農薬リスク評価との関連性を検討する。これらの弱点にはどのように対処できるか?
- 2)実験動物を用いた古典的な毒性学的研究を補完する疫学的研究は、農薬リスク評価の分野でどのような貢献 が期待できるか?
- 3) 農薬有効成分に特化した方法論的アプローチとして、疫学的研究をどのように適切に活用するかについて、指摘されたギャップや限界をどのように改善するかを中心に議論し、提案する。
- 4)リスク評価の目的で利用可能な疫学的証拠をより良く利用するための実践への再提案と推奨を提案する。疫学 的情報と実験毒性学のデータを統合するための方法論を議論し、提案する。

本意見書、特にセクション 2・4 は、科学としての疫学の基礎を論じることを意図したものではない。疫学の科学的側面を深めたいと考えている読者には、疫学の一般的な教科書(例:Rothman ら、2008 年)を読むことを勧める。

本意見書は、EU 規制の背景における農薬疫学研究にのみ焦点を当てており、一般的な科学的観点からではない ことを考慮に入れるべきである。したがって、実験的な毒性試験の実際の限界と弱点については、ここでは触れていない。

#### 1.4. 追加情報

上記のトピック 1・4(第 1.3 節)に完全に対応するために、疫学的研究の多くの関連するレビュー及び疫学の知識を 持つ他の国内外の機関の経験に注意を払い、疫学を農薬のリスク評価に特に適用した。付録 A ではこれらの研究に 詳細な注意を払い、この分野の理解に建設的に貢献してきた著者の経験に基づいている。また、付録 A では、いくつ かの公表された研究がどれほど役に立たないかを示すために、厳密さに欠けていると批判された公表情報を記録して いる。このような優れた(そしてあまり良くない)実践から得られた教訓は、附属書 A を相互に参照することで本文に組 み込まれている。このようにして、この科学的意見書(Scientific Opinion)は、それにもかかわらずアクセス可能なすべ ての裏付けとなるデータで読者を圧倒することなく、本文の議論を明確に抽出し、効果的に伝えることを目的としている。

さらに、付属書 B には、疫学研究におけるばく露評価のためのツールとしての労働安全衛生戦略におけるヒト生物 学的モニタリング(HBM)の役割をさらに調査し、農薬への職業上ばく露による潜在的な健康リスクの評価に貢献する ために、2015年に EFSA が委託したプロジェクトの主な成果の要約が含まれている(Bevan 6、2017年)。

# 2. 農薬に関する疫学研究の一般的枠組み

ここでは、農薬に関する疫学研究の基本的な要素を紹介し、他のタイプの研究との対比を行う。詳細については、疫 学の一般的な教科書を勧める(Rothman ら、2009 年)。

# 2.1. 研究デザイン

疫学は、いつ、どこで、どのようにして疾患が発生したかを確認するために、ヒトまたは他の標的種の集団における健 康影響の分布と決定要因を研究する。これは観察による研究や介入研究(すなわち臨床試験)®によって行うことができ、 潜在的なリスク因子へのばく露が異なる研究グループを比較する。どちらのタイプの研究も、実験室よりも管理の行き届 いていない自然環境で実施される。

<sup>&</sup>lt;sup>8</sup> In this opinion, 'human data' includes observational studies, also called epidemiological studies, where the researcher is observing natural relationships between factors and health outcomes without acting upon study participants. Vigilance data also fall under this concept. In contrast, intervention studies (also referred to as experimental studies) are outside the scope of this Opinion, and their main feature is that the researcher intercedes as part of the study design.

<sup>8</sup> この見解では、「ヒトデータ」には、皮学研究とも呼ばれる観察研究が含まれ、研究者は研究参加者に影響を与えることなく、因子と健康影響との 間の自然な関係を観察している。警板データやまた、この概念に該当する。これに対して、介入研究(実験研究ともいう)は本意見の対象外であ り、研究者が研究デザインの一部として介入することが大きな特徴である。

groups subject to differing exposure to a potential risk factor. Both types of studies are carried out in a natural setting, which is a less controlled environment than laboratories.

Information on cases of disease occurring in a natural setting can also be systematically recorded in the form of case reports or case series of exposed individuals only. Although case series/reports do not compare study groups according to differing exposure, they may provide useful information, particularly on acute effects following high exposures, which makes them potentially relevant for hazard identification.

In randomised clinical trials, the exposure of interest is randomly allocated to subjects and, whenever possible, these subjects are blinded to their treatment, thereby eliminating potential bias due to their knowledge about their exposure to a particular treatment. This is why they are called intervention studies. Observational epidemiological studies differ from clinical intervention studies in that the exposure of interest is not randomly assigned to the subjects enrolled and participants are often not blinded to their exposure. This is why they are called observational. As a result, randomised clinical trials rank higher in terms of design as they provide unbiased estimates of average treatment effects.

The lack of random assignment of exposure in observational studies represents a key challenge, as other risk factors that are associated with the occurrence of disease may be unevenly distributed between those exposed and non-exposed. This means that known confounders need to be measured and accounted for. However, there is always the possibility that unknown or unmeasured confounders are left unaccounted for, although unknown confounders cannot be addressed. Furthermore, the fact that study participants are often unaware of their current or past exposure or may not recall these accurately in observational studies (e.g. second-hand smoke, dietary intake or occupational hazards) may result in biased estimates of exposure if it is based on self-report. As an example, it is not unlikely that when cancer cases and controls are asked whether they have previously been exposed to a pesticide the cancer cases may report their exposure differently from controls, even in cases where the past exposures did not differ between the two groups.

Traditionally, designs of observational epidemiological studies are classified as either ecological, cross-sectional, case-control or cohort studies. This approach is based on the quality of exposure assessment and the ability to assess directionality from exposure to outcome. These differences largely determine the quality of the study (Rothman and Greenland, 1998; Pearce, 2012).

- Ecological studies are observational studies where either exposure, outcome or both are measured on a group but not at individual level and the correlation between the two is then examined. Most often, exposure is measured on a group level while the use of health registries often allows for extraction of health outcomes on an individual level (cancer, mortality). These studies are often used when direct exposure assessment is difficult to achieve and in cases where large contrast in exposures are needed (comparing levels between different countries or occupations). Given the lack of exposure and/or outcome on an individual level, these studies are useful for hypothesis generation but results generally need to be followed up using more rigorous design in either humans or use of experimental animals.
- In cross-sectional studies, exposure and health status are assessed at the same time, and prevalence rates (or incidence over a limited recent time) in groups varying in exposure are compared. In such studies, the temporal relationship between exposure and disease cannot be established since the current exposure may not be the relevant time window that leads to development of the disease. The inclusion of prevalent cases is a major drawback of (most) cross-sectional studies, particularly for chronic long-term diseases. Cross-sectional studies may nevertheless be useful for risk assessment if exposure and effect occur more or less simultaneously or if exposure does not change over time.
- · Case-control studies examine the association between estimates of past exposures among individuals that already have been diagnosed with the outcome of interest (e.g. cases) to a control group of subjects from the same population without such outcome. In populationbased incident case-control studies, cases are obtained from a well-defined population, with controls selected from members of the population who are disease free at the time a case is incident. The advantages of case-control studies are that they require less sample sizes, time and resources compared to prospective studies and often they are the only viable option when studying rare outcomes such as some types of cancer. In case-control studies, past exposure is most often not assessed based on 'direct' measurement but rather through less certain measurements such as a recall captured through interviewer or self-administered

12

www.efsa.europa.eu/efsajournal

#### Epidemiological studies and pesticides

自然環境で発生した疾病の事例に関する情報は、ばく露者のみを対象とした症例報告や症例シリーズという形で体 系的に記録することも可能である。症例報告や症例シリーズは、ばく露の違いによって研究グループを比較するもので はないが、有用な情報、特に高濃度ばく露後の急性影響に関する情報を提供することができ、ハザードの特定に役立 つ可能性がある。

無作為化臨床試験では、対象となるばく露が被験者に無作為に割り付けられ、可能な限り被験者は治療法を盲検 化し、それによって特定の治療法へのばく露に関する知識に起因する潜在的なバイアスを排除する。これが介入研究 と呼ばれる理由である。観察による疫学研究は臨床介入研究とは異なり、対象となるばく露が登録された被験者にラン ダムに割り付けられておらず、参加者はばく露について盲検化されていないことが多い。これが観察的研究と呼ばれる 理由である。その結果、無作為化臨床試験は平均的な治療効果のバイアスのない推定値を提供するため、計画の点 で上位にランクされている。

観察による研究におけるばく露の無作為割り付けがないことは、疾患の発生に関連する他のリスク因子がばく露者と 非ばく露者の間で不均等に分布している可能性があるため、重要な課題となる。これは、既知の交絡因子を測定して 説明する必要があることを意味する。しかし、未知の交絡因子は対処できないが、未知の交絡因子または測定されてい ない交絡因子が考慮されずに放置されている可能性が常にある。さらに、観察による研究で研究参加者が現在または 過去のばく露を知らないことが多い、またはこれらを正確に記憶していないことがある(例えば、副流煙、食事摂取量、 または職業上のハザード)という事実は、自己報告に基づいている場合、ばく露の推定値に偏りが生じる可能性がある。 例えば、がん症例と対照者が過去に農薬にばく露されたことがあるかどうかを尋ねられたとき、過去のばく露が両群間 で差がなかった場合でも、がん症例は対照者とは異なるばく露を報告する可能性は低くない。

伝統的に、観察による疫学研究計画は、生態学的研究、横断研究、症例対照研究、コホート研究のいずれかに分 類される。このアプローチは、ばく露評価の質とばく露から結果への方向性を評価する能力に基づいている。これらの 違いは、研究の質を大きく左右する(Rothman 及び Greenland、1998年; Pearce、2012年)。

- 生態学的研究は観察研究であり、ばく露、影響(結果)、またはその両方を個人レベルではなく集団レベルで測 定し、両者の相関関係を調べるものである。多くの場合、ばく露は集団レベルで測定されるが、健康登録を利用 することで、個人レベルでの健康影響(がん、死亡率)を抽出することができる。これらの研究は、直接のばく露 評価が困難な場合や、ばく露量の大きな対照が必要な場合(異なる国や職業間のレベルの比較)によく利用さ れる。個人レベルでのばく露及び/または影響がないことを考えると、これらの研究は仮説を立てるのに有用で あるが、一般的には、ヒトまたは実験動物を用いたより厳密な計画で結果をフォローアップ(追跡調査)する必要 がある。
- 横断研究では、ばく露と健康状態が同時に評価され、ばく露の程度が異なる群における有病率(または最近の 限られた時間における罹患率)が比較される。このような研究では、現在のばく露が疾患の発症につながる関連 時間枠ではないかもしれないので、ばく露と疾患の間の時間的関係は確立できない。有病率の高い症例を含 めることは、(ほとんどの)横断研究の大きな欠点であり、特に慢性的な長期疾患の場合には注意が必要である。 それでも、ばく露と影響が多かれ少なかれ同時に発生している場合や、ばく露が経時的に変化しない場合には、 横断研究はリスク評価に有用であるかもしれない。
- ・症例対照研究では、すでに対象となる疾患(例:症例)と診断されている個人の過去のばく露の推定値と、その ような疾患のない同一集団の対照との間の関連を調べるものである。集団ベースの症例対照研究では、症例は 十分に整備された集団から得られ、対照は症例が発生した時点で病気にかかっていない集団のメンバーから 選ばれる。症例対照研究の利点は、前向き研究に比べてサンプル数、時間、供給源が少なくて済むことであり、 ある種のがんのようなまれな疾患を研究する場合には、症例対照研究が唯一の実行可能な選択肢となることが 多い。症例対照研究では、ほとんどの場合、過去のばく露は「直接的な」測定に基づいて評価されるのではなく、 質問者または自己記入式のアンケートや職務記述書の肩書きや職務歴などの代用手段によって得られた想起 など、より確実性の低い測定を介して評価される。症例対照研究は適切なばく露評価を可能にするかもしれな いが、これらの研究はばく露を推定する際に想起バイアスに陥りやすい。その他の課題としては、適切な対照の EFSA Journal 2017:15(10):5007 www.efsa.europa.eu/efsajourna

questionnaires or proxies such as job descriptions titles or task histories. Although case-control studies may allow for proper exposure assessment, these studies are prone to recall-bias when estimating exposure. Other challenges include the selection of appropriate controls; as well as the need for appropriate confounder control.

· In cohort studies, the population under investigation consists of individuals who are at risk of developing a specific disease or health outcome at some point in the future. At baseline and at later follow-ups (prospective cohort studies) relevant exposures, confounding factors and health outcomes are assessed. After an appropriate follow-up period, the frequency of occurrence of the disease is compared among those differently exposed to the previously assessed risk factor of interest. Cohort studies are therefore by design prospective as the assessment of exposure to the risk factor and covariates of interest are measured before the health outcome has occurred. Thus, they can provide better evidence for causal associations compared to the other designs mentioned above. In some cases, cohort studies may be based on estimates of past exposure. Such retrospective exposure assessment is less precise than direct measure and prone to recall bias. As a result, the quality of evidence from cohort studies varies according to the actual method used to assess exposure and the level of detail by which information on covariates were collected. Cohort studies are particularly useful for the study of relatively common outcomes. If sufficiently powered in terms of size, they can also be used to appropriately address relatively rare exposures and health outcomes. Prospective cohort studies are also essential to study different critical exposure windows. An example of this is longitudinal birth cohorts that follow children at regular intervals until adult age. Cohort studies may require a long observation period when outcomes have a long latency prior to onset of disease. Thus, such studies are both complex and expensive to conduct and are prone to loss of follow-up.

# 2.2. Population and sample size

A key strength of epidemiological studies is that they study diseases in the very population about which conclusions are to be drawn, rather than a proxy species. However, only rarely will it be possible to study the whole population. Instead, a sample will be drawn from the reference population for the purpose of the study. As a result, the observed effect size in the study population may differ from that in the population if the former does not accurately reflect the latter. However, observations made in a non-representative sample may still be valid within that sample but care should then be made when extrapolating findings to the general population.

Having decided how to select individuals for the study, it is also necessary to decide how many participants should minimally be enrolled. The sample size of a study should be large enough to warrant sufficient statistical power. The standard power (also called sensitivity) is 80%, which means the ability of a study to detect an effect of a given magnitude when that effect actually exists in the target population; in other words, there is 80% probability of drawing the right conclusion from the results of the analyses and a corresponding probability of 20% or drawing the wrong conclusion and missing a true effect. Power analysis is often used to calculate the minimum sample size required to likely detect an effect of a given size. Small samples are likely to constitute an unrepresentative sample. The statistical power is also closely related to risk inflation, which needs to be given special attention when interpreting statistically significant results from small or underpowered studies (see Annex D).

Epidemiological studies, like toxicological studies in laboratory animals, are often designed to examine multiple endpoints unlike clinical trials that are designed and conducted to test one single hypothesis, e.g. efficacy of a medical treatment. To put this in context, for laboratory animal toxicology test protocols, OECD guidance for pesticides may prescribe a minimum number of animals to be enrolled in each treatment group. This does not guarantee adequate power for any of the multitude of other endpoints being tested in the same study. It is thus important to appropriately consider the power of a study when conducting both epidemiology and laboratory studies.

# 2.3. Exposure

The quality of the exposure measurements influences the ability of a study to correctly ascertain the causal relationship between the (dose of) exposure and a given adverse health outcome.

In toxicological studies in laboratory animals, the 'treatment regime' i.e. dose, frequency, duration and route are well defined beforehand and its implementation can be verified. This often allows

Epidemiological studies and pesticides

選択及び適切な交絡因子管理の必要性が挙げられる。

・コホート研究では、調査対象となる集団は、将来のある時点で特定の疾患や健康影響を発症するリスクがある 個人で構成されている。ベースライン時及びその後の追跡調査(前向きコホート研究)では、関連するばく露、 交絡因子及び健康影響が評価される。適切な追跡期間の後、以前に評価された対象となるリスク因子に異なる ばく露を受けた人々の間で、疾患の発生頻度が比較される。したがって、コホート研究は計画としては前向きで あり、対象となるリスク因子や共変量へのばく露の評価は健康影響が発生する前に測定される。したがって、コ ホート研究は、上記の他の計画と比較して、因果関係のより良いエビデンスを提供することができる。場合によっ ては、コホート研究が過去のばく露の推定値に基づいていることもある。このような回顧的ばく露評価は、直接測 定に比べて精度が低く、想起バイアスがかかりやすい。その結果、コホート研究から得られるエビデンスの質は、 ばく露を評価するために実際に使用された方法や共変量に関する情報が収集された詳細のレベルによって異 なる。コホート研究は、比較的一般的な健康影響に関する研究に特に有用である。規模の点で十分な検出力 があれば、比較的まれなばく露と健康影響に適切に対処するためにも利用できる。前向きコホート研究は、異な る臨界ばく露枠を研究するためにも不可欠である。その例として、成人になるまで一定間隔で子供を追跡する 縦断的出生コホート研究がある。コホート研究では、疾患発症前の潜伏期間が長い場合、長い観察期間を必要 とすることがある。このような研究は、実施するには複雑で費用がかかり、追跡調査の損失が生じやすい。

# 2.2. 母集団とサンプルサイズ

疫学研究の主な強みは、代理種ではなく、結論を出すべき集団の中で病気を研究することである。しかし、全集団を 調査できることは稀であり、その代わりに研究の目的のために参照母集団からサンプルが引き出される。その結果、前 者が後者を正確に反映していない場合、研究母集団で観察された効果量は、母集団で観察された効果量と異なる可 能性がある。しかし、非代表的なサンプルで行われた観察は、そのサンプル内ではまだ有効であるかもしれないが、結 果を一般集団に外挿する際には注意が必要である。

研究のために対象個人をどのように選択するかを決定した後、最小で何人の参加者を登録すべきかを決定すること も必要である。研究のサンプルサイズは、十分な統計的検出力を保証するのに十分な大きさでなければならない。標 準検出力(感度とも呼ばれる)は80%で、これは、ある研究が、その効果が対象集団に実際に存在するときに、ある大き さの効果を検出する能力を意味する。言い換えれば、解析の結果から正しい結論を導き出せる確率は80%で、それに 対応する確率は20%で、間違った結論を導き出して真の効果を見逃してしまう確率である。検出力解析は、与えられた サイズの効果を検出するのに必要な最小サンプルサイズを計算するためによく使用される。小規模サンプルは、非代 表的サンプルを構成する可能性が高い。統計的検出力はリスク・インフレーション(risk inflation)と密接に関係してお り、小規模または検出力不足の研究から統計的に有意な結果を解釈する際には特別な注意を払う必要がある(付属書 Dを参照)。

疫学研究は、実験動物を用いた毒性学的研究と同様に、多くの場合は複数のエンドポイントを調査するように計画さ れているが、臨床試験は単一の仮説、例えば治療の有効性などを検証するために計画され、実施される。この点では、 実験動物の毒性試験プロトコールについては、OECDの農薬に関するガイダンスでは、各投与群に登録する動物の 最小数が規定されているので、同じ研究で試験される他の多数のエンドポイントのいずれに対しても、十分な検出力を 保証することはできない。したがって、疫学研究と実験室研究の両方を実施する際には、研究の検出力を適切に考慮 することが重要である。

# 2.3. ばく露

ばく露測定の質は、ばく露(用量)と特定の毒性影響との間の因果関係を正確に確認する研究の能力に影響を与える。

実験動物を用いた毒性学的試験では、用量、頻度、期間、経路などの「試験実施計画」が事前に十分に定められており、その実施状況を確認することができる。これにより、例えば90日間の研究では、飼料中に存在する化学物質の目

expression of exposure in terms of external dose administered daily via oral route for example in a 90day study, by multiplying the amount of feed ingested every day by a study animal with the intended (and verified) concentration of the chemical present in the feed. Also, in the future, the internal exposure has to be determined in the pivotal studies.

In the case of pesticides, estimating exposure in a human observational setting is difficult as the dose, its frequency and duration over time and the route of exposure are not controlled and not even well known.

Measuring the intensity, frequency and duration of exposure is often necessary for investigating meaningful associations. Exposure may involve a high dose over a relatively short period of time, or a low-level prolonged dose over a period from weeks to years. While the effects of acute, high-dose pesticide exposure may appear within hours or days, the effects of chronic, low-dose exposures may not appear until years later. Also, a disease may require a minimal level of exposure but increase in probability with longer exposure.

There may be differences in absorption and metabolism via different routes (dermal, inhalation and oral). While dermal or inhalation are often the routes exposure occurs in occupational settings, ingestion (food, water) may be the major route of pesticide exposure for the general population. Pharmacokinetic differences among individuals may result in differing systemic or tissue/organ doses even where the absorbed external doses may appear similar.

#### 2.4. Health outcomes

The term health outcome refers to a disease state, event, behaviour or condition associated with health that is under investigation. Health outcomes are those clinical events (usually represented as diagnosis codes, i.e. International Classification of Diseases (ICD) 10) or outcomes (i.e. death) that are the focus of the research. Use of health outcomes requires a well-defined case definition, a system to report and record the cases and a measure to express the frequency of these events.

A well-defined case definition is necessary to ensure that cases are consistently diagnosed, regardless of where, when and by whom they were identified and thus avoid misclassification. A case definition involves a standard set of criteria, which can be a combination of clinical symptoms/signs, sometimes supplemented by confirmatory diagnostic tests with their known sensitivity and specificity. The sensitivity of the whole testing procedure (i.e. the probability that a person with an adverse health condition is truly diagnosed) must be known to estimate the true prevalence or incidence.

The clinical criteria may also involve other characteristics (e.g. age, occupation) that are associated with increased disease risk. At the same time, appropriately measured and defined phenotypes or hard clinical outcomes add validity to the results.

Disease registries contain clinical information of patients on diagnosis, treatment and outcome. These registries periodically update patient information and can thus provide useful data for epidemiological research. Mortality, cancer and other nation-wide health registries generally meet the case-definition requirements and provide (almost) exhaustive data on the incident cases within a population. These health outcomes are recorded and classified in national health statistics databases, which depend on accepted diagnostic criteria that are evolving and differ from one authority to another. This may confound attempts to pool data usefully for societal benefit. Registry data present many opportunities for meaningful analysis, but the degree of data completeness and validity may challenge making appropriate inferences. Also, changes in coding conventions over the lifetime of the database may have an impact on retrospective database research.

Although the disease status is typically expressed as a dichotomous variable, it may also be measured as an ordinal variable (e.g. severe, moderate, mild or no disease) or as a quantitative variable for example by measuring molecular biomarkers of toxic response in target organs or physiological measures such as blood pressure or serum concentration of lipids or specific proteins.

The completeness of the data capture and its consistency are key contributors to the reliability of the study. Harmonisation of diagnostic criteria, data storage and utility would bring benefits to the quality of epidemiological studies.

A surrogate endpoint is used as substitute for a well-defined disease endpoint, an outcome measure, commonly a laboratory measurement (biomarker of response). These measures are considered to be on the causal pathway for the clinical outcome. In contrast to overt clinical disease, such biological markers of health may allow to detect subtle, subclinical toxicodynamic processes. For such outcomes, detailed analytical protocols for quantification should be specified to enable comparison or replication across laboratories. The use of AOPs can highlight differences in case definitions.

標とする(そして確認された)濃度と、試験動物が毎日摂取した飼料の量を掛け合わせることで、経口経路を介して毎 日投与された外部ばく露量を把握することが可能になる。また、将来的には、重要な試験で内部ばく露量を決定しなけ ればならない。

農薬の場合、ヒトの観察環境においてはばく露濃度、ばく露経路、ばく露期間が管理されておらず曖昧のため正確 なばく露量を推定することは困難である。

意味のある関連性を調べるためには、ばく露の強度、頻度、期間を測定することが必要であることが多い。ばく露に は、比較的短期間の高濃度ばく露もあれば、数週間から数年にわたる低レベルの長期ばく露もある。急性の高用量の 農薬ばく露の影響は数時間から数日以内に現れるかもしれないが、慢性の低用量ばく露の影響は数年後にならないと 現れないかもしれない。また、病気によっては最小限のばく露で発現することもあろうが、ばく露期間が長くなればその 確率は高くなる。

異なるばく露経路(経皮、吸入、経口)では、吸収と代謝に違いが生じる可能性がある。経皮または吸入が職業上の 環境でばく露される経路であることが多いが、一般集団では経口摂取(食品、水)が農薬ばく露の主要な経路である。ヒ トにおける薬物動態には個人差が存在するため、吸収された外部ばく露量が類似している場合でも、異なる全身ばく 露または組織/器官ばく露をもたらす可能性がある。

# 2.4. 健康影響

健康影響という用語は、調査中の健康に関連する疾病状態、事象、行動、または状態を指す。健康影響とは、研究 の焦点となる臨床事象(通常は診断コード、すなわち国際疾病分類(ICD)10)または健康影響(すなわち死亡)として 表現されるものである。健康影響データを使用する際には、十分に詳細な症例定義、症例を報告し記録するシステム、 そしてこれらの事象の頻度を示す尺度が必要である。

明確な症例の定義は、どこで、いつ、誰によって診断されたかを問わず、一貫して診断されることを保証し、誤分類を 避けるのに必要である。症例定義には標準的な基準が必要であり、それは臨床症状や徴候の組み合わせであり、時に は感度と特異性が知られている診断検査によって補完されることもある。真の有病率または罹患率を推定するためには、 検査手順全体の検出感度(すなわち、健康状態の悪い人が本当に不健康と診断される確率)を認識する必要がある。

また、臨床基準には、疾患リスクの増加と関連する他の特性(例えば、年齢、職業)も含まれている。同時に、適切に 測定・定義された表現型あるいは困難な臨床結果は、調査結果の妥当性を高める。

疾患登録には、診断、治療、結果に関する患者の臨床情報が含まれている。これらの登録は定期的に患者情報を 更新しているため、疫学研究に有用なデータを提供することができる。死亡率、がん、その他の全国的な健康登録は、 一般的に症例定義の要件を満たしており、母集団内の偶発的な症例に関する(ほぼ)網羅的なデータを提供している。 これらの健康影響は、国民健康統計データベースに記録され、分類されているものの、内容的にまだ改善の余地が 多々あり、また、国ごとに異なる許容診断基準に依存していることも問題である。これは、社会的利益のために有効なデ ータを集積する試みを混乱させる可能性がある。登録データは有意義な解析を可能にするが、データの完全性と妥当 性の程度によっては、適切な推論を行うことを困難にするかもしれない。また、データベースの存続期間中におけるコ ーディング規約の変更は、後ろ向きデータベース研究に影響を与える可能性がある。

疾患状態は一般的に二分変数として表現されるが、順序変数(例えば、重度、中等度、軽度、無疾患)あるいは定量 的変数(例えば、標的臓器における毒性反応の分子バイオマーカーや血圧、脂質、特定タンパク質血清濃度などの生 理学的測定値)として測定されることもある。

データ収集の完全性とその一貫性は、研究の信頼性に大きく寄与する。診断基準、データ保存、有用性の調和は、 疫学研究の質に利益をもたらすであろう。

代替エンドポイント(surrogate endpoint)は、十分に定義された疾患エンドポイント、健康影響指標、一般的な臨床 検査値(反応のバイオマーカー)等の代替として使用される。これらの指標は、臨床事象の原因経路上にあると考えら れる。明白な臨床疾患とは対照的に、このような健康状態の生物学的マーカーは、微妙な不顕性の毒性力学的プロセ スを検出することができるかもしれない。このような健康影響のために、詳細な定量分析プロトコールは、研究室間での www.efsa.europa.eu/efsalourna

Although surrogate outcomes may offer additional information, the suitability of the surrogate outcome examined needs to be carefully assessed. In particular, the validity of surrogate outcomes may represent a major limitation to their use (la Cour et al., 2010). Surrogate endpoints that have not been validated should thus be avoided.

When the health status is captured in other ways, such as from self-completed questionnaires or telephone interviews, from local records (medical or administrative databases) or through clinical examination only, these should be validated to demonstrate that they reflect the underlying case definition.

#### 2.5. Statistical analysis and reporting

Reporting in detail materials, methods and results, and conducting appropriate statistical analyses are key steps to ensure quality of epidemiological studies. Regarding statistical analysis, one can distinguish between descriptive statistics and modelling of exposure–health outcome relationship.

#### 2.5.1. Descriptive statistics

Descriptive statistics aim to summarise the important characteristics of the study groups, such as exposure measures, health outcomes, possible confounding factors and other relevant factors. The descriptive statistics often include frequency tables and measures of central tendency (e.g. means and medians) and dispersion (e.g. variance and interquartile range) of the parameters or variables studied.

#### 2.5.2. Modelling exposure-health outcome relationship

Modelling of the exposure–health relationship aims to assess the possible relationship between the exposure and the health outcome under consideration. In particular, it can evaluate how this relationship may depend on dose and mode of exposure and other possible intervening factors.

Statistical tests determine the probability that the observations found in scientific studies may have occurred as a result of chance. This is done by summarising the results from individual observations and evaluating whether these summary estimates differ significantly between, e.g. exposed and non-exposed groups, after taking into consideration random errors in the data.

For dichotomous outcomes, the statistical analysis compares study groups by assessing whether there is a difference in disease frequency between the exposed and control populations. This is usually done using a relative measure. The relative risk (RR) in cohort studies estimates the relative magnitude of an association between exposure and disease comparing those that are exposed (or those that have a higher exposure level) with those that are not exposed (or those that have a lower exposure level). It indicates the likelihood of developing the disease in the exposed group relative to those who are not (or less) exposed. An odds ratio (OR), generally an outcome measure in case-control and cross-sectional studies, represents the ratio of the odds of exposure between cases and controls (or diseased and non-diseased individuals in a cross-sectional study) and is often the relative measure used in statistical testing. Different levels or doses of exposure can be compared in order to see if there is a dose-response relationship. For continuous outcome measures, mean or median change in the outcome are often examined across different level of exposure; either through analyses of variance or through other parametric statistics.

While the statistical analysis will show that observed differences are significantly different or not significantly different, both merit careful reflection (Greenland et al., 2016).

**Interpretation of the absence of statistically significant difference.** Failure to reject the null hypothesis does not necessarily mean that no association is present because the study may not have sufficient power to detect it. The power depends on the following factors:

- sample size: with small sample sizes, statistical significance is more difficult to detect, even if true;
- variability in individual response or characteristics, either by chance or by non-random factors: the larger the variability, the more difficult to demonstrate statistical significance;
- effect size or the magnitude of the observed difference between groups: the smaller the size of the effect, the more difficult to demonstrate statistical significance.

**Interpretation of statistically significant difference.** Statistical significance means that the observed difference is not likely due to chance alone. However, such a result still merits careful consideration.

比較や再現を可能にするために特定されるべきである。AOP の使用は、症例定義における違いを強調することができる。

代替健康影響(surrogate outcomes)は付加的な情報を提供するかもしれないが、検査された代替健康影響の適 合性は慎重に評価される必要がある。特に、代替健康影響の妥当性は、その主な使用制限となりうる(la Cour ら、 2010 年)。したがって、妥当性が確認されていない代替エンドポイントの採択は避けるべきである。

健康状態が他の方法により、例えば自己記入式のアンケートや電話インタビュー、地域の記録(医療や行政のデー タベース)から得られた場合、あるいは臨床検査のみで収集された場合、これらは基礎となる症例の定義を正確に反映 していることを実証するために検証されるべきである。

# 2.5. 統計的解析と報告

疫学研究の質を保証するためには、資料、方法、結果を詳細に報告し、適切な統計解析を行うことが重要である。統 計解析については、記述的統計及びばく露ー健康影響の関係のモデル化に分けることができる。

# 2.5.1. 記述的統計

記述的統計は、ばく露尺度、健康影響、可能性のある交絡因子やその他の関連因子など、研究対象グループの重要な特徴を要約することを目的としている。記述的統計には、しばしば頻度表と調査したパラメータまたは変数の中心傾向(平均値や中央値など)及びばらつき度(分散や四分位数範囲など)の測定が含まれる。

# 2.5.2. ばく露ー健康影響の関係のモデル化

ばく露ー健康の関係のモデル化は、検討中のばく露と健康影響との間に考えられる関係を評価することを目的とし ている。特に、この関係によってばく露の量や様式、その他の介入因子にどのように依存しているかを評価することがで きる。

統計的検定は、科学的研究で発見された結果が偶然の結果として起こった可能性があるかどうかを判定する。これ は、個々の所見からの結果を要約し、データのランダムエラーを考慮した後、これらの要約推定値が、例えば、ばく露 群と非ばく露群の間で有意に異なるかどうかを評価することによって行われる。

二分された調査結果については、統計解析によりばく露群と対照群との間で疾患頻度に差があるかどうかを検索す る。これは通常、相対的な尺度を用いて行われる。コホート研究における相対リスク(RR)は、ばく露群(または高ばく露 群)と非ばく露群(または低ばく露群)を比較して、ばく露と疾患との関連性の相対的な大きさを推定する。これは、ばく 露群では、非ばく露群(または低ばく露群)と比較して、病気を発症する可能性が高いことを示唆している。オッズ比 (OR)は、一般的に症例対照研究や横断研究における健康影響の指標であり、症例と対照(または横断研究では罹患 者と非罹患者)の間のばく露のオッズ比を表し、しばしば統計的検査で使用される相対的な尺度である。用量反応関 係については、異なるレベルまたは用量のばく露を比較することによって確認できる。連続的な健康影響測定の場合、 結果の平均値や中央値の変化は、分散分析やその他のパラメトリック統計を用いて、異なるばく露レベルにまたがって 検討されることが多い。

統計解析は、観察された変化に統計学的有意差があるか否かを確認することであるが、いずれの結果においても慎重な再検討が必要である(Greenlandら、2016年)。

統計的に有意差がないことの解釈。帰無仮説を棄却できなかったからといって、必ずしも関連性がないということで はなく、関連性の有無はその研究の検出力が十分か否かに起因する。検出力は以下の要因に依存する。

- ・標本サイズ:標本サイズが小さいと、たとえ真であっても統計的な有意差を検出するのは困難である。
- 偶然性または非ランダムな要因による個々の反応や特性のばらつき:ばらつきが大きいほど、統計的な有意性 を示すのは難しい。
- 効果の大きさ、またはグループ間の観察された差の大きさ:効果の大きさが小さければ小さいほど、統計的有意
   性を示すのは困難である。

- Biological relevance, Rejection of the null hypothesis does not necessarily mean that the association is biologically meaningful, nor does it mean that the relationship is causal (Skelly, 2011). The key issue is whether the magnitude of the observed difference (or 'effect size') is large enough to be considered biologically relevant. Thus, an association that is statistically significant may be or may be not biologically relevant and vice versa. While epidemiological results that are statistically significant may be dismissed as 'not biologically relevant', non-statistically significant results are seldom determined to be 'biologically relevant'. Increasingly, researchers and regulators are looking beyond statistical significance for evidence of a 'minimal biologically important difference' for commonly used outcomes measures. Factoring biological significance relevance into study design and power calculations, and reporting results in terms of biological as well as statistical significance will become increasingly important for risk assessment (Skelly, 2011). This is the subject of an EFSA Scientific Committee guidance document outlining generic issues and criteria to be taken into account when considering biological relevance (EFSA Scientific Committee, 2017a); also a framework is being developed to consider biological relevance at three main stages related to the process of dealing with evidence (EFSA Scientific Committee, 2017b).
- Random error. Evaluation of statistical precision involves consideration of random error within the study. Random error is the part of the study that cannot be predicted because that part is attributable to chance. Statistical tests determine the probability that the observations found in scientific studies have occurred as a result of chance. In general, as the number of study participants increases, precision (often expressed as standard error) of the estimate of central tendency (e.g. the mean) is increased and the ability to detect a statistically significant difference, if there is a real difference between study groups, i.e. the study's power, is enhanced. However, there is always a possibility, at least in theory, that the results observed are due to chance only and that no true differences exist between the compared groups (Skelly, 2011). Very often this value is set at 5% (significance level).
- <u>Multiple testing</u>. As mentioned previously when discussing sample size, modelling of the exposure-health relationship is in principle hypothesis-driven, i.e. it is to be stated beforehand in the study objectives what will be tested. However, in reality, epidemiological studies (and toxicological studies in laboratory animals) often explore a number of different health outcomes in relation to the same exposure. If many statistical tests are conducted, some 5% of them will be statistically significant by chance. Such testing of multiple endpoints (hypotheses) increases the risk of false positive results and this can be controlled for by use of Bonferroni, Sidak or Benjamini–Hochberg corrections or other suitable methods. But this is often omitted. Thus, when researchers carry out many statistical tests on the same set of data, they can conclude that there are real differences where in fact there are none. Therefore, it is important to consider large number of statistical results as preliminary indications that require further validation. The EFSA opinion on statistical significance and biological significance notes that the assumptions derived from a statistical analysis should be related to the study design (EFSA, 2011b).
- Effect size magnification. An additional source of bias, albeit one that is lesser known, is that which may result from small sample sizes and the consequent low statistical power. This lesser known type of bias is 'effect size magnification' which can result from low powered studies. While it is generally widely known that small, low-powered studies can result in false negatives since the study power is inadequate to reliably detect a meaningful effect size, it is less well known that these studies can result in inflation of effect sizes if those estimated effects pass a statistical threshold (e.g. the common p < 0.05 threshold used to judge statistical significance). This effect –also known as effect size magnification is a phenomenon by which a 'discovered' association (i.e. one that has passed a given threshold of statistical significance) from a study with suboptimal power to make that discovery will produce an observed effect size that is artificially and systematically inflated. This is because smaller, low-powered studies are more likely to be affected by random variation among individuals than larger ones. Mathematically, conditional on a result passing some predetermined threshold of statistical significance, the estimated effect size is a biased estimate of the true effect size, with the magnitude of this bias inversely related to power of the study.

As an example, if a trial were run thousands of times, there will be a broad distribution of observed effect sizes, with smaller trials systematically producing a wider variation in observed effect sizes than larger trials, but the median of these estimated effect sizes is close to the true

el usa noral

統計的に有意な差の解釈。統計的有意差とは、観察された差が偶然性だけによるものではないことを意味する。しか し、そのような結果はまだ慎重に検討する必要性がある。

- ・ 生物学的関連性:帰無仮説の否定は、必ずしも関連が生物学的に意味のあるものであることを意味するわけではなく、関連が因果関係にあることを意味するわけでもない(Skelly, 2011 年)。重要な問題は、観察された差の大きさ(または「効果の大きさ」)が、生物学的に関連性があると考えられるほど大きいかどうかということである。このように、統計的に有意な関連性は、生物学的に関連性があるかもしれないし、ないかもしれないし、その逆もある。統計的に有意な度学的結果は「生物学的に関連性がない」として却下されるかもしれないが、統計的に有意でない結果が「生物学的に関連性がある」と判断されることはめったにない。研究者や規制当局は、一般的に使用されている健康影響の指標について、統計的有意性を超えて「生物学的に重要な差が最小である」というエビデンスを求めているケースが増えている。生物学的有意性の関連性を研究デザインや検出力の計算に配慮した上で、統計的有意性と同様に生物学的有意性の観点から結果を報告することは、リスク評価においてますます重要になってくるであろう(Skelly, 2011 年)。これは、生物学的関連性を考慮する際に考慮すべき一般的な問題と基準を概説した EFSA Scientific Committee のガイダンス文書の対象となっている(EFSA Scientific Committee, 2017年a);また、エビデンスを扱うプロセスに関連した三つの主要な段階で生物学的関連性を考慮するためのフレームワークが開発されている(EFSA Scientific Committee, 2017年b)。
- ・偶発誤差(ランダムエラー):統計的精度の評価には、研究内の偶然誤差を考慮する必要がある。偶発誤差とは、研究における予見できない部分であり、その部分が偶然性に起因する。統計的検定は、科学的研究で発見された結果が偶然性の結果として発生した確率を決定する。一般的に、研究参加者の数が増えると、中心傾向(例えば平均値)の推定値の精度(標準誤差として表現されることが多い)が上がり、研究グループ間に実際の差がある場合、統計的に有意な差を検出する能力が向上する。しかし、少なくとも理論的には、観察された結果が偶然に起因するものであり、比較されたグループ間に真の違いが存在しないという可能性が常にある(Skelly、2011 年)。多くの場合、この値は 5%(有意水準)に設定される。
- 多重検定:サンプルサイズについて議論する際に前述したように、ばく露ー健康影響の関係のモデル化は、原則として仮説主導型であり、予め何を検索するかを研究目的に明記しておく必要がある。しかしながら、実際には、疫学的研究(及び実験動物を用いた毒性学的研究)では、多くの場合、同じばく露に関連して多くの異なる健康影響を調査している。多くの統計的検定が実施された場合、そのうちの5%程度は偶然にも統計的に有意な結果が得られることがある。このような複数のエンドポイント(仮説)の検定は、偽陽性結果のリスクを高めるが、これはBonferroni、Sidak、あるいはBenjamini-Hochbergの補正や、他の適切な方法を使用することでコントロールすることができる。しかし、これはしばしば省略される。このように、研究者が同じデータセットを対象に多くの統計的検定を行った場合、実際には何も変化はないのにも拘わらず差があるように結論づけられてしまうことがある。したがって、多くの統計結果は、さらなる検証を必要とする予備的な指標と考えることが重要である。統計的有意性と生物学的有意性に関する EFSA の見解は、統計解析から導き出される仮定は、研究デザインに関連して採択すべきであることに注意を促している(EFSA、2011年b)。
- · <u>効果量の拡大:</u>あまり知られていないとはいえ、バイアス追加の原因は、サンプルサイズが小さく、結果として統計 的検出力が低いことに起因する可能性がある。このあまり知られていないバイアスの種類として知られているのは、 低検出力研究から生じる「効果量の拡大」である。小規模で低検出力の研究では、研究の検出力が意味のある効 果量を確実に検出するには不十分であるため、偽陰性が生じる可能性があることは一般的に知られているが、推 定された効果が統計的閾値(例えば、統計的有意性の判定に使用される一般的な p<0.05 閾値)を通過した場合 に、これらの研究が効果量の誇張(インフレ)をもたらす可能性があることはあまり知られていない。この効果は、効 果量の拡大としても知られているが、これは、「発見された」関連性(すなわち、統計的有意性のある閾値を通過し たもの)を有効化することを目的とした最適下限の検出力を伴う研究から得られる現象であり、観察された効果量が、 人工的かつ系統的に誇張されることを意味する。これは、小規模で検出力の低い研究は、大規模な研究よりも個 人間のランダムな変動(ばらつき)の影響を受けやすいからである。数学的には、結果が統計的に有意であるという

effect size. However, in a small and low powered study, only a small proportion of observed effects will pass any given (high) statistical threshold of significance and these will be only the ones with the greatest of effect sizes. Thus, when these smaller, low powered studies with areater random variation do indeed find a significance-triggered association as a result of passing a given statistical threshold, they are more likely to overestimate the size of that effect. What this means is that research findings of small and significant studies are biased in favour of finding inflated effects. In general, the lower the background (or control or natural) rate, the lower the effect size of interest, and the lower the power of the study, the greater the tendency towards and magnitude of inflated effect sizes.

It is important to note, however, that this phenomenon is only present when a 'pre-screening' for statistical significance is done. The bottom line is that if it is desired to estimate a given quantity such as an OR or RR, 'pre-screening' a series of effect sizes for statistical significance will result in an effect size that is systematically biased away from the null (larger than the true effect size). To the extent that regulators, decision-makers, and others are acting in this way looking for statistically significant results in what might be considered a sea of comparisons and then using those that cross a given threshold of statistical significance to evaluate and judge the magnitude of the effect – will likely result in an exaggerated sense of the magnitude of the hypothesised association. Additional details and several effect size simulations are provided in Annex D of this document.

Confounding occurs when the relationship between the exposure and disease is to some extent attributable to the effect of another risk factor, i.e. the confounder. There are several traditionally recognised requirements for a risk factor to actually act as a confounder as described by McNamee (2003) and illustrated below. The factor must:

- be a cause of the disease, or a surrogate measure of the cause, in unexposed people; factors satisfying this condition are called 'risk factors';
- be correlated, positively or negatively, with exposure in the study populations independently from the presence of the disease. If the study population is classified into exposed and unexposed groups, this means that the factor has a different distribution (prevalence) in the two aroups:
- not be an intermediate step in the causal pathway between the exposure and the disease

Confounding can result in an over- or underestimation of the relationship between exposure and disease and occurs because the effects of the two risk factors have not been separated or 'disentangled'. In fact, if strong enough, confounding can also reverse an apparent association. For instance, because agriculture exposures cover many different exposure categories, farmers are likely to be more highly exposed than the general population to a wide array of risk factors, including biological agents (soil organisms, livestock, farm animals), pollen, dust, sunlight and ozone amongst others, which may act as potential confounding factors.

A number of procedures are available for controlling confounding, both in the design phase of the study or in the analytical phase. For large studies, control in the design phase is often preferable. In the design phase, the epidemiological researcher can limit the study population to individuals that share a characteristic which the researcher wishes to control. This is known as 'restriction' and in fact removes the potential effect of confounding caused by the characteristic which is now eliminated. A second method in the design phase through which the researcher can control confounding is by 'matching'. Here, the researcher matches individuals based on the confounding variable which ensures that this is evenly distributed between the two comparison groups.

Beyond the design phase, at the analysis stage, control for confounding can be done by means of either stratification or statistical modelling. One means of control is by stratification in which the association is measured separately, under each of the confounding variables (e.g. males and females, ethnicity or age group). The separate estimates can be 'brought together' statistically - when appropriate - to produce a common OR, RR or other effect size measure by weighting the estimates measured in each stratum (e.g. using Mantel-Haenszel approaches). This can be done at the cost of reducing the sample size for the analysis. Although relatively easy to perform, there can be difficulties associated with the inability of this stratification to deal with multiple confounders simultaneously. For these situations, control can be achieved through statistical modelling (e.g. multiple logistic regression).

あらかじめ決められた閾値を通過することを条件に、推定された効果量は真の効果量の偏った推定値となり、この 偏りの大きさは研究の検出力に反比例している。例えば、ある試験を何千回も実施した場合、観察された効果量に は広い分布があり、小規模な試験では大規模な試験よりも観察された効果量のばらつきが大きくなるが、これらの 推定効果量の中央値は真の効果量に近いものになる。しかし、小規模で低検出力の研究では、観察された効果 のうち、任意の(高い)統計的閾値を通過するのはごく一部であり、これらは最大の効果量を持つものだけである。 したがって、ランダム変動が大きい小規模で検出力の低い研究では、与えられた統計的閾値を通過した場合、実 際に有意性を重視することにより引き起こされる関連性については、その効果量を過大評価する可能性が高くなる。 このことが意味するものは、小規模研究における有意な研究結果は、効果を誇張して発見することに有利になるよ うに偏っているということである。一般的に、バックグラウンド(または対照または無処置)の割合が低く、対象となる 効果量が小さく、研究の検出力が低いほど、誇張効果量の増大傾向がみられる。

しかし、この現象は、統計的有意性のための「事前スクリーニング」が行われた場合にのみ存在することに注意する ことが重要である。要するに、オッズ比(OR)や相対リスク(RR)のような与えられた量を推定したい場合、統計的有 意性のために一連の効果量を「事前スクリーニング」すると、無効値から系統的に偏った(真の効果量よりも大きい) 効果量が得られるということである。規制当局、政策決定者、その他の人々がこの方法で行動している範囲では、 限りない比較と考えられるものの中から統計的に有意な結果を探し、効果の大きさを評価し判断するために統計的 有意性のある閾値を超えたものを使用しているため、仮定された関連の大きさを誇張した感覚になる可能性が高 い。追加の詳細といくつかの効果量のシミュレーションは、本書の付属書 D で提供されている。

**交絡**は、ばく露と疾病との関係が他のリスク因子の影響、すなわち交絡因子の影響にある程度起因している場合に 発生する。リスク因子が実際に交絡因子として作用するためには、McNamee(2003年)により提示(以下に図示)され、 従来から認識されているいくつかの要件がある。その因子は次のようなものでなければならない。

- ・ 被曝していない人に疾患を引き起こす原因、または原因の代替指標となること。この条件を満たす因子は「リスク 因子」と呼ばれる。
- 病気の存在とは無関係に、調査集団のばく露と正または負の相関があること。調査集団がばく露群と非ばく露群に 分類されている場合、その因子が2つの群で異なる分布(有病率)を持っていることを意味する。
- ばく露と疾患の間の因果関係の経路に中間段階はない。

交絡は、ばく露と疾病の関係を過大または過小に評価する結果となり、2 つのリスク因子の影響が分離されていなか ったり、「解放」されていなかったりするために起こる。実際には、十分に強固な場合、交絡はまた、見かけ上の関連性 を逆転させることもある。例えば、農業上ばく露は多くの異なるばく露カテゴリーがあるため、農業従事者は、生物学的 要因(土壤生物、家畜、農場動物)、花粉、粉塵、日光、オゾンなど、潜在的な交絡因子として作用する可能性のあるも のを含む、多種多様なリスク因子に一般集団よりも多くばく露されている可能性が高い。

交絡を制御するために、研究の計画段階または解析段階の両方で、多くの手順が利用可能である。大規模な研究 では、計画段階でのコントロールが好ましいことが多い。計画段階では、疫学研究者は、研究者がコントロールしたい 特徴を共有する個人に研究集団を限定することができる。これは「限定」として知られており、実際には、その特性によ って引き起こされる交絡の潜在的な影響を取り除くことができる。研究者が交絡をコントロールするための計画段階での 2つ目の方法は、「マッチング」によるものである。ここでは、研究者は交絡変数に基づいて個人をマッチングさせ、交絡 変数が2つの比較グループ間で均等に分布するようにする。

計画段階を超えて、解析段階では、層別化または統計的モデリングのいずれかの方法で交絡をコントロールすること ができる。コントロールの1つの手段は、交絡変数(例えば、男性と女性、民族、または年齢グループ)のそれぞれの下 で、関連性が別々に測定される層別化によるものである。別々の推定値は、各層で測定された推定値を重み付けする ことによって、共通のオッズ比(OR)、相対リスク(RR)、または他の効果量を生成するために(必要に応じて)統計学的 に「集積する」ことができる(例えば、Mantel-Haenszel アプローチを使用する)。これは、分析のサンプルサイズを小さ くする代償として行うことができる。比較的簡単に実行できるが、この層別化が複数の交絡因子を同時に扱うことができ ないことに起因する困難が生ずるかもしれない。このような状況では、統計的なモデル化(例えば、多重ロジスティック EFSA Journal 2017:15(10):5007 www.efsa.europa.eu/efsajourna

Regardless of the approaches available for control of confounding in the design and analysis phases of the study described above, it is important – prior to any epidemiological studies being initiated in the field – that careful consideration be given to confounders because researchers cannot control for a variable which they have not considered in the design or for which they have not collected data.

Epidemiological studies – published or not – are often criticised for ignoring potential confounders that may possibly either falsely implicate or inappropriately negate a given risk factor. Despite these critiques, rarely is an argument presented on the likely size of the impact of the bias from such possible confounding. It should be emphasised that a confounder must be a relatively strong risk factor for the disease to be strongly associated with the exposure of interest to create a substantial distortion in the risk estimate. It is not sufficient to simply raise the possibility of confounding; one should make a persuasive argument explaining why a risk factor is likely to be a confounder, what its impact might be and how important that impact might be to the interpretation of findings. It is important to consider the magnitude of the association as measured by the RR, OR, risk ratio, regression coefficient, etc. since strong relative risks are unlikely to be due to unmeasured confounding, while weak associations may be due to residual confounding by variables that the investigator did not measure or control in the analysis (US-EPA, 2010b).

Effect modification. Effects of pesticides, and other chemicals, on human health can hardly be expected to be identical across all individuals. For example, the effect that any given active substance might have on adult healthy subjects may not be the same as that it may have on infants, elderly, or pregnant women. Thus, some subsets of the population are more likely to develop a disease when exposed to a chemical because of an increased sensitivity. For this, the term 'vulnerable subpopulation' has been used, which means children, pregnant women, the elderly, individuals with a history of serious illness and other subpopulations identified as being subject to special health risks from exposure to environmental chemicals (i.e. because of genetic polymorphisms of drug-metabolising enzymes, transporters or biological targets). The average effect measures the effect of an exposure averaged over all subpopulations. However, there may be heterogeneity in the strength of an association between various subpopulations. For example, the magnitude of the association between exposure to chemical A and health outcome B may be stronger in children than in healthy adults, and absent in those wearing protective clothing at the time of exposure or in those of different genotype. If heterogeneity is truly present, then any single summary measure of an overall association would be deficient and possibly misleading. The presence of heterogeneity is assessed by testing for the presence of statistically significant interaction between the factor and the effect in the various subpopulations. But, in practice, this requires large sample size.

Investigating the effect in subpopulations defined by relevant factors may advance knowledge on the effect on human health of the risk factor of interest.

#### 2.6. Study validity

When either a statistically significant association or no such significant association between, for example, pesticide exposures and a health outcome is observed, there is a need to also evaluate the validity of a research study, assessing factors that might distort the true association and/or influence its interpretation. These imperfections relate to systematic sources of error that result in a (systematically) incorrect estimate of the association between exposure and disease. In addition, the results from a single study takes on increased validity when it is replicated in independent investigations conducted on other populations of individuals at risk of developing the disease.

**Temporal sequence.** Any claim of causation must involve the cause preceding in time the presumed effect. Rothman (2002) considered temporality as the only criterion that is truly causal, such that lack of temporality rules out causality. While the temporal sequence of an epidemiological association implies the necessity for the exposure to precede the outcome (effect) in time, measurement of the exposure is not required to precede measurement of the outcome. This requirement is easier met in prospective study designs (i.e. cohort studies), than when exposure is assessed retrospectively (case-control studies) or assessed at the same time than the outcome (cross-sectional studies). However, also in prospective studies, the time sequence for cause and effect and the temporal direction might be difficult to ascertain if a disease developed slowly and initial forms of disease were difficult to measure (Höfler, 2005).

The generalisability of the result from the population under study to a broader population should also be considered for study validity. While the random error discussed previously is considered a precision problem and is affected by sampling variability, **bias** is considered a validity issue. More

#### 回帰)によってコントロールを達成することができる。

上述の研究の計画と解析の段階で交絡をコントロールするために利用可能なアプローチにかかわらず、研究者が計 画で考慮しなかった変数や、データを収集しなかった変数をコントロールすることができないため、この分野で疫学研 究を開始する前に、交絡因子を慎重に考慮することが重要である。

度学研究は、公表されているかどうかにかかわらず、特定のリスク因子を誤って暗示したり、不適切に否定したりする 可能性のある潜在的な交絡因子を無視しているとして、しばしば批判される。このような批判にもかかわらず、そのよう な可能性のある交絡因子によるバイアスの影響の大きさについての議論が提示されることはほとんどない。交絡因子は、 リスク推定値に実質的な歪みを生じさせるためには、対象となるばく露に強く関連した疾患の比較的強いリスク因子で なければならないことを強調しなければならない。単に交絡の可能性を提起するだけでは十分ではなく、リスク因子が なぜ交絡因子になりやすいのか、その影響がどのようなものなのか、そしてその影響が結果の解釈にとってどれほど重 要なのかを説明する説得力のある議論をしなければならない。強い相対リスクは測定されていない交絡因子によるもの である可能性が低いのに対し、弱い交絡因子は、研究者が解析で測定または管理していない変数による残存交絡因 子によるものである可能性があるため、相対リスク(RR)、オッズ比(OR)、リスク比、回帰係数などで測定される交絡の 大きさを考慮することが重要である(US-EPA、2010 年 b)。

**効果修飾。**ドトの健康に対する農薬及びその他の化学物質の影響は、すべての個人で同一であるとは考えにくい。 例えば、ある特定の有効成分が成人の健康な被験者に及ぼす影響は、乳児、高齢者、妊婦に及ぼす影響と同じでは ない可能性がある。このように、ある化学物質にばく露された場合、ある集団の一部(サブセット)が感受性が高いことか ら疾患を発症する可能性が高くなる。このため、「脆弱な小集団」という用語が使用されているが、これは子供、妊婦、高 齢者、重病歴のある人に加え、環境化学物質へのばく露による特別な健康リスク(薬物代謝酵素、トランスポーター、ま たは生物学的標的の遺伝的多型のため)の対象となると同定された小集団を含む。平均効果とは、あるばく露の影響 をすべての小集団で平均化したものである。しかし、様々な小集団間の関連の強さには不均一性があるかもしれない。 例えば、化学物質 A へのばく露と健康影響 B との間の関連の程度は、健康な成人よりも子供の方が強く、また、ばく露 時に防護服を着用している人や遺伝子型の異なる人には同様な影響は見られないかもしれない。もし不均一性が本当 に存在するのであれば、全体的な関連性を示す単一の要約尺度は意味をなさず、誤解を招く可能性がある。不均質 性の存在は、様々な小集団における因子と効果の間に統計的に有意な相互作用があるかどうかを検定することによっ て評価される。しかし、実際には、これは大きな標本サイズを必要とする。

関連因子によって定義された小集団での効果を調査することは、対象となるリスク因子のとトの健康への影響につい ての知識を前進させるかもしれない。

# **2.6.** 研究の妥当性

例えば、農薬ばく露と健康影響の間に統計的に有意な関連が観察された場合、またはそのような有意な関連が観察 されなかった場合には、真の関連を歪めたり、その解釈に影響を及ぼす可能性のある要因を評価して、調査研究の妥 当性も評価する必要がある。これらの不完全性は、ばく露と疾病の間の関連性を(系統的に)誤って推定することになる 系統的な誤差の原因に関係している。さらに、単一の研究から得られた結果は、病気を発症するリスクのある他の集団 で実施された独立した調査で再現された場合、より高い妥当性を持つことになる。

時間的シーケンス(順序)。因果関係の断定は、推定される効果に先行する原因を時間的に関与させなければならない。Rothman(2002年)は、時間性を真に因果関係がある唯一の基準と考え、時間性の欠如は因果関係を排除する。疫学的関連の時間的順序は、時間的にはばく露が結果(効果)に先行する必要性を示唆しているが、ばく露の測定が結果の測定に先行する必要はない。この要件は、ばく露が後ろ向きに評価される場合(症例対照研究)や、結果と同時に評価される場合(横断研究)よりも、前向き研究の計画(すなわちコホート研究)では容易に満たされる。しかし、前向き研究においても、疾患の発症が遅かったり、初期の疾患形態が測定しにくかったりすると、原因と結果の時間的な順序や時間的な方向性を確認することが困難になることがある(Höfler、2005年)。

研究の妥当性については、研究対象集団からより広い集団への結果の一般化可能性も考慮しなければならない。 www.efsa.europa.eu/efsajourna EFSA Journal 2017;15(10):5007

specifically, bias issues generally involve methodological imperfections in study design or study analysis that affect whether the correct population parameter is being estimated. The main types of bias include selection bias, information bias (including recall bias and interviewer/observer bias) and confounding. An additional potential source of bias is effect size magnification, which has already been mentioned.

Selection bias concerns a systematic error relating to validity that occurs as a result of the procedures and methods used to select subjects into the study, the way that subjects are lost from the study or otherwise influence continuing study participation.

Typically, such a bias occurs in a case-control study when inclusion (or exclusion) of study subjects on the basis of disease is somehow related to the prior exposure status being studied. One example might be the tendency for initial publicity or media attention to a suspected association between an exposure and a health outcome to result in preferential diagnosis of those that had been exposed compared to those that had not. Selection bias can also occur in cohort studies if the exposed and unexposed groups are not truly comparable as when, for example, those that are lost from the study (loss to follow-up, withdrawn or non-response) are different in status to those who remain. Selection bias can also occur in cross-sectional studies due to selective survival: only those that have survived are included in the study. These types of bias can generally be dealt with by careful design and conduct of a study (see also Sections 4, 6 and 8).

The 'healthy worker effect' (HWE) is a commonly recognised selection bias that illustrates a specific bias that can occur in occupational epidemiology studies: workers tend to be healthier than individuals from the general population overall since they need to be employable in a workforce and can thus often have a more favourable outcome status than a population-based sample obtained from the general population. Such a HWE bias can result in observed associations that are masked or lessened compared to the true effect and thus can lead to the appearance of lower mortality or morbidity rates for workers exposed to chemicals or other deleterious substances.

**Information bias** concerns a systematic error when there are systematic differences in the way information regarding exposure or the health outcome are obtained from the different study groups that result in incorrect or otherwise erroneous information being obtained or measured with respect to one or more covariates being measured in the study. Information bias results in misclassification which in turn leads to incorrect categorisation with respect to either exposure or disease status and thus the potential for bias in any resulting epidemiological effect size measure such as an OR or RR.

Misclassification of exposure status can result from imprecise, inadequate or incorrect measurements; from a subject's incorrect self-report; or from incorrect coding of exposure data.

Misclassification of disease status can, for example, arise from laboratory error, from detection bias, from incorrect or inconsistent coding of the disease status in the database, or from incorrect recall. Recall bias is a type of information bias that concerns a systematic error when the reporting of disease status is different, depending on the exposure status (or vice versa). Interviewer bias is another kind of information bias that occurs where interviewers are aware of the exposure status of individuals and may probe for answers on disease status differentially – whether intended or not – between exposure groups. This can be a particularly pernicious form of misclassification – at least for case-control studies - since a diseased subject may be more likely to recall an exposure that occurred at an earlier time period than a non-diseased subject. This will lead to a bias away from null value (of no relation between exposure and disease) in any effect measure.

Importantly, such misclassifications as described above can be 'differential' or 'non-differential' and these relate to (i) the degree to which a person that is truly exposed (or diseased) is correctly classified as being truly exposed or diseased and (ii) the degree to which an individual who is truly not exposed (or diseased) is correctly classified in that way. The former is known as 'sensitivity' while the latter is referred to as 'specificity' and both of these play a role in determining the existence and possible direction of bias. Differential misclassification means that misclassification has occurred in a way that depends on the values of other variables, while non-differential misclassification refers to misclassifications that do not depend on the value of other variables.

What is important from an epidemiological perspective is that misclassification biases - either differential or non-differential - depend on the sensitivity and specificity of the study's methods used to categorise such exposures and can have a predictable effect on the direction of bias under certain (limited) conditions: this ability to characterise the direction of the bias based on knowledge of the study methods and analyses can be useful to the regulatory decision-maker since it allows the decision maker to determine whether the epidemiological effect sizes being considered (e.g. OR, RR) are likely underestimates or overestimates of the true effect size. While it is commonly assumed by some that

#### Epidemiological studies and pesticides

前述したランダムエラーは精度の問題と考えられ、サンプリング変動の影響を受けるが、バイアスは妥当性の問題と考 えられている。より具体的には、バイアスの問題は一般的に、正しい母集団パラメータが推定されているかどうかに影響 を与える研究デザインまたは研究分析における方法論的な不完全性を伴う。バイアスの主なタイプには、選択バイアス、 情報バイアス(想起バイアス,質問者/オブザーバーバイアスを含む)、交絡因子がある。追加の潜在的なバイアスの 発生源は、すでに述べた効果量の規模である。

選択バイアスは、被験者を研究に参加させるために使用された手順や方法、被験者が研究から外れる方法や、そう でなければ研究への継続的な参加に影響を与える結果として発生する妥当性に関する系統的な誤差に関係している。

典型的には、このようなバイアスは、症例対照研究において、疾患に基づいて被験者を含める(または除外する)こと が、研究対象となる前のばく露状態と何らかの形で関連している場合に発生する。一例としては、ばく露と健康影響との 間に関連性が疑われることに対する初期の広報やメディアの注目が、ばく露を受けた人はばく露を受けていない人に 比べて優先的に診断される傾向があるかもしれない。選択バイアスはまた、コホート研究においても、例えば、研究から 外れた人(追跡調査に参加できなくなった人、離脱した人、無回答の人)と残された人の状態が異なる場合のように、ば く露群と非ばく露群が真に比較可能でない場合に発生しうる。また、横断研究では、生存者のみを研究対象とする選択 的生存により、選択バイアスが生じることがある。このようなタイプのバイアスは、一般的に研究の慎重な計画と実施によ って対処できる(第4節、第6節、第8節も参照)。

「健康労働者効果」(HWE)は、一般的に認識されている選択バイアスであり、職域疫学研究で起こりうる特定のバイ アスを示すものである:労働者は、労働力として雇用される必要があるため、一般集団からの個人よりも健康である傾向 があり、そのため、一般集団から得られた集団ベースのサンプルよりも好ましい健康状態を持つことが多い。このような HWE バイアスは、観察された関連性が真の効果に比べて隠されたり、軽減されたりすることがあり、その結果、化学物 質やその他の有害物質にばく露された労働者の死亡率や罹患率が低く見えることがある。

情報バイアスとは、ばく露または健康影響に関する情報が異なる研究グループから得られる方法に系統的な違いが あり、その結果、研究で測定される1つ以上の共変量に関して不正確な情報が得られたり、測定されたりする場合の系 統的な誤差のことである。情報のバイアスは、結果として、ばく露または疾病状態のいずれかに関して誤った分類につ ながり、ORやRRのような疫学的効果の大きさの尺度にバイアスが生じる可能性がある。

ばく露状態の誤分類は、不正確、不十分、または不正確な測定値、被験者の不正確な自己申告、またはばく露デー タの不正確なコーディングに起因する可能性がある。

疾患状態の誤分類は、例えば、検査室のエラー、検出バイアス、データベース内の疾患状態の不正確な、または一 貫性のないコーディング、あるいは不正確な想起から生じることがある。想起バイアスは情報バイアスの一種であり、ば く露状態(またはその逆)に応じて疾患状態の報告が異なる場合の系統的な誤りに関係している。質問者・バイアスは、 質問者が個人のばく露状況を認識している場合に発生するもう一つの情報バイアスで、ばく露グループ間で意図して いるかどうかに関わらず、ばく露グループ間で異なる疾患状況に関する回答を求めてしまうことがある。なぜなら、病気 の被験者は、病気ではない被験者に比べて、より早い時期に発生したばく露を思い出す可能性が高いからである。こ れは、何らかの効果測定において帰無値(ばく露と疾病の間に関係がないという)から遠ざかるバイアスにつながる。

重要なことに、上述のような誤分類は、「差がある(differential)」場合と「差がない(non-differential)」場合があるこ とである。これらは、(i)真にばく露されている(または病気にかかっている)人が、真にばく露されている、または病気に かかっていると正しく分類される度合いと、(ii)真にばく露されていない(または病気にかかっていない)人が、そのよう に正しく分類される度合いに関係している。前者は「感度」として知られているが、後者は「特異性」と呼ばれ、これらの 両方がバイアスの存在と可能性のある方向性を決定する役割を果たしている。差異的誤分類とは、他の変数の値に依 存する方法で誤分類が発生したことを意味し、非差異的誤分類とは、他の変数の値に依存しない誤分類を意味する。

疫学的観点から重要なことは、誤分類バイアス(差異的か非差異的か)は、そのようなばく露を分類するために使用さ れた研究方法の感度と特異性に依存し、特定の(限定された)条件の下でバイアスの方向に予測可能な影響を及ぼす ことができるということである。すなわち、研究の方法や解析の知識に基づくバイアスの方向性を特性評価する能力は、 考慮される疫学的効果量(OR、RR など)が真の効果量の過小評価か過大評価かを政策決定者が判断することができ www.efsa.europa.eu/efsajourna

non-differential misclassification bias produces predictable biases towards the null (and thus systematically under-predicts the effect size), this is not necessarily the case. Also, the sometimes common assumption in epidemiology studies that misclassification is non-differential (which is sometimes also paired with the assumption that non-differential misclassification bias is always towards the null) is not always justified (e.g. see Jurek et al., 2005).

When unmeasured confounders are thought to affect the results, researchers should conduct sensitivity analyses to estimate the range of impacts and the resulting range of adjusted effect measures (US-EPA, 2010b). Quantitative sensitivity (or bias) analyses are, however, not typically conducted in many epidemiological studies, with most researchers instead describing various potential biases qualitatively in the form of a narrative in the discussion section of a paper.

It is often advisable that the epidemiological investigator performs sensitivity analysis to estimate the impact of biases, such as exposure misclassification or selection bias, by known but unmeasured risk factors or to demonstrate the potential effects that a missing or unaccounted for confounder may have on the observed effect sizes (see Lash et al., 2009; Gustafson and McCandless, 2010). Sensitivity analyses should be incorporated in the list of criteria for reviewing epidemiological data for risk assessment purposes.

#### 3. Key limitations of the available epidemiological studies on pesticides

# 3.1. Limitations identified by the authors of the EFSA external scientific report

The EFSA External scientific report (Ntzani et al., 2013; summarised in Annex A) identified a plethora of epidemiological studies which investigate diverse health outcomes. In an effort to systematically appraise the epidemiological evidence, a number of methodological limitations were highlighted. In the presence of these limitations, robust conclusions could not be drawn, but outcomes for which supportive evidence from epidemiology existed were highlighted for future investigation. The main limitations identified included (Ntzani et al., 2013):

- · Lack of prospective studies and frequent use of study designs that are prone to bias (casecontrol and cross-sectional studies). In addition, many of the studies assessed appeared to be insufficiently powered.
- · Lack of detailed exposure assessment, at least compared to many other fields within epidemiology. The information on specific pesticide exposure and co-exposures was often lacking, and appropriate biomarkers were seldom used. Instead, many studies relied on broad definition of exposure assessed through questionnaires (often not validated).
- · Deficiencies in outcome assessment (broad outcome definitions and use of self-reported outcomes or surrogate outcomes).
- Deficiencies in reporting and analysis (interpretation of effect estimates, confounder control and multiple testing).
- Selective reporting, publication bias and other biases (e.g. conflict of interest).

The observed heterogeneity in the results within each studied outcome was often large. However, heterogeneity is not always a result of biases and may be genuine and consideration of a priori defined subgroup analysis and meta-regression should be part of evidence synthesis efforts. Occupational studies, which are of particular importance to pesticide exposure, are also vulnerable to the healthy worker effect, a bias resulting in lower morbidity and mortality rates within the workforce than in the general population. The healthy worker effect tends to decline with increasing duration of employment and length of follow-up.

Studies with sufficient statistical power, detailed definition of pesticide exposure, data for many health outcomes and transparent reporting are rare, apart from the Agricultural Health Study (AHS) and other similarly designed studies. It is important to note that several of these methodological limitations have not been limited to pesticide exposure studies and, most importantly, are not specific in epidemiology and have been observed in other specific fields including in animal studies (Tsilidis et al., 2013).

Given the wide range of pesticides with various definitions found in the EFSA External scientific report, it is difficult to harmonise this information across studies. Although heterogeneity of findings across studies can be as informative as homogeneity, information needs to be harmonised such that replication can be assessed and summary effect sizes be calculated. This does not mean that if there is

るから、規制当局の政策決定に有用である。非差異的な誤分類バイアスが帰無値への予測可能なバイアスをもたらす (したがって、体系的に効果量を過小予測する)と一般的に想定されていますが、これは必ずしもそうではない。また、 誤分類は非差異的であるという疫学研究で時々みられる一般的な仮定(これは、非差異的な誤分類バイアスが常に帰 無(null)に向かっているという仮定と対になっていることもある)は、必ずしも正当化されているわけではない(例えば、 Jurekら、2005 年を参照)。

測定されていない交絡因子が結果に影響を与えると考えられる場合、研究者は感度分析を実施して、影響の範囲と その結果として生じる調整された効果測定値の範囲を推定すべきである(US-EPA、2010 年 b)。しかし、定量的感度 (またはバイアス)分析は、多くの疫学研究では一般的には行われておらず、ほとんどの研究者は、論文の考察で様々 な潜在的なバイアスを定性的に記述している。

疫学研究者は既知ではあるが測定されていないリスク因子によるばく露の誤分類や選択バイアスなどのバイアスの 影響を推定したり、見落としや考慮されていない交絡因子が観察された効果の大きさに及ぼす影響を示すために感度 分析を実施することが推奨されている(Lash ら、2009 年;Gustafson 及び McCandless、2010 年)。感度分析は、リ スク評価目的で疫学データをレビューする際の基準リストに組み込まれるべきである。

# 3. 農薬に関する利用可能な疫学研究の主な限界事項 3.1. EFSA 外部科学研究報告書の著者が指摘した限界

EFSA 外部科学報告書(Ntzani ら、2013 年;付属書 A に要約)では、多様な健康影響を調査する疫学的研究が 多数報告されている。疫学的証拠を体系的に評価する努力の中で、多くの方法論的限界が強調された。これらの限界 の存在下では、確固たる結論を導き出すことはできなかったが、疫学からの裏付けとなるエビデンスが存在する結果は、 今後の調査のために強調された。識別された主な限界は以下の通りである(Ntzaniら、2013年)。

- ・ 前向き研究の欠如と、バイアスがかかりやすい研究デザイン(症例対照研究と横断研究)の頻繁な使用。さら に、評価された研究の多くは、十分な検出力を持っていないようにみえる。
- 少なくとも疫学の他の多くの分野の疫学と比較して、詳細なばく露評価が欠如している。特定の農薬ばく露と混 合ばく露に関する情報は、多くの場合、不足しており、適切なバイオマーカーはほとんど使用されていない。代 わりに、多くの研究では、アンケート調査(多くの場合、妥当性が確認されていない)によって評価されたばく露 の大まかな定義に頼っていた。
- ・ 結果評価の不備(おおまかな結果の定義、自己申告性の健康影響または代替健康影響の使用)。
- 報告と解析の不備(効果推定値の解釈、交絡因子のコントロール、多重検定)。
- 選択的な報告・出版バイアスと、その他のバイアス(例:利害の対立)。

各研究結果の中で観察された結果の不均一性は、しばしば大きなものであった。しかし、不均一性は常にバイアス の結果であるとは限らず、本物である可能性があり、先験的に定義されたサブグループ解析やメタ回帰を考慮すること は、エビデンス統合の努力の一環であるべきである。農薬ばく露に関して特に重要な職域研究もまた、健康労働者効 果の影響を受けやすく、このバイアスによって労働者の罹患率と死亡率が一般集団よりも低くなっている。健康労働者 効果は、雇用期間と追跡調査の期間が長くなるにつれて低下する傾向がある。

十分な統計力を持ち、農薬ばく露の詳細な定義、多くの健康影響に関するデータ及び明白性な報告を備えている 研究は、農業健康調査(Agricultural Health Study: AHS)や他の同様の研究を除けば、稀である。これらの方法論 的限界のいくつかは、農薬ばく露研究に限定されたものではなく、最も重要なことは、疫学的には特異的なものではな く、動物試験を含む他の特異的な研究分野でも観察されていることに注意することが重要である(Tsilidis ら、2013 年)。

EFSA の外部科学報告書には様々に定義された広範囲の農薬が記載されているが、この情報を研究間で調和させ ることは困難である。研究間での結果の不均一性は、同質性と同じくらい有益な情報になるが、情報は、反復を評価し たり、要約効果量を計算したりできるように調和されている必要がある。これは、真の不均一性がある場合、異なる研究 をプールすることができないことを意味するものではない。単一の研究からは限られた結論を導き出すことができるのみ である。それにもかかわらず、報告書では、さらなる検討と調査に値する農薬と健康影響との間の多くの関連性が強調 EFSA Journal 2017:15(10):5007 www.efsa.europa.eu/efsajourna

genuine heterogeneity the different studies cannot be pooled. Limited conclusions can be made from a single study. Nonetheless, the report highlighted a number of associations between pesticides and health effects that merit further consideration and investigation. Of interest is the fact that a considerable proportion of the published literature focused on pesticides no longer approved for use in the EU and in most developed countries e.g. studies focusing solely on DDT and its metabolites constituted almost 10% of the eligible studies (Ntzani et al., 2013). These may still be appropriate since they may persist as pesticide residues or because they continue to be used in developing countries. Also, the report focused on epidemiological evidence in relation to any health outcome across an approximately 5-year window. Although the report is valuable in describing the field of epidemiological assessment of pesticide-health associations, it is not able to answer specific diseasepesticide questions thoroughly. A more in-depth analysis of specific disease endpoints associated with pesticides exposure is needed, where this information is available, and studies published earlier than the time window covered by the EFSA External scientific report should be also included.

#### 3.2. Limitations in study designs

For ethical reasons, randomised controlled trials are not allowed to test the safety of low dose pesticide exposure in the EU. Therefore, information on potential adverse health consequences in humans has to be extracted using observational studies.

For diseases with long-latency periods, measurement of exposure at one time point may not accurately reflect the long-term exposure which is needed to develop such diseases. This is particularly important for non-persistent pesticides, whose levels in biological samples are not constant but vary quite often. Thus, those studies that claim an association between a single measurement in urine samples and a long latency outcome should be carefully interpreted.

Among the 795 studies reviewed in the Ntzani report, 38% were case-control studies and 32% cross-sectional studies. As a result, evidence on potential adverse health consequences of pesticide exposure is largely based on studies that lack prospective design at least for outcomes that have long latency periods. For the cross-sectional studies, directionality cannot be assessed and observed associations may often reflect reverse causation (is the disease caused by the exposure, or does the disease influence the exposure?). Although reverse causation is a potential problem of cross-sectional studies in many fields of epidemiology, in pesticide epidemiology, it is less of an issue, because in most situations it is unlikely that a disease will cause exposure to pesticides.

Although case-control studies are frequently used for rare outcomes, such as several cancers, their main limitation is that they are prone to recall bias and they have to rely on retrospective assessment of exposure. However, they can still provide useful information, especially for rare outcomes. It is important to examine whether results from case-control and prospective studies converge. This was, for example, the case amongst studies that were conducted to examine associations between intake of trans-fatty acids and cardiovascular disease (EFSA, 2004), where both case-control and prospective studies consistently reported positive associations. The effect estimates between the two study designs were systematically different with prospective studies reporting more modest effect sizes but both study designs reached similar conclusions. As for pesticides, similar values have been observed for the magnitude of association between Parkinson's disease and pesticide exposure irrespective of the study design (reviewed in Hernández et al., 2016).

#### 3.3. Relevance of study populations

Because the environmentally relevant doses of pesticides to which individuals are exposed are lower than those required to induce observed toxicity in animal models, the associated toxic effects need to be understood in the context of differences of susceptibility of subpopulations. Potentially vulnerable groups are at an increased risk against exposure to low levels of pesticides than healthy individuals, sometimes during sensitive windows of exposure. This is the case of genetic susceptibility, which represents a critical factor for risk assessment that should be accounted for (Gómez-Martín et al., 2015). Genetic susceptibility largely depends on functional genetic polymorphisms affecting toxicokinetics (e.g. genes encoding xenobiotic metabolising enzymes and membrane transporters) and/or toxicodynamics (e.g. different receptor gene polymorphisms). This genetic variability should be considered on the basis of a plausible scientific hypothesis.

While different disorders, particularly neurodegenerative diseases (Parkinson's disease, Alzheimer's disease, amyotrophic lateral sclerosis) have been linked to exposures to environmental factors (e.g.

#### Epidemiological studies and pesticides

されている。興味深いのは、公表されている文献のかなりの割合が EU 及びほとんどの先進国で使用が認可されてい ない農薬に焦点を当てているという事実である(例えば、DDTとその代謝物のみに焦点を当てた研究は、対象となる研 究の10%近くを占めている(Ntzaniら、2013年)。これらの研究は、残留農薬として残留している可能性があることや、 開発途上国で使用され続けていることから、まだ適切であるかもしれない。また、報告書では、約5年の期間にわたる あらゆる健康影響に関連した疫学的証拠に焦点を当てている。この報告書は、農薬-健康影響の関連性の疫学的評 価の分野を記述する上で有用なものではあるが、特定の疾患と農薬の問題に完全に答えることはできない。農薬ばく 露に関連する疾患エンドポイントのより詳細な解析が必要であり、そのような情報が入手できる場合には、EFSA の外 部科学研究報告書でカバーされている期間よりも前に発表された研究も含めるべきである。

# 3.2. 研究デザインの限界

倫理的な理由から、EU では低用量の農薬ばく露の安全性を試験するための無作為化比較試験は認められていな い。したがって、ヒトにおける潜在的な有害健康影響に関する情報は、観察による研究を用いて抽出する必要がある。

潜伏期間の長い疾患では、ある時点でのばく露量を測定しても、そのような疾患の発症に必要な長期ばく露量を正 確に再現できない可能性がある。これは、生物学的サンプル中の濃度が一定ではなく、頻繁に変動する非持続性農薬 の場合に特に重要である。したがって、尿サンプル中の単一の測定値と長期の潜伏期間の結果との間に関連性がある と断定する研究は、慎重に解釈されるべきである。

Ntzani の報告書で検討された 795 件の研究のうち、38%が症例対照研究であり、32%が横断研究であった。その 結果、農薬ばく露による潜在的な有害健康影響のエビデンスは、少なくとも潜伏期間が長い結果については、前向き な計画を欠いた研究に大部分が基づいている。横断研究では方向性を評価することができず、観察された関連性はし ばしば逆因果関係(病気はばく露によって引き起こされたのか、それとも病気がばく露に影響を与えたのか)をもたらす 可能性がある。逆因果関係は多くの疫学の分野で横断研究の潜在的な問題であるが、農薬疫学では、ほとんどの場 合、病気が農薬へのばく露を引き起こすことはほとんどないため、問題にはならない。

いくつかのがんなどのまれな転帰に対しては症例対照研究が頻繁に用いられるが、その主な限界は、想起バイアス がかかりやすく、ばく露の後ろ向き評価に頼らなければならないことである。しかしながら、特にまれな転帰に対しては 有用な情報を提供することはできる。症例対照研究と前向き研究の結果が一致するかどうかを調べることが重要である。 例えば、トランス脂肪酸の摂取量と心血管疾患との関連を調べるために実施された研究(EFSA, 2004 年)では、症例 対照研究と前向き研究の両方で一貫して正の関連が報告されている。2 つの研究デザイン間の効果推定値は控えめ な効果量が報告された前向き研究とは系統的に異なるが、どちらの研究デザインも同様の結論に達した。農薬に関し ては、研究デザインにかかわらず、パーキンソン病と農薬ばく露との間の関連の大きさについては、同様の値が観察さ れている(レビューは Hernández ら、2016 年)。

# **3.3.** 研究対象の妥当性

個人がばく露される農薬の環境的に適切な用量は、動物モデルで観察された毒性を誘発するのに必要な用量よりも 低いため、関連する毒性影響は、小集団の感受性の違いとの関連で理解する必要がある。潜在的に脆弱な集団は、 健康な個人よりも低用量の農薬へのばく露に対してリスクが高く、時にはばく露の敏感な時期にばく露されることもある。 これは遺伝的感受性の場合であり、これはリスク評価のために説明されるべき重要な要因である(Gómez-Martín ら、 2015年)。遺伝的感受性は、毒物動態に影響を与える機能的な遺伝的多型(例えば、異物代謝酵素及び膜トランスポ ーターをコードする遺伝子)及び/または毒力学に影響を与える機能的な遺伝的多型(例えば、異なる受容体遺伝子) 多型)に大きく依存する。この遺伝的多様性は、妥当な科学的仮説に基づいて考慮されるべきである。

さまざまな障害、特に神経変性疾患(パーキンソン病、アルツハイマー病、筋萎縮性側索硬化症)は、環境因子(例 えば農薬)へのばく露と結び付けられてきたが、多くの場合、病気の遺伝子構造は考慮されていない。特定の集団では、 特定の遺伝子変異の有病率は 5-10%に達し、時には症例の 20%を超えることもある(Gibson ら、2017 年)ので、農薬 ばく露とこれらの疾患の関連性は、研究対象となる集団内の遺伝的構造によって大きく影響を受ける可能性がある。こ EFSA Journal 2017:15(10):5007 www.efsa.europa.eu/efsajourna

pesticides), in many instances the genetic architecture of the disorder has not been taken into account. The prevalence of specific gene mutations may reach 5–10% and sometimes over 20% of cases in certain populations (Gibson et al., 2017), so that the links of these diseases to pesticide exposure may be heavily influenced by genetic structure within populations under study. Given the small effect sizes for many of these disorders, the underlying effects of specific genes not accounted for in the study design may modify the disease risk estimates. Hence, associations with pesticide exposure may need to be evaluated in the light of common genetic influences known to be associated with a spectrum of neurodegenerative diseases. However, genetic variation by itself does not predispose people for an increased pesticide exposure.

A subgroup of population of special interest is represented by children, because their metabolism, physiology, diet and exposure patterns to environmental chemicals differ from those of adults and can make them more susceptibile to their harmful effects. The window(s) of biologic susceptibility remain unknown for the most part, and would be expected to vary by mechanism. Gender-based susceptibility also merits consideration in case of pesticide-related reproductive toxicity and endocrine disruption. Those subgroups are currently considered during the risk assessment process but may deserve more attention to provide additional protection.

#### 3.4. Challenges in exposure assessment

The main limitations of epidemiological studies conducted on pesticides derive from uncertainty in exposure assessment. Limitations include the fact that most currently approved pesticides tend to have short elimination half-lives and that their use involves application of various formulations depending on the crop and season. As a result, accurate assessment needs to capture intermittent long-term exposure of these non-persistent chemicals as well as being able to quantify exposure to individual pesticides.

Numerous studies have assessed internal exposure by measuring urinary non-active metabolites common for a large group of pesticides (for example, dialkyl phosphates for organophosphates, 3-phenoxybenzoic acid for pyrethroids or 6-chloronicotinic acid for neonicotinoids). These data should not be utilised to infer any risk because: (a) a fraction of these metabolites might reflect direct exposure through ingestion of preformed metabolites from food and other sources, rather than ingestion of the parent compound and (b) the potency of the different parent pesticides can vary by orders of magnitude. Thereby, HBM data based on those urine metabolites can be unhelpful unless they are paired with other data indicating the actual pesticide exposure.

Ideally exposure should be quantified on an individual level using biomarkers of internal dose. As most available biomarkers reflect short term (few hours or days) exposure and given the cost and difficulty of collecting multiple samples over time, many studies quantify exposure in terms of external dose. Quantitative estimation of external dose needs to account for both frequency and duration of exposure and should preferably be done on an individual but not group level. Often external exposure is quantified using proxy measures such as:

- subject- or relative-reported jobs, job titles, tasks or other lifestyle habits which are being
  associated with the potential exposure to or actual use of pesticides in general;
- handling of a specific product or set of products and potential exposure to these as documented through existing pesticide records or diaries or estimated from crops grown;
- environmental data: environmental pesticide monitoring, e.g. in water, distance from and/or duration of residence in a particular geographical area considered to be a site of exposure.

In many cases, these proxy measures are recorded with use of questionnaires, which can be either interviewer-administered or based on self-report. However, questionnaire data often rely on individual recall and knowledge and are thus potentially subject to both recall bias and bias introduced by the interviewer or study subjects. These sources of bias can to some extent be quantified if the questionnaires are validated against biomarkers (that is, to what extent do individual questions predict biomarker concentrations in a sub-sample of participants). If the exposure is assessed retrospectively the accuracy of the recall is for obvious reasons more likely to be compromised and impossible to validate. When exposure is based on records, similar difficulties may occur due to, e.g. incomplete or inaccurate records.

In many previous studies, duration of exposure is often used as a surrogate of cumulative exposure, assuming that exposure is uniform and continuous over time (e.g. the employment period) but this assumption must be challenged for pesticides. Although for some chemicals the exposure patterns may be fairly constant, exposures for the large number of pesticides available in the market

#### Epidemiological studies and pesticides

れらの疾患の多くの効果量が小さいことを考えると、研究デザインでは考慮されていない特定の遺伝子の根本的な効 果が、疾患リスクの推定値を修正する可能性がある。したがって、農薬ばく露との関連は、一連の神経変性疾患に関連 することが知られている一般的な遺伝的変異に照らして評価する必要があるかもしれない。しかし、遺伝的変異はそれ 自体が人々を農薬ばく露の増加に向かわせるものではない。

特に注目すべきサブグループは子供であり、彼らの代謝、生理、食生活、環境化学物質へのばく露パターンは成人 とは異なり、有害な影響を受けやすくなるからである。生物学的感受性の窓口はほとんどの場合不明のままであり、メカ ニズムによって異なると予想される。性別に基づく感受性は、農薬に関連した生殖毒性や内分泌かく乱の場合にも考 慮する必要がある。これらのサブグループは現在リスクアセスメントの過程で考慮されているが、追加的な保護を提供 するためには、より注意を払う必要があるかもしれない。

# 3.4. ばく露評価における課題

農薬に関する疫学研究の主な限界は、ばく露評価の不確実性に由来する。現在認可されているほとんどの農薬は、 消失半減期が短い傾向があり、作物や季節に応じて様々な製剤を散布しなければならないという事実もその限界に含 まれている。その結果、正確な評価には、これらの非難分解性化学物質の間欠的な長期ばく露を把握し、個々の農薬 へのばく露を定量化する必要がある。

多くの研究では、大規模な農薬群に共通する尿中の非活性代謝物(例えば、有機リン酸塩の場合はジアルキルリン 酸塩、ビレスロイドの場合は3・フェノキシ安息香酸、ネオニコチノイドの場合は6・クロロニコチン酸)を測定することで内 部ばく露を評価している。これらのデータを、以下の理由からリスクを推測するために利用すべきではない。(a)これら の代謝物の一部は、親化合物を摂取するのではなく、食品やその他の供給源から事前に生成された代謝物を摂取す ることで直接ばく露を反映する可能性があり、(b)異なる親化合物農薬の効果は桁違いに異なる可能性があるからであ る。そのため、これらの尿中代謝物に基づくHBMデータは、実際の農薬ばく露量を示す他のデータと組み合わせな い限り、役に立たない可能性がある。

理想的には、内部ばく露量を示すバイオマーカーを使用して個人レベルでばく露量を定量化する必要がある。利用 可能なバイオマーカーのほとんどは短期間(数時間または数日)のばく露を対象としており、長期にわたって複数のサ ンプルを収集するコストと困難さを考えると、多くの研究では外部ばく露量として定量化されている。外部ばく露量の定 量的な推定には、ばく露の頻度と期間の両方を考慮する必要があり、グループレベルではなく個人レベルで行うことが 望ましい。多くの場合、外部ばく露は以下のような代理指標を用いて定量化される。

- 一般的な農薬への潜在的ばく露または実際の使用に関連する、対象者または親族が報告した仕事、職種、作業、 その他のライフスタイルの習慣。
- 特定の製品または製品群の取り扱いと、既存の農薬の記録や日誌を通じて文書化された、または栽培された作物から推定された、これらへの潜在的なばく露。
- 環境データ:環境農薬モニタリング、例えば水中、ばく露場所と考えられる特定の地理学上の地域からの距離及び /または居住期間。

多くの場合、これらの代理指標測定は、質問者によるものでも、自己申告に基づくものでもよいアンケート調査を用い て記録される。しかし、アンケートデータはしばしば個人の想起と知識に依存しており、想起バイアスや質問者や被験者 によってもたらされるバイアスの影響を受ける可能性がある。これらのバイアスの原因は、アンケートがバイオマーカーに 対して検証されていれば、ある程度定量化することができる(つまり、個々の質問が参加者のサンプルにおけるバイオマ ーカー濃度をどの程度予測しているか)。ばく露が後ろ向きに評価された場合、明らかな理由により、想起の精度が損 なわれ、検証が不可能になる可能性が高くなる。ばく露が記録に基づいて評価される場合も、例えば記録が不完全で あったり、不正確であったりすることで、同様の困難が生じる可能性がある。

これまでの多くの研究では、ばく露の持続時間が累積ばく露の代用として使用されることが多く、ばく露は時間的に 均一で連続的であると仮定している(例えば、雇用期間)が、農薬の場合はこの仮定に疑問を呈しなければならない。 一部の化学物質ではばく露パターンはかなり一定であるかもしれないが、市場に出回っている多数の農薬のばく露は、 www.efsa.europa.eu/efsalourna EFSA Journal 2017;15(10):5007

will vary with season, by personal protective equipment (PPE) and by work practices, and in many cases, uses are not highly repetitive. At an individual level, exposures can vary on a daily and even hourly basis, and often involve several pesticides. This temporal variability can result in particularly high variation in systemic exposures for pesticides with short biological half-lives and considerable uncertainty in extrapolating single or few measurements to individual exposures over a longer term. Hence, many repeated measurements over time may be required to improve exposure estimates.

#### 3.5. Inappropriate or non-validated surrogates of health outcomes

Self-reported health outcomes are frequently used in epidemiological research because of the difficulty of verifying responses in studies with large samples and limited funds, among other reasons. Although a number of studies have examined agreement between self-reported outcomes and medical records, the lack of verification of such metrics can lead to misclassification, particularly in large population-based studies, which may detract from reliability of the associations found.

Reliance on clinically manifested outcomes can increase the likelihood that individuals who have progressed along the toxicodynamic continuum from exposure to disease but have not yet reached an overt clinical disease state will be misclassified as not having the disease (Nachman et al., 2011). Thereby, delay in onset of clinical symptoms following exposure may cause underreporting where clinical assessment alone is used at an inappropriate point in time.

In the case of carcinogenesis, there are some examples where subclinical outcomes have been assessed as preneoplastic lesions with potential to progress to neoplastic conditions. This is the case of monoclonal gammopathy of undetermined significance (MGUS), which has been associated with pesticide exposure in the AHS (Landgren et al., 2009), as this condition has a 1% average annual risk of progression to malignant multiple myeloma (Zingone and Kuehl, 2011). However, it is difficult to predict if and when an MGUS will progress to multiple myeloma. Since there are studies indicating that pesticide exposure may be associated with the risk of precancerous lesions in animal research, a combined epidemiological analysis of both preneoplastic and neoplastic outcomes may increase the power of such an analysis.

Surrogate outcomes may seem an attractive alternative to clinically relevant outcomes since there may be various surrogates for the same disease and they may occur sooner and/or be easier to assess, thereby shortening the time to diagnosis. A valid surrogate endpoint must, however, be predictive of the causal relationship and accurately predict the outcome of interest. In addition, these surrogates should be relevant to the mode of action of a pesticide such that they should be anchored to established toxicological endpoints to support their predictivity. Although surrogate markers may correlate with an outcome, they may not capture the effect of a factor on the outcome. This may be because the surrogate may not be causally or strongly related to the clinical outcome, but only a concomitant factor, and thus may not be predictive of the clinical outcome. The validity of surrogate outcomes may thus represent a major limitation to their use (la Cour et al., 2010).

However, concerns arise as to whether critical regulatory decisions can be made based on epidemiological studies that did not directly measure the adverse health outcome but valid surrogates instead. The use of surrogates as replacement endpoints should be considered only when there is substantial evidence to establish their reliability in predicting clinical meaningful effects.

#### 3.6. Statistical analyses and interpretation of results

The statistical analyses and the interpretation of scientific findings that appear in the epidemiological literature on the relationship between pesticides and health outcomes do not substantially deviate from those reported in other fields of epidemiological research. Therefore, the advantages and limitations of epidemiological studies presented in Section 2.5 also apply to the epidemiological studies on pesticides.

The few distinctive features of the epidemiological studies on pesticides include the following: (a) sparse use of appropriate statistical analyses in the presence of measurement errors when assessing exposure to pesticides and (b) paucity of information on other important factors that may affect the exposure-health outcome relationship. These features are expanded on in the following paragraphs.

a) Statistical analyses in the presence of measurement errors

The difficulties inherent in correctly measuring exposure are frequent in many areas of epidemiological research, such as nutritional epidemiology and environmental epidemiology. It is not

23

www.efsa.europa.eu/efsajournal

e usa numi

#### Epidemiological studies and pesticides

季節や個人用保護具(PPE)、作業習慣によって異なり、多くの場合、使用の反復性は高くない。個人のレベルでは、 ばく露量は日ごと、時間ごとに異なることがあり、多くの場合、複数の農薬が関与している。この時間的変動性は、生物 学的半減期が短い農薬の全身ばく露において特に高い変動性をもたらし、長期にわたって個人のばく露に単一または 少数の測定値を外挿する際にかなりの不確実性をもたらす可能性がある。したがって、ばく露の推定値を改善するため には、時間をかけて多くの測定を繰り返すことが必要になるかもしれない。

# 3.5. 不適切な、あるいは検証されていない健康影響のサロゲート

疫学研究では自己申告による健康影響が頻繁に用いられているが、その理由は、大規模なサンプルや限られた資 金を用いた研究では、回答を検証することが困難であることなどが挙げられる。多くの研究では、自己報告された影響 と医療記録との一致について調べられているが、このような指標の検証が不足しているために、特に大規模な集団ベ ースの研究では、誤分類につながる可能性があり、発見された関連性の信頼性を損なう可能性がある。

臨床的に明らかになった結果に依存すると、ばく露から疾患への毒力学的連続して進行したが、まだ明らかな臨床 的疾患状態に達していない人が、疾患を持っていないと誤分類される可能性が高くなる可能性がある(Nachman ら、 2011 年)。そのため、ばく露後の臨床症状の発現が遅れると、不適切な時期に臨床評価だけが用いられた場合、過小 申告の原因となることがある。

発がん性の場合、無症状であるが、腫瘍性状態に進行する可能性のある前腫瘍性病変として評価されている例があ る。これは、AHS における農薬ばく露と関連している有効性が未決定である単クローン性ガンマグロブリン血症 (MGUS)の例であり(Landgren 6、2009 年)、この状態は悪性多発性骨髄腫に進行するリスクが年平均 1%である (Zingone 及び Kuehl、2011)。しかし、MGUS が悪性多発性骨髄腫に進行するかどうか、いつ、どのように進行する かを予測することは困難である。動物実験では、農薬ばく露が前がん病変のリスクと関連している可能性があることを示 す研究があるので、前がん病変とがん病変の両方の転帰を組み合わせた疫学的解析を行うことで、そのような解析の 検出力を高めることができるかもしれない。

代替健康影響は、臨床的に関連する転帰に代わる注目される選択肢である。なぜならば、同じ疾患の様々な代替健康影響が存在し、それらの健康影響はより早く発生したり、評価が容易であったりして、診断までの時間を短縮できるからである。しかし、有効な代替エンドボイントは、因果関係を予測し、対象となる健康影響を正確に予測するものでなければならない。さらに、これらの代替指標は農薬の作用機序に関連していなければならず、その予測性を裏付けるために、確立された毒物学的エンドポイントに固定されていなければならない。代替指標は健康影響と相関があるかもしれないが、健康影響に対する要因の効果を捉えていないかもしれない。これは、代替指標が臨床健康影響の因果関係または強く関連しているのではなく、付随する要因に過ぎないため、臨床健康影響の予測にはならない可能性があるからである。このように、代替健康影響の妥当性は、サロゲートを使用する上での大きな制限となりうる(la Cour 6、2010年)。

しかし、有害健康影響を直接測定したのではなく、代わりに有効な代替指標を用いた疫学研究に基づいて、規制上 の政策決定を下すことができるかどうかについては、懸念がある。代替エンドポイントとしての代替指標の使用は、臨床 的に意味のある影響を予測する上での信頼性を立証する十分なエビデンスがある場合にのみ検討されるべきである。

#### 3.6. 統計解析と結果の解釈

農薬と健康影響との関係に関する疫学的文献にみられる統計解析と科学的知見の解釈は、他の分野で報告された 疫学研究と大きく異なるものではない。したがって、2.5 節で示した疫学研究の利点と限界は、農薬に関する疫学研究 にも適用される。

農薬の疫学研究のいくつかの特徴は以下の通りである。(a) 農薬へのばく露を評価する際の測定誤差の存在下で の適切な統計解析を行うことが少ないこと、(b) ばく露ー健康影響の関係に影響を及ぼす可能性のある他の重要な因 子に関する情報が不十分なことである。これらの特徴については、次の段落で詳しく説明する。

23

a)測定誤差のある統計解析

easy to gauge the short- and long-term exposure outside controlled laboratory experimental settings. In large populations, individuals are exposed to a variety of different agents in a variety of different forms for varying durations and with varying intensities.

Unlike nutritional or environmental epidemiology, however, pesticide epidemiology has so far made little use of statistical analyses that would appropriately incorporate measurement errors, despite their wide availability and sizable literature on the topic. A direct consequence of this is that the inferential conclusions may not have been as accurate and as precise as they could have been if these statistical methods were utilised (Bengtson et al., 2016; Dionisio et al., 2016; Spiegelman, 2016).

#### b) Information on other important factors of interest

Identifying and measuring the other relevant factors that might affect an outcome of interest is a recurrent and crucial issue in all fields of science. For example, knowing that a drug effectively cures a disease on average may not suffice if such drug is indeed harmful to children or pregnant women. Whether or not age, pregnancy and other characteristics affect the efficacy of a drug is an essential piece of information to doctors, patients, drug manufacturers and drug-approval agencies alike.

Pesticide epidemiology provides an opportunity for careful identification, accurate measuring and thorough assessment of possible relevant factors and their role in the exposure-health outcome relationship. Most often, relevant factors have been screened as potential confounders. When confounding effects were detected, these needed to be adjusted for in the statistical analyses. This has left room for further investigations that would shed light on this important issue by reconsidering data that have already been collected and that may be collected in future studies. The statistical methods in the pesticide literature have been mainly restricted to standard applications of basic regression analyses, such as binary probability and hazard regression models. Potentially useful analytical approaches, such as propensity score matching, mediation analyses, and causal inference, would be helpful for pesticide epidemiology (Imbens and Rubin, 2015).

#### 4. Proposals for refinement to future epidemiological studies for pesticide risk assessment

This section is aimed at addressing methods for assessment of available pesticide epidemiological studies and proposals for improvement of such studies to be useful for regulatory purposes.

When considering the potential regulatory use of epidemiological data, many of the existing epidemiological studies on pesticides exposure and health effects suffer from a range of methodological limitations or deficiencies which limit their value in the assessment of individual active substances. Epidemiological studies on pesticides exposure and health effects would ideally generate semi-quantitative data or be able to have greater relevance to quantitative risk assessment with respect to the output from prediction models. This would allow epidemiological results to be expressed in terms more comparable to the quantitative risk assessments, which are more typically used in evaluating the risks of pesticides. The question arises how such epidemiological data could be considered for risk assessment when judged in comparison to the predictive models. A precisely measured quantitative dose-response relationship is presently rarely attainable as a result of current pesticide epidemiological studies.

The quality, reliability and relevance of the epidemiological evidence in relation to pesticide exposure and health effects can be enhanced by improving (a) the quality of each individual study and (b) the assessment of the combined evidence accrued from all available studies.

# 4.1. Assessing and reporting the guality of epidemiological studies

The quality and relevance of epidemiological research should be considered when selecting epidemiological studies from the literature for use in risk assessment. The quality of this research can be enhanced by (US-EPA, 2012; Hernández et al., 2016);

- a) an adequate assessment of exposure, preferentially biomarker concentrations at individual level reported in a way which will allow for a dose-response assessment;
- b) a reasonably valid and reliable outcome assessment (well-defined clinical entities or validated surrogates);
- c) an adequate accounting for potentially confounding variables (including exposure to multiple chemicals);
- d) the conduct and reporting of subgroup analysis (e.g. stratification by gender, age, ethnicity). 24

ばく露量を正確に測定するための困難さは、栄養疫学や環境疫学などの疫学研究の多くの分野で頻繁にみられる。 制御された実験室での実験環境の外で、短期及び長期のばく露を評価することが容易ではない。大規模集団では、個 人は様々な期間、様々な強度で様々な形で様々な薬剤にばく露されている。

しかし、栄養疫学や環境疫学とは異なり、農薬疫学では、測定誤差を適切に考慮した統計解析が広く利用可能であ り、このテーマに関する膨大な文献があるにもかかわらず、これまでのところほとんど利用されていない。その直接的な 結果として、これらの統計的手法が利用されていたとしても、推論的結論が正確で、精密なものではなかった (Bengtsonら、2016年; Dionisioら、2016年; Spiegelman、2016年)。

b)その他の重要な関係因子に関する情報

対象となる結果に影響を与える可能性のある他の関連因子を特定して測定することは、科学のすべての分野で繰り 返し起こる重要な問題である。例えば、ある薬が平均的に病気を効果的に治すということを知っていても、その薬が子 供や妊婦に有害であるかもしれない。年齢、妊娠、その他の特性が薬の有効性に影響を与えるかどうかは、医師、患者、 製薬会社、医薬品承認機関にとって重要な情報である。

農薬疫学は、可能性のある関連因子を慎重に特定し、正確に測定し、徹底的に評価し、ばく露と健康結果の関係に おけるそれらの役割を評価する機会を提供している。最も多くの場合、関連因子は潜在的な交絡因子としてスクリーニ ングされている。交絡因子の影響が検出された場合には、統計解析で補正する必要があった。このことは、すでに収集 されたデータや今後の研究で収集される可能性のあるデータを再検討することで、この重要な問題を明らかにするため の更なる調査の余地を残している。農薬の文献における統計的手法は、主に二項確率やハザード回帰モデルなどの 基本的な回帰分析の標準的な応用に限定されてきた。潜在的に有用な解析アプローチ、例えば、傾向スコアマッチン グ、媒介分析、因果推論などは、農薬疫学に役立つであろう(Imbens 及び Rubin、2015 年)。

# 4. 農薬リスク評価のための将来の疫学研究への再検討案

このセクションでは、利用可能な農薬の疫学的研究の評価方法と、規制目的に役立つようにそのような研究を改善 するための提案を取り上げることを目的としている。

疫学的データの潜在的な規制上の利用の可能性を検討する際に、農薬ばく露と健康影響に関する既存の疫学的 研究の多くは、個々の有効成分の評価においてその価値を制限する様々な方法論的限界や不完全性に悩まされてい る。農薬ばく露と健康影響に関する疫学研究は、半定量的なデータを生成するか、予測モデルのアウトプットに関して 定量的なリスク評価との関連性を高めることが理想的である。これにより、疫学的な結果は、農薬のリスク評価に一般的 に用いられる定量的なリスク評価に匹敵する言葉で表現できるようになる。このような疫学データを予測モデルと比較し てリスク評価を行う際に、どのように考えればよいのかという疑問が生じる。現行の農薬疫学研究の結果では、正確に測 定された定量的な用量反応関係はほとんど達成されていない。

農薬ば<露と健康影響に関連した疫学的証拠の質、信頼性、妥当性は、(a)個々の研究の質及び(b)利用可能な すべての研究から得られた複合的なエビデンスの評価を改善させることによって向上させることができる。

# 4.1 疫学研究の質の評価と報告

リスク評価に使用するために文献から疫学研究を選択する際には、疫学研究の質と関連性を考慮する必要がある。 この研究の質は、次のようにして高めることができる(US-EPA、2012年:Hernándezら、2016年)。

a) ばく露の適切な評価、特に個人レベルでのバイオマーカー濃度が用量反応評価を可能にする方法で報告されて いること。

b) 合理的に有効で信頼性の高い健康影響評価(よく観察された臨床症状または有効な代替指標)。

c)交絡変数(複数の化学物質へのばく露を含む)を適切に考慮していること。

d)サブグループ解析の実施と報告(例えば、性別、年齢、民族による層別化)。

生物医学的研究が多様な限界の対象となり、その限界に苦しむことは広く受け入れられている。農薬に関する疫学 EESA Journal 2017:15(10):5007 www.efsa.europa.eu/efsajourna

It is widely accepted that biomedical research is subject to and suffers from diverse limitations. An assessment of weaknesses in the design, conduct and analysis of epidemiology research studies on pesticides is essential to identify potentially misleading results and identify reliable data.

CI USA INVIL

EFSA Journal 2017;15(10):5007

Guidelines and checklists help individuals meet certain standards by providing sets of rules or principles that guide towards the best behaviour in a particular area. Several tools and guidelines have been developed to aid the assessment of epidemiological evidence; however, there is no specific tool for assessing studies on pesticides. Although these studies have special considerations around exposure assessment that require specific attention, standard epidemiological instruments for critical appraisal of existing studies may apply. Existing reporting guidelines usually specify a minimum set of information needed for a complete and clear account of what was done and what was found during a research study focusing on aspects that might have introduced bias into the research (Simera et al., 2010).

A number of tools were specifically designed for quality appraisal of observational epidemiological studies, such as the Newcastle–Ottawa scale (NOS) and the Research Triangle Institute (RTI) item bank. The latter is a practical and validated tool which consists of a checklist of 29 questions for evaluating the risk of bias and precision of epidemiological studies of chemical exposures. In addition, the Biomonitoring, Environmental Epidemiology, and Short–Lived Chemicals (BEES-C) instrument was developed to evaluate the quality of epidemiological research that use biomonitoring to assess short-lived chemicals (LaKind et al., 2015), but it can also be used for persistent chemicals and environmental measures as its main elements are cross-cutting and are more broadly applicable. Two earlier efforts to develop evaluative schemes focused on epidemiology research on environmental chemical exposures and neurodevelopment (Amler et al., 2006; Youngstrom et al., 2011).

Regarding quality of reporting, the Enhancing the QUAlity and Transparency Of health Research (EQUATOR) Network, officially launched in June 2008, is an international initiative that promotes transparent and accurate reporting of health research studies. It currently lists over 90 reporting guidelines with some of them being specific for observational epidemiological studies (e.g. Strengthening the Reporting of OBservational studies in Epidemiology (STROBE)). The STROBE statement includes recommendations on what should be included in an accurate and complete report of an observational study including cross-sectional, case-control and cohort studies using a checklist of 22 items that relate to the title, abstract, introduction, methods, results and discussion sections of articles (von Elm et al., 2007). The STROBE statement has been endorsed by a growing number of biomedical journals which refer to it in their instructions for authors. Table 1 presents a summary of the main features that STROBE proposes to be taking into account when assessing the quality of reporting epidemiological studies. Extensions to STROBE are available including the STROBE Extension to Genetic Association studies (STREGA) initiative and the STROBE-ME statement for assessment of molecular epidemiology studies. Since the STROBE checklist mentions only in a general way exposure and health outcomes, the PPR Panel recommends that an extension of the STROBE statement be developed, for inclusion in the EOUATOR network library, specifically relevant to the area of pesticide exposure and health outcomes. This would greatly assist researchers and regulatory bodies in the critical evaluation of study guality.

Table 1: Main features of the STROBE tool to assess quality of reporting of epidemiological studies

STROBE Statement Items		
Factor	Item	Recommendation
Title and Abstract		
	1	<ul> <li>a) Indicate the study's design with a commonly used term in the title of the abstract</li> <li>b) Provide in the abstract an informative and balanced summary of what was done and what was found</li> </ul>
Introduction		
Background/rationale	2	Explain the scientific background and rationale for the investigation being reported
Objectives	3	State specific objectives, including prespecified hypotheses
Methods		
Study design	4	Present key elements of study design early in the paper
Setting	5	Describe the setting, locations and relevant dates, including periods of recruitment, exposure, follow-up and data collection

Epidemiological studies and pesticides

研究の計画、実施、解析における弱点の評価は、誤解を招く可能性のある結果を特定し、信頼性の高いデータを特定 するために不可欠である。

ガイドラインやチェックリストは、特定の分野での最良の行動に向けて導く一連のルールや原則を提供することで、個人が特定の基準を満たすのを助けるものである。疫学的証拠の評価を助けとなるためにいくつかのツールやガイドラインが開発されているが、農薬に関する研究を評価するための特定のツールは存在しない。これらの研究には、特定の注意を必要とするばく露評価に関する特別な考慮事項があるが、既存の研究を批判的に評価するための標準的な疫学的手法を適用できる可能性がある。現行の報告ガイドラインは通常、研究にバイアスをもたらした可能性のある側面に焦点を当て、調査研究中に何が行われ、何が発見されたかを完全かつ明確に説明するために必要な最低限の情報を規定している(Simera6, 2010年)。

観察による疫学研究の品質評価のために、Newcastle-Ottawa スケール(NOS)や Research Triangle Institute (RTI)のアイテムバンクなど、多くのツールが特別に計画されている。後者は、化学物質ばく露の疫学研究のバイアス のリスクと精度を評価するための 29 の質問のチェックリストからなる実用的で検証済みのツールである。また、バイオモ ニタリング、環境疫学、短命化学物質(BEES-C)は、バイオモニタリングを用いて短命化学物質を評価する疫学研究 の質を評価するために開発されたが(LaKind ら、2015 年)、主な要素が横断であり、より広範囲に適用可能であるた め、難分解性化学物質や環境対策にも利用できる。評価スキームの開発に向けた 2 つの先行研究は、環境化学物質 ばく露と神経発達に関する疫学研究に焦点を当てたものである(Amler ら、2006 年; Youngstrom ら、2011 年)。

報告の質に関しては、2008 年 6 月に発足した EQUATOR ネットワーク(Enhancing the QUAlity and Transparency Of health Research (EQUATOR) Network)は、健康調査研究の明白性と正確な報告を促進する 国際的な取り組みである。現在、90 以上の報告ガイドラインがリストアップされており、その中には観察による疫学研究 に特化したものもある(例:Strengthening the Reporting of OBservational studies in Epidemiology (STROBE))。STROBE ステートメントには、論文のタイトル、要約、緒言、方法、結果、考察のセクションに関連する 22 項目のチェックリストを使用して、横断、症例対照、コホート研究を含む観察による研究の正確で完全な報告に何を 含めるべきかについての勧告が含まれている(von Elm ら、2007 年)。STROBE ステートメントは、著者への指示書の 中で言及されている生物医学雑誌の数が増えてきており、支持されている。表 1 は、疫学研究の報告の質を評価する 際に STROBE が考慮すべき主な特徴をまとめたものである。STROBE の拡張機能として、STROBE Extension to Genetic Association studies (STREGA) や分子疫学研究の評価のための STROBE・ME ステートメントがある。 STROBE チェックリストではばく露と健康の影響について一般的にしか言及されていないため、PPR パネルは、農薬 ばく露と健康影響の分野に特化した EQUATOR ネットワークライブラリに含めるための STROBE ステートメントの拡張 版を開発することを推奨する。これは、研究者や規制機関が研究の質を批判的に評価する際に大いに役立つであろう。

#### 表 1:疫学研究報告の質を評価するための STROBE ツールの主な特徴

ファクター	項目	推奨
タイトルと概要		
	1	a) 要約のタイトルに一般的に使用される用語を用いて、研究の計画を示す。 b) 何が行われ、何が発見されたかについて、有益でパランスのとれた要約を記載する
序章		
背景・根拠	2	報告された調査の科学的背景と根拠を説明する。
目的	3	事前に決められた仮説を含めた具体的な目的を述べる。
方法		
研究デザイン	4	研究デザインの重要な要素を論文の前の方で提示する。
設定	5	募集期間、ばく露期間、追跡調査期間、データ収集期間を含めて、環境、場所、関連す 日付を記述する。
参加者	6	a) コホート研究-参加資格の基準、参加者の選択の情報源と方法を示す。フォローア プの方法を記述する。 症例対照研究-適格性の基準及び症例の確認及び対照の選択の情報源と方法を示す。

Factor	Item	Recommendation
Participants	6	<ul> <li>a) Cohort study – Give the eligibility criteria, and the sources and methods of selection of participants. Describe methods of follow-up Case-control study – Give the eligibility criteria, and the sources and methods of cases ascertainment and control selection. Give the rationale for the choice of cases and controls</li> <li>Cross-sectional study – Give eligibility criteria, and the sources and methods of selection of participants</li> <li>b) Cohort study – For matched studies, give matching criteria and the number of exposed and unexposed</li> <li>Case-control study – For matched studies, giving matching criteria and the number of controls per case</li> </ul>
Variables	7	Clearly define all outcomes, exposures, predictors, potential confounders and effect modifiers. Give diagnostic criteria, if applicable
Data sources/ measurements	8*	For each variable of interest, give sources of data and details of methods of assessment (measurement). Describe comparability of assessment methods if there is more than one group
Bias	9	Describe any efforts to address potential sources of bias
Study size	10	Explain how the study size was arrived at
Quantitative variables	11	Explain how quantitative variables were handled in the analyses. If applicable, describe which groupings were chosen and why
Statistical methods	12	<ul> <li>a) Describe all statistical methods, including those used to control for confounding</li> <li>b) Describe any methods used to examine subgroups and interactions</li> <li>c) Explain how missing data were addressed</li> <li>d) Cohort study – If applicable, explain how loss to follow-up was addressed Case-control study – If applicable, explain how matching of cases and controls was addressed</li> <li>Cross-sectional study – If applicable, describe analytical methods taking account of sampling strategy</li> <li>e) Describe any sensitivity analyses</li> </ul>
Results		
Participants	13*	<ul> <li>a) Report numbers of individuals at each stage of study – e.g. numbers potentially eligible, examined for eligibility, confirmed eligible, included in the study, completing follow-up and analysed</li> <li>b) Give reasons for non-participation at each stage</li> <li>c) Consider use of a flow diagram</li> </ul>
Descriptive data	14*	<ul> <li>a) Give characteristics of study participants (e.g. demographic, clinical, social) and information on exposures and potential confounders</li> <li>b) Indicate number of participants with missing data for each variable of interest</li> <li>c) Cohort study – Summarise follow-up time (e.g. average and total amount)</li> </ul>
Outcome data	15*	Cohort study – Report numbers of outcome events or summary measures over time Case-control study – Report numbers in each exposure category, or summary measures of exposure Cross-sectional study – Report numbers of outcome events or summary measures
Main results	16	<ul> <li>a) Give unadjusted estimates and, if applicable, confounder-adjusted estimates and their precision (e.g. 95% confidence interval). Make clear which confounders were adjusted for and why they were included</li> <li>b) Report category boundaries when continuous variables were categorised</li> <li>c) If relevant, consider translating estimates of relative risk into absolute risk for a meaningful time period</li> </ul>

その他の分析	17	実施したその他の分析(サブグループと相互作用の分析、感度分析など)を報告する。

STROBE Statement Items			
Factor	Item	Recommendation	
Other analyses	17	Report other analyses done – e.g. analyses of subgroups and interactions, and sensitivity analyses	
Discussion			
Key results	18	Summarise key results with reference to study objectives	
Limitations	19	Discuss limitations of the study, taking into account sources of potential bias or imprecision. Discuss both direction and magnitude of any potential bias	
Interpretation	20	Give a cautious overall interpretation of results considering objectives, limitations, multiplicity of analyses, results from similar studies, and other relevant evidence	
Generalisability	21	Discuss the generalisability (external validity) of the study results	
Other information	n		
Funding	22	Give the source of funding and the role of the funders for the present study and, if applicable, for the original study on which the present article is based	

\*: Give information separately for cases and controls in case-control studies and, if applicable, for exposed and unexposed groups in cohort and cross-sectional studies.

Selective reporting can occur because non-significant results or unappealing significant results may not be published. Investigators should avoid the selective reporting of significant results and high-risk estimates. In this regard, standardisation of reporting of epidemiological studies could help to reduce or avoid selective reporting. The STROBE statement and similar efforts are useful tools for this purpose. Although some epidemiological research will remain exploratory and *post hoc* in nature, this should be clarified in the publications and selective reporting minimised, so that epidemiological findings could be interpreted in the most appropriate perspective (Kavvoura et al., 2007).

Preregistration of studies and prepublication of protocols are the measures taken by some Journal editors and Ethics Committees to reduce reporting bias and publication bias in clinical trials on pharmaceuticals. Although a similar proposal has been suggested for observational epidemiological studies in order to be conducted as transparently as possible to reduce reporting bias and publication bias, there is no consensus among epidemiologists (Pearce, 2011; Rushton, 2011). In contrast, a number of initiatives have been undertaken by professional societies to foster good epidemiological practice. This is the case, for example, of the International Epidemiological Association (IEA, 2007) or the Dutch Society for Epidemiology on responsible epidemiologic Research Practice (DSE, 2017).

Data quality assessment of formal epidemiological studies is based solely on the methodological features of each individual study rather than on the results, regardless of whether they provide evidence for or against an exposure/outcome association. However, for risk assessment, it is important to assess not only the quality of study methods but also the quality of the information they provide. Indeed, good studies may be dismissed during the formal quality assessment by the poor reporting of the information.

#### 4.2. Study design

Well conducted prospective studies with appropriate exposure assessment provide the most reliable information and are less prone to biases. When prospective studies are available, results from studies of less robust design can give additional support. In the absence of prospective studies the results from cross-sectional and case-control studies should be considered but interpreted with caution. However, it is acknowledged that a well-designed case-control study may be superior to a less well designed cohort study. Analytical approaches should be congruent with the study design, and assumptions that the statistical methods required should be carefully evaluated.

Ideally observational studies for long-term diseases should be prospective and designed such that the temporal separation between the exposure and the health outcome is appropriate with respect to the time it takes to develop the disease. For outcomes such as cancer or cardiovascular diseases, which often have a long latency period (> 10 years), exposure should be assessed more than once prior to the outcome assessment. For other outcomes with a shorter latency period, such as immune function disturbances, the appropriate temporal separation may be in the range of days or weeks and a single exposure assessment may be adequate. In short, the ideal design of a study depends on the latency period for the outcome under consideration. The expected latency period the determines both the length of follow-up and the frequency for which the exposure has to be quantified.

\*:症例対照研究では症例と対照について、また、コホート研究及び横断研究では、該当する場合には、ばく露群と非ばく露群につい て、別々に情報を提供する。

選択的報告は、有意性のない結果や注目されない有意な結果が公表されないことで起こる可能性がある。研究者は、 有意な結果やリスクの高い推定値の選択的報告を避けるべきである。この点では、疫学研究の報告の標準化は、選択 的な報告を減らすか回避するのに役立つであろう。STROBE 声明や同様の取り組みは、この目的のための有用なツ ールである。疫学研究の中には探索的でその場限りの性質を持つ研究もあるだろうが、これは出版物に明記されるべ きであり、選択的報告は最小限に抑えられるべきであり、そうすれば疫学研究の結果は最も適切な観点から解釈される (Kavvoura 6、2007 年)。

研究の事前登録とプロトコールの事前発表は、医薬品の臨床試験における報告バイアスと出版バイアスを減らすた めに、いくつかの雑誌の編集者と倫理委員会によって取られている措置である。観察による疫学研究についても、でき るだけ明白性をもって報告バイアスや出版バイアスを減らすことを実施するために、同様の提案がなされているが、疫 学者の間ではコンセンサスが得られていない(Pearce、2011年; Rushton、2011年)。これとは対照的に、優れた疫学 的実践を促進するための多くの取り組みが専門学会によって実施されてきた。例えば、国際疫学協会(IEA、2007年) やオランダ疫学協会の responsible epidemiologic Research Practice (DSE、2017年)などがその例である。

正式な疫学研究のデータの質の評価は、ばく露/影響の関連性についてのエビデンスを提供するか否かに関わらず、結果よりも個々の研究の方法論的特徴のみに基づいている。しかし、リスク評価においては、研究方法の質だけでなく、研究が提供する情報の質も評価することが重要である。実際、優れた研究であっても、正式な品質評価の際に、 情報の報告が不十分なために却下されてしまうことがある。

# 4.2. 研究デザイン

適切なばく露評価を行い、十分に実施された前向き研究は、最も信頼性の高い情報を提供し、バイアスがかかりにく い。前向き研究が利用可能な場合には、計画があまり強固でない研究の結果が追加的な裏付けとなることがある。前 向き研究がない場合は、横断研究や症例対照研究の結果を考慮すべきであるが、慎重に解釈すべきである。しかし、 適切に計画された症例対照研究は、あまり適切に計画されていないコホート研究よりも優れている可能性があることは 認められている。解析的アプローチは研究デザインに合致したものでなければならず、必要とされる統計的手法の仮 定は慎重に評価されるべきである。

長期疾患の観察による研究は前向きであることが理想的であり、ばく露と健康影響との間の時間区分は、疾患の発症に要する時間に関して適切であるように計画されるべきである。がんや心血管疾患のように潜伏期間が長い(10年以上)ことが多い健康影響については、健康影響の評価に先立って複数回のばく露評価を行うべきである。免疫機能障害のような潜伏期間の短い他の健康影響では、適切な時間区分は数日から数週間の範囲であり、1回のばく露評価で十分であろう。要するに、研究の理想的な計画は、検討されている健康影響の潜伏期間に依存する。予測される潜伏期間は、追跡調査の長さとばく露量が定量化されなければならない頻度の両方を決定する。

#### 4.3. Study populations

The EU population, which exceeds 500 million people, can be assumed to be fairly heterogeneous and so expected to include a number of more sensitive individuals that may be affected at lower doses of pesticide exposure. To address this, in stratified sampling, the target population is divided into subgroups following some key population characteristics (e.g. sex, age, geographic distribution, ethnicity or genetic variation) and a random sample is taken within each subgroup. This allows subgrouplations to be represented in a balanced manner in the study population.

Vulnerable populations should then be examined in epidemiological studies either through subgroup or sensitivity analysis. However, such analyses need to be defined *a priori*. In case of ad hoc subgroup sensitivity analysis, the statistical thresholds should be adjusted accordingly and the replication of results should follow. Evidence of vulnerable subpopulations would ideally involve prospective studies that include assessment of biomarkers of exposure, subclinical endpoints and disease incidence over time.

It may be impossible to find a threshold of a toxic-induced increase in disease in the population because a large number of people are in a preclinical state and would be sensitive to the low end of the dose-response curve. For that to be evident, the epidemiology data would need to characterise the relationship between chemical exposure and risk of disease in a broad cross-section of the population (or look at precursor lesions or key events) and allow a robust examination of a low-dose slope.

On the basis of the degree of evidence relevant to a vulnerable subpopulation, consideration should be given to whether dose-response assessment will focus on the population as a whole or will involve separate assessments for the general population and susceptible subgroups. If it is the population as a whole, the traditional approach is to address variability with uncertainty factors; it may also be possible to analyse the effect of variability on risk by evaluating how the risk distribution of the disease shifts in response to the toxicant. In essence, the risk distribution based on a subclinical biomarker is an expression of toxicodynamic variability that can be captured in dose-response assessment.

The alternative approach is to address vulnerable subpopulations as separate from the general population and assign them unique potencies via dose–response modelling specific to the groups that might be based on actual dose–response data for the groups, on adjustments for specific toxicokinetic or toxicodynamic factors, or on more generic adjustment or uncertainty factors. For a pesticide, if it is known that a particular age group, disease (or disease-related end-point), genetic variant or co-exposure creates unique vulnerability, efforts should be made to estimate the potency differences relative to the general population and on that basis to consider developing separate potency values or basing a single value on the most sensitive group or on the overall population with adjustments for vulnerable groups.

#### 4.4. Improvement of exposure assessment

The difficulties often associated with pesticide exposure assessment in epidemiological studies have been highlighted above. The description of pesticide exposure (in particular quantitative information on exposure to individual pesticides) is generally reported in insufficient detail for regulatory purposes and this limitation is difficult to overcome, especially for diseases with a long latency period (e.g. many cancers and neurodegenerative disorders).

It is noteworthy that the methods necessary to conduct exposure monitoring are to be submitted by the applicant in the dossier. The regulation requirements do ask for validated methods that can be used for determining exposure. The Commission Regulation (EU) No 283/2013, setting out the data requirements for active substances, in accordance with Regulation (EC) No 1107/2009 of the European Parliament and of the Council concerning the placing of PPP on the market, addresses information on methods of analysis required to support both pre-approval studies and post-approval monitoring. In this context, the post-approval requirements are the most relevant and the regulation literally states:

 $^{\rm V4.2.}$  Methods for post-approval control and monitoring purposes – Methods, with a full description, shall be submitted for:

 a) the determination of all components included in the monitoring residue definition as submitted in accordance with the provisions of point 6.7.1 in order to enable Member States to determine compliance with established maximum residue levels (MRLs); they shall cover residues in or on food and feed of plant and animal origin;

Epidemiological studies and pesticides

# 4.3. 研究対象集団

EUの人口は5億人を超えており、かなり雑多であるため、低用量の農薬ばく露で影響を受ける可能性のある、より 感受性の高い個人が多数含まれていることが予想される。これに対処するために、層別サンプリングでは、いくつかの 主要な集団特性(性別、年齢、地理的分布、民族性、遺伝的変動など)に従って対象集団をサブグループに分割し、 各サブグループ内で無作為にサンプルを採取する。これにより、調査母集団の中でサブグループをバランスよく表現す ることができる。

次に、脆弱な集団は、小集団解析または感度分析のいずれかを用いて疫学研究で調査されるべきである。しかし、 そのような解析は事前に行う必要がある。事後的なサブグループ感度分析の場合、統計的閾値はそれに応じて調整さ れるべきで、結果の再現性はそれに従うべきである。脆弱な小集団のエビデンスは、理想的には、ばく露のバイオマー カー、前駆症状、経時的な疾患発生率の評価を含む前向き研究を必要とする。

多くの人が前臨床状態にあり、用量反応曲線の下端に敏感に反応してしまうため、集団における毒性による疾病の 増加の閾値を特定することは不可能かもしれない。このことを明らかにするためには、疫学データが、集団の広範な横 断面における化学物質ばく露と疾病リスクの関係を特徴づけ(あるいは前兆病変や重要事象を調べ)、低用量の傾きを しっかりと検討する必要がある。

脆弱な小集団に関連するエビデンスの程度に基づいて、用量反応評価が集団全体に焦点を当てるのか、一般集団 と影響を受けやすいサブグループに分けて評価するのかを検討すべきである。集団全体を対象とする場合、従来のア プローチでは、不確実性因子を用いて変動性に対処することになるが、毒性物質に反応して疾患のリスク分布がどのよ うに変化するかを評価することで、変動性のリスクへの影響を解析することも可能である。要するに、不顕性バイオマー カーに基づくリスク分布は、用量反応評価で捉えることができる毒力学的変動の表現である。

別のアプローチとしては、脆弱な小集団を一般集団とは別個のものとして扱い、その集団の実際の用量反応データ、 特定の薬物動態または毒物動態学的要因の調整、またはより一般的な補正や不確実性の要因に基づいた用量反応 モデルを用いて、その集団に固有の効果を割り当てることである。農薬については、特定の年齢層、疾患(または疾患 関連のエンドポイント)、遺伝的変異、または共ばく露が独特の脆弱性を生んでいることが分かっている場合には、一般 集団に対する効果の差を推定するよう努めるべきであり、それに基づいて、別個の効果を開発するか、または最も感受 性の高い集団または脆弱性のある集団に対する補正を加えた全体の集団に対する単一の効果をベースにすることを 検討すべきである。

# 4.4. ばく露評価の改善

疫学研究における農薬ばく露評価の困難さは、上記したように強調されている。農薬ばく露の記述(特に個々の農薬 へのばく露に関する定量的な情報)は、一般的に規制目的のためには十分な詳細が報告されておらず、特に潜伏期 間の長い疾患(多くのがんや神経変性疾患など)では、この限界を克服するのは困難である。

ばく露モニタリングを実施するために必要な方法は、申請者が申請書類の中で提出しなければならないことは注目 に値する。この規則の要求事項は、ばく露量の判定に使用できる有効な方法を要求している。欧州議会及び理事会の PPPの上市に関する規則(EC)No 1107/2009に基づき、有効成分のデータ要求を定めた欧州委員会規則(EU)No 283/2013 では、承認前の試験と承認後のモニタリングの両方をサポートするために必要な分析方法に関する情報が 記載されている。この文脈では、承認後の要求が最も有用性が高く、規則には実際に次の通りに記載されている。

- <sup>4.2.</sup> 承認後の管理及びモニタリング目的のための方法-方法は、以下の目的で提出されなければならない。
- a)加盟国が確立された最大残留レベル(MRL)への準拠を決定できるようにするために、6.7.1 項の規定に従って 提出されたモニタリング残留物の定義に含まれるすべての成分の決定;これは、植物及び動物由来の食品及び飼料に含まれる、または上述の残留物を対象とする。

b)7.4.2項の規定に従って提出された土壌及び水の残留基準をモニタリングする目的のための含有全成分の測定。c)申請者が、作業者、労働者、住民または居合わせただけの者(bystanders)のばく露が無視できる程度であることを示さない場合には、散布中または散布後に生成された有効成分及び関連する分解生成物の大気中の分析。

CI USA INVI

- b) the determination of all components included for monitoring purposes in the residue definitions for soil and water as submitted in accordance with the provisions of point 7.4.2;
- c) the analysis in air of the active substance and relevant breakdown products formed during or after application, unless the applicant shows that exposure of operators, workers, residents or bystanders is negligible;
- d) the analysis in body fluids and tissues for active substances and relevant metabolites.

As far as practicable these methods shall employ the simplest approach, involve the minimum cost, and require commonly available equipment. The specificity of the methods shall be determined and reported. It shall enable all components included in the monitoring residue definition to be determined. Validated confirmatory methods shall be submitted if appropriate. The linearity, recovery and precision (repeatability) of methods shall be determined and reported.

Data shall be generated at the LOQ and either the likely residue levels or ten times the LOQ. The LOO shall be determined and reported for each component included in the monitoring residue definition. For residues in or on food and feed of plant and animal origin and residues in drinking water, the reproducibility of the method shall be determined by means of an independent laboratory validation (ILV) and reported'.

From this, it can be concluded that the requirements exist, but are somewhat less stringent for human biomonitoring than for monitoring of residues in food and feed.

Failure to use these existing methods restricts the potential for the use of epidemiological evidence in the regulation of specific pesticides. It is therefore important that those contemplating future studies carefully consider approaches to be used to avoid misclassification of exposure, and to conduct appropriate detailed exposure assessments for specific pesticides, which allow for sound doseresponse analyses, and demonstrate the validity of the methods used.

A given exposure may have a different health impact depending on the period in the lifespan when exposure takes place. Greater attention needs to be paid to exposures occurring during periods of potential susceptibility for disease development by ensuring that the exposure assessment adequately addresses such critical times. This may be particularly relevant for studies involving neurodevelopment, obesity or allergic responses, which are complex multistage developmental processes that occur either prenatally or in the early post-natal life. For this reason, measurement of the exposure at one single time period may not properly characterise relevant exposures for all health effects of the environmental factors, and thus, the possibility arises of needing to measure the exposure at several critical periods of biological vulnerability to environmental factors. It is particularly challenging to construct an assessment of historical exposures which may deviate from current exposures, in both the range of chemicals and intensity of exposure and also co-exposure to other substances which are not included in the scope of study.

There are advantages and disadvantages to all methods of measuring pesticide exposure, and specific study designs and aims should be carefully considered to inform a specific optimal approach.

Exposure assessment can be improved at the *individual* level in observational research by using:

a) **Personal exposure monitoring:** This can be used to document exposures as readings measure pesticide concentration at the point of contact. Personal exposure monitors have been costly and burdensome for study participants. However, technological advances have recently driven personal exposure monitoring for airborne exposures to inexpensive, easy to use devices and these are suitable for population research. Personal exposure monitors that are specific to pesticide exposure could involve sensors to measure airborne concentrations, 'skin' patches to measure dermal concentrations, indoor home monitors that capture dust to measure other means of exposure. These mobile technology advances can be employed to provide observational studies with detailed and robust exposure assessments. Such equipment is now increasingly being adapted to serve large-scale population research and to capture data from large cohort studies. These coupled with other technological advances, such as real time data transfers via mobile phones and mobile phone applications to capture lifestyle and other habits, could bring next generation observational studies far more detailed and robust exposure assessments compared to current evidence. However, the generation of huge volumes of data can pose organisational, statistical and technical challenges, particularly with extended follow-up times. Ethics and personal data protection issue should be taken into account, and local regulations may prevent extensive use of such technologies. However, use of such personal monitors only provides information for one of the different potential routes of exposure.

b) Biomarkers of exposure (human biomonitoring (HBM)). An alternative and/or complementary approach is to ascertain the internal dose, which is the result of exposure via different routes (dermal, 29

www.efsa.europa.eu/efsajournal

d) 体液中及び組織中の有効成分及び関連代謝物の分析。

これらの方法は、可能な限り、最も簡単な方法を採用し、最小限のコストで、一般的に利用可能な機器を必要とする ものとする。分析の特異性を確認し、報告されなければならない。それにより、モニタリング残留物の定義に含まれるす べての成分を測定できるようにしなければならない。必要に応じて、検証された測定法を提出しなければならない。方 法の直線性、回収率、精度(再現性)が測定され、報告されなければならない。

データは、LOQと残留可能性の高いレベル、またはLOQの10倍のいずれかで生成されなければならない。LOQ は、モニタリング残留物の定義に含まれる各成分について決定され、報告されなければならない。植物や動物由来の 食品や飼料中の残留物や飲料水中の残留物については、方法の再現性は、独立した試験施設のバリデーション(ILV) によって確認され、報告されなければならない。

このことから、要求事項は存在するが、食品や飼料中の残留物のモニタリングよりもヒトのバイオモニタリングの方が やや厳しくないと結論づけることができる。

これらの既存の方法を使用しないと、特定の農薬の規制における疫学的証拠の使用の可能性が制限される。したが って、今後の研究を検討する際には、ばく露の誤分類を避けるために使用する手法を慎重に検討することが重要であ り、当該農薬について適切で詳細なばく露評価を行い、適切な用量反応分析を可能にし、使用された方法の妥当性を 証明することが重要である。

ばく露は、ばく露される生涯の期間に応じて、異なる健康影響を及ぼす可能性がある。ばく露評価がそのような重要 な時期に適切に対応していることを確実にすることで、疾患発症の可能性がある時期のばく露には、より大きな注意を 払う必要がある。これは、神経発達、肥満、アレルギー反応など、出生前または出生後早期に発生する複雑な多段階 の発達過程を伴う研究に特に関連していると考えられる。このため、単一の期間におけるばく露の測定では、環境因子 のすべての健康影響に対する関連ばく露を適切に特徴付けることができない可能性があり、したがって、環境因子に 対するいくつかの重要な生物学的に脆弱な期間におけるばく露を測定する必要がある可能性が生じてくる。化学物質 の範囲とばく露の強度及び研究範囲ではない他の物質とのばく露も含めた中で、現在のばく露とは異なる可能性があ る過去のばく露の評価を構築することは、特に困難である。

農薬ばく露を測定するすべての方法には長所と短所があり、特定の研究計画と目的は、特定の最適なアプローチを 通知するために慎重に考慮されるべきである。

観察による研究では、個人レベルのばく露評価は以下の方法を用いて改善することができる。

a) 個人のばく露モニタリング:これは、測定装置を接触時での農薬濃度を記録するために使用することができる。個 人用ばく露モニターは、研究参加者にとって高価で負担が大きいものであった。しかし、技術の進歩により、最近では 大気中の浮游物質ばく露のための個人ばく露モニターが安価で使いやすい装置になり、これらは集団研究に適してい る。農薬ばく露に特化した個人ばく露モニターには、空気中の濃度を測定するためのセンサー、経皮濃度を測定する ための「皮膚」パッチ、他のばく露手段を測定するための塵埃を捕らえる屋内家庭用モニターなどがある。これらのモバ イル技術の進歩は、詳細で強固なばく露評価がなされた観察による研究を提供するために利用することができる。この ような機器は現在、大規模な集団研究や大規模なコホート研究からのデータを収集するために、ますます適応が増え ている。これらは、ライフスタイルやその他の習慣を捉えるための携帯電話や携帯電話アプリケーションを介したリアル タイムのデータ転送などの他の技術的進歩と相まって、次世代の観察による研究では、現在のエビデンスと比較して、 はるかに詳細で強固なばく露評価が可能になるだろう。しかし、膨大な量のデータを生成することは、組織的、統計的、 技術的な課題、特に追跡調査時間の延長をもたらす可能性がある。倫理や個人データ保護の問題を考慮しなければ ならず、地域の規制により、このような技術の大規模な使用が妨げられる可能性がある。しかし、このような個人モニター の使用は、異なる潜在的なばく露経路のうちの1つの情報を提供するにすぎない。

b) ばく露のバイオマーカー(ヒト・バイオモニタリング(HBM))。代替的及び/または補完的なアプローチとして、異 なる経路(経皮、吸入及び経口のばく露)を介したばく露の結果である内部ばく露量の確認がある。これらのバイオマー カーは、農薬への総体的なばく露を評価し、累積的なリスク評価に情報を提供する上で重要な役割を果たす可能性が ある。バイオモニタリングには、検討対象の化学物質(親化合物または代謝物)またはその病態生理学的影響のマーカ ー(付加生成物など)の生体試料中の濃度を測定することが必要である。しかし、課題としては、生体試料中の濃度測

inhalation and dietary exposure). These biomarkers have the potential to play an important role in assessing aggregate exposure to pesticides and informing cumulative risk assessment. Biomonitoring requires measurements in biological samples of concentrations of chemical under consideration (parent or metabolites) or markers of pathophysiologic effects thereof (such as adducts). However, challenges may include uncertainties relating to extrapolation of measured concentrations in biological samples to relevant doses.

Although biomonitoring has the potential to provide robust estimates of absorbed doses of xenobiotics, modern pesticides and their metabolites are eliminated from the body relatively quickly, with excretion half-lives typically measured in a few days (Oulhote and Bouchard, 2013). Consequently, use of biomarkers is both resource intensive and intrusive. The process is even more intrusive when it has to be conducted repeatedly on large numbers of individuals to monitor exposures over long durations.

Nevertheless, because of the potential to provide accurate integrated estimates of absorbed doses, biological monitoring of pesticides and their metabolites can be usefully employed to calibrate other approaches of exposure assessment. A good example of such an approach is that used by the Agricultural Health Study (Thomas et al., 2010; Coble et al., 2011; Hines et al., 2011). Also, HBM methods can be used with other forms of exposure assessment for the construction of long exposure histories.

Biomonitoring improves the precision in characterisation of exposure and allows the investigation of changes in exposure that occur at environmentally relevant exposure concentrations. Data collected in large-scale biomonitoring studies can be useful in setting reference ranges to assist in exposure classification in further epidemiological studies. Biomonitoring data also provide critical information for conducting improved risk assessment and help to identify subpopulations at special risk for adverse outcomes.

Biobanks, as repositories of biological samples, can be exploited to assess biomarkers of exposure with the aim of investigating early exposure–late effect relationships. That is, whether exposures occurring during early life are critical for disease development later in life (e.g. neurobehavioral impairment, children tumours, immunotoxic disorders, etc.) and to retrospectively assess health risks according to current health guidelines.

The results of measurements of metabolite levels in human matrices, e.g. urine, blood or hair do not provide the complete story with respect to the actual received dose. Additional assessment, possibly employing physiological-based toxicokinetic (PBTK) approaches, may be required to estimate the total systemic or tissue/organ doses. A PBTK model is a physiologically based compartmental model used to characterise toxicokinetic behaviour of a chemical, in particular for predicting the fate of chemicals in humans. Data on blood flow rates, metabolic and other processes that the chemical undergoes within each compartment are used to construct a mass-balance framework for the PBTK model. PBTK models cannot be used only to translate external exposures into an internal (target) dose in the body, but also to infer external exposures from biomonitoring data. Furthermore, PBTK models need to be validated.

Toxicokinetic processes (ADME) determine the 'internal concentration' of an active substance reaching the target and help to relate this concentration/dose to the observed toxicity effect. Studies have been prescribed by the current regulations, but it would be beneficial to survey all the evidence, be it from *in vitro*, animal or human studies, about toxicokinetic behaviour of an active substance. Further discussion on quality assurance issues and factors to consider in relation to HBM studies is present in the report of the EFSA outsourced project (Bevan et al., 2017).

Exposure assessment can also be improved at the population level in observational research by using:

a) Larger epidemiological studies that make use of novel technologies and big data availability, such as **registry data** or data derived from large databases (including administrative databases) on health effects and pesticide usage, could provide more robust findings that might eventually be used for informed decision-making and regulation. Much effort needs to concentrate around the use of registered data which may contain records of pesticide use by different populations, such as farmers or other professional users that are required to maintain.<sup>9</sup> Such data could be further linked to

定値を関連する用量に外挿することに伴う不確実性が含まれる場合がある。

バイオモニタリングは異物の吸収量を確実に推定できる可能性があるが、現代の農薬とその代謝物は比較的迅速に 体内から排泄され、排泄半減期は通常数日で測定される(Oulhote 及び Bouchard、2013 年)。そのため、バイオマ ーカーの使用はそのため、バイオマーカーの使用は、資源を必要とし、かつ煩わしいものとなります。長期にわたるばく 露を監視するために、多数の人を対象に繰り返し実施しなければならない場合には、このプロセスはさらに煩わしいも のとなる。

とはいえ、吸収量の正確な積算値を提供できる可能性があるため、農薬とその代謝物の生物学的モニタリングは、ば く露評価の他のアプローチを調整するために有効に利用できる。このようなアプローチの例は、農業健康調査 (Agricultural Health Study)で使用されているものである(Thomas ら、2010 年;Coble ら、2011 年;Hines ら、 2011 年)。また、長いばく露履歴を構築するために、他の形態のばく露評価と組み合わせて HBM の手法を使用する こともできる。

バイオモニタリングは、ばく露の特性評価の精度を向上させ、環境に関連するばく露濃度で発生するばく露の変化を 調査することを可能にする。大規模なバイオモニタリング研究で収集されたデータは、今後の疫学研究におけるばく露 の分類を支援するための基準範囲を設定するのに有用である。また、バイオモニタリングデータは、リスク評価の改訂を 実施するための重要な情報を提供し、有害な健康影響に対して特別なリスクのある小集団を特定するのに役立つ。

生体試料他(Biobanks)は、生物試料の保管場所として、早期ばく露と遅発影響の関係を調査する目的で、ばく露 のバイオマーカーを評価するために利用することができる。すなわち、生涯初期に発生したばく露が、生涯後期におけ る疾患(神経行動障害、小児腫瘍、免疫毒性障害など)の発症に重要であるかどうかを調べ、現在の健康ガイドライン に沿って健康リスクを後ろ向きに評価することができる。

尿、血液、毛髪などのヒトの試料中の代謝物レベルの測定結果だけは、実際に受けたばく露量を完全に把握できな い。全身または組織・器官の総ばく露量を推定するためには、場合によっては生理学的毒物動態学(PBTK)アプロー チを用いた追加評価が必要となる。PBTK モデルは、化学物質の毒物動態を特徴づけるために使用される生理学的 なコンパートメントモデルであり、特にヒトにおける化学物質の運命を予測するために使用される。各コンパートメント内 で化学物質が受ける血流速度、代謝及びその他のプロセスに関するデータは、PBTK モデルのマス-バランス・フレ ームワークを構築するために使用される。PBTK モデルは、外部ばく露を体内の内部(標的)ばく露量に変換するだけ でなく、バイオモニタリングデータから外部ばく露を推測するためにも使用することができる。さらに、PBTK モデルは検 証される必要がある。

毒物動態プロセス(ADME)は、標的に到達した有効成分の「内部濃度」を決定し、この濃度/用量を観察された毒 性効果と関連付けるのに役立つ。現行の規制でも試験実施が規定されているが、in vitro 試験、動物試験、ヒト試験な ど、有効成分の毒物動態に関するすべてのエビデンスを調査することは有益であろう。品質保証の問題や HBM 試験 に関連して考慮すべき要素についての更なる議論は、EFSA が委託したプロジェクトの報告書(Bevan 6、2017 年)に 記載されている。

ばく露評価は、観察による研究における集団レベルでも、以下のような方法で改善することができる。

a)健康影響や農薬使用に関する登録データや大規模データベース(行政データベースを含む)から得られたデー タなど、新しい技術やビッグデータを利用した大規模な疫学研究は、より確かな知見が得られ、最終的には情報に基づ いた政策決定や規制に利用できる可能性がある。このようなデータは、維持管理が義務付けられている農家やその他 の専門的ユーザーなど、異なる集団による農薬使用の記録が含まれている可能性がある登録データの利用を中心に、 多くの努力が必要である<sup>9</sup>。このようなデータは、電子的健康記録(上記参照)にさらにリンクされ、これまでにないサンプ ルサイズ及びばく露とその後の病気に関する情報を持つ研究を提供し、最終的にはこれまで回答のなかった強固な問

<sup>&</sup>lt;sup>9</sup> Regulation 1107/2009 Article 67 states: Record-keeping 1. Producers, suppliers, distributors, importers, and exporters of plant protection products shall keep records of the plant protection products they produce, import, export, store or place on the market for at least 5 years. Professional users of plant protection products shall, for at least 3 years, keep records of the plant protection products shall, for at least 3 years, keep records of the plant protection products they use, containing the name of the plant protection product, the time and the dose of application, the area and the crop where the plant protection product was used. They shall make the relevant information contained in these records available to the competent authority on request. Third parties such as the drinking water industry, retailers or residents, may request access to this information by addressing the competent authority. The competent authorities shall provide access to such information in accordance with applicable national or Community law.

<sup>9</sup> 規則1107/2009第67条は次のように述べている。記録の保持 1. 植物保護製剤(農薬)の必定産者、供給者、流通業者、輸入業者及び輸出業者 は、自らが生産、輸入、輸出、保管又は市場に出した植物保護製剤(農薬)の記録を少なくとも5年間保管しなければならない。植物保護製剤(農 業)の専門的使用者は、使用した植物防疫製品(農業)の記録を少なくとも3年間(除物保護製剤(農薬)の名称、適用時間及び適用量、植物保 護製剤(農薬)が使用された地域及び作物を記載して保管しなければならない。これらの記録に含まれる関連情報は、要求があれば所轄官庁に 提供しなければならない。飲料水製造業界、小売業者又は住民などの第三者は、所轄官庁に運絡することにより、この情報へのアクセスを要求す ることができる。所轄官庁に、適用される国内法または共同体法に従って、当該情報へのアクセスを提供するものとする。

electronic health records (*vide supra*) and provide studies with unprecedented sample size and information on exposure and subsequent disease and will eventually be able to answer robustly previously unanswered questions. At the same time, information on active substances needs to be better captured in these registries and large databases. Dietary pesticide residue exposure can be estimated more accurately by using spraying journal data in combination with supervised residue trials. This method has the advantage of including more comprehensive and robust source data, more complete coverage of used pesticides and more reliable and precise estimates of residues below standard limit of quantification (LOQ) (Larsson et al., 2017).

b) Novel sophisticated approaches to geographical information systems (GIS) and small area studies might also serve as an additional way to provide estimates of residential exposures. Exposure indices based on GIS (i.e. residential proximity to agricultural fields and crop surface with influence around houses), when validated, may represent a useful complementary tool to biomonitoring and have been used to assess exposure to pesticides with short biological half-lives (Cornelis et al., 2009). As some such exposures maybe influenced by wind direction, amongst other factors, this should be taken into account through a special analysis of outcomes to make best of use of the approach. Also, these indices could be more representative, albeit non-specific, measures of cumulative exposure to non-persistent pesticides for long periods of time than biomonitoring data (González-Alzaga et al., 2015).

As already discussed, to be useful for the regulatory risk assessments of individual compounds epidemiological exposure assessments should provide information on specific pesticides. However, epidemiological studies which include more generic exposure assessments also have the potential to identify general risk factors and suggest inferences of causal associations in relevant human populations. Such observations may be important both informing overall regulatory policies, and for identification of matters for further epidemiological research.

Recent advances in modern technologies make it possible to estimate pesticide exposures to an unprecedented extent using novel analytical strategies:

a) The development of the so called **-omic techniques**, such as metabolomics and adductomics, also presents intriguing possibilities for improving exposure assessment through measurement of a wide range of molecules, from xenobiotics and metabolites recorded over time in biological matrices (blood, saliva, urine, hair, nails, etc.), to covalent complexes with DNA and proteins (adductomics) and understanding biological pathways. These methodologies could be used in conjunction with other tools. There is also both interest and the recognition that further work is required before such techniques can be applied in regulatory toxicology. The use of the exposome (the totality of exposures received by an individual during life) might be better defined by using 'omics' technologies and biomarkers appropriate for human biomonitoring. Nevertheless, important limitations have to be acknowledged because of the lack of validation of these methodologies and their cost, which limits their use at large scale.

b) Environmental exposures are traditionally assessed following 'one-exposure-one-health-effect' approach. In contrast, the **exposume** encompass the totality of human environmental exposures from conception onward complementing the genetics knowledge to characterise better the environmental exposures but also other external and or internal environmental factors, such as infections, physical activity, diet, stress and internal biological factors (metabolic factors, gut microflora, inflammation and oxidative stress). A complete exposure would have to integrate many external and internal exposures from different sources continuously over the life course. However, a truly complete exposome will likely never be measured. Although all these domains of the exposome need to be captured by using different approaches than the traditional ones, it is envisaged that no single tool will be enough to this end.

The more holistic approach of exposure is not intended to replace the traditional 'one-exposureone-health-effect' approach of current epidemiological studies. However, it would improve our understanding of the predictors, risk factors and protective factors of complex, multifactorial chronic diseases. The exposome offers a framework that describes and integrates, holistically, the environmental influences or exposures over a lifetime (Nieuwenhuijsen, 2015).

Collaborative research and integration of epidemiological or exploratory studies forming large consortia are needed to validate these potential biomarkers and eventually lead to improved exposure assessment. The incorporation of the exposome paradigm into traditional biomonitoring approaches offers a means to improve exposure assessment. Exposome-wide association studies (EWAS) allow to measurement of thousands of chemicals in blood from healthy and diseased people, test for disease

#### Epidemiological studies and pesticides

題に答えることができるようになるだろう。同時に、これらの登録や大規模なデータベースでは、有効成分に関する情報 をよりよく把握する必要がある。食品中の残留農薬ばく露は、監督下の残留試験と組み合わせて散布日誌データを使 用することで、より正確に推定することができる。この方法は、より包括的で強固な源データを含み、使用された農薬を より完全にカバーし、標準的な定量限界(LOQ)以下の残留物のより信頼性が高く正確な推定値を得ることができると いう利点がある(Larsson 6、2017年)。

b) 地理的情報システム(GIS) や小地域調査への新しい高度なアプローチも、住居ばく露の推定値を提供する追加 的な方法として役立つかもしれない。GIS に基づくばく露指標(すなわち、農業用地への住居の近接性や住居周辺へ の影響のある農地面積)は、検証された場合、バイオモニタリングを補完する有用なツールとなる可能性があり、生物学 的半減期の短い農薬へのばく露を評価するために使用されてきた(Cornelis 6、2009 年)。このようなばく露の中には、 他の要因の中でも特に風向によって影響を受けるものがあるため、このアプローチを最大限に活用するためには、結 果の特別な分析を通じて、この点を考慮に入れる必要がある。また、これらの指標は、特定の指標ではないにせよ、生 物モニタリングデータよりも、長期にわたる非残留性農薬への累積ばく露のより代表的な指標となり得る(González-Alzaga 6、2015 年)。

すでに議論したように、個々の化合物の規制リスク評価に有用であるためには、疫学的ばく露評価は特定の農薬に 関する情報を提供すべきである。しかし、より一般的なばく露評価を含む疫学的研究は、一般的なリスク因子を特定し、 関連するとト集団における因果関係の推論を示唆する可能性もある。このような観察結果は、全体的な規制政策の情 報提供と、さらなる疫学的研究のための事項の特定の両方に重要であるかもしれない。

現代技術の最近の進歩により、新しい分析方法を用いて農薬ばく露を前例のない範囲で推定することが可能になった。

a)メタボロミクス(metabolomics)やアダクトミクス(adductomics)などのいわゆる**オミクス技術**の発展は、生物学的 マトリックス(血液、唾液、尿、毛髪、爪など)中に経時的に記録された異物や代謝物から、DNA やタンパク質との共有 結合体(アダクトミクス)や生物学的経路の理解に至るまで、幅広い分子の測定を通じてばく露評価を改善するための 魅力のある可能性を提示している。これらの方法論は、他のツールと組み合わせて使用することができる。また、このよ うな技術を規制毒性学に応用するには、さらなる研究が必要であるという認識と関心がある。エクスポソーム(exposome) (一生の間に個人が受けたばく露の全体)の利用は、「オミックス」技術ととトのバイオモニタリングに適したバイオマーカ ーを使用することで、より良い結果を得ることができるかもしれない。それにもかかわらず、これらの方法論の検証が不 足していることと、大規模での使用を制限するコストのため、重要な制限が認められなければならない。

b)環境ばく露は従来「一回のばく露に一回の健康影響」というアプローチで評価されてきた。これに対して、エクスポ ソームは、受胎以降のヒト環境ばく露の全体を網羅しており、遺伝学の知識を補完することで、疾患の病因における環 境要因をよりよく特徴づけることができる。このように、エクスポソームには、生涯にわたる化学的ばく露だけでなく、感染 症、身体活動、食事、ストレス、内部生物学的因子(代謝因子、腸内フローラ、炎症、酸化ストレス)などの外部環境因 子や内部環境因子も含まれている。完全なエクスポソームを構築するためには、生涯にわたって継続的に異なる源か らの多くの外部ばく露と内部ばく露を統合しなければならない。しかし、真に完全なエクスポソームを測定することは不 可能である。エクスポソームのこれらすべての領域を従来のものとは異なるアプローチで捉える必要があるが、この目的 のためには単一のツールでは十分ではないと考えられている。

ばく露のより総合的なアプローチは、現在の疫学研究における従来の「一回のばく露-一回の健康影響」アプロー チに取って代わることを意図したものではない。しかし、それは複雑で多因子性の慢性疾患の予測因子、リスク因子、 保護因子についての理解を向上させるものである。エクスポソームは、生涯にわたる環境の影響やばく露を総合的に 記述し、統合する枠組みを提供している(Nieuwenhuijsen、2015年)。

これらの潜在的なバイオマーカーを検証し、最終的にはばく露評価の改善につなげるためには、共同研究や、大規 模なコンソーシアムを形成する疫学研究や探索的研究の統合が必要である。エクスポソームパラダイムを従来のバイオ モニタリング手法に組み込むことは、ばく露評価を改善する手段となる。エクスポソーム拡大関連研究(EWAS)は、健 康な人と病気の人の血液中の何千もの化学物質を測定し、病気との関連性を検査し、ばく露源を特定し、作用機序を 確立し、因果関係を明らかにするために、その後の調査で対象とすることができるばく露の有用なバイオマーカーを特

associations and identify useful biomarkers of exposure that can be targeted in subsequent investigations to locate exposure sources, establish mechanisms of action and confirm causality (Rappaport, 2012). After identifying these key chemicals and verifying their disease associations in independent samples of cases and controls, the chemicals can be used as biomarkers of exposures or disease progression in targeted analyses of blood from large populations.

In relation to the exposome concept, the -omics technologies have the potential to measure profiles or signatures of the biological response to the cumulative exposure to complex chemical mixtures. An important advance would be to identify a unique biological matrix where the exposome could be characterised without assessing each individual exposure separately in a given biological sample. The untargeted nature of omics data will capture biological responses to exposure in a more holistic way and will provide mechanistic information supporting exposure-related health effects. Importantly, omics tools could shed light on how diverse exposures act on common pathways to cause the same health outcomes.

While improved exposure assessment increases the power to detect associations, in any individual study it is necessary to maximise the overall power of the study by optimising the balance between the resource used for conducting an exposure assessment for each subject and the total number of subjects.

#### 4.5. Health outcomes

For pesticides, the health outcomes are broad as these chemicals have not shown a particular effect in relation to just one single disease area. For each health outcome, multiple definitions may exist in the literature with a varying degree of validation and unknown reproducibility across different databases, which are limited by the lack of generalisability. A proper definition of a health outcome is critical to the validity and reproducibility of observational epidemiological studies, and the consistency and clarity of these definitions need to be considered across studies. While prospective observational studies have explicit outcome definitions, inclusion and exclusion criteria and standardised data collection, retrospective studies usually rely on identification of health outcomes based largely on coded data, and classification and coding of diseases may change over time. Detailed description of the actual codes used to define key health outcomes and the results of any validation efforts are valuable to future research efforts (Stang et al., 2012; Reich et al., 2013). An example of coded diseases is the ICD-10, which for instance can be used as a tool to standardise the broad spectrum of malignant diseases.

In some surveillance studies, it is preferable to use broader definitions with a higher sensitivity to identify all potential cases and then apply a narrower and more precise definition with a high positive predictive value to reduce the number of false positives and resulting in more accurate cases. In contrast, in formal epidemiological studies, a specific event definition is used and validated to determine its precision; however, the 'validation' does not test alternative definitions, so it is not possible to determine sensitivity or specificity.

Surrogate endpoints should be avoided unless they have been validated. Some criteria to assess the validity of a surrogate outcome include:

- The surrogate has been shown to be in the causal pathway of the disease. This can be supported by the following evidence: correlation of biomarker response to pathology and improved performance relative to other biomarkers; biological understanding and relevance to toxicity (mechanism of response); consistent response across mechanistically different compounds and similar response across sex, strain and species; the presence of dose-response and temporal relationship to the magnitude of response; specificity of response to toxicity; that is, the biomarker should not reflect the response to toxicities in other tissues, or to physiological effects without toxicity in the target organ.
- At least one well conducted trial using both the surrogate and true outcome (Grimes and Schulz, 2005; la Cour et al., 2010). Several statistical methods are used to assess these criteria and if they are fulfilled the validity of the surrogate is increased. However, many times some uncertainty remains, making it difficult to apply surrogates in epidemiological studies (la Cour et al., 2010).

The data on health outcomes over the whole EU is potentially very extensive. If it can be managed effectively, it will open the prospect of greater statistical power for epidemiological studies assessing deleterious effects using very large sample sizes. Necessary prerequisites for these studies which may

32

定することを可能にする(Rappaport、2012 年)。これらの主要な化学物質を特定し、症例と対照の独立したサンプル で疾患との関連性を検証した後、これらの化学物質は、大規模な集団からの血液を対象とした分析において、ばく露ま たは疾患進行のバイオマーカーとして使用することができる。

エクスポソームの概念に関連して、オミクス技術は複雑な化学物質の混合物への累積ばく露に対する生物学的反応 の特性やシグネチャーを測定する可能性を持っている。重要な進歩は、特定の生物学的試料中の個々のばく露を個 別に評価することなく、エクスポソームを特徴づけることができるユニークな生物学的マトリックスを特定することであろう。 オミクスデータの非標的特性は、ばく露に対する生物学的反応をより全体的な方法で捉え、ばく露に関連した健康影 響を裏付けるメカニズム論的な情報を提供することになる。重要なことは、オミクスツールは、多様なばく露がどのように して共通の経路で作用し、同じ健康影響を引き起こす仕組みを明らかにすることができるということである。

改良されたばく露評価は関連性を検出する力を高めるが、どのような個々の研究においても、各被験者のばく露評 価を実施するために使用する供給源と被験者の総数のバランスを最適化することにより、研究の全体的な力を最大化 することが必要である。

# 4.5. 健康影響

農薬については、これらの化学物質が単一の疾患領域に関連して特定の効果を示していないため、健康影響は広範囲にわたる。それぞれの健康影響について、文献には複数の定義が存在していて、程度の差こそあれ異なるデータベース間での再現性は不明であり、一般化できないという制限がある。健康影響の適切な定義は、観察による疫学研究の妥当性と再現性にとって非常に重要であり、これらの定義の一貫性と明確さは研究間で考慮する必要がある。前向きな観察研究では、明確な健康影響の定義、包含基準と除外基準、標準化されたデータ収集があるが、後ろ向き研究では通常、主にコード化されたデータに基づいた健康影響の同定に頼っており、疾患の分類とコード化は時間の経過とともに変化する可能性がある。主要な健康影響を定義するために使用された実際のコードの詳細な記述と検証作業の結果は、今後の研究活動にとって貴重なものである(Stang ら、2012 年; Reich ら、2013 年)。コード化された疾患の例としては、例えば ICD-10 があり、これは広範囲の悪性疾患を標準化するためのツールとして使用することができる。

いくつかのサーベイランス研究では、すべての潜在的な症例を特定するために感度の高いより広い定義を使用し、 その後、偽陽性の数を減らし、結果としてより正確な症例を得るために、高い陽性予測値のより狭く、より正確な定義を 適用することが望ましいとされている。対照的に、正式な疫学研究では、特定のイベントの定義が使用され、その精度 を決定するために検証される。しかしながら、「検証」では新たな定義をテストしないので、感度や特異度を測定できな いでだろう。

代替エンドポイントは、有効性が確認されていない限り避けるべきである。代替健康影響の妥当性を評価する基準に は、以下のようなものがある。

- ・代替指標が疾患の原因経路内にあることが示されていること。これは以下のエビデンスによって裏付けられる:バイオマーカーの反応が病理学と相関しており、他のバイオマーカーと比較して性能が向上していること;生物学的な理解と毒性との関連性(反応のメカニズム);メカニズム的に異なる化合物に対する一貫した反応と性、系統、種の違いによる類似した反応;用量反応の存在と反応の大きさと時間的関係;毒性に対する反応の特異性;すなわち、バイオマーカーは他の組織の毒性に対する反応や、標的臓器の毒性を伴わない生理学的効果を伴わない生理的効果を反映してはならない。
- ・代替健康影響と真の健康影響の両方を使用した少なくとも1 つのよく実施された試験があること(Grimes 及び Schulz、2005年; la Courら、2010年)。これらの基準を評価するために、いくつかの統計的手法が使用されて、 それらが満たされていれば、代替指標の妥当性が高まる。しかし、多くの場合、不確実性が残っているため、疫学 研究に代替指標を適用することは困難である(la Courら、2010年)。

EU 全体の健康影響に関するデータは非常に広範囲に及ぶ可能性がある。これを効果的に管理することができれば、非常に大規模なサンプルサイズを用いて悪影響を評価する疫学研究において、より大きな統計力を発揮できる可能性がある。これらの研究に必要な前提条件は、新たな軽微な影響、慢性的な影響、または層別化した場合の小集団

detect new subtle effects, chronic effects or effects on subpopulations when stratified are beyond the remit of risk assessment. They include trans-national approaches to health informatics where harmonised diagnostics, data storage and informatics coupled with legally approved access to anonymised personal data for societal benefit are established. Health records should include adequate toxidrome classification. The latter may in turn require improvements in medical and paramedical training to ensure the quality of the input data.

Another opportunity for biological monitoring to be employed is where the investigation involves the so-called biomarkers of effect. That is a quantifiable biochemical, physiological, or other change that, depending on the magnitude, is associated with an established or possible health impairment or disease. Biomarkers of effect should reflect early biochemical modifications that precede functional or structural damage. Thus, knowledge of the mechanism ultimately leading to toxicity is necessary to develop specific and useful biomarkers, and vice versa, an effect biomarker may help to explain a mechanistic pathway of the development of a disease. Such biomarkers should identify early and reversible events in biological systems that may be predictive of later responses, so that they are considered to be preclinical in nature. Advances in experimental -omics technologies will show promise and provide sound information for risk assessment strategies, i.e. on mode of action, response biomarkers, estimation of internal dose and dose–response relationships (DeBord et al., 2015). These technologies must be validated to assess their relevance and reliability. Once validated, they can be made available for regulatory purposes.

## 5. Contribution of vigilance data to pesticides risk assessment

In addition to the formal epidemiological studies discussed in Sections 2–4, other human health data can be generated from ad hoc reports or as a planned process, i.e. through monitoring systems that have been implemented at the national level by public health authorities or authorisation holders. Consistent with Sections 2–4, this section first reviews how such a monitoring system should operate, what the current situation is regarding the monitoring of pesticides and what recommendations for improvement can be made.

#### 5.1. General framework of case incident studies

A continuous process of collection, reporting and evaluation of adverse incidents has the potential to improve the protection of health and safety of users and others by reducing the likelihood of the occurrence of the same adverse incident in different places at later times, and also to alleviate consequences of such incidents. This obviously also requires timely dissemination of the information collected on such incidents. Such a process is referred to as vigilance.<sup>10</sup>

For example in the EU, the safety monitoring of medicines is known as pharmacovigilance; the pharmacovigilance system operates between the regulatory authorities in Member States, the European Commission and the European Medicines Agency (EMA). In some Member States, regional centres are in place under the coordination of the national Competent Authorities. Manufacturers and health care professionals report incidents to the Competent Authority at the national level, which ensures that any information regarding adverse reactions is recorded and evaluated centrally and also notifies other authorities for subsequent actions. The records are then centralised by the EMA which supports the coordination of the European pharmacovigilance system and provides advice on the safe and effective use of medicines.

#### 5.2. Key limitations of current framework of case incident reporting

Several EU regulations require the notification and/or collection and/or reporting of adverse events caused by pesticides in humans (occurring after acute or chronic exposure in the occupational setting, accidental or deliberate poisoning, etc.). These include:

 Article 56 of EC Regulation 1107/2009 requires that 'The <u>holder of an authorisation</u> for a plant protection product shall immediately notify the Member States [...] In particular, potentially

33

```

CI USA INVI

への影響を検出する可能性があるが、リスク評価の範囲を超えている。これらの研究には、調和のとれた診断、データ 保存及び社会的利益のための匿名化された個人データへの法的に承認されたアクセスと相まって、健康情報学への 国境を越えたアプローチが含まれている。健康記録には、適切な中毒症候群の分類が含まれていなければならない。 後者は、入力データの品質を保証するために、医療と医療補助のトレーニングの改善を必要とするかもしれない。

生物学的モニタリングが採用されるもう一つの機会は、調査がいわゆる影響のバイオマーカーを含む場合である。こ れは、定量化可能な生化学的、生理学的、またはその他の変化であり、その大きさに応じて、確立された、または可能 性のある健康障害や病気に関連している。影響のバイオマーカーは、機能的または構造的損傷に先行する初期の生 化学的変化を反映している必要がある。このように、最終的に毒性につながるメカニズムの知識は、特定の有用なバイ オマーカーを開発するために必要であり、その逆もまた然りで、影響のバイオマーカーは、疾患の発生のメカニズムの 経路を説明するのに役立つかもしれない。このようなバイオマーカーは、生物学的システムにおける初期の可逆的な事 象を特定するものであり、後の反応を予測するものでなければならず、その性質上、前臨床的なものと考えられる。実 験的ーオミクス技術の進歩は有望であり、リスク評価戦略、すなわち作用機序、反応バイオマーカー、内部ばく露量の 推定、用量ー反応関係に関する確かな情報を提供するだろう(DeBord 6、2015 年)。これらの技術は、その妥当性と 信頼性を評価するために検証されなければならない。妥当性が確認されれば、それらの技術は規制目的で利用できる ようになる。

# 5. 農薬リスク評価への警戒データの貢献

第2-4節で議論した正式な疫学調査に加えて、その他のヒトの健康データは、その場限りの報告書から、あるいは計 画的なプロセスとして、すなわち公衆衛生当局や認可者によって国家レベルで実施されているモニタリングシステムを 通じて、生成することができる。第2-4節に沿って、本節ではまず、このようなモニタリングシステムがどのように運用され るべきか、農薬のモニタリングに関する現状はどうなっているのか、そして改善のためにどのような勧告ができるのかを レビューする。

# 5.1. ケースインシデント研究の一般的な枠組み

有害事象の収集、報告、評価を継続的に行うことは、同じ有害事象が後から別の場所で発生する可能性を減らすこ とで、利用者やその他の人々の健康と安全の保護を向上させ、また、そのような事象の結果を緩和する可能性がある。 そのためには、当然ながら、収集した情報をタイムリーに発信する必要がある。このようなプロセスを警戒(vigilance)と 呼んでいる<sup>10</sup>。

例えば、EU では、医薬品の安全性監視は医薬品安全性監視 (pharmacovigilance)して知られており、医薬品安 全性監視システムは、加盟国の規制当局、欧州委員会、欧州医薬品庁 (EMA)の間で運営されている。一部の加盟国 では、国内の管轄当局の調整の下に地域センターが設置されている。製造業者や医療従事者は、国レベルの管轄当 局に事件を報告する。これにより、有害事象に関するあらゆる情報が記録され、一元的に評価され、その後の対応につ いて他の当局に通知することができる。記録は EMA によって一元化され、欧州の医薬品安全性監視システムの調整 をサポートし、医薬品の安全で効果的な使用に関するアドバイスを提供する。

# 5.2. ケースインシデント報告の現在の枠組みの主な限界

いくつかの EU の規制では、ヒトに農薬が原因で発生した有害事象(職業環境での急性または慢性ばく露後に発生 したもの、偶発的または故意の中毒など)の通知及び/または収集及び/または報告を義務付けている。これらには 以下のものが含まれる。

・ EC 規則 1107/2009 の第 56 条は、「植物保護製剤(農薬)の認可を受けた者は、直ちに加盟国に通知しなけれ

<sup>&</sup>lt;sup>10</sup> The concept of <u>survey</u> refers to a single effort to measure and record something, and <u>surveillance</u> refers to repeated standardized surveys to detect trends in populations in order to demonstrate the absence of disease or to identify its presence or distribution to allow for timely dissemination of information. <u>Monitoring</u> implies the intermittent analysis of routine measurements and observations to detect changes in the environment or health status of a population, but without eliciting a response. <u>Vigilance</u> is distinct from surveillance and mere monitoring as it implies a process of paying close and continuous attention, and in this context addresses specifically post marketing events related to the use of a chemical.

<sup>10</sup> 調査という概念は、何かを測定し記録するための単一の努力を意味し、サーベイランスとは、疾病の不在を証明したり、疾病の存在や分布を特定して情報を適時に発信できるようにするために、集団の傾向を検出するために、標準化された調査を繰り返すことを意味する。モニタリングとは、集団の環境や健康状態の変化を検出するために、日常的な測定や観察を断続的に分析することを意味するが、反応を引き出すことはない、監視は、綿密かつ継続的に注意を払うプロセスを意味するため、監視や単なるモニタリングとは異なり、この背景では特に化学物質の使用に関連した販売後の事象を扱う。

www.efsa.europa.eu/efsajourna

harmful effects of that plant protection product, or of residues of an active substance, its metabolites, a safener, synergist or co-formulant contained in it on human health [...] shall be notified. To this end the authorisation holder shall record and report all suspected adverse reactions in humans, in animals and the environment related to the use of the plant protection product. The obligation to notify shall include relevant information on decisions or assessments by international organisations or by public bodies which authorise plant protection products or active substances in third countries'.

Article 7 of EC Directive 128/2009 establishing a framework for Community action to achieve the sustainable use of pesticides requires that: '2. <u>Member States</u> shall put in place systems for gathering information on pesticide acute poisoning incidents, as well as chronic poisoning developments where available, among groups that may be exposed regularly to pesticides such as operators, agricultural workers or persons living close to pesticide application areas. 3. To enhance the comparability of information, <u>the Commission</u>, in cooperation with the Member States, shall develop by 14 December 2012 a strategic guidance document on monitoring and surveying of impacts of pesticide use on human health and the environment'. However, at the time of publishing this scientific opinion, this document has still not been released.

There are three additional regulations that apply, although indirectly, to pesticides and reporting:

- EC Regulation 1185/2009 concerning statistics on pesticides requires that Member States shall collect data on pesticide sales and uses according to a harmonised format. The statistics on the placing on the market shall be transmitted yearly to the Commission and the statistics on agricultural use shall be transmitted every 5 year.
- Article 50 of Regulation (EC) 178/2002, laying down the general principles and requirements of food law, set up an improved and broadened rapid alert system covering food and feed (RASFF). The system is managed by the <u>Commission</u> and includes as members of the network Member States, the Commission and the Authority. It reports on non-authorised occurrences of pesticides residues and food poisoning cases.
- Article 45 (4) of EC Regulation 1272/2008 (CLP Regulation): <u>importers and downstream users</u> placing hazardous chemical mixtures on the market of an EU Member State will have to submit a notification to the Appointed Body/Poison Centre of that Member State. The notification needs to contain certain information on the chemical mixture, such as the chemical composition and toxicological information, as well as the product category to which the mixture belongs. The inclusion of information on the product category in a notification allows Appointed Bodies/Poison Centres to carry out comparable statistical analysis (e.g. to define risk management measures), to fulfil reporting obligations and to exchange information among MS. The product category is therefore not used for the actual emergency health response as such, but allows the identification of exposure or poisoning trends and of possible measures to prevent future poisoning cases. When formally adopted, the new Regulation will apply as of 1 January 2020.

While there are substantial legislative provisions, to this date a single unified EU 'phytopharmacovigilance'<sup>11</sup> system akin to the pharmacovigilance system does not exist for PPP. Rather, a number of alerting systems have been developed within the EU to alert, notify, report and share information on chemical hazards that may pose a risk to public health in Member States. These systems cover different sectors including medicines, food stuffs, consumer products, industrial accidents, notifications under International Health Regulations (IHR) and events detected by EU Poisons Centres and Public Health Authorities. Each of these systems notify and distribute timely warnings to competent authorities, public organisations, governments, regulatory authorities and public health officials to enable them to take effective action to minimise and manage the risk to public health (Orford et al., 2014).

In the EU, information on acute pesticide exposure/incident originates mainly from data collected and reported by Poison Control Centres (PCC's). PCC's collect both cases of acute and chronic exposure/poisoning they are aware of, in the general population and in occupational settings. Cases are usually well-documented and information includes circumstances of exposure/incident, description of the suspected causal agent, level and duration of exposure, the clinical course and treatment and an assessment of the causal relationship. In severe cases, the toxin and/or the metabolites are usually

#### Epidemiological studies and pesticides

ばならない」と規定している。この目的のために、認可保有者は、植物保護製剤(農薬)の使用に関連して、ヒト、動 物及び環境におけるすべての疑われる有害な反応を記録し、報告しなければならない。通知義務には、国際機関 や第三国の植物保護製剤(農薬)や有効成分を認可する公的機関による決定や評価に関する関連情報も含まれ ていなければならない。

・農薬の持続可能な使用を達成するための共同体行動の枠組みを確立した EC 指令 128/2009 の第7条は、次の ように要求している。加盟国は、作業者、農業労働者、農薬散布地域の近くに住む人など、定期的に農薬にばく露 される可能性のある集団の間で、農薬による急性中毒事故や慢性中毒の発生状況に関する情報を収集するシス テムを設置しなければならない。3.3.情報の類似性を高めるために、欧州委員会は加盟国と協力して、2012年12 月 14 日までに「農薬使用が比トの健康と環境に与える影響のモニタリングと調査に関する戦略的ガイダンス文書」 を作成する。しかし、この意見書を発表した時点では、この文書はまだ公表されていない。

間接的ではあるが、農薬と報告に適用される追加の規制が3つある。

- ・ 農薬の統計に関する EC 規則 1185/2009 は、加盟国が調和のとれたフォーマットに従って農薬の販売と使用に 関するデータを収集することを要求している。上市に関する統計は毎年欧州委員会に、農業利用に関する統計は 5年ごとに送信されなければならない。
- ・食品法の一般原則と要件を定めた規則(EC)178/2002の第50条では、食品と飼料を対象とした改良・拡大された迅速警報システム(RASFF)が設定されている。このシステムは欧州委員会によって管理されており、ネットワーク加盟国、欧州委員会、当局が加盟している。それは残留農薬の認可されていない事例や食中毒の事例を報告する。
- ・ EC 規則 1272/2008 (CLP 規則)第 45 条(4): EU 加盟国の市場に危険な化学物質の混合物を市場に出す輸入 業者と顧客ユーザーは、その加盟国の任命機関/毒物センターに通知書を提出しなければならない。通知書に は、化学成分や毒物学的情報、混合物が属する製品カテゴリーなど、混合物に関する特定の情報を記載する必 要がある。通知書に製品分類に関する情報を含めることで、指定団体/毒物取締センターは、同等の統計解析 (例えば、リスク管理措置の実施)を行い、報告義務を果たし、MS 間で情報交換を行うことができる。したがって、 製品カテゴリーは実際の緊急時の医療対応には使用されないが、ばく露や中毒の傾向を特定し、将来の中毒事 例を防ぐための対策をとることができる。正式に採択された場合、新規則は 2020 年 1 月 1 日から適用される。

実質的な立法規定がある一方で、今日までのところ、医薬品安全性監視システムに類似した単一の EU「植物薬理 監視」<sup>11</sup>システムは PPP には存在しない。むしろ、加盟国の公衆衛生にリスクをもたらす可能性のある化学物質のハザ ードについて警告、通知、報告、情報共有を行うための多くの警告システムが EU 内で開発されている。これらのシステ ムは、医薬品、食品、消費者製品、労働災害、国際保健規則(IHR)に基づく通知、EU 毒物センターや公衆衛生当局 によって検知した事象など、さまざまな分野をカバーしている。これらのシステムのそれぞれは、管轄官庁、公的機関、 政府、規制当局、公衆衛生当局にタイムリーな警告を通知し、配布して、公衆衛生へのリスクを最小限に抑え、管理す るための効果的な行動をとることを可能にしている(Orford ら、2014 年)。

EUでは、急性農薬ばく露・事故に関する情報は、主に毒物管理センター(PCC)によって収集・報告されたデータに 基づいている。PCCは、一般集団や職業環境において、自分たちが知っている急性と慢性のばく露/中毒の両方の 事例を収集している。通常、症例は十分に文書化されており、情報にはばく露・事故の状況、原因物質と疑われるもの の説明、ばく露のレベルと期間、臨床経過と治療、因果関係の評価が含まれている。重症の場合は、通常、血液や尿 中の毒素や代謝物の測定が行われる。しかし、センターに報告された症例の追跡調査は、長期化する可能性のある影 響を特定するために、さらに注意を払う必要がある。

毒物センターのデータを使用するには、2 つの重要な障害がある:各国の毒物センターからの報告書は常に公表さ

<sup>&</sup>lt;sup>11</sup> 'phytovigilance' would refer to a vigilance system for plants; as pesticides are intended to be 'medicines' for crops, the term 'phytopharmacovigilance' is considered to be the more appropriate one here. Furthermore, it is a broad term used in France covering soil, water, air, environment, animal data, etc.

www.efsa.europa.eu/efsajournal

<sup>11「</sup>フィトビジランス(phytovigilance)」は植物に対する警戒システムを意味し、農薬は作物の「薬」であることを意図しているため、ここでは「フィトファーマコビジランス(phytopharmacovigilance)」という用語がより適切であると考えられている。さらに、フランスでは、土壌、水、大気、環境、動物のデータなどをカバーする広い用語として使われている。

measured in blood or urine. However, follow-up of cases reported to the centres merits further attention to identify potential long-term protracted effects.

There are two key obstacles to using Poison Centres data: official reports from national Poisons Centres are not always publicly available and when they are, there is a large heterogeneity in the format of data collections and coding, and assessment of the causal relationship. Indeed, each Member State has developed its own tools for collection activities resulting in difficulties for comparing and exchanging exposure data. In 2012, the European Commission funded a collaborative research and development project to support the European response to emerging chemical events: the Alerting and Reporting System for Chemical Health Threats, Phase III (ASHTIII) project. Among the various tools and methodologies that were considered, methods to exchange and compare exposure data. However, results of a consultation with the PCC community showed that further coordination of data coding and collection activities is supported. It was concluded that more support and coordination is required at the EU and Member States level so that exposures data can be compared between Member States (Orford et al., 2015).

In addition to data collected by PCC's, several Member States have set up programmes dedicated to occupational health surveillance.<sup>12</sup> The purpose of these programmes is to identify the kinds of jobs, types of circumstances and pesticides that cause health problems in workers in order to learn more about occupational pesticide illnesses and injuries and how to prevent them. They are based on voluntary event notification by physicians (sometimes self-reporting by users) of any case of suspected work-related pesticide injury or illness or poisoning. In addition to medical data, information gathered includes data regarding type of crop, mode of application, temperature, wind speed, wearing of personal protection equipment, etc. Once collected, these data are examined and a report is released periodically; they provide a useful support to evaluate the safety of the products under re-registration. These data also highlight emerging problems and allow definition of evidence-based preventive measures for policy-makers. At EU level, the European Agency for Safety and Health at Work (EU-OSHA)<sup>13</sup> has very little in the way of monitoring of occupational pesticide-related illnesses data. In the USA, a programme specifically dedicated to pesticides funded and administered by the National Institute for Occupational Safety and Health (NIOSH) is in operation in a number of States.<sup>14</sup>

In summary, currently human data may be collected in the form of case reports or case series, poison centres information, coroner's court findings, occupational health surveillance programmes or post-marketing surveillance programmes. However, not all this information is present in the medical data submitted by applicants mainly because the different sources of information are diverse and heterogeneous by nature, which makes some of them sometimes not accessible.

- Data collected through occupational health surveillance of the plant production workers or if they do so, the medical data are quite limited being typically basic clinical blood measurements, physical examinations, potentially with simple indications of how and where exposed took place, and there usually is no long-term follow up. Furthermore, worker exposures in modern plants (especially in the EU) are commonly very low, and often their potential exposure is to a variety of pesticides (unless it is a facility dedicated to a specific chemical).
- Moreover, the reporting of data from occupational exposure to the active substances during
  manufacture is often combined with results from observations arising from contact with the
  formulated plant protection product as the latter information results from case reports on
  poisoning incidents and epidemiological studies of those exposed as a result of PPP use.
  Indeed, the presence of co-formulants in a plant protection product can modify the acute
  toxicological profile. Thus, to facilitate proper assessment, when reporting findings collected in
  humans it should be clearly specified whether it refers to the active substance per se or a PPP.

With regard to the requirements of specific data on diagnoses of poisoning by the active substance or formulated plant protection products and proposed treatments, which are also part of chapter 5.9 of the EC Regulation 283/2013, information is often missing or limited to those cases where the toxic mode of action is known to occur in humans and a specific antidote has been identified.

35

EFSA Journal 2017;15(10):5007

el usa muni

れているわけではなく、公表されている場合でも、データ収集の形式やコーディング、因果関係の評価には大きな不均 ー性がある。実際、各加盟国は独自の収集活動のためのツールを開発しており、ばく露データの比較や交換には困難 が伴う。2012 年、欧州委員会は、新たな化学物質事象への欧州の対応を支援するための共同研究開発プロジェクト 「化学物質健康脅威のための警告・報告システムフェーズ III(ASHTIII)プロジェクト」に資金を提供した。検討された 様々なツールや方法論の中で、欧州の PCC からのばく露データを交換・比較する方法が開発された。実現可能な研 究として、ワークパッケージ 5 には、加盟国が農薬ばく露データを比較できるようにするための、調和のとれた強固なコ ード化システムの開発が含まれていた。しかし、PCC コミュニティとの協議の結果、データのコーディングと収集活動の さらなる調整が必要であることが示された。その結果、ばく露データを加盟国間で比較できるようにするためには、EUと 加盟国レベルでの更なる支援と調整が必要であると結論づけられた(Orford ら、2015 年)。

PCC が収集したデータに加えて、いくつかの加盟国は、労働衛生監視に特化したプログラムを立ち上げた<sup>12</sup>。これら は、業務上の農薬による傷害や病気、中毒が疑われる症例について、医師による自発的なイベント通知(使用者による 自己申告の場合もある)に基づいている。医療データに加えて、収集された情報には、作物の種類、散布方法、温度、 風速、個人用保護具の着用状況などに関するデータが含まれる。一度収集されたこれらのデータは調査され、定期的 に報告書が発行され、再登録中の製品の安全性を評価するための有用な情報となる。これらのデータは調査され、定期的 に報告書が発行され、再登録中の製品の安全性を評価するための有用な情報となる。これらのデータはまた、新たな 問題を浮き彫りにし、政策立案者のためのエビデンスに基づく予防措置を策定することを可能にする。EU レベルでは、 欧州労働安全衛生庁(EU-OSHA)<sup>13</sup>は、職業上の農薬関連疾病データのモニタリング方法をほとんど持っていない。 米国では、国立労働安全衛生研究所(NIOSH)が資金を提供し、農薬に特化したプログラムがいくつかの州で実施さ れている<sup>14</sup>。

要約すると、現在、ヒトのデータは、症例報告書や症例集積、毒物センターの情報、検視官の裁判結果、労働衛生 監視プログラムや市販後の監視プログラムの形で収集されている。しかし、申請者が提出した医療データには、このよう な情報がすべて含まれているわけではない。これは、さまざまな情報源が多様で異質な性質を持っているため、アクセ スできないものもあるためである。

- ・工場生産労働者の労働衛生監視を通じて収集されたデータ、あるいはそれが行われたとしても、医療データは非常に限られており、一般的には基本的な臨床血液測定、身体検査、潜在的にはどこでどのようにばく露されたかという単純な指標であり、通常は長期的なフォローアップは行われていない。さらに、最新の工場(特に EU)での労働者のばく露は一般的に非常に低く、多くの場合、潜在的なばく露は(特定の化学物質に特化した施設でない限り)様々な農薬へのばく露である。
- ・さらに、製造中の有効成分への職業上ばく露からのデータの報告は、しばしば調合された植物保護製剤(農薬)との接触から生じる観察結果と組み合わされる。実際、植物保護製剤(農薬)中の共配合剤の存在は、急性毒性学的プロフィルを変更することができる。したがって、適切な評価を容易にするために、ヒトで収集した結果を報告する際には、それ自体が有効成分なのか PPP なのかを明確に特定しなければならない。

EC 規則 283/2013 の第 5.9 章の一部でもある有効成分や配合された植物保護製剤(農薬)や提案された治療法に よる中毒の診断に関する特定のデータの要求に関しては、情報が欠落していたり、毒性作用のモードがヒトで起こること が知られていて特定の解毒剤が特定されている場合に限定されていたりすることがよくある。

<sup>&</sup>lt;sup>12</sup> For example: Phyt'attitude in France is a vigilance programme developed by the Mutualité Sociale Agricole: http://www.msa. fr/lfr/sst/phyt-attitude

# 5.3. Proposals for improvement of current framework of case incident reporting

In order to avoid duplication and waste of effort, a logical next step would be to now develop, with all concerned public and private sector actors, an EU 'phytopharmacovigilance' system for chemicals similar to the ones that have been put in place for medicines. This network could be based on committed and specifically trained occupational health physicians and general practitioners in rural areas, and resources should be allocated by Member States to establish and to successfully maintain the system. Indeed such a network would be useful in detecting acute effects; it would also act as a sentinel surveillance network for specific health effects (such as asthma, sensitisation, etc.) or for the detection of emerging work-related disease. In fact, while much experience has already been gained on how to gradually build such a system, it is nevertheless envisioned that this will take a number of vears to be put in place. Several difficulties will arise because of the nature of the data collected (the sources of information are potentially diverse), the quality and completeness of the collected information for every case (especially the circumstances), the grading of severity and accountability of the observed effects (the link between the observed effect and the product). Rules should be defined so that they are identical from one 'evaluator' to another. The network should be stable over time (e.g. continuity in national organisations involved, consistent methodology employed, etc.), to ensure that the phytopharmacovigilance system fully complies with the objectives, i.e. monitoring changes over time. The use of phytopharmacovigilance data is unlikely to be limited to risk assessment purposes and may have an impact on risk management decisions (e.g. revisions in the terms and conditions of product authorisations or ultimately product withdrawal); this should be clear to all stakeholders from the outset.

Such a system may not merit being established solely for chemicals that are (predominantly) used as pesticides. However, given the legislative provisions already in place for pesticides, its development may need to be prioritised for pesticides.

In conclusion, the European Commission together with the Member States should initiate the development of an EU-wide vigilance framework for pesticides. These should include:

- harmonisation of human incident data collection activities at the EU level:
- coordination of the compilation of EU-wide databases;
- improving the collaboration between Poison Centres and regulatory authorities at national level in order to collect all the PPP poisonings produced in each Member State;
- guidance document on monitoring the impact of pesticide use on human health with harmonisation of data assessment for causal relationships;
- regular EU-wide reports.

#### 6. Proposed use of epidemiological studies and vigilance data in support of the risk assessment of pesticides

This section briefly reviews the risk assessment process (Section 6.1) based on experimental studies and discusses what information epidemiological studies could add to that process. Next, the assessment of the reliability of epidemiological studies is addressed in Section 6.2. In Section 6.3, the relevance of one or more studies found to be reliable is assessed.

#### 6.1. The risk assessment process

Risk assessment is the process of evaluating risks to humans and the environment from chemicals or other contaminants and agents that can adversely affect health. For regulatory purposes, the process used to inform risk managers consists of four steps (EFSA, 2012a). On the one hand, information is gathered on the nature of toxic effects (hazard identification) and the possible doseresponse relationships between the pesticide and the toxic effects (hazard characterisation). On the other hand, information is sought about the potential exposure of humans (consumers, applicators, workers, bystanders and residents) and of the environment (exposure assessment). These two elements are weighed in the risk characterisation to estimate that populations be potentially exposed to quantities exceeding the reference dose values, that is, to estimate the extra risk of impaired health in the exposed populations. Classically, this is used to inform risk managers for regulatory purposes.

36

a) Step 1. Hazard identification.

# 5.3. ケースインシデント報告の現行枠組みの改善提案

重複と努力の無駄を避けるために、論理的な次のステップは、すべての関係する公的部門と民間部門の関係者と一 緒に、医薬品のために実施されているものと同様の化学物質のための EU の「植物薬理監視」システムを開発すること であろう。このネットワークは、献身的で特別な訓練を受けた地方の産業保健医や開業医を基盤とすることができ、シス テムを確立し、成功裏に維持するために加盟国が供給源を配分すべきである。実際、このようなネットワークは急性の 影響を検出するのに有用であろう。また、特定の健康影響(喘息、感作など)や新たな職業関連疾患の検出のためのセ ンチネルサーベイランスネットワークとしても機能するであろう。実際、このようなシステムを段階的に構築する方法につ いては、すでに多くの経験が得られているが、それにもかかわらず、これが実施されるまでには何年もかかることが想定 されている。収集されるデータの特性(情報源は多様である可能性がある)、収集された情報の質と完全性(特に状況)、 観察された効果の重症度と説明責任(観察された効果と製品との間のリンク)など、いくつかの困難が生じる。ルールは、 ある「評価者」から別の「評価者」まで同一であるように定義されなければならない。植物薬理監視システムが目的に完 全に適合していることを保証するために、ネットワークは長期的に安定していなければならない(例えば、関与する国の 組織の継続性、採用された一貫した方法論など)。植物薬剤モニタリングデータの使用は、リスク評価の目的に限定さ れることはなく、リスク管理上の政策決定(例えば、製品認可の条件の改定や最終的には製品の取り下げなど)に影響 を及ぼす可能性があるが、これは最初からすべての利害関係者に明確でなければならない。

このようなシステムは、(主に)農薬として使用されている化学物質のみを対象としたものでは意味がないかもしれない。しかし、すでに農薬に関する法律の規定があることを考えると、このシステムの開発は農薬に優先して行われる必要があるかもしれない。

結論として、欧州委員会は加盟国とともに、EU 全体の農薬の警戒枠組みの開発に着手すべきである。これには以下が含まれるべきである。

- ・ EU レベルでのヒトでの健康影響データ収集活動の調和
- ・ EU 全体のデータベースの編集の調整
- 各加盟国で発生したすべての PPP 中毒を収集するために、各国レベルでのポイズンセンターと規制当局との連携を改善すること
- ・ 因果関係のデータ評価の整合化を伴う農薬使用がとトの健康に及ぼす影響のモニタリングに関するガイダンス文書
- ・ EU 全体を対象とした定期的な報告書

# 6. 農薬のリスク評価を支援するための疫学研究と監視データの利用の提案

本節では、実験的研究に基づくリスク評価プロセス(第 6.1 節)を概説し、そのプロセスに疫学的研究がどのような情報を付加しうるかを論じる。 次に、第 6.2 節では、疫学研究の信頼性の評価について述べる。 6.3 節では、信頼性があると認められた 1 つ以上の研究の関連性を評価する。

# 6.1. リスク評価プロセス

リスクアセスメントとは、健康に悪影響を及ぼす可能性のある化学物質やその他の汚染物質、薬剤によるヒトや環境 へのリスクを評価するプロセスである。規制目的のために、リスク管理者に情報を提供するために使用されるプロセスは、 4 つのステップで構成されている(EFSA、2012 年 a)。一方では、毒性影響の特性(ハザード同定)と、農薬と毒性影 響の間に考えられる用量反応関係(ハザード特性評価)に関する情報が収集される。一方で、ヒト(消費者、散布者、労 働者、居合わせただけの者、住民)と環境へばく露可能性についての情報が求められる(ばく露評価)。これら2つの要 素は、集団が基準ばく露量を超える量にばく露される可能性があることを推定するために、リスク特性評価の中で考慮 される。通常、これは規制目的のためのリスク管理者への情報提供に用いられる。

#### a) ステップ 1. ハザードの同定

疫学的研究と監視データは、農薬ばく露と健康影響とが関連する可能性を示すことができるため、ハザードの特定 に関連している。この背景では、疫学的データは、実験モデルでは検出されなかった影響を「ホライズン・スキャニング」

Epidemiological studies and vigilance data are relevant for hazard identification as they can point to potential link between pesticide exposure and health. In this context, epidemiological data can provide invaluable information in 'scanning the horizon' for effects not picked up in experimental models. Importantly, these studies also provide information about potentially enhanced risks for vulnerable population subgroups, sensitive parts of the lifespan, and gender selective effects.

b) Step 2, Hazard characterisation (dose-response assessment). As previously discussed a classic dose-response framework is not normally considered when using epidemiological data as the exposure dose is rarely assigned. The challenge presented when high guality epidemiological studies are available is to see whether these can best be integrated into the scheme as numerical input. A doseresponse framework is rarely considered when using epidemiological data for risk assessment of pesticides. However, previous scientific opinions of the EFSA CONTAM Panel have used epidemiology as basis for setting reference values, particularly in the case of cadmium, lead, arsenic and mercury, which are the most well-known and data rich (EFSA, 2009a,b, 2010b, 2012b). Even when they may not form the basis of a dose-response assessment, vigilance and epidemiological data may provide supportive evidence to validate or invalidate a dose-response study carried out in laboratory animals. Characterisation of the relationships between varying doses of a chemical and incidences of adverse effects in exposed populations requires characterisation of exposure or dose, assessment of response and selection of a dose-response model to fit the observed data in order to find a no-effect level. This raises two questions; can a dose-response be derived from epidemiological data to identify a no-effect level. If not, can epidemiological information otherwise contribute to the hazard characterisation?

Understanding dose-response relationships could also be relevant where adverse health outcomes are demonstrated to be associated with uses with higher exposures than EU good plant protection practice would give rise to, but where no association is observed from uses with lower exposures. It is clear that in this context the statistical summary of an epidemiological study defining RR or OR is potentially useful quantitative information to feed into the hazard characterisation process, when the study design meets the necessary standards.

c) Step 3. Exposure assessment. Data concerning the assessment of exposure are often hard to estimate in complex situations where a variety of uncontrolled 'real-world' factors confound the analysis. As discussed previously, contemporary biological monitoring is rarely carried out in the general human population for practical reasons including high cost, test availability and logistics. However, it is anticipated that in the near future biomonitoring studies and data on quantitative exposure to pesticides will increase.

Step 4. Risk characterisation. In this final step, data on exposure are compared with health-based reference values to estimate the extra risk of impaired health in the exposed populations. Human data can indeed help verify the validity of estimations made based on extrapolation from the full toxicological database regarding target organs, dose-response relationships and the reversibility of toxic effects, and to provide reassurance on the extrapolation process without direct effects on the definition of reference values (London et al., 2010).

Epidemiological data might also be considered in the context of uncertainty factors (UFs). An UF of 10 is generally used on animal data to account for interspecies variability of effects and this is combined with a further factor of 10 to account for variation in susceptibility of different parts of the human population. However, there are cases where only human data are considered (when this is more critical than animals data) and a single factor of 10 for intraspecies variability will apply. It is noted that at this moment Regulation (EC) No 1107/2009 Article 4(6) stipulates that: 'In relation to human health, no data collected on humans shall be used to lower the safety margins resulting from tests on animals'. The implication of this is that for risk assessment epidemiological data may only be used to increase the level of precaution used in the risk assessment, and not to decrease UFs even where relevant human data are available.

#### Assessment of the reliability of individual epidemiological studies 6.2.

Factors to be considered in determining how epidemiology should be considered for a WoE assessment are described below and have been extensively outlined by available risk of bias tools for observational epidemiological studies.<sup>15</sup> The following examples represent factors to look for not an exhaustive list:

• Study design and conduct. Was the study design appropriate to account for the expected distributions of the exposure and outcome, and population at risk? Was the study conducted primarily in a hypothesis generating or a hypothesis-testing mode?

e usa muni

する上で、非常に貴重な情報を提供することができる。重要なことは、これらの研究はまた、脆弱な集団のサブグルー プ、牛涯における感受性の高い時期、性別による選択的影響など、リスクが高まる可能性についての情報を提供するこ とである。

b) ステップ 2. ハザードの特性評価(用量反応評価)

前述したように、通常、疫学的データを使用する場合には、ばく露量が割り当てられることはほとんどないため、古典 的な用量反応の枠組みは考慮されない。質の高い疫学研究が利用可能な場合の課題は、それらを数値入力としてス キームに統合するのが最善かどうかを見極めることである。農薬のリスク評価に疫学的データを使用する場合、用量反 応フレームワークが考慮されることはほとんどない。しかし、EFSA CONTAM パネルのこれまでの科学的見解では、基 準ばく露量を設定するための基礎として疫学を使用してきた、特にカドミウム、鉛、ヒ素、水銀の場合は、最もよく知られ ていてデータが豊富である(EFSA、2009年a,b、2010年b、2012年b)。これらが用量反応評価の基礎とならない場 合でも、監視と疫学的データは、実験動物を用いた用量反応研究の妥当性を検証したり、無効にしたりするための裏 付けとなるエビデンスを提供することがある。化学物質の様々な用量とばく露された集団における有害な影響の発生率 との間の関係を特性評価するためには、ばく露または用量の特性評価、反応の評価、無影響量を特定するために観察 されたデータが適合する用量反応モデルの選択が必要である。2 つの課題が提起される。すなわち、無影響量を特定 するために、疫学的データから用量反応を導き出すことができるのか、ということである。もしそうでない場合、疫学的情 報はハザードの特性評価に貢献できるのか、ということである。

用量反応関係を理解することは、EU の優れた植物保護対策が予想されるよりも高いばく露量の使用による有害な 健康影響が関連していることが証明されるが、低いばく露量の使用では関連性が観察されない。この背景では、RR ま たは OR を明らかにした疫学研究の統計的要約は、研究デザインが必要な基準を満たしている場合には、ハザード特 性評価プロセスに投入するための有用な定量的情報となる可能性があることは明らかである。

#### c) ステップ 3. ばく露評価

ばく露の評価に関するデータは、制御されていない様々な「実社会」の要因が解析を混乱させる複雑な状況では、 推定が困難なことが多い。前述したように、現代の生物学的モニタリングは、コストの高さ、実施可能性、ロジスティック スなどの実際的な理由から、一般のビト集団ではほとんど実施されていない。しかし、近い将来、農薬への定量的ばく 露に関する生物学的モニタリング研究やデータが増加することが予想されている。

ステップ 4. リスクの特性評価。この最後のステップでは、ばく露に関するデータを健康ベースの基準値と比較し、ば く露された集団における健康障害のリスクを推定する。ヒトのデータは、標的臓器、用量反応関係、毒性影響の可逆性 に関する完全な毒性学的データベースからの外挿に基づいて行われた推定の妥当性を検証するのに役立ち、基準値 の定義に直接影響を与えずに外挿のプロセスを再確認するのに役立つ(London ら、2010 年)。

疫学的データは、不確実性因子(UF)との関連で考慮されることもある。一般的に動物データでは、影響の種間変 動を考慮するために 10 の UF が使用され、これにさらに 10 の係数を加えてヒト集団の異なる部分の感受性の変動を 考慮する。しかし、ヒトのデータのみを考慮する場合(動物のデータよりも重要な場合)もあり、種族間のばらつきを考慮 した 10 の係数が適用される。現時点では、規則(EC)No 1107/2009 の第4条(6)が次のように規定していることに留 意する。「ヒトの健康に関連して、ヒトから収集したデータがない場合、動物試験に由来する安全マージンを低下させて はならない」と規定している。このことの意味するところは、リスク評価において疫学的データはリスク評価で使用される 警戒レベルを高めるためにのみ使用され、関連するヒトのデータが入手可能であっても UF を低下させるために使用さ れてはならないということである。

# 6.2. 個々の疫学研究の信頼性の評価

WOE 評価のために疫学をどのように考慮すべきかを決定する際に考慮すべき因子は以下に記載されており、観察 疫学的研究のためのバイアスのリスクツールで広く概説されている15。以下の例は、網羅的なリストではないが注目すべ

www.efsa.europa.eu/efsajourna

<sup>&</sup>lt;sup>15</sup> Assessing Risk of Bias and Confounding in Observational Studies of Interventions or Exposures: Further Development of the RTI Item Bank (https://www.ncbi.nlm.nih.gov/books/NBK154464/) and Cochrane handbook. 37

<sup>15</sup> 介入またはばく露の観察研究におけるバイアスと交絡因子のリスクの評価。RTI アイテムバンクのさらなる発展 (https://www.ncbi.nlm.nih.gov/books/NBK154464/)とコクランハンドブック

- ejusano
- Population. Did the study sample the individuals of interest from a well-defined population? Did the study have adequate statistical power and precision to detect meaningful differences for outcomes between exposed and unexposed groups?
- Exposure assessment. Were the methods used for assessing exposure valid, reliable and adequate? Was a wide range of exposures examined? Was exposure assessed at quantitative level or in a categorical or dichotomous (e.g. ever vs never) manner? Was exposure assessed prospectively or retrospectively?
- Outcome assessment. Were the methods used for assessing outcomes valid, reliable and adequate? Was a standardised procedure used for collecting data on health outcomes? Were health outcomes ascertained independently from exposure status to avoid information bias?
- Confounder control: were potential confounding factors appropriately identified and considered? How were they controlled for? Were the methods used to document these factors valid, reliable and adequate?
- Statistical analysis. Did the study estimate quantitatively the independent effect of an exposure on a health outcome of interest? Were confounding factors appropriately controlled in the analyses of the data?
- Is the *reporting* of the study adequate and following the principles of transparency and the guidelines of the STROBE statement (or similar tools)?

Study evaluation should provide an indication on the nature of the potential limitations each specific study may have and an assessment of overall confidence in the epidemiological database.

Furthermore, the nature and the specificity of the outcome with regards to other known risk factors can influence the evaluation of human data for risk assessment purposes, particularly in case of complex health endpoints such as chronic effects with long induction and latency periods.

Table 2 shows the main parameters to be evaluated in single epidemiological studies and the associated weight (low, medium and high) for each parameter. Specific scientific considerations should be applied on a case-by-case basis, but it would be unrealistic to implement these criteria in a rigid and unambiguous manner.

	Table 2:	Study guality	considerations	for weighting	epidemiological	observational studies <sup>(a),(b)</sup>
--	----------	---------------	----------------	---------------	-----------------	--

Parameter	High	Moderate	Low
Study design and conduct	Prospective studies. Prespecified hypothesis (compound and outcome specific)	Case-control studies. Prospective studies not adequately covering exposure or outcome assessment	Cross-sectional, ecological studies Case–control studies not adequately covering exposure or outcome assessment
Population	Random sampling. Sample size large enough to warrant sufficient power Population characteristics well defined (including vulnerable subgroups)	Questionable study power, not justified in detail Non-representative sample of the target population Population characteristics not sufficiently defined	No detailed information on how the study population was selected Population characteristics poorly defined
Exposure assessment	Accurate and precise quantitative exposure assessment (human biomonitoring or external exposure) using validated methods Validated questionnaire and/or interview for chemical-specific exposure answered by subjects	Non-valid surrogate or biomarker in a specified matrix and external exposure Questionnaire and/or interview for chemical-specific exposure answered by subjects or proxy	and/or interview; information collected for groups of chemicals No chemical-specific exposure information collected;
Outcome Assessment	Valid and reliable outcome assessment. Standardised and validated in study population Medical record or diagnosis confirmed	individuals Standardised outcome, not validated in population, or screening tool; or, medical record non-confirmed	general evaluated Non-standardised and non-validated health outcome Inappropriate or self-reported outcomes.

#### Epidemiological studies and pesticides

Parameter	High	Moderate	Low
Confounder control	Adequate control for important confounders relevant to scientific question, and standard confounders Careful consideration is given to clearly indicated confounders	Confounders are partially controlled for Moderately control of confounders and standard variables Not all variables relevant for scientific question are considered	No control of potential confounders and effect modifiers in the design and analysis phases of the study
Statistical Analysis	Appropriate to study design, supported by adequate sample size, maximising use of data, reported well (not selective) Statistical methods to control for confounding are used and adjusted and unadjusted estimates are presented. Subgroups and interaction analysis are conducted	Acceptable methods, analytic choices that lose information, not reported clearly Post hoc analysis conducted but clearly indicated	Only descriptive statistics or questionable bivariate analysis is made Comparisons not performed or described clearly Deficiencies in analysis (e.g. multiple testing)
Reporting	Key elements of the Material and Methods, and results are reported with sufficient detail Numbers of individuals at each stage of study is reported A plausible mechanism for the association under investigation is provided	Some elements of the Material and Methods or results are not reported with sufficient detail Interpretation of results moderately addressed	Deficiencies in reporting (interpretation of effect estimates, confounder control) Selective reporting Paucity of information on relevant factors that may affect the exposure-health relationship. Misplaced focus of the inferential objectives Not justified conclusions

(a): Overall study quality ranking based on comprehensive assessment across the parameters.

(b): Adapted from US-EPA (2016), based in turn on Muñoz-Quezada et al. (2013) and LaKind et al. (2014).

If the above assessment is part of the evidence synthesis exercise, where epidemiological research is being assessed and quantitatively summarised, it permits more accurate estimation of absolute risk related to pesticide exposure and further quantitative risk assessment.

In the particular case of pesticide epidemiology data, three basic categories are proposed as a first tier to organise human data with respect to risk of bias and reliability<sup>16</sup>: (a) low risk of bias and high reliability (all or most of the above quality factors have been addressed with minor methodological limitations); (b) medium risk of bias and medium reliability (many of the above quality factors have been addressed with moderate methodological limitations); (c) high risk of bias and low reliability, because of serious methodological limitations or flaws that reduce the validity of results or make them largely uninterpretable for a potential causal association. The latter studies are considered unacceptable for risk assessment mainly because of poor exposure assessment, misclassification of exposure and/or health outcome, or lack of statistical adjustment for relevant confounders. Risk assessment should not be based on results of epidemiological studies that do not meet well-defined data guality standards. Furthermore, results of exploratory research will need to be confirmed in future research before they can be used for risk assessment.

### 6.3. Assessment of strength of evidence of epidemiological studies

This section briefly discusses some important issues specifically related to combining and summarising results from different epidemiological studies on the association between pesticides and human health.

The approach for weighting epidemiological studies is mainly based on the modified Bradford Hill criteria, which are a group of conditions that provide evidence bearing on a potentially causal relationship between an incidence and a possible consequence (strength, consistency, specificity, temporality, biological gradient, plausibility, coherence, experiment and analogy) (Table 3). Clearly, the Epidemiological studies and pesticides

	ていること	な場合

(a):パラメータ全体の総合的な評価に基づく総合的な研究品質ランキング。

(b): Muñoz-Ouezada ら (2013) と LaKind ら (2014) を順に引用した US-EPA (2016) からの引用。

上記の評価が、疫学研究が評価され定量的にまとめられているエビデンス総合演習の一部である場合、農薬ばく露 に関連する絶対的リスクをより正確に推定し、さらに定量的なリスク評価を行うことが可能となる。

農薬疫学データの場合には、バイアスのリスクと信頼性に関してヒトデータを整理するための第一段階として、3 つの 基本的なカテゴリーが提案されている16。(a)バイアスのリスクが低く、信頼性が高い(上記の品質要因のすべて、また は大部分が軽微な方法論的限界で対処されている):(b)バイアスのリスクが中程度で信頼性が中程度(上記の品質要 因の多くが中程度の方法論的限界で対処されている);(c)バイアスのリスクが高く、信頼性が低い(結果の妥当性を低 下させる、または潜在的な因果関係をほとんど解釈できない、といった重大な方法論的限界や欠陥があるため)。後者 の研究は、主にばく露評価の不備、ばく露及び/または健康影響の誤分類、または関連する交絡因子の統計的調整 の欠如により、リスク評価には受け入れられないと考えられている。リスク評価は、十分に定義されたデータ品質基準を 満たしていない疫学研究の結果に基づくべきではない。さらに、予備的研究の結果は、リスク評価に使用する前に、将 来の研究で確認する必要がある。

## 6.3. 疫学研究のエビデンスの強さの評価

このセクションでは、農薬ととト健康影響との関連性に関する様々な疫学研究から得られた結果を組み合わせて要約 することに関連したいくつかの重要な問題について簡潔に論じている。

疫学研究の重み付けのアプローチは、主に修正された Bradford Hill 基準に基づいている。これは、事象と起こりえ る結果(強さ、一貫性、特異性、時間性、生物学的勾配、妥当性、統一性、実験と類推)との間の潜在的な因果関係を 示すエビデンスを提供する条件のグループである(表 3)。明らかに、これらの基準を満たせば満たすほど、意味のある

<sup>&</sup>lt;sup>16</sup> These categories are in accordance with those currently used by EFSA for the peer review of pesticide active substances: acceptable, supplementary and unacceptable. 39

<sup>16</sup> これらのカテゴリーは、現在 EFSA が農薬有効成分のピアレビューに使用している、許容可能、補助的、非許容のカテゴリーに準拠している。 EFSA Journal 2017:15(10):5007 www.efsa.europa.eu/efsajourna 39

ejusanu

more of these criteria that are met the stronger the basis for invoking the association as evidence for a meaningful association. However, Bradford Hill was unwilling to define what causality was and never saw the criteria as sufficient or even absolutely necessary but simply of importance to consider in a common-sense evaluation.

Table 3:	Considerations for WoE analysis based on the modified Bradford Hill criteria for evidence	
	integration	

Category	Considerations
Strength of Association	The assessment of the strength of association (not only the magnitude of association but also statistical significance) requires examination of underlying methods, comparison to the WoE in the literature and consideration of other contextual factors including the other criteria discussed herein
Consistency of Association	Associations should be consistent across multiple independent studies, particularly those conducted with different designs and in different populations under different circumstances. This criterion also applies to findings consistent across all lines of evidence (epidemiology, animal testing, <i>in vitro</i> systems, etc.) in light of modern data integration
Specificity	The original criteria of evidence linking a specific outcome to an exposure can provide a strong argument for causation has evolved and may have new and interesting implications within the context of data integration. Data integration may elucidate some mechanistic specificity among the varied outcomes associated with complex exposures. The lack of specificity can help to narrow down specific agents associated with disease
Temporality	Evidence of a temporal sequence between exposure to an agent and appearance of the effect within an appropriate time frame constitutes one of the best arguments in favour of causality. Thus, study designs that ensure a temporal progression between the two measures are more persuasive in causal inference
Biological Gradient (Dose-response)	Increased effects associated with greater exposures, or duration of exposures, strongly suggest a causal relationship. However, its absence does not preclude a causal association
Biological Plausibility	Data explained and supported by biologically plausible mechanisms based on experimental evidence strengthen the likelihood that an association is causal. However, lack of mechanistic data should not be taken as evidence against causality
Coherence	The interpretation of evidence should make sense and not to conflict with what is known about the biology of the outcome in question under the exposure-to-disease paradigm. If it does, the species closest to humans should be considered to have more relevance to humans
Experimental Evidence	Results from randomised experiments provide stronger evidence for a causal association than results based on other study designs. Alternatively, an association from a non- experimental study may be considered as causal if a randomised prevention derived from the association confirms the finding
Sequence of Key events	Provide a clear description of each of the key events (i.e. measurable parameters from a combination of <i>in vitro</i> , <i>in vivo</i> or human data sources) that underlie the established MoA/AOP for a particular health outcome. A fully elucidated MoA/AOP is a not requirement for using epidemiology studies in human health risk assessment

Adapted from Höfler (2005), Fedak et al. (2015) and US-EPA (2016).

For predictive causality, care must be taken to avoid the logical fallacy *post hoc ergo propter hoc* that states 'Since event Y followed event X, event Y must have been caused by event X'. Höfler (2005) quotes a more accurate 'counterfactual' definition as follows 'but for E, D will not occur or would not have occurred, but given E it will/would have occurred'. Yet, more detailed descriptions using symbolic logic are also available (Maldonado and Greenland, 2002). Rothman and Greenland (2008) stated that 'the only *sine qua non* for a counterfactual effect is the condition that the cause must precede the effect. If the event proposed as a result or "effect" precedes its cause, there may be an association between the events but certainly no causal relationship'.

#### 6.3.1. Synthesis of epidemiological evidence

Systematic reviews and meta-analysis of observational studies can provide information that strengthens the understanding of the potential hazards of pesticides, exposure-response characterisation, exposure scenarios and methods for assessing exposure, and ultimately risk characterisation (van den Brandt, 2002). Systematic reviews entail a detailed and comprehensive plan

#### Epidemiological studies and pesticides

関連性の証拠としてその関連性を提起する根拠が強くなる。しかし、Bradford Hill は、因果関係とは何かを明確にすることを目的とせず、基準を十分に、あるいは絶対的に必要なものとしてかんがえず、単に常識的な評価の中で考慮することが重要であると考えている。

#### 表 3:エビデンス統合のための修正された Bradford Hill 基準に基づく WOE 解析の考察

カテゴリー	考察事項
関連性の強さ	関連性の強さ(関連性の大きさだけでなく、統計的有意性も)の評価には、基礎となる方法の 検討、文献の WOE との比較及びここで議論されている他の基準を含む他の背景的要因の考慮 が必要である。
関連性の一貫性	関連性は、複数の独立した研究、特に異なる計画で、異なる状況下で異なる集団で実施された 研究において一貫性があるべきである。この基準は、現代のデータ統合に照らして、すべての エビデンス系統(疫学、動物実験、in vitro システムなど)にまたがって一貫性のある結果に も適用される。
特異性	特定の結果をばく露に結びつけるエビデンスの独自の基準は、因果関係についての強力な諱 論を提供できるようになり、データ統合の背景の中で新たな興味深い意味合いを持つように なったかもしれない。データの統合は、複雑なばく露に関連した様々な結果の中から、いくつ かのメカニズム論的な特定性を明らかにするかもしれない。特異性の欠如は、疾患に関連する 特異的な薬剤を絞り込むのに役立つかもしれない。
時間性	薬剤へのばく露と適切な時間枠内での影響の出現との間の時間的順序のエビデンスは、因果関係を支持する最良の論拠の一つを構成する。このように、2つの尺度間の時間的進行を確実にする研究デザインは、因果関係の推論においてより説得力がある。
生物学的勾配(用量反 応)	より大きなばく露またはばく露の持続時間に関連した影響の増加は、因果関係を強く示唆している。しかし、その不在は因果関係を排除するものではない。
生物学的妥当性	実験的エビデンスに基づいた生物学的に信憑性のあるメカニズムによって説明され、支持されたデータは、関連性が因果関係にある可能性を強化する。しかし、メカニズム論的データの 欠如は因果関係に反するエビデンスとして捉えられるべきではない。
統一性	エビデンスの解釈は理にかなったものでなければならず、ばく露-疾病パラダイムの下で問題となっている健康影響の生物学について知られていることと矛盾するものであってはならない。もしそうであれば、ヒトに最も近い種の方がヒトとの関連性が高いと考えるべきである。
実験的エビデンス	無作為化実験の結果は、他の研究デザインに基づく結果よりも因果関係の強いエビデンスを 提供する。あるいは、非実験的研究からの関連は、関連から導き出された無作為化予防が結論 を導く場合には、因果関係があると考えられる。
重要事象の結果	特定の健康影響について確立された MOA/AOP の基礎となる重要事象(すなわち、in vitro、 in vivo、またはヒトのデータ源を組み合わせた測定可能なパラメータ)をそれぞれ明確に説明 する。完全に解明された MOA/AOP は、ヒト健康リスク評価に疫学研究を使用するための要 件ではない。

Höfler (2005)、Fedak ら(2015)及び US-EPA(2016)からの引用。

予測的因果関係については、「事象 Y が事象 X の後に続いたので、事象 Y は事象 X によって引き起こされたに違 いない」という論理的誤謬を避けるために注意を払わなければならない。Höfler(2005 年)は、より正確な「反事実」の 定義を次のように引用している:「しかし、E があれば、D は発生しないか、発生しなかっただろうが、E があれば発生す るだろう/しただろう」。しかし、記号論理を用いたより詳細な記述もある(Maldonado 及び Greenland、2002 年)。 Rothman 及び Greenland (2008 年)は、「反事実効果の唯一の必須条件は、原因が効果に先行しなければならない という状態である」と述べている。結果または「影響」として提案された事象がその原因に先行している場合、事象間の 関連性はあるかもしれないが、因果関係は確かにない」と述べている。

# 6.3.1. 疫学的証拠の統合

観察による研究のシステマティックレビューとメタアナリシスは、農薬の潜在的なハザード、ばく露反応の特徴、ばく露 シナリオとばく露評価の方法、そして最終的にはリスクの特性評価の理解を強化する情報を提供することができる(van den Brandt、2002 年)。システマティックレビューは、特定のトピックに関するすべての関連研究を特定し、評価し、統 合することでバイアスを低減することを目的とした、詳細で包括的な計画と事前に定められた検索戦略を伴う。システマ ティックレビューの主なステップは以下の通りである:研究課題の策定、包含基準と除外基準の定義、異なるデータベ www.efsa.europa.eu/efsajourna EFSA Journal 2017;15(10):5007

and search strategy defined a priori aimed at reducing bias by identifying, appraising and synthesising all relevant studies on a particular topic. The major steps of a systematic review are as follows: formulation of the research question; definition of inclusion and exclusion criteria; search strategy for studies across different databases; selection of studies according to predefined strategy; data extraction and creation of evidence tables; assessment of methodological quality of the selected studies; including the risk of bias; synthesis of data (a meta-analysis can be performed if studies allow); and interpretation of results and drawing of conclusions (EFSA, 2010a). Evidence synthesis is, however, challenging in the field of pesticide epidemiology as standardisation and harmonisation is difficult. Nonetheless, evidence synthesis should play a pivotal role in assessing the robustness and relevance of epidemiological studies.

Statistical tools have been developed that can help assess this evidence. When multiple studies on nearly identical sets of exposures and outcomes are available, these can provide important scientific evidence. Where exposure and outcomes are quantified and harmonised across studies, data from individual epidemiological studies with similar designs can be combined to gain enough power to obtain more precise risk estimates and to facilitate assessment of heterogeneity. Appropriate systematic reviews and quantitative synthesis of the evidence needs to be performed regularly (e.g. see World Cancer Research Fund approach to continuous update of meta-analysis for cancer risk factor<sup>17</sup>). Studies should be evaluated according to previously published criteria for observational research and carefully examine possible selection bias, measurement error, sampling error, heterogeneity, study design, and reporting and presentation of results.

Meta-analysis is the term generally used to indicate the collection of statistical methods for combining and contrasting the results reported by different studies (Greenland and O'Rourke, 2008). Meta-analysis techniques could be used to examine the presence of diverse biases in the field such as small study effects and excess significance bias. Meta-analyses, however, do not overcome the underlying biases that may be associated with each study design (i.e. confounding, recall bias or other sources of bias are not eliminated). The extent to which a systematic review or meta-analysis can draw conclusions about the effects of a pesticide depends strongly on whether the data and results from the included studies are valid, that is, on the quality of the studies considered. In particular, consistent findings among original studies resulting from a consistent bias will produce a biased conclusion in the systematic review. Likewise, a meta-analysis of invalid studies may produce a misleading result, vielding a narrow confidence interval around the wrong effect estimate.

In addition to summarising the basic study characteristics of the literature reviewed, a typical metaanalysis should include the following components: (a) the average effect size and effect size distribution for each outcome of interest and an examination of the heterogeneity in the effect size distributions; (b) subgroup analysis in which the variability present in the effect size distribution is systematically analysed to identify study characteristics that are associated with larger or smaller effect sizes; (c) publication bias analysis and other sensitivity analyses to assess the validity of conclusions drawn (Wilson and Tanner-Smith, 2014).

In a meta-analysis, it is important to specify a model that adequately describes the effect size distribution of the underlying population of studies. Meta-analysis using meaningful effect size distributions will help to integrate quantitative risk into risk assessment models. The conventional normal fixed- and random-effects models assume a normal effect size population distribution, conditionally on parameters and covariates. Such models may be adequate for estimating the overall effect size, but surely not for prediction if the effect size distribution exhibits a non-normal shape (Karabatsos et al., 2015).

#### 6.3.2. Meta-analysis as a tool to explore heterogeneity across studies

When evaluating the findings of different studies, many aspects should be carefully evaluated. Researchers conducting meta-analyses may tend to limit the scope of their investigation to the determination of the size of association averaged over the considered studies. The motivation often is that aggregating the results yields greater statistical power and precision for the effect of interest. Because individual estimates of effect vary by chance, some variation is expected. However, estimates must be summarised only when meaningful. An important aspect that is often overlooked is heterogeneity of the strength of associations across subgroups of individuals. Heterogeneity between

el usa muni

ースにまたがる研究の検索戦略、事前に定めた戦略に従った研究の選択、データ抽出とエビデンス表の作成、選択し た研究の方法論的品質の評価、バイアスのリスクを含めた評価、データの統合(研究が許せばメタアナリシスを行うこと もできる)、結果の解釈と結論の導き出し(EFSA、2010 年 a)。しかし、農薬疫学の分野では、標準化と調和が困難で あるため、エビデンスの統合は困難である。それにもかかわらず、疫学研究の強固性と妥当性を評価する上で、エビデ ンス統合は極めて重要な役割を果たすべきである。

このエビデンスの評価に役立つ統計ツールが開発されている。ほぼ同一のばく露と転帰に関する複数の研究が利 用可能な場合、これらの研究は重要な科学的証拠を提供することができる。ばく露と転帰が研究間で定量化され、調 和されている場合には、類似した計画の個々の疫学研究からのデータを組み合わせることで、より正確なリスク推定値 を得るのに十分な検出力を得ることができ、不均一性の評価を容易にすることができる。適切なシステマティックレビュ ー及びエビデンスの定量的な統合を定期的に行う必要がある(例えば、世界がん研究基金のがんリスク因子のメタアナ リシスの継続的な更新のためのアプローチ17)。研究は、以前に発表された観察による研究の基準に従って評価され、 可能性のある選択バイアス、測定誤差、サンプリング誤差、異質性、研究デザイン及び結果の報告と提示について慎 重に検討されるべきである。

メタアナリシスとは、一般的に、異なる研究で報告された結果を組み合わせて比較するための統計的手法の集積を 示すために使用される用語である(Greenland 及び O'Rourke、2008 年)。メタアナリシスの技術は、小さな研究効果 や過剰な有意性バイアスなど、研究分野における多様なバイアスの存在を調べるために使用されることがある。しかし、 メタアナリシスは、各研究デザインに関連している可能性のある根本的なバイアスを克服するものではない(すなわち、 交絡、想起バイアス、または他のバイアスの原因が排除されない)。システマティックレビューやメタアナリシスが農薬の 影響について結論を導き出すことができる範囲は、含まれた研究から得られたデータや結果が有効かどうか、つまり検 討された研究の質に大きく依存する。特に、一貫したバイアスの結果として、オリジナルの研究間で一貫した結論が得 られれば、システマティックレビューでは偏った結論が得られることになる。同様に、無効な研究のメタアナリシスでは、 誤った影響推定値に狭い信頼性間隔が生じるなど、誤解を招く結果になる可能性がある。

レビューされた文献の基本的な研究の特徴を要約することに加えて、典型的なメタアナリシスには以下の要素が含ま れるべきである。(a) 対象となる各健康影響の平均影響量と影響量分布及び影響量分布の不均一性の検討(b) 影響 量分布に存在する変動性を系統的に解析し、効果量の大小に関連する研究の特徴を特定するサブグループ解析(c) 引き出された結論の妥当性を評価するための出版バイアス解析及びその他の感度分析(Wilson 及び Tanner Smith, 2014年)。

メタアナリシスでは、基礎となる研究集団の影響量分布を適切に記述するモデルを指定することが重要である。意味 のある影響量分布を用いたメタアナリシスは、定量的リスクをリスク評価モデルに統合するのに役立つ。従来の正規の 固定影響モデル及びランダム影響モデルは、パラメータと共変量に条件付きで正規の影響量母集団分布を仮定して いる。このようなモデルは、全体的な影響量を推定するのには適切かもしれないが、影響量分布が非正規の形状を示 す場合には予測には確実に適していない(Karabatsosら、2015年)。

# 6.3.2. 研究間の異質性を探索するツールとしてのメタアナリシス

異なる研究の結果を評価する際には、多くの側面を慎重に評価すべきである。メタアナリシスを行う研究者は、調査 の範囲を、考慮した研究を平均した関連性の大きさの結果に限定する傾向があります。その動機は、多くの場合、考慮 した研究を平均した関連性の強さの決定に限定する傾向がある。影響の個々の推定値は偶然性によって変化するた め、ある程度のばらつきは予想される。しかし、推定値は意味のある場合にのみ要約されなければならない。見落とさ れがちな重要な側面として、サブグループを超えた個人間の関連の強さの不均一性がある。研究間の不均一性は評 価され、存在する場合には定量化される必要がある(Higgins、2008 年)。メタアナリシスでは、異なる研究からの結果 の間の不均一性は、同質性と同じくらい有益であるかもしれない。観察された結果の矛盾の根底にある理由を探ること

ejusanou

studies needs to be assessed and quantified when present (Higgins, 2008). In meta-analysis, heterogeneity among results from different studies may indeed be as informative as homogeneity. Exploring the reasons underlying any observed inconsistencies of findings is generally conducive of great understanding.

Figure 1 shows three forest plots from a fictitious example in which each of three pesticides (A, B and C) is evaluated in meta-analysis of two studies. It is assumed that both studies for each pesticide are of the highest quality and scientific rigor. No biases are suspected.

**Figure 1:** Forest plots from a fictitious example in which each of three pesticides (A, B and C) is evaluated in a meta-analysis of two studies. The x-axis in each plot represents the estimated risk ratio of the disease of interest comparing exposed and unexposed individuals. The squares denote the estimated risk ratio in each study and the grey diamonds the summarised risk ratio. The horizontal lines indicate 95% confidence intervals

The following text contains short comments on the interpretation of the results in Figure 1, one pesticide at a time.

- Exposure to pesticide A seems to double the risk of the disease. The results are consistent
  between the two studies and the confidence intervals do not contain the null value, one. These
  results, however, do not imply that (a) the risk ratio would be about 2 in any other study that
  was conducted on the same exposure and disease; or that (b) the risk ratio is two in any
  group of individuals (e.g. males or females, young or old).
- Exposure to pesticide B seems to halve the risk of the disease. The results are consistent between the two studies and the confidence intervals do not contain the null value, one. These results, however, do not imply that (a) the risk ratio would be about a half in any other study that was conducted on the same exposure and disease; or that (b) the risk ratio is about a half in any group of individuals (e.g. males or females, young or old).
- Exposure to pesticide C seems to double the risk of the disease in one study and to halve the
  risk in the other. The results are inconsistent between the two studies and the confidence
  intervals do not contain the null value, one. These results, however, do not imply that (a) the
  risk ratio would be about one in any other study that was conducted on the same exposure
  and disease; or that (b) the risk ratio is about one in any group of individuals (e.g. males or
  females, young or old).

#### What evidence can the results shown in Figure 1 provide?

The risk ratio reported by any study can be generalised to other populations only if all the relevant factors have been controlled for (Bottai, 2014; Santacatterina and Bottai, 2015). In this context, relevant factors are variables that are stochastically dependent with the health outcome of interest. For example, cardiovascular diseases are more prevalent among older subjects than among younger individuals. Age is therefore a relevant factor for cardiovascular diseases. The evidence provided by the results shown in Figure 1 are potentially valid only if this step was taken in each of the studies considered. If that was the case for the studies, then, there is evidence that exposure to pesticide A doubles the risk in the specific group of individuals considered by each of the two studies. If the risk ratios are summary measures over the respective study populations, then none of the findings should be generalised. However, if the risk ratios for pesticide A were not adjusted for any factor, and the underlying populations were very different

#### Epidemiological studies and pesticides

## は、一般的に大きな理解につながる。

図1は、3つの農薬(A、B、C)のそれぞれが2つの研究のメタアナリシスで評価されている仮想例の3つのフォレストプロットを示している。各農薬の両方の研究が、最高の品質と科学的な厳密さを持っていると仮定している。バイアスが疑われない。

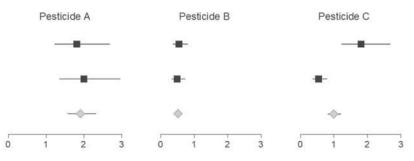

図 1:3 つの農薬(A, B, C)のそれぞれが 2 つの研究のメタアナリシスで評価されている仮想例のフォレストプロット。 各プロットの x 軸は、ばく露した個体とばく露していない個体を比較した、対象疾患の推定リスク比を表している。 四角は各研究における推定リスク比を示し、灰色のダイヤモンドは要約されたリスク比を示している。横線は 95%信頼区間を示す。

以下の文章には、図1の結果の解釈について、農薬を1つずつ、短くコメントしている。

- ・農薬Aへのばく露は、病気のリスクを2倍にするようである。結果は2つの研究の間で一致しており、信頼区間には帰無値である1が含まれていない。しかし、これらの結果は、(a)同じばく露と疾患について実施された他の研究では、リスク比が約2であること、または(b)個人のどのグループ(例えば、男性か女性か、若年者か高齢者)でもリスク比が2であることを暗示するものではない。
- ・農薬 B へのばく露は、病気のリスクを半減させるようである。結果は2つの研究の間で一致しており、信頼区間には帰無値である1は含まれていない。しかし、これらの結果は、(a)同じばく露と疾患について実施された他の研究では、(a)リスク比が約半分になること、または(b)個人のどのグループ(例えば、男性か女性か、若年者か高齢者か)でもリスク比が約半分になることを暗示するものではない。
- ・農薬 C へのばく露は、一方の研究では病気のリスクが2倍になり、他方の研究ではリスクが2分の1になるようである。結果は2つの研究の間で矛盾しており、また、信頼区間には帰無値である1が含まれていない。しかし、これらの結果は、(a)同じばく露と疾患について実施された他の研究では、リスク比が約1であること、または(b)個人のどのグループ(例えば、男性か女性か、若年者か高齢者か)でもリスク比が約1であることを暗示するものではない。

図1に示された結果は、どのようなエビデンスを提供できるか?

どのような研究で報告されたリスク比も、すべての関連因子がコントロールされている場合にのみ、他の集団に一般 化することができる(Bottai, 2014 年; Santacatterina 及び Bottai, 2015 年)。この背景では、関連因子とは、対象と なる健康影響に確率的に依存する変数のことである。例えば、心血管疾患は、若年者よりも高齢者の方が多い。したが って、年齢は心血管疾患の関連因子である。図1に示された結果から得られるエビデンスは、検討した各研究でこのス テップを踏んだ場合にのみ有効となる可能性がある。もしそうであれば、2 つの研究のそれぞれで考慮された個人の特 定のグループでは、農薬A へのばく露がリスクを2倍にするというエビデンスがある。リスク比がそれぞれの研究集団の 要約測定値であるならば、どの結論も一般化されるべきではない。しかし、農薬Aのリスク比がいかなる因子でも調整さ れておらず、基礎となる母集団が2 つの研究で大きく異なっていた場合、関連因子が存在せず、農薬A はどのサブグ across the two studies, then there would still be evidence that there may be no relevant factors and pesticide A doubles the risk in any subgroup of individuals. Pesticide B appears to halve the risk, and the estimated confidence intervals are narrower for pesticide B than for pesticide A. Generalisability of the findings, however, holds for pesticide B under the conditions stated above for pesticide A. As for pesticide C, the forest plot provides evidence that exposure to this pesticide raises the risk of the disease in the group of individuals in one of the studies and decreases it in the group considered in the other study. Again, if the risk ratios are summary measures over the respective study populations, then none of the findings should be generalised. Investigating the reasons behind the inconsistency between the two studies on pesticide C can provide as much scientific insight as investigating the reasons behind the similarity between the studies on pesticide A or pesticide B.

In general, the overall summary measures provided by forest plots, such as the silver diamonds in each of the three panels of Figure 1, are of little scientific interest. When evaluating the findings of different studies, many aspects should be carefully evaluated. An important aspect that is often overlooked is heterogeneity of the strength of associations across subgroups of individuals. When information about subgroup analysis is provided in the publications that describe a study, this should be carefully evaluated. Sensitivity analyses should complement the results provided by different studies. These should aim to evaluate heterogeneity and the possible impact of uncontrolled for relevant factors along with information and sampling error. A synoptic diagram is displayed in Figure 2.

### 6.3.3. Usefulness of meta-analysis for hazard identification

Human data can be used for many stages of risk assessment. Single epidemiological studies, if further studies on the same pesticide are not available, should not be used as a sole source for hazard identification, unless they are high quality studies (according to criteria shown in Table 2). Evidence synthesis techniques which bring together many studies, such as systematic reviews and meta-analysis (where appropriate) should be utilised instead. Although many meta-analyses have been carried out for the quantitative synthesis of data related to chronic diseases, their application for risk assessment modelling is still limited.

Importantly, evidence synthesis will provide a methodological assessment and a risk of bias assessment of the current evidence highlighting areas of uncertainties and identifying associations with robust and credible evidence.

Figure 3 shows a simple methodology proposed for the application of epidemiological studies into risk assessment. The first consideration is the need of combining different epidemiological studies

43

#### Epidemiological studies and pesticides

ループの個人においてもリスクを2倍にするというエビデンスが残っている。農薬Bはリスクを半減させるようであり、推定された信頼区間は農薬Aよりも農薬Bの方が狭い。しかしながら、農薬Aについての上記の条件のもとでは結果を一般化できる可能性は農薬Bについても維持されている。農薬Cに関しては、フォレストプロットから、この農薬へのばく露が、一方の研究では個人のグループで病気のリスクを上げ、他方の研究ではリスクを下げるというエビデンスが得られた。繰り返しになるが、リスク比がそれぞれの研究集団の要約測定値であるならば、どの結果も一般化されるべきではない。農薬Cに関する2つの研究間の矛盾の背後にある理由を調査することは、農薬Aまたは農薬Bに関する研究間の類似性の背後にある理由を調査するのと同じくらい多くの科学的予測を提供することができる。

ー般的に、図1の3つのパネルのそれぞれにある銀色のダイヤモンドのようなフォレストプロットによって提供される 全体的な要約評価尺度は、ほとんど科学的な関係を持たない。異なる研究の結果を評価する際には、多くの側面を慎 重に評価しなければならない。見落とされがちな重要な側面は、サブグループを超えた個人間の関連の強さの不均一 性である。研究を記述した出版物でサブグループ解析に関する情報が提供されている場合、これは慎重に評価される べきである。感度分析は、異なる研究で得られた結果を補完すべきである。これらの解析は、異質性と、情報とサンプリ ング誤差とともに、関連する因子を制御していない場合の影響を評価することを目的とすべきである。図2に総観図を 示す。

# 6.3.3. ハザード同定のためのメタアナリシスの有用性

ヒトのデータはリスク評価の多くの段階で利用できる。単一の疫学研究(同じ農薬に関する追加研究が入手できない 場合)は、質の高い研究(表 2 に示す基準による)でない限り、単独のハザード同定のための情報源として使用すべき ではない。代わりに、システマティックレビューやメタアナリシス(必要に応じて)など、多くの研究をまとめたエビデンス統 合技術を利用すべきである。慢性疾患に関連するデータの定量的な統合のために多くのメタアナリシスが実施されて いるが、リスク評価モデリングへの応用はまだ限られている。

重要なことは、エビデンス統合は、現在のエビデンスの方法論的評価とバイアスのリスク評価を提供し、不確実性の 領域を強調し、強固で信頼性の高いエビデンスとの関連を特定することである。

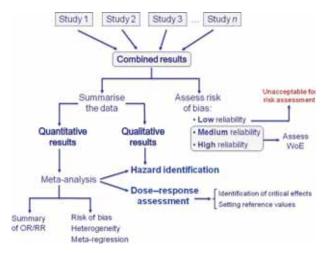

図 3 は、疫学研究をリスク評価に適用するために提案された簡単な方法論を示している。最初の考慮事項は、同じ 健康影響を扱う異なる疫学研究を組み合わせる必要性である。これは、EFSA のシステマティックレビューのためのガ イダンス(EFSA、2010 年 a)で提案されている基準に従って行うことができる。次に、研究デザインと実施、母集団、ば く露評価、健康影響評価、交絡因子の管理、統計解析、結果の報告など、WOE 評価のための 6.2 節に記載されてい

www.efsa.europa.eu/efsajourna

addressing the same outcome. This can be made following criteria proposed by EFSA guidance for systematic reviews (EFSA, 2010a). Then, the risk of bias is assessed based on the factors described in Section 6.2 for a WoE assessment, namely: study design and conduct, population, exposure assessment, outcome assessment, confounder control, statistical analysis and reporting of results. Those studies categorised as of low reliability will be considered unacceptable for risk assessment. The remaining studies will be weighted and used for hazard identification.

If quantitative data are available, a meta-analysis can be conducted to create summary data and to improve the statistical power and precision of risk estimates (OR, RR) by combining the results of all individual studies available or meeting the selection criteria. As meta-analyses determine the size of association averaged over the considered studies, they provide a stronger basis for hazard identification. Moreover, under certain circumstances, there is the possibility to move towards risk characterisation metrics because these measured differences in health outcomes (OR, RR) can be converted to dose-response relationships (Nachman et al., 2011). Although quite unusual in practice, this would allow for the identification of critical effects in humans and/or setting reference values without the need of using animal extrapolation.

Since heterogeneity is common in meta-analyses, there is a need to assess which studies could be combined quantitatively. Heterogeneity can be genuine, representing diverse effects in different subgroups, or might represent the presence of bias. If heterogeneity is high (I<sup>2</sup> greater than 50%), individual studies should not be combined to obtain a summary measure because of the high risk of aggregating bias from different sources. Sources of heterogeneity should be explored through sensitivity analysis and/or meta-regression. Furthermore, the presence of diverse biases in the meta-analysis should be examined, such as small study effects, publication bias and excess significance bias. It is important to find models that adequately describe the effect size distribution of the underlying studied populations.

#### Figure 3: Methodology for utilisation of epidemiological studies for risk assessment

6.3.4. Pooling data from similar epidemiological studies for potential dose-response modelling

As in other fields of research, findings from a single epidemiological study merit verification through replication. When the number of replications is abundant, it may be worthwhile to assess the entire set of replicate epidemiological studies through a meta-analysis and ascertain whether, for key outcomes, findings are consistent across studies. Such an approach will provide more robust conclusions about the existence of cause-effect relationships.

る要素に基づいてバイアスのリスクを評価する。信頼性が低いと分類された研究は、リスク評価のために受け入れられ ないと考えられる。残りの研究は重み付けを行い、ハザードの特定に使用する。

定量的データが利用可能な場合、メタアナリシスを実施して要約データを作成し、利用可能な、あるいは選択基準を 満たすすべての個々の研究の結果を組み合わせることで、統計的な検出力とリスク推定値(OR, RR)の精度を向上さ せることができる。メタアナリシスは、関連の大きさが検討した研究の平均値に決定するので、ハザード同定のためのよ り強力な基盤を提供する。さらに、特定の状況下では、健康影響におけるこれらの測定された差(OR, RR)を用量反応 関係に変換できるため、リスク特性の測定基準に移行する可能性がある(Nachman 6、2011 年)。実際には非常に珍 しいことではあるが、これにより、動物からの外挿法を使用することなく、ヒトにおける重大影響の同定や基準値の設定 が可能になる。

メタアナリシスでは不均一性が一般的であるため、どの研究を定量的に組み合わせることができるかを評価する必要 がある。異質性は、異なるサブグループにおける多様な影響を表す真正なものである場合もあれば、バイアスの存在を 表す場合もある。異質性が高い場合(I<sup>2</sup>が 50%を超える場合)は、異なる情報源からのバイアスを集約するリスクが高い ため、要約尺度を得るために個々の研究を組み合わせるべきではない。感度分析及び/またはメタ回帰によって異質 性の原因を探るべきである。さらに、メタアナリシスにおける多様なバイアスの存在、例えば、小規模な研究効果、出版 バイアス、過剰な有意性バイアスなどを調べるべきである。基礎となる研究集団の影響量分布を適切に記述するモデ ルをみつけることが重要である。

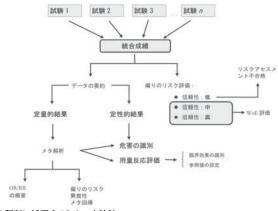

図3:疫学研究をリスク評価に活用するための方法論

# 6.3.4. 潜在的な用量反応モデル化のための類似の疫学研究からのデータの蓄積

他の研究と同様に、単一の疫学研究から得られた結果は、複製によって検証する価値がある。複製の数が豊富な場 合には、メタアナリシスによって複製された疫学研究の全セットを評価し、主要な健康影響事象について、研究間で結 果が一貫しているかどうかを確認することについては価値があるかもしれない。このようなアプローチにより、因果関係 の存在についてより強固な結論が得られるであろう。

ハザードが同定されると、リスク評価の次のステップは、異なるばく露レベルでの有害な影響のリスクを推定するための用量反応評価を実施することであり、特定の集団に対して健康への有害な影響が認められない濃度以下のばく露レベルを推定する。しかし、このステップでは、個人レベルでの完全に定量的な(または少なくとも半定量的な)ばく露データが必要である。定量的統合から得られた要約推定値は、研究間の相対比較が可能となるようなばく露の連続変数の変化(またはばく露のある一定割合の変化)に対する OR を示すものであれば、リスク評価にとってより有益であり、研www.efsa.europa.eu/efsajourna

Once a hazard has been identified, the next step in risk assessment is to conduct a dose-response assessment to estimate the risk of the adverse effect at different levels of exposure and/or the concentration level below which no appreciable adverse health effect can be assumed for a given population. However, this step requires fully quantitative (or at least semi-quantitative) exposure data at an individual level. Summary estimates resulting from quantitative synthesis would be more informative for risk assessment if they present an OR for a given change in the continuous variable of exposure (or per a given percentile change in exposure) as this allows for relative comparisons across studies and could be of help to derive health-based reference values. Only within such a framework can data from human studies with similar designs be merged to gain enough power to model proper dose-response curves (Greenland and Longnecker, 1992; Orsini et al., 2012).

Conversely, meta-analytical approaches may be of limited value if a combined OR is calculated based on meta-analyses interpreting exposure as a 'yes' or a 'no' (ever vs never) because exposures are not necessarily to active ingredients in the same proportion in all studies included. Even though in these cases, meta-analyses may consistently find an increased risk associated with pesticide exposure, for risk assessment the exposure needs to characterise the effect of specific pesticide classes or even better individual pesticides as their potency may differ within the same class (Hernández et al., 2016).

This approach would allow points of departure to be identified (e.g. benchmark doses (BMD)) and would be relevant for the integration of epidemiological studies into quantitative risk assessment. Although BMD modelling is currently used for analysing dose–response data from experimental studies, it is possible to apply the same approach to data from observational epidemiological studies (Budtz-Jørgenson et al., 2004). The EFSA Scientific Committee confirmed that the BMD approach is a scientifically more advanced method compared to the no observed-adverse-effect level (NOAEL) approach for deriving a Reference Point, since it makes extended use of the dose–response data from experimental and epidemiological studies to better characterise and quantify potential risks. This approach, in principle, can be applicable to human data (EFSA Scientific Committee, 2017b), although the corresponding guidelines are yet to be developed.

Dose-response data from observational epidemiological studies may differ from typical animal toxicity data in several respects and these differences are relevant to BMD calculations. Exposure data often do not fall into a small number of well-defined dosage groups. Unlike most experimental studies, observational studies may not include a fully unexposed control group, because all individuals may be exposed to some extent to a chemical contaminant. In this case, the BMD approach still applies since fitting a dose-response curve does not necessarily require observations at zero exposure. However, the response at zero exposure would then need to be estimated by low-dose extrapolation. Hence, the BMD derived from epidemiological data can be strongly model-dependent (Budtz-Jørgensen et al., 2001).

Epidemiology data need to be of sufficient quality to allow the application of the BMD approach, especially in terms of assigning an effect to a specific pesticide and its exposure. Clear rules and guidance, and definition of model parameters need to be considered for such a BMD approach, which might differ from BMD approaches from controlled experimental environments. Although the BMD modelling approach has been applied to epidemiological data on heavy metals and alcohol (Lachenmeier et al., 2011), currently, few individual studies on pesticides are suitable for use in dose–response modelling, much less in combination with other studies. However, future studies should be conducted and similarly reported so that they could be pooled together for a more robust assessment.

#### 7. Integrating the diverse streams of evidence: human (epidemiology and vigilance data) and experimental information

This section first considers in Section 7.1 the different nature of the main streams of evidence, i.e. originating either from experimental studies or from epidemiological studies. The approach used is that recommended by the EFSA Scientific Committee Guidance on WoE (EFSA Scientific Committee, 2017b), which distinguishes three successive phases to assess and integrate these different streams of information: reliability, relevance and consistency. The first step, consists in the assessment of the reliability of individual studies be they epidemiological (addressed in Section 6) or experimental (beyond the scope of this Scientific Opinion). Then, the relevance (strength of evidence) of one or more studies found to be reliable is assessed using principles of epidemiology (addressed in Section 6) and toxicology. Next, Section 7.2 considers how to bring together different streams of relevant information from epidemiological and experimental studies, which is considered in a WoE approach, to assess consistency and biological plausibility for humans.

45

究間の相対比較が可能となり、健康に基づく基準値を導き出すのに役立つ。このような枠組みの中でのみ、類似した 計画のヒト研究からのデータを統合して、適切な用量反応曲線をモデル化するのに十分な力を得ることができる (Greenland 及び Longnecker、1992年; Orsini ら、2012年)。

逆に、メタアナリシス的アプローチは、すべての研究で同じ割合で含まれる有効成分へのばく露が必ずしも必要では ないため、ばく露を「はい」または「いいえ」(これまでにあり、または決してない)と解釈するメタアナリシスに基づいて複 合 OR が計算された場合には、限られた価値しかないかもしれない。これらのケースでは、メタアナリシスは一貫して農 薬ばく露に関連したリスクの増加を示しているが、リスク評価のためには、ばく露は特定の農薬クラスの影響を特性評価 する必要があり、同じクラス内でも効力が異なる可能性があるため、個々の農薬の影響を特性評価する必要がある (Hernándezら、2016 年)。

このアプローチは、Point of Departure を特定することを可能にし(例えば、ベンチマーク用量(BMD))、疫学研究 を定量的リスク評価に統合することに関連するであろう。現在、BMD モデリングは実験研究からの用量反応データの 解析に使用されているが、観察による疫学研究からのデータにも同様のアプローチを適用することが可能である (Budtz-Jørgenson 5、2004 年)。EFSA 科学委員会は、BMD アプローチは、実験研究や疫学研究からの用量反応 データを利用して潜在的なリスクをよりよく特徴付け、定量化するために、Reference Pointを得るための NOAEL(no observed-adverse-effect level)アプローチと比較して、より科学的に進んだ方法であると結論づけている。このアプロ ーチは、原則としてヒトのデータにも適用可能である(EFSA Scientific Committee、2017 年 b)が、対応するガイドラ インはまだ作成されていない。

観察による疫学研究からの用量反応データは、いくつかの点で典型的な動物試験の毒性データとは異なる可能性 があり、これらの違いは BMD の計算に関連する。ばく露データは、多くの場合、少数の十分に定義された用量群に当 てはまらないことが多い。ほとんどの実験研究とは異なり、観察による研究には完全に未ばく露の対照群が含まれてい ない場合がある。この場合、用量反応曲線を作成することは必ずしもばく露量ゼロでの観察を必要としないため、BMD アプローチが適用される。しかし、ばく露量ゼロでの反応は低用量外挿法で推定する必要がある。したがって、疫学デ ータから得られる BMD はモデル依存性が強い(Budtz-Jørgensen 6、2001年)。

疫学データは、BMD アプローチを適用するためには、特に特定の農薬とそのばく露に影響を与えるという点で、十 分な品質のものでなければならない。このような BMD アプローチについては、明確なルールとガイダンス、モデルパラ メータの定義を考慮する必要があり、制御された実験環境からの BMD アプローチとは異なる可能性がある。BMD モ デリングアプローチは重金属やアルコールに関する疫学データに適用されているが(Lachenmeier ら、2011 年)、現 在のところ、農薬に関する個別の研究は、用量反応モデリングに使用するのに適しているものはほとんどなく、他の研 究と組み合わせて使用することはあまりない。しかし、今後も研究は実施され、同様の報告がなされ、それらの研究を蓄 積して、より強固な評価を行うことができるようにすべきである。

# 7. 多様なエビデンスの統合:ヒト(疫学データと警戒データ)と実験の情報

本節では、まず第 7.1 節で、実験研究や疫学研究に由来する主なエビデンスの特性の違いについて考察する。使用したアプローチは、EFSA Scientific Committee Guidance on WOE(EFSA Scientific Committee、2017 年 b) で推奨されているもので、これらの異なる情報を評価し統合するために、信頼性、関連性、一貫性の 3 つの段階を区別している。最初の段階では、疫学的研究(セクション 6 で述べている)や実験的研究(この意見書の範囲を超えている) である個々の研究の信頼性の評価で構成されている。次に、信頼性があると判断された 1 件以上の研究の関連性(エビデンスの確実性)を疫学(第 6 節に記載)と毒物学の原則を用いて評価する。次に、第 7.2 節では、WOE アプローチで検討された疫学的及び実験的研究からの様々な関連情報を、ヒトに対する一貫性と生物学的妥当性を評価する ために、どのようにしてまとめるかを検討する。

# 7.1. Sources and nature of the different streams of evidence Comparison of experimental and epidemiological approaches

In the regulatory risk assessment of pesticides, the information on the toxic effects is based on the results of a full set of experiments as required by Regulation (EC) 283/2013 and 284/2013, and conducted according to OECD guidelines. They are carried out in vivo or in vitro, so there will always be some high-quality experimental data available for pesticides as required to be provided by applicants under Regulation (EC) 1107/2009. A number of categories are established for rating the reliability of each stream of evidence according to the EFSA peer review of active substances: acceptable, supplementary and unacceptable. The data quality and reliability of in vivo or in vitro toxicity studies should be assessed using evaluation methods that better provide more structured support for determining a study's adequacy for hazard and risk assessments. Criteria have been proposed for conducting and reporting experimental studies to enable their use in health risk assessment for pesticides (Kaltenhäuser et al., 2017).

Animal (in vivo) studies on pesticide active substances conducted according to standardised test guidelines and good laboratory practices (GLP, e.g. OECD test guidelines) are usually attributed higher reliability than other research studies. Notwithstanding, since there is no evidence that studies conducted under such framework have a lower risk of bias (Vandenberg et al., 2016), evidence from all relevant studies, both GLP and non-GLP, should also be considered and weighted. Thus, data from peer-reviewed scientific literature should be taken into account for regulatory risk assessment of pesticide active substances, provide they are of sufficient quality after being assessed for methodological reliability. Their contribution to the overall WoE is influenced by factors including test organism, study design and statistical methods, as well as test item identification, documentation and reporting of results (Kaltenhäuser et al., 2017).

The internal validity of in vitro toxicity studies should be evaluated as well to provide a better support for determining a study's adequacy for hazard and risk assessments. In silico modelling can be used to derive structure-activity relationships (SAR) and to complement current toxicity tests for the identification and characterisation of the mode or mechanisms of action of the active substance in humans. These alternative toxicity testing (and non-testing) approaches could be helpful in the absence of animal data, e.g. to screen for potential neurodevelopmental or endocrine disruption effects of pesticides, and to increase confidence in animal testing. Considering the demand for minimising the number of animal studies for regulatory purposes, non-animal testing information can provide relevant stand-alone evidence that can be used in the WoE assessment.

A number of toxicological issues are amenable for systematic review, from the impact of chemicals on human health to risks associated with a specific exposure, the toxicity of chemical mixtures, the relevance of biomarkers of toxic response or the assessment of new toxicological test methods (Hoffmann et al., 2017). For instance, in a previous Scientific Opinion EFSA used a systematic review for the determination of toxicological mechanisms in the frame of AOP approach (Choi et al., 2016; EFSA Scientific Committee, 2017c).

Besides toxicity data on the active substance, such data may also be required on metabolites or residues if human exposure occur through the diet or drinking water. Results from these studies are then considered in relation to expected human exposures estimated through food consumption and other sources of exposure. The strength of this approach is that in vivo studies account for potential toxic metabolites, though not always animal metabolic pathways parallels the ones of humans.

Experimental studies in laboratory animals are controlled studies where confounding is eliminated by design, which is not always the case with epidemiological studies. Animals used in regulatory studies are, however, typically inbred, genetically homogeneous and due to the controlled environment they lack the full range of quantitative and qualitative chemical susceptibility profiles. Nevertheless, animal surrogates of human diseases are being challenged by their scientific validity and translatability to humans, and the lack of correlation often found between animal data and human outcomes can be attributed to the substantial interspecies differences in disease pathways and disease-induced changes in gene expression profiles (Esch et al., 2015). Thereby, many experimental models do not capture complex multifactorial diseases making animal-to-human extrapolation subject to considerable uncertainty. Current risk assessment is therefore by its nature predictive and may be insufficient because it is chemical-specific and humans are exposed to a large number of chemicals from environmental, dietary and occupational sources or because of different toxicokinetic differences. In recognition of the uncertain nature of animal-to-human extrapolation, the regulatory risk assessment advice does not just consider the relevant point(s) of departure (NOAEL, LOAEL or BMDL) that have

Epidemiological studies and pesticides

# 7.1. 異なるエビデンスの起源と特性 実験的アプローチと疫学的アプローチの比較

農薬の規制リスク評価では、毒性影響に関する情報は、規則(EC)283/2013 及び 284/2013 で要求され、OECD ガイドラインに従って実施された一連の実験結果に基づいている。これらの実験は in vivo または in vitro で実施され ているため、規則(EC)1107/2009 に基づき申請者が提供することが要求されているように、農薬については常に質の 高い実験データが存在している。EFSA の有効成分のピアレビューによると、各エビデンスの信頼性を評価するために、 許容範囲、補足範囲、不許容範囲といういくつかのカテゴリーが設定されている。in vivo または in vitro 毒性試験の データの質及び信頼性は、ハザード及びリスク評価のための試験の妥当性を判断するためのより構造的な裏付けをよ り良く提供する評価方法を用いて評価されるべきである。農薬の健康リスク評価に使用できるように、実験的研究の実 施と報告のための基準が提案されている(Kaltenhäuserら、2017年)。

標準化された試験ガイドラインや優良試験所規範(GLP、例えば OECD 試験ガイドライン)に従って実施された農薬 有効成分の動物(in vivo)試験は、通常、他の研究よりも信頼性が高いとされている。しかし、このような枠組みの下で 実施された研究の方がバイアスのリスクが低いというエビデンスはないため(Vandenbergら、2016年)、GLPと非GLP の両方を問わず、関連するすべての研究から得られたエビデンスも考慮し、重み付けを行うべきである。このように、査 読された科学文献からのデータは、方法論的信頼性を評価した後に十分な品質のものであれば、農薬有効成分の規 制リスク評価のために考慮されるべきである。WOE 全体への貢献は、試験系、試験計画、統計的方法、試験項目の特 定、結果の文書化、報告などの要因によって左右される(Kaltenhäuserら、2017年)。

ハザード及びリスク評価のための試験の妥当性を判断するためのより良い補助とするために、in vitro 毒性試験の 内部妥当性も評価されるべきである。in silico モデルは、構造活性相関(SAR)を導出し、ヒトにおける有効成分の作 用様式や作用機序の同定や特性評価のための現行の毒性試験を補完するために使用することができる。これらの代 替毒性試験(及び非試験)アプローチは、動物データがない場合、例えば農薬の潜在的な神経発達や内分泌かく乱 作用をスクリーニングし、動物試験の信頼性を高めるのに役立つ可能性がある。規制目的のために動物試験の数を最 小限にすることが求められていることを考慮すると、動物試験以外の情報はWOE評価に使用できる適切な独立したエ ビデンスを提供することができる。

化学物質のヒト健康への影響から特定の化学物質へのばく露に伴うリスク、化学物質の混合物の毒性、毒性反応の バイオマーカーの関連性、あるいは新しい毒性試験法の評価まで、多くの毒性学的問題がシステマティックレビューの 対象となっている(Hoffmann ら、2017年)。例えば、以前の Scientific Opinion では、EFSA は AOP アプローチの 枠内で毒性学的メカニズムの決定にシステマティックレビューを使用した(Choi ら、2016 年: EFSA Scientific Committee、2017年c)。

有効成分の毒性データの他に、食事や飲料水を通じてヒトにばく露された場合には、代謝物や残留物についてもデ ータが必要となる場合がある。これらの研究から得られた結果は、食品消費やその他のばく露源から推定される予想さ れるとトばく露量との関連で検討される。このアプローチの長所は、動物の代謝経路が必ずしもとトの代謝経路と類似し ているとは限らないにもかかわらず、in vivo 試験では潜在的な毒性代謝物を考慮していることである。

実験動物を用いた実験研究は、交絡因子が排除されるように計画された研究であるが、疫学研究では必ずしもそうと は限らない。しかし、規制研究に使用される動物は、一般的には近親交配されて遺伝的に同一であり、制御された環 境のために、定量的及び定性的な化学物質感受性のすべての特性を欠いている。それにもかかわらず、ヒト疾患の動 物代替は、その科学的妥当性ととトへの外挿性が問われており、動物データととトの結果との間にしばしば見られる相 関性の欠如は、疾患経路や遺伝子発現プロフィルにおける疾患誘発性の変化における実質的な種間差に起因してい ると考えられている(Esch ら、2015年)。そのため、多くの実験モデルは複雑な多因子疾患を捉えていないため、動物 からヒトへの外挿はかなりの不確実性を伴うものとなっている。したがって、現在のリスク評価はその特性上、予測的なも のであり、化学物質に特化したものであり、ヒトは環境、食事、職業上の源からの多数の化学物質にばく露されているた め、あるいは異なる毒物動態の違いのために、十分ではないかもしれない。動物からとトへの外挿の不確実性を考慮し て、規制当局のリスク評価のアドバイスは、単に安全性が確認されている関連の Point of Departure (NOAEL、 EFSA Journal 2017:15(10):5007 www.efsa.europa.eu/efsajourna

been identified as safe but lowers these values using uncertainty factors (UFs) to propose safe reference dose values, either for acute or chronic toxicity.

Given the limitations of studies in laboratory animals, epidemiological studies in the 'real world' are needed, even if they have limitations of their own. Epidemiological studies incorporate the true (or estimated) range of population exposures, which usually are intermittent and at inconsistent doses instead of occurring at a consistent rate and dose magnitude (Nachman et al., 2011). Since epidemiological studies are based on real-world exposures, they provide insight into actual human exposures that can then be linked to diseases, avoiding the uncertainty associated with extrapolation across species. Hence, it can be said that they address the requirements of Regulation 1107/2009 Article 4, which stipulates that the risk assessment should be based on good plant protection practice and realistic use conditions. Thus, epidemiological studies assist problem formulation and hazard/risk characterisation whilst avoiding the need for high dose extrapolation (US-EPA, 2010).

Epidemiological studies therefore provide the opportunity to (a) identify links with specific human health outcomes that are difficult to detect in animal models; (b) affirmation of the human relevance of effects identified in animal models; (c) ability to evaluate health effects for which animal models are unavailable or limited (Raffaele et al., 2011). Epidemiological evidence will be considered over experimental animal evidence only when sufficiently robust pesticide epidemiological studies are available. However, in epidemiological studies, there are always a variety of factors that may affect the health outcome and confound the results. For example, when epidemiological data suggest that exposures to pesticide formulations are harmful they usually cannot identify what component may be responsible due to the complexity of accurately assessing human exposures to pesticides. While some co-formulants are not intrinsically toxic, they can be toxicologically relevant if they change the toxicokinetics of the active substance. In addition, confounding by unmeasured factor(s) associated with the exposure can never be fully excluded; however, a hypothetical confounder (yet unrecognised) may not be an actual confounder and has to be strongly associated with disease and exposure in order to have a meaningful effect on the risk (or effect size) estimate, which is not always the case.

Many diseases are known to be associated with multiple risk factors; however, a hazard-by-hazard approach is usually considered for evaluating the consequences of individual pesticide hazards on vulnerable systems (Figure 4A). Specifically, single-risk analysis allows a determination of the individual risk arising from one particular hazard and process occurring under specific conditions, while it does not provide an integrated assessment of multiple risks triggered by different environmental stressors (either natural or anthropogenic) (Figure 4B). Risk assessment would benefit by developing procedures for evaluating evidence for co-occurrence of multiple adverse outcomes (Nachman et al., 2011), which is more in line with what happens in human setting. For these reasons, if appropriately conducted, epidemiological studies can be highly relevant for the risk assessment process.

47

LOAEL、または BMDL)を考慮するのではなく、不確実性因子(UF)を用いてこれらの値を下げ、急性毒性または慢性毒性の安全な参照用量値を提案するものである。

実験動物を用いた研究の限界を考えると、たとえそれ自体に限界があるとしても、「実社会」での疫学研究が必要で ある。疫学的研究では、集団のばく露の真の範囲(または推定された範囲)を組み入れているが、これは通常、一貫し た速度と用量の大きさで発生するのではなく、断続的で一貫性のない用量で発生する(Nachman 6、2011 年)。疫学 的研究は実社会のばく露に基づいているため、実際のといのばく露についての予測を提供し、それを疾病に結びつけ ることができ、種を超えた外挿に関連する不確実性を回避することができる。したがって、リスク評価は、優れた植物保 護対策(Good Plant Protection Practice)と現実的な使用条件に基づいて行われるべきであると規定した規制 1107/2009 の第4条の要件に対応していると言える。このように、疫学的研究は、高用量外挿の必要性を回避しつつ、 問題の定式化とハザード/リスクの特性評価を支援する(US-EPA、2010 年)。

したがって、疫学的研究は、(a)動物モデルでは検出が困難な特定のといの健康影響との関連性を特定する。(b)動 物モデルで特定された影響のとトへの関連性を明らかにする(c)動物モデルが利用できない、または限定された、健康 影響を評価する能力を提供する(Raffaele ら、2011 年)。疫学的証拠は、十分に強固な農薬の疫学的研究が利用可 能な場合にのみ、動物実験によるエビデンスよりも考慮される。しかし、疫学研究では、健康影響に影響を与え、結果 を混乱させる様々な要因が常に存在する。例えば、疫学的データが農薬製剤へのばく露が有害であることを示唆して いても、通常、農薬へのとトばく露を正確に評価することの複雑さから、どの成分が原因であるかを特定することはでき ない。一部の製剤補助剤は本質的には毒性がないが、有効成分の毒物動態を変化させる場合には、毒性学的に関連 性がある可能性がある。さらに、ばく露に関連した測定されていない因子による交絡を完全に排除することはできない が、仮説的な交絡因子(まだ認識されていない)は実際の交絡因子ではない可能性があり、リスク(または効果量)の推 定値に意味のある影響を与えるためには、疾患やばく露と強く関連していなければならないが、必ずしもそうとは限らな い。

多くの病気は複数のリスク因子と関連していることが知られているが、脆弱なシステムに対する個々の農薬のハザードの影響を評価するためには、通常、ハザードごとのアプローチが考慮される(図 4A)。特に、単一リスク解析では、特定の条件下で発生する特定のハザードやプロセスに起因する個々のリスクを決定することができるが、異なる環境ストレス要因(自然現象または人為的要因のいずれか)によって引き起こされる複数のリスクを統合的に評価することはできない(図 4B)。リスク評価は、複数の有害な健康影響の同時発生のエビデンスを評価するための手順を開発することが有用である(Nachman 6、2011 年)が、これはよりとトの環境で起こることと一致している。これらの理由から、適切に実施されれば、疫学研究はリスク評価プロセスとの関連性が高い。

Classical single hazard approach: Α driven by regulatory frameworks

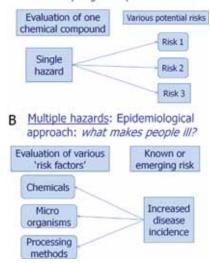

Figure 4: Role of epidemiological studies when compared to classical toxicological studies

In parallel with epidemiological data, vigilance data can provide an additional stream of evidence, especially for acute toxicity. Cases are usually well-documented and information can be used at different steps of the risk assessment; these include: level and duration of exposure, clinical course and assessment of the causal relationship. In severe cases, the toxin and/or the metabolites are usually measured in blood or urine which allows for comparison with animal data and in some cases for setting toxicological values.

In summary, experimental studies or epidemiological studies and vigilance data represent two different approaches to collect and assess evidence i.e. one emanating from controlled exposures (usually to a single substance) using experimental study design and a relatively homogeneous surrogate population, the other reflecting the changes observed in a heterogeneous target population from mixed (and varying) exposure conditions using non-experimental study design (ECETOC, 2009). Epidemiology and toxicology each bring important and different contributions to the identification of human hazards. This makes both streams of evidence complementary, and their combination represents a powerful approach. Animal studies should always inform the interpretation of epidemiological studies and vice versa; hence, they should not be studied and interpreted independently.

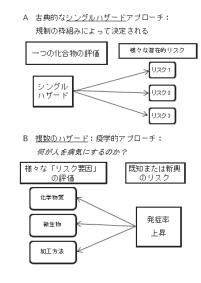

# 7.2. Principles for weighting of human observational and laboratory animal experimental data

Following the identification of reliable human (epidemiological or vigilance) studies and the assessment of the relevance of the pooled human studies, the separate lines of evidence that were found to be relevant need to be integrated with other lines of evidence that were equally found to be relevant.

The first consideration is thus how well the health outcome under consideration is covered by toxicological and epidemiological studies. When both animal and human studies are considered to be available for a given outcome/endpoint, this means that individual studies will first have been assessed for reliability and strength of evidence (Sections 6.2 and 6.3, respectively, for epidemiological studies)

48

www.efsa.europa.eu/efsajournal

#### 図 4:古典的な毒性学的研究と比較した場合の疫学的研究の役割

疫学的データと並行して、特に急性毒性については、警戒データが追加のエビデンスの流れを提供することができ る。通常、症例は十分に文書化されており、リスク評価のさまざまな段階で情報を利用することができる。これらの情報 には、ばく露のレベルと期間、臨床経過、因果関係の評価などが含まれる。重度のケースでは、毒素及び/または代 謝物が通常、血液または尿中で測定され、動物データとの比較が可能であり、場合によっては毒性値を設定することが できる。

要約すると、実験的研究、疫学的研究、及び警戒データは、エビデンスを収集し評価するための 2 つの異なるアプ ローチを表している。すなわち、実験的な研究計画と比較的均質な代理母集団を用いた(通常は単一物質に対する) 管理されたばく露から得られるものと、非実験的な研究デザインを用いた混合ばく露条件(及び変化する)から不均質 な対象集団で観察される変化を反映したものである(ECETOC、2009年)。疫学と毒物学は、それぞれがヒトへのハザ ードの特定に重要かつ異なる貢献をしている。このことは、両方のエビデンスの流れを補完的なものにしており、それら を組み合わせることで強力なアプローチが可能になる。動物実験は常に疫学的研究の解釈に情報を与えるものである べきであり、その逆もまた然りであるため、これらを独立して研究・解釈すべきではない。

# 7.2. ヒトの観察データと実験動物の実験データの重み付けの原則

信頼性の高いとト(疫学的または警戒研究)研究の特定し、プールされたとト研究の関連性の評価した後、関連性が あると判断された別個のエビデンスを、同様に関連性があると判断された他のエビデンスと統合する必要がある。

したがって、最初の検討事項は、検討対象の健康影響がどれだけ毒性学的及び疫学的研究でカバーされているか ということである。特定の健康影響/エンドポイントについて動物試験とヒト試験の両方が利用可能であると考えられる 場合、これは、様々なエビデンス源の重み付けに先立って、個々の試験が信頼性とエビデンスの強固さを評価されるこ とになる(疫学的研究については、それぞれ 6.2 項と 6.3 項)。異なるデータセットは補完的で確実なものであるが、個 別には不十分な場合があり、ヒトの健康リスクを適切に特定するための課題となる可能性がある。良好な観察データが EFSA Journal 2017:15(10):5007 www.efsa.europa.eu/efsajourna

prior to the weighting of the various sources of evidence. Although the different sets of data can be complementary and confirmatory, individually they may be insufficient and pose challenges for characterising properly human health risks. Where good observational data are lacking, experimental data have to be used. Conversely, when no experimental data is available, or the existing experimental data were found not to be relevant to humans, the risk assessment may have to rely on the available and adequate observational studies.

A framework is proposed for a systematic integration of data from multiple lines of evidence (in particular, human and experimental studies) for risk assessment (Figure 5). Such integration is based on a WoE analysis accounting for relevance, consistency and biological plausibility using modified Bradford Hill criteria (Table 3). For a comparative interpretation of human and animal data, this framework should rely on the following principles (adapted from ECETOC, 2009; Lavelle et al., 2012):

- Although the totality of evidence should be assessed, only the studies that are found to be reliable (those categorised as acceptable or supplementary evidence) are considered further. If the data from the human or the experimental studies is considered to be of low reliability (categorised as unacceptable), no risk assessment can be conducted.
- A WoE approach should be followed where several lines of evidence are found to be relevant. For pesticide active substances, experimental studies following OECD test guidelines are deemed high reliability unless there is evidence to the contrary. The strength of evidence from animal studies can be upgraded if there is high confidence in alternative pesticide toxicity testing or non-testing methods (e.g. *in vitro* and *in silico* studies, respectively). As for epidemiological evidence, the conduct of meta-analysis provides a more precise estimate of the magnitude of the effect than individual studies and also allows for examining variability across studies (see Section 6.3).
- Next, the studies that are found to be more relevant for the stage being assessed are to be given more weight, regardless of whether the data comes from human or animal studies. Where human data are of highest relevance, and supported by a mechanistic scientific foundation, they should take precedence for each stage of the risk assessment. When human and experimental data are of equal or similar relevance, it is important to assess their concordance (consistency across the lines of evidence) in order to determine whether and which data set may be given precedence.
- In case of concordance between human and experimental data, the risk assessment should use all the data as both yield similar results in either hazard identification (e.g. both indicate the same hazard) or hazard characterisation (e.g. both suggest similar safe dose levels). Thus, both can reinforce each other and similar mechanisms may be assumed in both cases.
- In case of non-concordance, the framework needs to account for this uncertainty. For hazard identification, the data suggesting the presence of a hazard should generally take precedence. For dose-response, the data resulting in the lower acceptable level should take precedence. In every situation of discordance, the reasons for this difference should be considered. If the reason is related to the underlying biological mechanisms, or toxicokinetic differences between humans and animal models, then confidence in the risk assessment will increase. Conversely, if the reason cannot be understood or explained, then the risk assessment may be less certain. In such cases, efforts should be made to develop a better understanding of the biological basis for the contradiction.

49

#### Epidemiological studies and pesticides

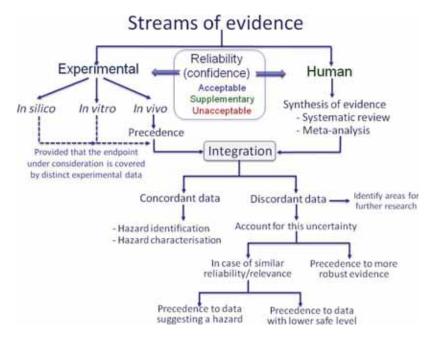

不足している場合は、実験データを使用しなければならない。逆に、実験データが利用できない場合や、既存の実験 データがとトに関連していないことが判明した場合には、リスク評価は利用可能で適切な観察による研究に頼らなけれ ばならないかもしれない。

リスク評価のために、複数のエビデンス(特にヒト研究と実験研究)から得られたデータを体系的に統合するためのフレームワークが提案されている(図 5)。このような統合は、修正された Bradford Hill 基準(表 3)を用いて、関連性、一 貫性、生物学的妥当性を考慮した WOE 解析に基づいている。ヒトと動物のデータを比較解釈するためには、この枠組 みは以下の原則に依存すべきである(ECETOC、2009 年; Lavelle ら、2012 年)。

- エビデンスの全体を評価すべきであるが、信頼性があると判断された研究(許容可能なエビデンスまたは補足的エ ビデンスに分類された研究)のみがさらに検討される。とト研究または実験研究から得られたデータの信頼性が低い(許容できないと分類される)と考えられる場合は、リスク評価を行うことはできない。
- ・複数のエビデンスが関連していることが判明した場合には、WOE アプローチに従うべきである。農薬有効成分については、OECDの試験ガイドラインに従った実験研究は、それに反するエビデンスがない限り、信頼性が高いとみなされる。動物実験からのエビデンスの強固さは、代替的な農薬毒性試験または非試験方法(例えば、それぞれ in vitro 試験と in silico 試験)に高い信頼性がある場合に向上させることができる。疫学的証拠については、メタアナリシスを実施することで、個々の研究よりも効果の大きさをより正確に推定でき、また、研究間のばらつきを調べることができる(第 6.3 節参照)。
- 次に、評価されるステージに関連性が高いと判断された研究は、データがヒトまたは動物の研究からのものである かどうかに関わらず、より重要視されるべきである。ヒトのデータが最も関連性が高く、作用機序的な科学的根拠に 支えられている場合には、リスク評価の各段階で優先されるべきである。ヒトデータと実験データの関連性が同等ま たは類似している場合には、どのデータセットが優先されるかを判断するために、それらのデータの一致性(エビ デンス系統間の一貫性)を評価することが重要である。
  - ーヒトデータと実験データが一致している場合、リスク評価では、ハザードの特定(例:両方とも同じハザードを示 す)またはハザードの特性評価(例:両方とも同じような安全用量を示唆する)のいずれにおいても類似した結 果が得られるため、すべてのデータを使用すべきである。このように、両者は互いに補強し合うことができ、両 方のケースで同様のメカニズムを想定することができる。
  - -不一致の場合、フレームワークはこの不確実性を考慮する必要がある。ハザードの特定については、一般的 にハザードの存在を示唆するデータが優先されるべきである。用量反応については、低い許容量のデータが 優先されるべきである。不一致が生じた場合には、この相違の理由を検討すべきである。その理由が基礎と なる生物学的メカニズム、またはヒトと動物モデル間の毒物動態学的差異に関連している場合は、リスク評価 の信頼性が高まる。逆に、その理由が理解できない、あるいは説明できない場合は、リスク評価の信頼性が 低下するかもしれない。このような場合には、生物学的エビデンスにおける矛盾に対する考察を行うべきであ る。

#### Figure 5: Methodology for the integration of human and animal data for risk assessment

Epidemiological studies provide complementary data to analyse risk and should be contextualised in conjunction with well-designed toxicological in vivo studies and mechanistic studies. The overall strength of the evidence achieved from integrating multiple lines of evidence will be at least as high as the highest evidence obtained for any single line. This integrated approach provides explicit guidance on how to weight and integrate toxicological and epidemiological evidence. This is a complex task that becomes even more difficult when epidemiological data deal with multifactorial, multihit, chronic diseases for which toxicological models, or disease-specific animal models, are limited.

#### Weighting all the different sources of evidence 7.3.

The WHO/IPCS defines the WoE approach as a process in which all of the evidence considered relevant for risk assessment is evaluated and weighted (WHO/IPCS, 2009). The WoE approach, taking the risk assessment of chemical substances as an example, requires the evaluation of distinct lines of evidence (in vivo, in vitro, in silico, population studies, modelled and measured exposure data, etc.). The challenge is to weight these types of evidence in a systematic, consistent and transparent way (SCENIHR, 2012). The weighting may be formally quantitative or rely on categorisation according to criterion referencing of risk.

An EFSA Working Group was established to provide transparent criteria for the use of the WoE approach for the evaluation of scientific data by EFSA's Panels and Scientific Committee (EFSA, 2015b). The aim of this Working Group was to provide support to stakeholders on how individual studies should be selected and weighted, how the findings integrated to reach the final conclusions and to identify uncertainties regarding the conclusions.

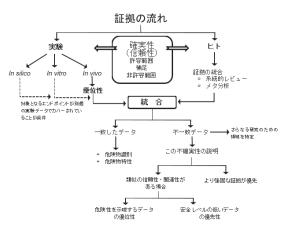

The WoE approach is not consistently considered in the risk assessment of pesticides in the peer review process of DAR or RAR. Expert judgement alone, without a structured WoE approach, has been more commonly used. A few examples can be found, such as the peer review of glyphosate (EFSA, 2015c), where the rapporteur Member State (RMS) considered all the data either from industry or

Epidemiological studies and pesticides

#### 図 5:リスク評価のためのヒトと動物のデータ統合の方法論

疫学研究はリスクを解析するための補完的なデータを提供するものであり、十分に計画された毒物学的 in vivo 研 究やメカニズム研究と併せて文脈を考慮する必要がある。複数のエビデンスを統合して得られたエビデンスの総合的な 強度は、少なくとも単一のエビデンスで得られた最高のエビデンスと同程度になる。この統合的アプローチは、毒性学 的証拠と疫学的証拠をどのように重み付けして統合するかについての明確な指針を提供するものである。これは複雑 な作業であり、疫学的データが多因子性、多発性、慢性の疾患を対象としている場合には、毒物学的モデルや疾患特 異的動物モデルが限られているため、さらに困難な作業となる。

# 7.3. 異なる起源のエビデンスの重み付け

WHO/IPCSは、WOEアプローチをリスク評価に関連すると考えられるすべてのエビデンスが評価され、重み付けさ れるプロセスと定義している(WHO/IPCS, 2009 年)。WOE アプローチは、化学物質のリスク評価を例にとると、異な る一連のエビデンス(in vivo, in vitro, in silico, 母集団研究、モデル化されたばく露データや測定されたばく露デー タなど)の評価を必要とする。課題は、体系的で一貫性がある明確な方法で、これらのタイプのエビデンスを重み付け することである(SCENIHR、2012 年)。重み付けは、形式的には定量的なものであってもよいし、リスクの基準を参照 した分類に依存するものであってもよい。

EFSA のパネルと科学技術委員会による科学技術データの評価に WOE アプローチを使用するための明確な基準 を提供するために EFSA ワーキンググループが設立された(EFSA、2015 年 b)。このワーキンググループの目的は、 個々の研究がどのように選択され、どのように重み付けされるべきか、結論に到達するためにどのように知見を統合し、 結論に関する不確実性をどのように特定するかについて、利害関係者に支援を提供することであった。

WOE アプローチは、DAR や RAR のピアレビュープロセスにおける農薬のリスク評価において一貫して考慮されて いない。構造化された WOE アプローチを用いずに専門家の判断だけで行うことがより一般的になっている。いくつか の例を挙げると、グリホサートのピアレビュー(EFSA、2015年 c)では、報告者である加盟国(RMS)は、疫学的データ を含む産業界または公的文献からのすべてのデータを考慮し、確立された事後基準と、探索された毒性の各エンドポ イントについて「全体的な」NOAELを提案するために利用可能なすべてのデータを考慮した特定のWOEアプローチ を採用している。

US-EPA は最近、「健康リスク評価にヒトの疫学的データと事象データを組み込むためのフレームワーク」に従って、 EFSA Journal 2017:15(10):5007 www.efsa.europa.eu/efsajourna 50

from public literature, including epidemiological data, and took a specific WoE approach with established *ad hoc* criteria and considering all data available for proposing an 'overall' NOAEL for each endpoint of toxicity explored.

The US-EPA has recently applied specific criteria for the WoE approach to the peer review of the pesticide chlorpyrifos by following the 'Framework for incorporating human epidemiologic & incident data in health risk assessment'. In this specific case, a WoE analysis has been conducted to integrate quantitative and qualitative findings across many lines of evidence including experimental toxicology studies, epidemiological studies and physiologically based pharmacokinetic and pharmacodynamic (PBPK-PD) modelling. Chlorpyrifos was also used as an example for the EFSA Guidance on literature search under Regulation (EC) No 1107/2009. In addition, an EFSA conclusion (EFSA, 2014a) took into consideration the US-EPA review (2011) to revise its first conclusion produced in 2011.

In sum, a broader WoE approach can be applied to evaluate the available scientific data using modified Bradford Hill criteria as an organisational tool to increase the likelihood of an underlying causal relationship (Table 3). Although epidemiology increasingly contributes to establishing causation, an important step to this end is the establishment of biological plausibility (US-EPA, 2010; Adami et al., 2011; Buonsante et al., 2014).

#### 7.4. Biological mechanisms underlying the outcomes

A biological mechanism describes the major steps leading to a health effect following interaction of a pesticide with its biological targets. The mechanism of toxicity is described as the major steps leading to an adverse health effect. An understanding of all steps leading to an effect is not necessary, but identification of the key events following chemical interaction is required to describe a mechanism (of toxicity in the case of an adverse health effect). While many epidemiological studies have shown associations between pesticide exposures and chronic diseases, complementary experimental research is needed to provide mechanistic support and biological plausibility to the human epidemiological observations. Experimental exposures should be relevant to the human population provided that the biologic mechanisms in laboratory animals occur in humans.

Establishing biological plausibility as part of the interpretation of epidemiological studies is relevant and should take advantage of modern technologies and approaches (Section 7.6). In this context, the AOP framework can be used as a tool for systematically organising and integrating complex information from different sources to investigate the biological mechanisms underlying toxic outcomes and to inform the causal nature of links observed in both experimental and observational studies (Section 7.5).

The use of data to inform specific underlying biological mechanisms or pathways of the potential toxic action of pesticides is limited since only selected pesticide chemicals have been investigated for biological function in relation to a specific health outcome. It may be possible to formulate a mode of action (MoA) hypothesis, particularly where there is concordance between results of comparable animal studies or when different chemicals show the same pattern of toxicity. It is essential to identify the toxicant and the target organ as well as the dose–response curve of the considered effect and its temporal relationship. If the different key events leading to toxicity and a MoA hypothesis can be identified, it is sometimes possible to evaluate the plausibility of these events to humans (ECETOC, 2009).

Sulfoxaflor is an example where MoA has been extensively studied and has been also widely used as an example during the ECHA/EFSA MOA/HRF workshop held in November 2014. Sulfoxaflor induced hepatic carcinogenicity in both rats and mice. Studies to determine the MoA for these liver tumours were performed in an integrated and prospective manner as part of the standard battery of toxicology studies such that the MoA data were available prior to, or by the time of, the completion of the carcinogenicity studies. The MoA data evaluated in a WoE approach indicated that the identified rodent liver tumour MoA for sulfoxaflor would not occur in humans. For this reason, sulfoxaflor is considered not to be a potential human liver carcinogen.

Furthermore, sometimes MoA data may indicate a lack of possible effects. If there are biological data that indicate an adverse effect is not likely to occur in humans, this should inform the interpretation of epidemiological studies. Nevertheless, while primary target site selectivity between pests and humans plays an important role in pesticides safety, secondary targets in mammals must also be considered.

In the case of exposure to multiple pesticides, the decision to combine risks can be taken if the pesticides share a common mechanism of toxicity (act on the same nolecular target at the same target tissue, act by the same biochemical mechanism of action, and share a common toxic intermediate) which may cause the same critical effect or just based on the observation that they share the same target organ (EFSA 2013a,b). However, cumulative risk assessment is beyond the scope of this Opinion.

#### Epidemiological studies and pesticides

農薬のクロルビリホスのピアレビューに WOE アプローチのための特定の基準を適用した。この特定のケースでは、実験的毒性研究、疫学研究、生理学的ベースの薬物動態・薬力学(PBPK-PD)モデリングを含む多くのエビデンスを横断して、定量的・定性的な知見を統合するために WOE 解析が実施された。クロルビリホスは、規則(EC)No 1107/2009に基づく文献検索に関する EFSA ガイダンスの例としても使用されている。さらに、EFSA の結論(EFSA、2014年a)は、2011年に出された最初の結論を修正するために US-EPA のレビュー(2011年)を考慮に入れている。

まとめると、根本的な因果関係の可能性を高めるための組織的なツールとして、修正された Bradford Hill 基準を使 用して、利用可能な科学的データを評価するために、より広範な WOE アプローチを適用することができる(表 3)。疫 学は因果関係の立証にますます貢献しているが、この目的のための重要なステップは、生物学的妥当性の立証である (US-EPA、2010年:Adami ら、2011:Buonsante ら、2014年)。

# 7.4. 健康影響の基礎となる生物学的メカニズム

生物学的メカニズムとは、農薬とその生物学的標的との相互作用に続く健康影響につながる主要なステップを記述 したものである。毒性のメカニズムは、健康への悪影響につながる主要なステップとして記述されている。影響につなが るすべてのステップを理解する必要はないが、化学的相互作用に続く重要なイベントを特定することは、メカニズム(健 康に悪影響を及ぼす場合の毒性)を記述するために必要である。多くの疫学研究で農薬ばく露と慢性疾患との関連性 が示されているが、ヒトの疫学的観察にメカニズム的な裏付けと生物学的な妥当性を与えるためには、補完的な実験研 究が必要である。実験でのばく露は、実験動物の生物学的メカニズムがヒトで発生することを条件に、ヒトの集団に関連 するものでなければならない。

疫学研究の解釈の一部として生物学的妥当性を確立することは重要であり、最新の技術とアプローチを活用すべき である(7.6 節)。この意味では、AOPの枠組みは、毒性結果の基礎となる生物学的メカニズムを調査し、実験研究と観 察による研究の両方で観察された関連性の因果関係を知るために、異なる情報源からの複雑な情報を体系的に整理 し、統合するためのツールとして利用できる(7.5 節)。

農薬の潜在的な毒性作用の基礎となる生物学的メカニズムや経路について特定の情報を提供するためのデータの 利用は、特定の健康影響に関連した生物学的機能について調査された農薬化学物質のみであるため、限られたもの である。特に、同等の動物実験の結果の間に一致点がある場合や、異なる化学物質が同じ毒性パターンを示す場合 には、作用機序(MOA)仮説を立てることが可能な場合がある。毒物と標的臓器を特定することは、考えられる影響の 用量反応曲線とその時間的関係と同様に不可欠である。毒性につながるさまざまな主要事象と MOA 仮説を特定でき れば、ヒトに対するこれらの事象の妥当性を評価することが可能になることもある(ECETOC、2009 年)。

農薬のスルホキサフロル (Sulfoxaflor)は、MOA が広範囲に研究されてきた例であり、2014 年 11 月に開催された ECHA/EFSA MOA/HRF ワークショップでも広く取り上げられている。スルホキサフロルはラットとマウスの両方で肝発 がん性を誘発した。これらの肝腫瘍に対する MOA を決定するための試験は、発がん性試験が終了する前または終了 するまでに MOA データが入手できるように、標準的な毒性試験のバッテリーの一部として、統合的かつ前向きな方法 で実施された。WOE アプローチで評価された MOA データは、スルホキサフロルの齧歯類での肝腫瘍の MOA がヒト では発生しないことを示している。この理由から、スルホキサフロルはヒトの潜在的な肝臓発がん性物質ではないと考え られている。

さらに、MOA データが影響の可能性がないことを示す場合もある。仮に、ヒトでは有害な影響が発生する可能性が ないことを示す生物学的データがある場合は、疫学研究の解釈に反映させる必要がある。それにもかかわらず、害虫と ヒトの間の一次標的部位選択性は農薬の安全性において重要な役割を果たしているが、哺乳類における二次標的も 考慮しなければならない。

複数の農薬にばく露した場合、リスクを組み合わせるかどうかの判断は、農薬が共通の毒性メカニズム(同じ標的組 織で同じ分子標的に作用し、同じ生化学的作用機序で作用し、共通の毒性中間体を共有する)を共有しており、同じ 重大影響を引き起こす可能性がある場合、あるいは単に同じ標的臓器を共有しているという観察に基づいて判断する ことができる(EFSA、2013 年 a,b)。しかし、累積リスク評価は本意見書の範囲を超えている。

#### 7.5. Adverse Outcome Pathways (AOPs)

The AOP methodology provides a framework to collect and evaluate relevant chemical, biological and toxicological information in such a way that is useful for risk assessment (OECD, 2013). An AOP may be defined as the sequence of key events following the interaction of a chemical with a biological target (molecular initiating event (MIE)) to the *in vivo* adverse outcome relevant to human health. All these key events are necessary elements of the MoA and should be empirically observable or constitute biologically based markers for such an event. An AOP is therefore a linear pathway from one MIE to one adverse outcome at a level of biological organisation relevant to risk assessment. The goal of an AOP is to provide a flexible framework to describe the cascade of key events that lead from a MIE to an adverse outcome in a causal linkage (EFSA PPR Panel, 2017). The 'key events' must be experimentally measurable and the final adverse effect is usually associated with an *in vivo* OECD Test Guideline. However, in some cases the adverse outcome may be at a level of biological organisation below that of the apical endpoint described in a test guideline (OECD, 2013).

A particular MIE may lead to several final adverse effects and, conversely, several MIEs may converge in the same final adverse effect. However, each AOP will have only one MIE and one final adverse effect, but may involve an unlimited number of intermediate steps (Vinken, 2013). It should be noted that key events at different levels of biological organisation provide a greater WoE than multiple events at the same level of organisation (OECD, 2013).

The essential biochemical steps involved in a toxic response are identified and retrieved from an indepth survey of relevant scientific literature or from experimental studies. Any type of information can be incorporated into an AOP, including structural data, 'omics-based' data and *in vitro*, *in vivo* or *in silico* data. However, *in vivo* data are preferred over *in vitro* data and endpoints of interest are preferred to surrogate endpoints (Vinken, 2013). The AOPs identified must not be incompatible with normal biological processes, since they need to be biologically plausible.

Qualitative AOPs (intended as an AOP including the assembly and evaluation of the supporting WoE following the OECD guidance for AOP development) should be the starting and standard approach in the process of integration of epidemiology studies into risk assessment by supporting (or identifying the lack of support for) the biological plausibility of the link between exposure to pesticides affecting the pathway and the adverse outcome. Accordingly, qualitative AOPs may be developed solely for the purpose of hazard identification, to support biological plausibility of epidemiological studies based on mechanistic knowledge (EFSA PPR Panel, 2017).

The AOP framework is a flexible and transparent tool for the review, organisation and interpretation of complex information gathered from different sources. This approach has the additional advantage of qualitatively characterising the uncertainty associated with any inference of causality and identifying whether additional mechanistic studies or epidemiological research would be more effective in reducing uncertainty. The AOP framework is therefore a useful tool for risk assessment to explore whether an adverse outcome is biologically plausible or not. For the purpose of analysing the biological plausibility, AOPs can serve as an important tool, particularly when the regulatory animal toxicological studies are useful tool for relevant biomarkers) observed in epidemiological studies is considered inadequate based on the AOP. By means of mechanistically describing apical endpoints, the AOP contributes to the hazard identification and characterisation steps in risk assessment. As the AOP framework is chemically agnostic, if complemented by the MoA and/or Integrated Approach on Testing and Assessment (IATA) framework, it will support the chemical specific risk assessment (EFSA PPR Panel, 2017).

AOP and MoA data can be used to assess the findings of epidemiological studies to weight their conclusions. Whether those findings are inconsistent with deep understanding of biological mechanisms, or simply empirical, they should be given less weight than other findings that are consistent with AOP or MoA frameworks once established. However, there are relatively few examples of well-documented AOPs and a full AOP/MoA framework is not a requirement for using epidemiological studies in risk assessment.

AOPs are thus a critical element to facilitate moving towards a mechanistic-based risk assessment instead of the current testing paradigm relying heavily on apical effects observed in animal studies. Shifting the risk assessment paradigm towards mechanistic understanding would reduce limitations of the animal data in predicting human health effects for a single pesticide, and also support the current efforts being made on cumulative risk assessment of pesticide exposure (EFSA PPR Panel, 2017).

Epidemiological studies and pesticides

# 7.5. 有害転帰経路(AOPs)

AOP の解析法は、リスク評価に有用な方法で、関連する化学的、生物学的、毒物学的な情報を収集し、評価するた めの枠組みを提供している(OECD、2013年)。AOPは、化学物質と生物学的標的との相互作用(標的分子への作用 (Molecular initiating event:MIE))から、とトの健康に関連する in vivo での有害な事象に至るまでの一連の重要 事象として定義することができる。これらの重要事象はすべて MOA の必要な要素であり、経験的に観察可能であるか、 またはそのような事象の生物学的ベースのマーカーを構成するものでなければならない。したがって、AOP は、リスク 評価に関連する生物学的組織のレベルで、1 つの MIE から 1 つの有害な事象に至る直線的な経路である。AOP の 目的は、因果関係の連鎖において、1 つの MIE から 1 つの有害な事象へとつながる重要事象の段階を記述するため の、柔軟なフレームワークを提供することである(EFSA PPR パネル、2017年)。重要な事象は実験的に測定可能で なければならず、有害な事象は通常、in vivo での OECD 試験ガイドラインに関連している。しかし、場合によっては、 有害な事象が試験ガイドラインに記載されている先端エンドポイントよりも低いレベルの生物学的組織のレベルにあるこ ともある(OECD、2013年)。

特定の MIE はいくつかの毒性影響につながる可能性があり、逆に、複数の MIE は同じ毒性影響に収束する可能 性がある。しかし、各 AOP は 1 つの MIE と 1 つの毒性影響象のみであるが、無制限の数の中間ステップを伴うことも ある(Vinken、2013 年)。生物学的組織の異なるレベルでの重要事象は、同じレベルの組織での複数の事象よりも大 きな WOE をもたらすことに留意すべきである(OECD、2013 年)。

毒性反応に関与する重要な生化学的ステップは、関連する科学文献の詳細な調査や実験研究から同定され、検索 される。構造データ、「オミクスベース」データ、in vitro、in vivo、あるいは in silico のデータなど、あらゆるタイプの情 報を AOP に組み込むことができる。しかし、in vitro データよりも in vivo データの方が優先され、対象となるエンドポ イントは代替エンドポイントよりも優先される(Vinken、2013 年)。特定された AOP は、生物学的に妥当性をもつ必要 があるため、正常な生物学的プロセスと両立しないものであってはならない。

定性的 AOP (AOP 開発のための OECD ガイダンスに従った WOE の組み立てと評価を含む AOP として意図され ている) は、経路に悪影響を与える農薬へのばく露と有害な影響との間の関連性の生物学的妥当性を裏付ける(また は裏付けがないことを特定する)ことによって、疫学研究をリスク評価に統合するプロセスの出発点であり、標準的なア プローチであるべきである。したがって、定性的な AOP は、メカニズム的知見に基づく疫学研究の生物学的妥当性を 裏付けるために、ハザード同定の目的のためだけに開発される可能性がある(EFSA PPR パネル、2017 年)。

AOP フレームワークは、異なる情報源から収集された複雑な情報のレビュー、整理、解釈を行うための柔軟で透明 性の高いツールである。このアプローチには、因果関係の推論に関連する不確実性を定性的に特徴づけ、不確実性 を低減するためには、追加のメカニズム的研究や疫学研究がより効果的であるかどうかを特定するという付加的な利点 がある。したがって、AOP フレームワークは、有害な影響が生物学的にもっともらしいかどうかを探るためのリスク評価に 有用なツールである。生物学的に妥当性を解析する目的では、AOP は重要なツールとなり得る。特に、規制上の動物 を用いた毒性試験が陰性であっても、疫学研究で観察された先端エンドポイント(または関連するバイオマーカー)の 評価が AOP に基づいて不十分であると考えられる場合には、AOP は重要なツールとなり得る。先端エンドポイントをメ カニズム的に記述することにより、AOP はリスク評価におけるハザードの特定と特性評価のステップに貢献する。AOP フレームワークは化学的には不明確な点があるため、MOA 及び/または試験・評価に関する統合的アプローチ (IATA)フレームワークで補完されれば化学物質特有のリスク評価をサポートすることになる(EFSA PPR パネル、 2017 年)。

AOPとMOAのデータは、疫学研究の結果を評価し、その結論に重み付けをするために使用できる。それらの結論 が生物学的メカニズムの深い理解と矛盾するものであろうと、あるいは単に経験的なものであろうと、一度確立された AOPや MOAの枠組みと一致する他の結論よりも、それらの結論の重要性は低く設定されるべきである。しかし、十分 に文書化された AOP の例は比較的少なく、完全な AOP/MOA の枠組みはリスク評価に疫学的研究を用いるための 要件ではない。

したがって、AOP は、動物実験で観察された末端の影響(apical effects)に大きく依存する現在の試験パラダイム

EFSA Journal 2017;15(10):5007

# 7.6. Novel tools for identifying biological pathways and mechanisms underlying toxicity

The elucidation of toxicity pathways brings the opportunity of identifying novel biomarkers of early biological perturbations in the toxicodynamic progression towards overt disease, particularly from advances in biomonitoring, in -omics technologies and systems biology (toxicology). The revolution of omics in epidemiology holds the promise of novel biomarkers of early effect and offers an opportunity to investigate mechanisms, biochemical pathways and causality of associations.

The growing recognition of the value of biomonitoring data in epidemiological investigations may help to reduce misclassification by providing objective measures of exposure and outcome. As long as biomarker data for exposure, outcome and susceptibility are increasingly generated, epidemiology will have a greater impact in the understanding of toxicodynamic progression as a function of pesticide exposure and eventually in risk assessment. A challenge for risk assessors will be to acknowledge where subtle and early changes along the toxicodynamic pathway are indicative of increased potential for downstream effects (Nachman et al., 2011). Omics data can be used for gaining insight to the MoA by identifying pathways affected by pesticides and as such can assist hazard identification, the first step in risk assessment.

Transcriptomic, metabolomic, epigenomic and proteomic profiles of biological samples provide a detailed picture, sometimes at individual molecule resolution, of the evolving state of cells under the influence of environmental chemicals, thus revealing early mechanistic links with potential health effects. Nowadays, the challenges and benefits that advances in -omics techniques can bring to regulatory toxicology are still being explored (Marx-Stoelting et al., 2015). Clear rules for assessing the specificity of these biomarkers are necessary.

Those -omic applications most relevant and advanced in the context of toxicology are analysis of MoA and the derivations of AOP, and biomarker identification, all of which potentially assist epidemiology too. For example, (a) transcriptomics: comparing gene expression (mRNA) profiles can be used for biomarker discovery, grouping expressed genes into functional groups (Gene Ontology categories) or for Gene Set Analysis. Such techniques may provide varying information regarding biological mechanisms. (b) Proteomics: studying the protein profile of samples, with sophisticated analysis of protein quantity and post-translational modifications which may be associated with changes in biological pathways following exposure and possible disease development, utilising informatics and protein databases for identification and quantification. (c) Metabolomics uses nuclear magnetic resonance spectroscopy or mass-spectrometry based techniques to produce data which are analysed via software, and databases, to identify markers (molecular signatures and pathways) that correlate with exposure or disease. (d) The use of the exposome (the totality of exposures received by an individual during life) might be better defined by using -omics technologies and biomarkers appropriate for human biomonitoring. Nevertheless, important limitations stemming from the lack of validation of these methodologies and their cost limit their use at large scale.

The application of -omics technologies to environmental health research requires special consideration to study design, validation, replications, temporal variance and meta-data analysis (Vlaanderen et al., 2010). For larger studies, intra-individual variability in the molecular profiles measured in biological samples should show less variability than the interindividual variation in profiles of gene expression, protein levels or metabolites, which are highly variable over time. It is important that these inter-individual variations should not be larger than variation related to exposure changes, but it is not certain if this will be true.

The biologically meaningful omics signatures identified by performing omics-exposure and omicshealth association studies provide useful data for advanced risk assessment. This approach supports moving away from apical toxicity endpoints towards earlier key events in the toxicity pathway resulting from chemical-induced perturbation of molecular/cellular responses (NRC, 2007).

#### 7.7. New data opportunities in epidemiology

The current technological landscape permits the digitisation and storage of unprecedented amount of data from many sources, including smart phones, text messages, credit card purchases, online activity, electronic medical records, global positioning system (GPS) and supermarket purchasing data. While some of these data sources may provide valuable information for risk assessment, many of them contain personal information that can outpace legal frameworks and arise questions about the ethics of its use for scientific or regulatory purposes. A specific example is constituted by data containing

53

el usa muni

#### Epidemiological studies and pesticides

ではなく、メカニズムに基づくリスク評価への移行を促進するための重要な要素である。リスク評価のパラダイムをメカニ ズム的な理解へと移行させることで、単一の農薬のヒトへの健康影響を予測する上での動物データの限界を下げること になり、また、農薬ばく露の累積リスク評価に関する現在の取り組みを支援することにもなる(EFSA PPR パネル、2017 年)。

#### 7.6. 毒性の基礎となる生物学的経路とメカニズムを特定するための新しいツール

毒性経路の解明は、特にバイオモニタリング、オミクス技術、システムバイオロジー(毒性学)の進歩から、顕在化した 疾患への毒性力学的進行における初期の生物学的摂動の新規バイオマーカーを特定する機会をもたらしている。疫 学におけるオミクスの革命は、早期効果の新しいバイオマーカーの可能性を秘めており、関連のメカニズム、生化学的 経路、因果関係を調査する機会を提供している。

疫学調査におけるバイオモニタリングデータの価値が認識されつつあることは、ばく露と転帰の客観的な尺度を提供 することで、誤分類を減らすのに役立つかもしれない。ばく露、転帰、感受性に関するバイオマーカーデータが増加し ている限り、疫学は農薬ばく露の関数としての毒性力学的進行の理解と最終的にはリスク評価に大きな影響を与えるこ とになるであろう。リスク評価者にとっての課題は、毒性力学的経路に沿った軽微で初期の変化が、下流への影響の可 能性の増大を示唆していることを認識することである(Nachman ら、2011 年)。オミクスデータは、農薬の影響を受ける 経路を特定することで MOA への理解を深め、リスク評価の第一段階であるハザードの特定を支援することができる。

生物学的サンプルのトランスクリプトーム(Transcriptomic,)、メタボローム(metabolomic)、エピゲノム (epigenomic)、プロテオミクス(proteomic)のプロファイリングは、環境化学物質の影響下での細胞の進化状態の詳 細な画像を、時には個々の分子レベルで提供し潜在的な健康影響との早期のメカニズム的な関連性を明らかにするこ とができる。今日では、オミクス技術の進歩が規制毒性学にもたらす課題と長所については、まだ研究が進められてい る(Marx-Stoelting ら、2015 年)。これらのバイオマーカーの特異性を評価するための明確なルールが必要である。

毒物学の文脈において、最も有用であり進歩しているオミクス技術は、MOAの解析とAOPの誘導、バイオマーカー の同定であり、これらはすべて疫学にも役立つ可能性がある。例えば、(a)トランスクリプトミクス:遺伝子発現(mRNA) プロファイルの比較は、バイオマーカーの発見、発現遺伝子の機能グループ(Gene Ontology カテゴリー)へのグルー プ化、または遺伝子セット分析に使用することができる。これらの手法により、生物学的メカニズムに関する様々な情報 が得られる可能性がある。(b)プロテオミクス:試料のタンパク質プロファイリングを調べ、タンパク質の量や転写後の修 飾を高度に分析し、ばく露後の生物学的経路の変化や疾患の発症に関連している可能性がある。(c)メタボロミクスは、 核磁気共鳴分光法や質量分析法をベースにした技術を用いてデータを作成し、ソフトウェアやデータベースを介して 分析することで、ばく露や疾患と相関のあるマーカー(分子シグネチャーや経路)を特定するものである。(d)エクスポソ ーム(個人が生活の中で受けたばく露の総量)の利用は、ヒトのバイオモニタリングに適したオミクス技術とバイオマーカ ーを使用することで、より良い結果を得ることができるかもしれない。それにもかかわらず、これらの方法論の検証不足と そのコストの問題から、大規模な使用には限界がある。

オミクス技術を環境衛生研究に応用するには、研究デザイン、バリデーション、再現性、時間的分散、メタデータ分析 に特別な配慮が必要である(Vlaanderen ら、2010年)。大規模な研究では、生体サンプルで測定された分子プロファ イルの個人内変動は、時間の経過とともに大きく変動する遺伝子発現、タンパク質レベル、または代謝物のプロファイ ルの個人間変動よりも少ない変動を示す。これらの個人間変動がばく露変化に関連した変動よりも大きくならないことが 重要であるが、これが実現するかどうかは定かではない。

生物学的に意味のあるオミクスのシグネチャーは、オミクスーばく露及びオミクスー健康の関連性の研究を行うことに よって同定され、高度なリスク評価に有用なデータを提供する。このアプローチは、末端の毒性エンドポイントから、化 学物質によって誘発された分子/細胞応答の摂動に起因する毒性経路の初期の主要イベントへと移行することを支 持するものである(NRC、2007年)。

# 7.7. 疫学における新たなデータの機会

現在の技術的状況では、スマートフォン、テキストメッセージ、クレジットカードでの購入、オンラインでの行動、電子カ

www.efsa.europa.eu/efsajourna

personal information related to health, which are considered sensitive or especially protected, such as electronic medical records, information from occupational or environmental questionnaires, geographic location, health or social security number, etc. These various forms of health information are being easily created, stored and accessed. Big data provide researchers with the ability to match or link records across a number of data sources. Linking of big data sources of health and heritable information offers great promise for understanding disease predictors (Salerno et al., 2017); however, there are challenges in using current methods to process, analyse and interpret the data systematically and efficiently or to find relevant signals in potential oceans of noise, as noted by the Board on Environmental Studies and Toxicology of the National Academies of Sciences, Engineering, and Medicine in its 2017 report.<sup>18</sup>

In addition, medico-administrative data, such as drug reimbursements drawn from National Health Insurance or hospital discharge databases, can be cross-linked with data on agricultural activities drawn from agricultural census or geographical mapping. It is acknowledged that in several instances this information can be obtained at group level only, and an important challenge will be to obtain data at individual level and/or on individual habits.

Biobanks also constitute new data sources from healthy or diseased populations. They consist of an organised collection of human biological specimens and associated information stored for diverse research purposes. These biosamples are available for application of novel technologies with potential for generating data valuable for exposure assessment or exposure reconstruction. If studies' design and conduct are harmonised, data and samples can be shared between biobanks to promote powerful pooled analyses and replications studies (Burton et al., 2010).

Large scale epidemiological studies with deep phenotyping provide also unprecedented opportunities to link well phenotyped study participants with the aforementioned data. For example, UK Biobank, has recruited over 500,000 individuals with questionnaire, medical history and physical measurements data as well as stored blood and urine samples with available genome wide association data for all 500,000 participants, and linkage to Hospital Episode Statistics, national registry data and primary care records. To gain information on air pollution and noise levels, the postcode of participants has been linked to air pollution or noise estimates. In addition, piloting of personal exposure monitoring will take place in order to collect individual level data on these exposures. These approaches could be extended to gain information on pesticide exposure, either through geographical linkage, linkage with purchasing and occupational registries, and personal exposure monitoring. Similar biobanks exist in many other EU countries (http://www.bbmri-eric.eu/BBMRI-ERIC has collected most EU studies).

#### 8. Overall recommendations

#### 8.1. Recommendations for single epidemiological studies:

The following recommendations for improving epidemiological studies are aimed to conform to the 'recognised standards' mentioned in Regulation (EU) No 1107/2009 to make them of particular value to risk assessment of pesticides ('where available, and supported with data on levels and duration of exposure, and conducted in accordance with recognised standards, epidemiological studies are of particular value and must be submitted'). Accordingly, these recommendations can indeed not be considered as a practical guidance for researchers on how to conduct such studies, but for those who are planning to conduct a study for further use in pesticide risk assessment.

#### a) Study design (including confounding)

- Since prospective epidemiological designs provide stronger evidence for causal inference, these studies are encouraged over the other designs for pesticide risk assessment.
- 2) Future epidemiological studies should be conducted using the appropriate sample size in order to properly answer the question under investigation. A power analysis should thus be performed at the study design stage.
- Future studies should take into consideration heterogeneity, subpopulations, exposure windows and susceptibility periods and conditions (pregnancy, development, diseases, etc.).

54

el usa muni

#### Epidemiological studies and pesticides

ルテ、全地球測位システム(GPS)、スーパーマーケットの購買データなど、多くの情報源からの前例のない量のデータ のデジタル化と保存が可能になっている。これらのデータ源の中には、リスク評価のための貴重な情報を提供するもの もあるが、それらの多くには法的枠組みを超えて、科学的または規制上の目的のために使用することの倫理性につい て疑問が生じることもある。具体的な例としては、電子カルテ、職業や環境に関するアンケート、地理的な位置、健康や 社会保障番号など、機密性が高い、または特に保護されていると考えられる健康に関連する個人情報を含むデータが 挙げられる。これらの様々な形態の健康情報が容易に作成、保存、アクセスされている。ビッグデータは、研究者に多く のデータ源をまたいで記録を照合したり、リンクしたりする能力を提供する。健康情報と遺伝性情報のビッグデータ源の リンクは、病気の予測因子を理解するための大きな可能性を期待されている(Salerno 6、2017 年)。しかし、現在の方 法を用いてデータを体系的かつ効率的に処理、解析、解釈すること、あるいは大量データの中から関連するシグナル を特定することには課題がある(全米科学・工学・医学の環境研究・毒物学委員会が 2017 年の報告書で指摘している) <sup>18</sup>。

さらに、国民健康保険や退院データベースから抽出された薬剤費などの医療行政データは、農業人口調査や地理 的マッピングから抽出された農業活動に関するデータと相互にリンクさせることができる。このような情報が集団レベル でしか得られない場合もあることは認識されているが、個人レベル及び/または個人の習慣に関するデータを得ること が重要な課題である。

バイオバンクはまた、健康な集団や病気にかかった集団からの新たなデータ源を構成するものである。バイオバンク は、多様な研究目的のために保存されているとトの生物学的標本と関連情報の整理されたコレクションで構成されてい る。これらのバイオサンプルは、ばく露評価やばく露の再構成に有用なデータを生成する可能性のある新技術の応用 に利用可能である。研究の計画と実施が調和されていれば、データとサンプルはバイオバンク間で共有され、強力な 蓄積分析や反復研究を促進することができる(Burton 6、2010 年)。

深い表現型(deep phenotyping)を用いた大規模な疫学研究は、優れた表現型を持つ研究参加者と前述のデータ を結びつける前例のない機会を提供する。例えば、英国のバイオバンクでは、アンケート、病歴、身体測定データだけ でなく、50 万人以上の参加者全員のゲノムワイドな関連データを持つ血液と尿のサンプルを保存し、病院の事例統計、 国の登録データ、プライマリーケアの記録とリンクさせている。大気汚染や騒音レベルに関する情報を得るために、参 加者の郵便番号を大気汚染や騒音の推定値にリンクさせている。さらに、これらのばく露に関する個人レベルのデータ を収集するために、個人ばく露モニタリングの試験的実施が行われる予定である。これらのアプローチは、地理的リンク、 購買・職業登録とのリンク、個人のばく露モニタリングのいずれかを通じて、農薬ばく露に関する情報を得るために拡張 される可能性がある。同様のバイオバンクは、他の多くの EU 諸国にも存在する(http://www.bbmri-eric.eu/BBMRI-ERIC は、ほとんどの EU の研究を収集している)。

# 8. 全体的な推奨事項

# 8.1. 単一の疫学的研究に関する勧告

疫学的研究を改善するための以下の勧告は、規制(EU)No 1107/2009 で言及されている「認知された基準」に準拠し、農薬のリスク評価に特に価値のあるものとすることを目的としている(「利用可能で、ばく露レベルとばく露期間に関するデータを裏付けとし、認識された基準に従って実施された場合、疫学的研究は特に価値があり、提出しなければならない」としている)。したがって、これらの勧告は、このような研究をどのように実施するかについての研究者のための実践的な指針としてではなく、農薬リスク評価にさらに活用するための研究を計画している研究者のためのものと考えることができる。

#### a)研究デザイン(交絡を含む)

 前向き疫学的デザインは因果関係推論のためのより強力なエビデンスを提供するので、農薬リスク評価のための 他の計画よりもこれらの研究が奨励される。

- e usa muni
- 4) A wide range of potential confounding variables (including co-exposure to other chemicals, lifestyle, socioeconomic factors, etc.) should be measured or accounted for during the design stage (e.g. matching) of the study.
- 5) Consideration of host factors that may influence toxicity and act as effect modifiers. These will include genetic polymorphisms data (e.g. paraoxonase-1 genotype) or nutritional factors (e.g. iodine status) among others.
- 6) Collaboration between researchers is encouraged to build-up consortia that enhance the effectiveness of individual cohorts.

Collection and appropriately storage of relevant biological material should be undertaken for future exposure assessment, including the use of novel technologies.

# b) **Exposure** (measurement, data transformation for reporting and statistical analysis):

- 1) Collection of specific information on exposure should avoid as far as possible broad definitions of exposure, non-specific pesticide descriptions and broad exposures classifications such as 'never' vs. 'ever' categories. Nevertheless, these categories may be valuable under certain circumstances, e.g. to anticipate a class effect.
- 2) Studies which only look at broad classes of pesticides (generic groups of unrelated substances), or 'insecticides', 'herbicides', etc. or even just 'pesticides' in general are of much less use (if any) for risk assessment. Studies that investigate specific named pesticides and co-formulants are more useful for risk assessment.
- 3) Pesticides belonging to the same chemical class or eliciting the same mode of toxic action or toxicological effects might be grouped in the same category. Further refinement with information on frequency, duration and intensity of exposure might help in estimating exposure patterns.
- 4) In occupational epidemiology studies, operator and worker behaviour and proper use of PPE should be adequately reported as these exposure modifiers may significantly change exposures and thereby potential associations.
- 5) Improving the accuracy of exposure measurement is increasingly important, particularly for cohort studies. Long-term cohort studies which cover the etiologically relevant time period should improve the accuracy of measures of exposures by use of repeated biologic measures or repeated updates of self-reported exposures.
- 6) Indirect measures of environmental exposure for wider populations, including records on pesticide use, registry data, GIS, geographical mapping, etc., as well as data derived from large databases (including administrative databases) may be valuable for exploratory studies. If these data are not available, records/registries should be initiated. Likewise, estimation of dietary exposure to pesticide from food consumption databases and levels of pesticide residues from monitoring programmes can be used as well. As with direct exposure assessment, each method of indirect measurement should be reviewed for risk of bias and misclassification and weighted appropriately.
- 7) Whenever possible, exposure assessment should use direct measurements of exposure to named pesticides in order to establish different levels of exposure (e.g. personal exposure metering/biological monitoring), possibly in conjunction with other methods of exposure assessment which are more practicable or even necessary for large studies and historical exposures. New studies should explore novel ways of personal exposure monitoring. Results should be expressed using standardised units to normalise exposure across populations
- 8) The characterisation of exposure assessment over time can benefit by undertaken a more comprehensive exposure monitoring strategy coupled with information on exposure determinants over a longer time period collected from questionnaires or job-exposure matrices supported by biomonitoring data. Exposure assessment models can be comprehensively supported by HBM studies, which would allow identification of the critical exposure parameters. If such case, adjustments can then be made to the parameter assumptions within the models, leading to more realistic evaluations of exposure.
- 9) The use of the exposome concept and metabolomics in particular hold great promise for next-generation epidemiological studies both for better exposure measurement (biomarkers of exposure), for identification of vulnerable subpopulations and for biological interpretation of toxicity pathways (biomarkers of disease).

- 2) 今後の疫学研究は、調査対象の課題に適切に答えるために、適切な標本数を用いて実施されるべきである。その ためには、研究デザインの段階で検出力解析を行う必要がある。
- 3)今後の研究では、異質性、小集団、ばく露方法、感受性の時期や条件(妊娠、発育、疾患など)を考慮する必要 がある。
- 4)幅広い潜在的交絡変数(他の化学物質への共ばく露、ライフスタイル、社会経済的要因など)を研究の計画段階 (例:マッチング)で測定または考慮すべきである。
- 5) 毒性に影響を与え、効果を調節する宿主因子を考慮する。これらには、遺伝的多型データ(例:パラオキソナーゼ -1遺伝子型)や栄養因子(例:ヨウ素の状態)などが含まれる。
- 6)研究者間の共同研究は、個々のコホートの有効性を高めるコンソーシアムを構築するために奨励される。
- 将来のばく露評価のために、新規技術の利用を含め、関連する生物学的試料の収集と適切な保管を行うべきである。 b) ばく露(測定、報告のためのデータ変換、統計解析)
- 1) ばく露に関する特定の情報の収集は、可能な限り、ばく露の広範な定義、非特定の農薬の記述及び「一度もない」 対「今までにあり」のような広範なばく露の分類を避けるべきである。それにもかかわらず、これらのカテゴリーは、 特定の状況下では、例えばクラス効果を予測するために価値があるかもしれない。
- 2) 農薬の幅広いクラス(無関係な物質の一般的なグループ)、または「殺虫剤」、「除草剤」など、あるいは一般的な 「農薬」だけを対象とした研究は、リスク評価にはあまり役に立たない(あるとすれば)。特定の名前のついた農薬や 共調合製剤を調査した研究の方がリスク評価には有用である。
- 3)同じ化学クラスに属する農薬、または同じ毒性作用モードや毒性学的効果をもたらす農薬は、同じカテゴリーにグ ループ化されている可能性がある。ばく露の頻度、持続時間、ばく露の強度などの情報を追加することで、ばく露 パターンの推定に役立てることができるかもしれない。
- 4)職域疫学研究では、作業者や労働者の行動や PPE の適切な使用は、これらのばく露修飾がばく露を大幅に変 化させ、それによって潜在的な関連性を変化させる可能性があるため、適切に報告されなければならない。
- 5) ばく露測定の精度を向上させることは、特にコホート研究において、ますます重要になってきている。病因学的に 関連する期間をカバーする長期のコホート研究では、繰り返しの生物学的測定や自己報告されたばく露の繰り返 しの更新を使用することにより、ばく露の測定の精度を向上させるべきである。
- 6) 農薬の使用記録、登録データ、GIS、地理的マッピングなどを含むより広い集団の環境ばく露の間接的な尺度及 び大規模なデータベース(行政データベースを含む)から得られたデータは、探索的研究には貴重であるかもしれ ない。これらのデータが利用できない場合は、記録・登録を開始すべきである。同様に、食品消費データベースか らの農薬への食事ばく露の推定や、モニタリングプログラムからの残留農薬レベルの推定も利用できる。直接的な ばく露評価と同様に、間接測定の各方法は、偏りや誤分類のリスクを検討し、適切な重み付けを行うべきである。
- 7) 可能な限り、ばく露評価は、異なるばく露レベルを確立するために、指定された農薬へのばく露の直接測定を使 用すべきである(例えば、個人的なばく露測定/生物学的モニタリング)。新しい研究では、個人ばく露モニタリン グの新しい方法を探求すべきである。結果は、集団間のばく露を標準化するために、標準化された単位を用いて 表現されるべきである。
- 8)長期にわたるばく露評価の特性評価は、より包括的なばく露モニタリング戦略を実施し、アンケートやバイオモニタ リングデータに裏付けられた作業ばく露マトリックスから収集された長期にわたるばく露決定要因に関する情報と 相まって、利益を得ることができる。ばく露評価モデルは、重要なばく露パラメータを特定することを可能にする HBM の研究によって包括的にサポートされることができる。そのような場合には、モデル内のパラメータの仮定を 調整することで、より現実的なばく露の評価につなげることができる。
- 9) エクスポソームの概念とメタボロミクスの使用は、特に、より良いばく露測定(ばく露のバイオマーカー)、脆弱な小 集団の特定、毒性経路の生物学的解釈(疾患のバイオマーカー)のための次世代の疫学研究に大きな可能性を 秘めている。
- 10) 農薬混合物へのばく露(及び毒性)に関する知識の向上は、包括的なリスク評価に有益である。共通の標的に作 EFSA Journal 2017:15(10):5007 www.efsa.europa.eu/efsajourna 55

www.efsa.europa.eu/efsajournal

10) Improved knowledge on exposure (and toxicity) to pesticide mixtures will be beneficial for comprehensive risk assessment. Consideration of the joint action of combined exposures to multiple pesticides acting on common targets, or eliciting similar adverse effects, is relevant for cumulative risk assessment. This requires all the components of the mixture to be known as well as an understanding of the MoA, dose-response characteristics and potential interactions between components. Characterisation of the exposure is a key element for combined exposure to multiple pesticides where the pattern and magnitude of exposure changes over time.

#### c) Adverse Outcomes (measurement, data transformation for reporting and statistical analysis):

- Self-reported health outcomes should be avoided or confirmed by independent, blinded assessment of disease status by a medical expert assigned to the study.
- 2) Outcomes under study should be well defined and surrogate endpoints should be avoided unless they have been validated. Care must be taken when definitions of diseases and subclasses of diseases change over time (cancer, neurodegenerative disorders, etc.).
- 3) Use should be made of biological markers of early biological effect to improve the understanding of the pathogenesis of diseases. These quantitative biological parameters from mechanistic toxicology will enhance the usefulness of epidemiology because they improve the study sensitivity, reduce misclassification and enhance human relevance as compared to findings from studies in experimental animals. Since these refined endpoints are early events in the toxicodynamic pathway and often measured on a continuous scale, they might be preferable to more overt and traditional outcomes.
- 4) The use of biomarkers of effect may be helpful in assessing aggregate exposure to pesticides and informing cumulative risk assessment.
- Developing read across methods allowing health outcomes to be identified using epidemiological studies and to link acute and chronic incidents records with experimental findings.

#### d) Statistical (descriptive statistics, modelling of exposure-effect relationship):

- Statistical analysis should be based on *a priori* defined analytical (statistical) protocols, to avoid post hoc analyses for exploratory studies and report all the results, regardless of whether they are statistically significant or not.
- 2) Data should be reported in such a way that permit, where appropriate, mathematical modelling to estimate individual/population exposures and dose-response assessment irrespective of whether direct or indirect measures are used.
- Reports should include both unadjusted and adjusted proportions and rates of outcome of interest across studies that are based on underlying populations with different structure of relevant factors and exposures.
- 4) Possible relevant factors, and their role in the exposure-health outcome relationship, should be carefully identified, accurately measured and thoroughly assessed. Most often, relevant factors have been screened as potential confounders. When confounding effects were detected, these needed to be adjusted for using appropriate statistical methods that include sensitivity analysis.
- 5) Potentially useful analytical approaches, such as propensity score matching, mediation analyses, and causal inference are encouraged to be applied in pesticide epidemiology.
- 6) When the association between a given pesticide exposure and a disease is found to be statistically significant, particularly in (presumed) low powered studies, it would be general good practice to perform a power analysis/design calculation to determine the degree to which the statistically significant effect size estimate (e.g. OR or RR) may be artificially inflated or magnified.<sup>19</sup>

56

#### Epidemiological studies and pesticides

用する複数の農薬への複合ばく露の共同作用を考慮すること、または類似の有害作用を誘発することは、累積リ スク評価に関連している。そのためには、混合物の全成分を把握し、MOA、用量反応特性、成分間の潜在的な 相互作用を理解しておく必要がある。ばく露の特性を把握することは、ばく露のパターンや大きさが時間の経過と ともに変化する複数の農薬への複合ばく露において重要な要素である。

c) 有害な健康影響(測定、報告のためのデータ変換、統計解析)。

- 1)自己申告による健康上の影響は、研究に指定された医療専門家による病状の独立した盲検評価により、回避する か、または結論を出すべきである。
- 2)研究の対象となる健康影響は十分に定義されているべきであり、妥当性が確認されている場合を除き、代替エンドポイントは避けるべきである。疾患や疾患のサブクラスの定義が時間の経過とともに変化する場合には注意が必要である(がん、神経変性疾患など)。
- 3)早期の生物学的効果を示す生物学的マーカーを利用して、疾患の病態の理解を深めるべきである。これらの定量 的な生物学的パラメータは、実験動物を用いた研究から得られた結果と比較して、研究の感度を向上させ、誤分 類を減らし、ヒトへの関連性を高めることができるため、疫学の有用性を高めることができる。これらの再定義された エンドポイントは、毒性力学的経路における初期のイベントであり、連続的なスケールで測定されることが多いため、 よりあからさまな従来の健康影響よりも好ましいかもしれない。
- 4) 効果のバイオマーカーの使用は、農薬への総体的ばく露を評価し、累積的なリスク評価に役立てることができるか もしれない。
- 5)健康影響を疫学研究を用いて特定し、急性・慢性の事故記録と実験結果を結びつけることを可能にするリードアク ロス手法(read across methods)を開発する。
- d)統計(記述的統計、ばく露と影響の関係のモデル化)。
- 1)統計解析は、事前に定められた解析(統計)プロトコールに基づき、探索的研究のための事後的な解析を避け、統計的に有意であるかどうかにかかわらず、すべての結果を報告すべきである。
- 2)データは、適切な場合には、直接または間接的な測定法が使用されているかどうかにかかわらず、個人/集団のばく露と用量反応評価を推定するための数学的モデル化を可能にするような方法で報告されなければならない。
- 3)報告書には、関連因子やばく露の構造が異なる基礎となる集団に基づいた研究において、未調整と調整の両方の割合と、対象となる結果の割合と率を含めるべきである。
- 4)考えられる関連因子及びばく露と健康転帰の関係におけるそれらの役割は、慎重に同定され、正確に測定され、 徹底的に評価されるべきである。ほとんどの場合、関連因子は潜在的な交絡因子としてスクリーニングされている。 交絡因子が検出された場合には、感度分析を含む適切な統計的手法を用いて、交絡因子を調整する必要がある。
- 5) プロペンシティスコアマッチング (propensity score matching)、メディエーション解析 (mediation analyses)、因 果推論などの潜在的に有用な解析手法を農薬疫学に適用することが奨励されている。
- 6)対象とした農薬ばく露と疾患との間の関連が統計的に有意であることが判明した場合、特に(推定される)検出力の低い研究では、統計的に有意な効果の大きさの推定値(例えば、オッズ比 OR または相対リスク RR)が人為的に増大するか、または拡大するかの程度を決定するために、検出力解析/設計計算を実行することが一般的に良い対応とされている<sup>19</sup>。

<sup>&</sup>lt;sup>19</sup> Additional information on power and sample size recommendations and related issues including effect size magnification and design calculations are provided in Annex D to this report. Specifically, a power calculation requires 3 values to be clearly reported by epidemiological studies: (i) the number of subjects in the non-exposed group (including individuals with and without the disease of interest); (iii) the number of subjects in the non-exposed group.

www.efsa.europa.eu/efsajournal

<sup>&</sup>lt;sup>19</sup>検出力とサンプルサイズの推奨事項及び効果量の算出とデザインの計算を含む関連問題に関する追加情報は、本報告書の附属書 D に記載されている。特に、検出力の計算では、疫学研究で明確に報告されるべき3つの値が必要である。(i)非ばく露群の被験者数(対象となる疾患の有無を含む)、(iii)ばく露群の被験者数(対象となる疾患の有無を含む)、(iii)非ばく露群の福患者数。

#### e) Reporting of results:

- 1) These should follow practices of good reporting of epidemiological research outlined in the STROBE statement and in the EFSA guideline on statistical reporting (EFSA, 2014b) and include the further suggestions identified in this Opinion including effect size inflation estimates.
- 2) Although some epidemiological research will remain exploratory and post hoc in nature, this should be acknowledged and supported by appropriate statistical analysis.
- 3) Epidemiological studies are encouraged to provide access to raw data for further investigations and to deposit their full results and scripts or software packages used for analyses.
- 4) Report, or deposit using online sources, all results along with scripts and statistical tools used to allow the reproducibility of results to be tested.
- 5) Report all sources of funding and adequately report financial and other potential conflicts of interest.

As a general recommendation, the PPR Panel encourages development of guidance for epidemiological research in order to increase its value, transparency and accountability for risk assessment.<sup>20</sup> An increased quality of epidemiological studies, together with responsible research conduct and scientific integrity, will benefit the incorporation of these studies into risk assessment.

#### 8.2. Surveillance

- 1) Increase the reporting of acute and chronic incidents by setting up post-marketing surveillance programmes (occupational and general population) as required by article 7 of EU directive 2009/128; this should be fulfilled by developing surveillance networks with occupational health physicians and by boosting the collaboration between national authorities dealing with PPP and poison control information centres.
- 2) Develop a valid method for assessing the weight/strength of the causal relationship ('imputability') for acute and chronic incidents, and develop glossaries and a thesaurus to support harmonised reporting between EU member states.
- 3) Harmonised data from member states should be gathered at the EU level and examined periodically by the Commission/EFSA and a report should be released focussing on the most relevant findings.
- 4) Develop an EU-wide vigilance framework for pesticides.
- 5) There is scope for training improvements regarding pesticide toxidromes in toxicology courses for medical and paramedical staff responsible for diagnostic decisions, data entry and management.
- 8.3. Meta-analysis of multiple epidemiological studies
  - 1) Evidence from epidemiological studies might be pooled by taking into account a thorough evaluation of the methods and biases of individual studies, an assessment of the degree of heterogeneity among studies, development of explanations underlying any heterogeneity and a quantitative summary of the evidence (provided that it is consistent).
  - 2) For every evidence synthesis effort, studies should be reviewed using relevant risk of bias tools. Studies with different designs, or with different design features, may require (some) different questions for risk of bias assessments.
  - 3) Evidence syntheses should not be restricted to specific time frames; they should include the totality of evidence. These efforts are more relevant if focused on specific health outcome or disease categories.
  - 4) In evidence synthesis efforts, beyond the quantitative synthesis of the effect sizes, there should be consideration on the calculated predictive intervals, small study effects and asymmetry bias, conflicts of interest, confounding, excess significance bias,<sup>21</sup> and heterogeneity estimates.

#### Epidemiological studies and pesticides

#### e)結果の報告

- 1)結果報告は、STROBE 声明及び統計報告に関する EFSA ガイドライン (EFSA, 2014 年 b) に概説されている疫 学研究の良好な報告の慣行に従うべきであり、効果量の推定値を含む本意見書で指摘されている更なる提案を 含むべきである。
- 2)いくつかの疫学研究は探索的で事後的な特性を持つものもあるがが、そのことを認識し、適切な統計解析によっ て裏付けられるべきである。
- 3) 疫学研究は、さらなる調査のために生データへのアクセスを提供し、その全結果と解析に使用したスクリプトやソフ トウェアパッケージを提供することが奨励されている。
- 4)結果の再現性を検証するために使用したスクリプトや統計ツールとともに、すべての結果を報告するか、またはオ ンライン源を利用して寄託する。
- 5) すべての資金源を報告し、財務上の問題やその他の潜在的な利害関係者を適切に報告する。

一般的な勧告として、PPR パネルは、リスク評価における疫学研究の価値、透明性、説明責任を高めるために、疫 学研究のためのガイダンスの開発を奨励している20。 疫学研究の質の向上は、責任ある研究の実施と科学的誠実さと ともに、リスク評価にこれらの研究を組み入れることに利益をもたらすであろう。

# 8.2. サーベイランス

- 1) EU 指令 2009/128 の第7 条で要求されている市販後サーベイランスプログラム(産業用及び一般集団)を設定 することにより、急性及び慢性の事故の報告を増加させる。これは、産業保健医とのサーベイランスネットワークを 構築し、PPPを扱う国の当局と毒物管理情報センターとの連携を強化することにより達成すべきである。
- 2) 急性・慢性事故の因果関係の程度/強度(「推定可能性」)を評価するための有効な方法を開発し、EU 加盟国 間の整合化された報告を支援するための用語集と類義語集を開発する。
- 3) EU 加盟国からの整合化されたデータを EU レベルで収集し、欧州委員会/EFSA が定期的に検討し、最も関 連性の高い結果に焦点を当てた報告書を発表すべきである。
- 4) 農薬に関する EU 全体の警戒体制を構築する。
- 5)診断決定、データ入力、管理を担当する医療・救急スタッフのための毒物学コースにおいて、農薬のトキシドロー ムに関する研修を改善する余地がある。

# 8.3. 複数の疫学研究のメタアナリシス

- 1) 個々の研究の方法とバイアスの徹底的な評価、研究間の異質性の程度の評価、異質性の根底にある説明の展開、 エビデンスの定量的な要約(一貫性があれば)を考慮に入れて、疫学研究からのエビデンスを蓄積することができ る。
- 2) すべてのエビデンス統合作業において、関連するバイアスのリスクツールを用いて研究をレビューすべきである。 計画が異なる研究や計画の特徴が異なる研究では、バイアスのリスク評価のために(いくつかの)異なる課題が必 要になるかもしれない。
- 3) エビデンス統合は、特定の期間に限定されるべきではなく、エビデンス全体を含めるべきである。これらの努力は、 特定の健康影響または疾患カテゴリーに焦点を当てれば、より適切である。
- 4) エビデンス統合の取り組みでは、効果量の定量的な統合に加えて、計算された予測間隔、小試験効果と非対称 性バイアス、対象となる対角線、交絡、過剰な有意性バイアス21及び不均一性の推定値についても考慮すべきで ある。

<sup>&</sup>lt;sup>20</sup> An example is the guideline developed by the Dutch Society for Epidemiology on responsible epidemiologic Research Practice (2017).

<sup>&</sup>lt;sup>21</sup> Excess significance bias refers to the situation in which there are too many studies with statistically significant results in the published literature on a particular outcome. This pattern suggests strong biases in the literature, with publication bias, selective outcome reporting, selective analyses reporting, or fabricated data being possible explanations (Ioannidis and Trikalinos, 2007).

<sup>20</sup> 例として、オランダ疫学協会が責任ある疫学的研究実践に関するガイドラインを作成した(2017年)

<sup>21</sup> 過剰シグニフィカンスバイアスとは、特定のアウトカムに関する公表されている文献の中に、統計的に有意な結果が得られた研究が多すぎる状況 を指す。このパターンは、出版バイアスを伴う文献の強いバイアスを示唆している。 選択的な結果報告、選択的な分析報告、または捏造されたデータが説明の対象となる可能性がある(Ioannidis and Trikalinos、2007年)。

EFSA Journal 2017:15(10):5007 www.efsa.europa.eu/efsajourna 57

- 5) In the presence of heterogeneity, studies with highly selected populations, albeit unrepresentative of their respective populations, may prove valuable and deserve consideration as they may represent genuine and not statistical heterogeneity.
- 6) A more consistent reporting such as for age, race and gender across studies would enhance the meta-analyses.
- 7) Where quantitative data of individual pesticides are available from epidemiological studies, they can be combined or pooled for dose–response modelling, which could enable development of quantitative risk estimates and points of departure (BMDL, NOAEL).
- International consortium of cohort studies should be encouraged to support data pooling to study disease-exposure associations that individual cohorts do not have sufficient statistical power to study (e.g. AGRICOH).
- 8.4. Integration of epidemiological evidence with other sources of information
  - 1) All lines of evidence (epidemiology, animal, *in vitro* data) should be equally scrutinised for biases.
  - Validated and harmonised methods should be developed to combine observational studies, animal/basic science studies and other sources of evidence for risk assessment.
  - Experimental and human data should both contribute to hazard identification and to doseresponse assessment.
  - 4) A systematic integration of data from multiple lines of evidence should be based on a WoE analysis accounting for relevance, consistency and biological plausibility using modified Bradford Hill criteria. The principles underlying this framework are described in Section 7.2 and summarised in Figure 5.
  - 5) Epidemiological findings should be integrated with other sources of information (data from experimental toxicology, mechanism of action/AOP) by using a WoE approach. An integrated and harmonised approach should be developed by bringing together animal, mechanistic and human data in an overall WoE framework in a systematic and consistent manner.
  - 6) The AOP framework offers a structured platform for the integration of various kinds of research results.
  - 7) Animal, *in vitro* data and human data should be assessed as a whole for each endpoint. A conclusion can be drawn as to whether the results from the experiments are confirmed by human data for each endpoint and this could be included in the RARs.

# 9. Conclusions

This Scientific Opinion is intended to help the peer review process during the renewal of pesticides authorisation (and, where possible, during the approval process) under Regulation 1107/2009 which requires a search of the scientific peer-reviewed open literature, including existing epidemiological studies. These are more suitable for the renewal process of active substances, also in compliance with Regulation 1141/2010, which indicates that the dossiers submitted for renewal should include new data relevant to the active substance.

The four key elements of the terms of reference are repeated below and the parts of the text addressing the individual terms are identified in order. As they follow from the text passages grouped with each of the ToRs the recommendations relevant to each of the ToRs are also indicated as follows.

'The PPR Panel will discuss the associations between pesticide exposure and human health effects observed in the External scientific report (Ntzani et al., 2013) and how these findings could be interpreted in a regulatory pesticide risk assessment context. Hence, the PPR Panel will systematically assess the epidemiological studies collected in the report by addressing major data gaps and limitations of the studies and provide recommendations thereof'.

'The PPR Panel will specifically':

- Collect and review all sources of gaps and limitations, based on (but not necessarily limited to) those identified in the External Scientific report in regard to the quality and relevance of the available epidemiological studies. Responses in Section 3 pp. 20–24, Section 5.2 pp. 33–35: no Recommendations appropriate.
- Based on the gaps and limitations identified in point 1, propose potential refinements for future epidemiological studies to increase the quality, relevance and reliability of the findings

#### Epidemiological studies and pesticides

- 5) 不均質性が存在する場合、高度に選択された母集団を用いた研究は、それぞれの母集団を代表するものではないが、統計的な不均質性ではなく真の不均質性を示すものである可能性があるため、価値があることが証明され、 検討に値する。
- 6)年齢、人種、性別など、研究間での一貫性のある報告があれば、メタアナリシスがより充実すると思われる。
- 7)個々の農薬の定量的データが疫学研究から得られる場合には、それらのデータを組み合わせたり、プールして用 量反応モデリングを行うことで、定量的なリスク推定値や Point of Departure (BMDL、NOAEL)の開発が可能 となる。
- 8)個々のコホートでは十分な統計的力がない疾病ばく露関連を研究するために、コホート研究の国際的なコンソーシアムがデータプールを支援するよう奨励されるべきである(例:AGRICOH)。

# 8.4. 疫学的証拠と他の情報源との統合

すべてのエビデンス(疫学、動物、試験管内データ)は、バイアスがなく、平等に精査されるべきである。
 リスク評価のために、観察による研究、動物/基礎科学研究、その他のエビデンス源を組み合わせるために、有効かつ調和のとれた方法を開発すべきである。

- 3)実験データとヒトデータの両方が、ハザードの特定と用量反応評価に寄与するべきである。
- 4)複数のエビデンスから得られたデータを体系的に統合することは、Bradford Hill 基準を修正したものを用いて、 関連性、一貫性、生物学的妥当性を考慮した WOE 解析に基づくべきである。この枠組みの基礎となる原則は 7.2 節に記載され、図5 に要約されている。
- 5) WOE アプローチを用いて、疫学的知見を他の情報源(実験毒性学からのデータ、作用機序/AOP)と統合すべ きである。統合された調和のとれたアプローチは、体系的かつ一貫した方法で WOE の全体的な枠組みの中で動 物、メカニズム、ヒトのデータをまとめることによって開発されなければならない。
- 6) AOP フレームワークは、様々な種類の研究成果を統合するための構造化されたプラットフォームを提供する。
- 7)動物データ、in vitro データ、ヒトデータは、それぞれのエンドポイントについて全体として評価されるべきである。 実験から得られた結果が各エンドポイントのヒトのデータと一致しているかどうかの結論を導き出すことができ、これ を RARs に含めることができる。

# 9. 結論

本意見書は、既存の疫学研究を含む科学的に査読された公表文献の検索を要求する規制 1107/2009 の下で、農 薬の認可更新時(可能であれば認可プロセス時)の査読プロセスを支援することを目的としている。これらは有効成分 の更新プロセスに適しており、更新のために提出される書類には有効成分に関連する新しいデータを含める必要があ ることを示す規則 1141/2010 にも準拠している。

以下では、参照条件の4つの重要な要素を繰り返し、個々の用語に対応する部分を順番に示している。それぞれの ToRs でグループ化された文章から導かれるように、それぞれのToR に関連する推奨事項も以下のように示す。

「PPR パネルは、外部科学報告書 (Ntzani ら、2013 年)で観察された農薬ばく露とたの健康影響との関連性と、こ れらの知見が規制上の農薬リスク評価の文脈でどのように解釈され得るかを検討する。したがって、PPR パネルは、報 告書で収集された疫学研究を体系的に評価し、研究の主要なデータギャップと限界に対処し、その提言を行う」。 PPR パネルは特に以下を行う。

- 1)利用可能な疫学研究の質と妥当性に関して外部科学報告書で明らかにされたものに基づいて(必ずしもこれに限 定されないが)ギャップと限界のすべての情報源を収集し、レビューする。セクション 3、20-24 頁、セクション 5.2 33-35頁:勧告は適切ではない。
- 2)ポイント1で明らかになったギャップと限界に基づき、調査結果の質、妥当性、信頼性を向上させ、それが農薬リスク評価にどのように影響を与えるかについて、将来の疫学的研究のための潜在的な改善点を提案する。これには、研究デザイン、ばく露評価、データの質とアクセス、健康影響の診断分類、統計解析が含まれる。(セクション 4の

www.efsa.europa.eu/efsajourna

and how they may impact pesticide risk assessment. This may include study design, exposure assessment, data quality and access, diagnostic classification of health outcomes, and statistical analysis. Responses in Section 4 pp 24–33: recommendations in Sections 8.1, 8.2 and 8.3 pp. 54–58.

- 3) Identify areas in which information and/or criteria are insufficient or lacking and propose recommendations for how to conduct pesticide epidemiological studies in order to improve and optimise the application in risk assessment. These recommendations should include harmonisation of exposure assessment (including use of biomonitoring data), vulnerable population sub-groups and/or health outcomes of interest (at biochemical, functional, morphological and clinical level) based on the gaps and limitations identified in point 1. Responses in Sections 4.2–4.5 pp. 27–33, Section 5.3 pp. 36: recommendations in Section 8.1 c) 1–4, pp. 56.
- 4) Discuss how to make appropriate use of epidemiological findings in risk assessment of pesticides during the peer review process of draft assessment reports, e.g. WoE as well as integrating the epidemiological information with data from experimental toxicology, AOPs, mechanism of actions, etc. Responses in Sections 6.2 and 6.3 pp. 37–45 and 7 pp. 45–54: Responses in Section 8.4 pp. 58.

As explained above, appropriate epidemiological data and post-approval surveillance may usefully contribute to the risk assessment framework by hazard identification, and – with methodological improvements – hazard characterisation. It can be improved by contributions from WoE analysis, Uncertainty analysis, and identification and estimation of biases. It is the responsibility of applicants to collect the available relevant literature, to consider its relevance and quality using relevant EFSA criteria including those for systematic review and to introduce discussion of the outcomes within the DAR, RAR and post-approval frameworks that are prescribed under EU law.

The definition of appropriate quality will require analysis of sample size, statistical procedures, estimates of effect size inflation, assessment of biases and their contribution to the conclusions drawn.

The nature of the studies will require consideration at all relevant points in the risk assessment process so that for example epidemiological data on reproductive topics will be considered alongside laboratory animal studies designed to reveal reproductive effects and in the context of recommendation for labelling for reproductive toxicity (for ECHA).

Unless there is history of use in countries outside the EU, the relevant epidemiological studies will be restricted in their effect on the DAR but the RAR and Surveillance framework is potentially able to benefit from epidemiology progressively as time after first approval passes and from prior use of Active Ingredients in other jurisdictions. It is recommended that RAR and surveillance protocols should reflect this difference.

The specific recommendations listed above follow from detailed arguments based on an analysis of present and foreseen **s**trengths **w**eaknesses **o**pportunities and **th**reats related to the use of epidemiological data in risk assessment. Broadly these are as follows:

#### Strengths. Include:

- The fact that the evidence concerns human specific risks.
- That health outcomes are integrated measures of the effects of all exposure to toxins.
- The ability to elicit subjective experience from potentially affected people.

#### Weaknesses. Include:

- The exposures to pesticides are usually complex; contribution of a specific active ingredient is not easily deciphered.
- · The exposures occur in various settings where precisely controlled conditions are lacking.
- Most data reflect the responses of mixed populations.
- Many data show low level associations that are inconsistently repeatable and require sophisticated analysis.

**Opportunities**. Despite the range of limitations described in this Opinion, which apply to many available published epidemiological studies, there are opportunities to benefit risk assessment of pesticides. These include:

59

 The access to very large numbers of potentially exposed individuals for studies that may reveal subtle health effects and reveal the experience of sensitive sub-groups.

CI USA INVI

回答 24-33 頁: セクション 8.1、8.2 及び 8.3 の推奨事項 54-58 頁。54-58)

3)情報及び/または基準が不十分または不足している分野を特定し、リスク評価における適用を改善し最適化する ために、農薬疫学的研究をどのように実施するかについての提言を行う。これらの推奨事項には、第1項で特定 されたギャップと限界に基づいて、ばく露評価(バイオモニタリングデータの使用を含む)、脆弱な集団のサブグル

ープ及び/または対象となる健康影響(生化学的、機能的、形態学的、臨床的レベルでの)の調和を含むべきで ある。(セクション 4.2-4.5 の回答 27-33 頁、セクション 5.3 36 頁:セクション 8.1 c) 1-4、56 頁の推奨事項)

4) WOE などの評価報告書草案のピアレビュープロセスにおいて、疫学的情報を実験毒性学、AOP、作用機序などのデータと統合しながら、農薬のリスク評価に疫学的知見を適切に活用する方法について議論する。(6.2 及び)

6.3節の回答 37-45 頁、7節 45-54 頁:8.4節の回答 58頁)

上記で説明したように、適切な疫学的データと承認後のサーベイランスは、ハザードの特定や、方法論の改善により ハザードの特徴を明らかにすることで、リスク評価の枠組みに有用に貢献することができる。WOE 解析、不確実性分析、 バイアスの同定と推定により改善することができる。利用可能な関連文献を収集し、システマティックレビューを含む関 連する EFSA 基準を用いてその妥当性と質を検討し、EU 法で規定されている DAR、RAR、承認後の枠組みの中で 結果の議論を導入することは申請者の責任である。

適切な品質の定義には、サンプルサイズの解析、統計的手続き、効果の大きさの推定値の浮動、バイアスの評価、 導き出された結論への寄与が必要である。研究の特性は、リスク評価プロセスのすべての関連ポイントで考慮する必要 があり、例えば、生殖に関する疫学的データは、生殖影響を明らかにするために計画された実験動物研究と一緒に考 慮され、生殖毒性(ECHAの場合)のための表示勧告の背景で考慮される。

EU 域外の国での使用実績がない限り、関連する疫学的研究は、DAR への影響が制限されるが、RAR とサーベイ ランスの枠組みは、最初の承認後の時間が経つにつれて、また他の法域での原薬の先行使用がある場合には、段階 的に疫学から恩恵を受けることができる可能性がある。RAR とサーベイランスのプロトコールはこの違いを反映させるこ とが推奨される。

上記の提言は、リスク評価における疫学的データの利用に関連した現在及び将来の強み・弱み・機会・脅威の解析 に基づく詳細な論拠に基づくものである。大まかには以下の通りである。

# 強み:

- ・その証拠は人間の特定のリスクに関するものであること。
- ・健康影響は、毒素へのすべてのばく露の影響を総合的に測定するものであること。
- 影響を受ける可能性のある人々から主観的な経験を引き出すことができること。

#### 弱み:

- ・農薬へのばく露は通常複雑である;特定の有効成分の寄与は容易に解読されない。
- ・ばく露は、正確に管理された条件が不足している様々な設定で発生する。
- ほとんどのデータは混合集団の反応を再現している。
- 多くのデータは低レベルの関連性を示しており、再現性がなく、高度な解析を必要とする。

機会:本意見書に記載されている限界は、公表されている多くの疫学研究に適用されるが、農薬のリスク評価に利益 をもたらす機会がある。これには以下が含まれる。

- ・軽微な健康影響を明らかにし、敏感な小集団の経験を明らかにする可能性のある研究のために、非常に多くの潜 在的にばく露された個人にアクセスできること。
- 潜在的な毒素とその残留物の組織負荷を確立するためのバイオモニタリングと新しい分子アプローチを用いたば く露推定の改善の見通し。
- 実験動物の反応に基づく従来のリスク評価にとトのデータを完全に統合する可能性。
- WOE, AOP, Expert judgement, Expert Knowledge Elicitation(EEKE)及び Uncertainty Analysis を利 用して、潜在的に関連性のあるデータの質の違いを評価する。
- ・専門の疫学者や統計学者と協力して、疫学的結果の解釈を再検討し、慢性ばく露リスクや複合ばく露リスク、用量 www.efsa.europa.eu/efsajourna
   EFSA Journal 2017;15(10):5007

- The prospect of improving exposure estimation using biomonitoring and new molecular approaches to establish tissue burdens of potential toxins and their residues.
- The possibility of fully integrating human data into the conventional risk assessment based on responses in laboratory animals.
- Utilising WoE, AOP, Expert judgement, Expert Knowledge Elicitation (EKE) and Uncertainty Analysis to evaluate differences in the quality of potentially relevant data.
- The opportunity to engage professional epidemiologists and statisticians to refine interpretation
  of epidemiological findings and to recommend improved designs to tackle difficult areas such
  as chronic and combined exposure risks and dose–response data.
- A major information technology opportunity exists in pooling data from a variety of national sources. Once the relevant legal, methodological and ethical issues are overcome much more valuable data can be collected. When this data is made available, in a form that can be used in a 'big data' setting for societal benefit there will be potential for significant improvements in epidemiological studies. First, however, it will be necessary to preserve individual privacy and essential commercial confidentiality. Once these obstacles are overcome the statistical power of epidemiological studies can be improved and applied to identify and possibly characterise hazards better. These aims can be realised effectively by agreed actions at a high EU level. Interstate approval for providing data and interactive platforms will need to be backed by harmonisation of population health information, food consumption data, active substance and co-formulant spatial and temporal application data. Such rich data can be expected to assist in increasing consistency, a criterion that strengthens evidence of causality and reliability. It promises larger sample sizes for epidemiological studies that will be better able to identify vulnerable groups that may require special protection from pesticide toxicity.

#### Threats. Include:

- Widespread perception of risk levels to the human population or to wildlife and the environment that are unrealistic and that cause negative consequences in societies.
- Poor experimental design yielding false positive or false negative conclusions that undermine data from other valid sources.
- Failure to respond to emerging risks as a result of ineffective surveillance or unwillingness to make appropriate anonymised data available for societal benefit.
- Waste of data through failure to collect appropriate information regarding exposure (specifically occupational exposure) by registries (cancer or congenital anomalies) or surveillance programmes which hinders linking health outcomes to exposure.
- Waste of data through failure to harmonise diagnostic criteria, failure to record data in a sufficiently detailed combinable form for integrated analysis, poor training of medical and paramedical staff in relevant toxidromes that will allow optimum quality of data entered into Health Statistics Databases.

#### Epidemiological studies and pesticides

反応データなどの困難な分野に取り組むための改善案を提案する機会がある。

・様々な国の情報源からのデータを蓄積することには、大きな情報技術の機会が存在する。関連する法的、方法論 的、倫理的な問題が克服されれば、より多くの価値あるデータを収集することができる。このデータが社会的利益 のために「ビッグデータ」の設定で使用できる形で利用できるようになれば、疫学研究を大幅に改善できる可能性 がある。しかし、第一に、個人のプライバシーと本質的な商業的な機密性を守る必要がある。これらの障害が克服 されれば、疫学研究の統計的な力を向上させ、ハザードをより良く特定し、場合によっては特徴づけるために応用 することができる。これらの目的は、EUの高いレベルで合意された行動によって効果的に実現することができる。 データとインタラクティブなブラットフォームを提供するための相互間承認は、集団の健康情報、食品消費データ、 有効成分と共調合製剤の空間的・時間的な適用データの調和によって裏付けられる必要がある。このような豊富 なデータは、因果関係と信頼性のエビデンスを強化する基準である一貫性の向上を支援することが期待できる。そ れは、農薬毒性からの特別な保護を必要とするかもしれない脆弱なグループをよりよく特定できるようになる疫学研 究のためのより大きなサンプルサイズを約束している。

## 脅威:

- 非現実的であり、社会に否定的な結果をもたらすとト集団や野生生物、環境に対するリスクレベルの認識が広まっていること。
- ・他の有効な情報源からのデータを損なうような、誤った陽性または誤った陰性の結論をもたらす不十分な実験計 画。
- 効果的なサーベイランスが行われていなかったり、匿名化された適切なデータを社会的利益のために利用できる ようにする気がなかったりした結果、新たなリスクに対応できなかったこと。
- ・登録(がんや先天性異常)やサーベイランスプログラムによるばく露(特に職業上ばく露)に関する適切な情報収集の失敗によるデータの浪費。
- ・診断基準の調和の失敗、統合解析のための十分に詳細な組み合わせ可能な形でデータを記録しなかったことに よるデータの浪費、健康統計データベースに入力されるデータの最適な品質を可能にするための関連するトキシ ドロームについての医療や救急医療スタッフのトレーニング不足。

#### Glossarv and Abbreviations

ADI		ure of the amount of a pesticide in food or sted (orally) on a daily basis over a lifetime sk.
ADME	Abbreviation used in pharmacolo	ogy (and toxicology) for absorption, distribution, chemical o pharmaceutical compound and
AOP	Adverse Outcome Pathway. A st leading to adverse effects releva	ructured representation of biological events ant to risk assessment.
ARfD	Acute Reference Dose. An estim water (normally expressed on a	nate of the amount a pesticide in food or drinking body weight basis) that can be ingested in a but appreciable health risks to the consumer on
Biomarker	and evaluated as an indication of	r'. A characteristic that is objectively measured of normal biologic processes, pathogenic ponses to a therapeutic intervention

# 用語集と略語

- ADI 一日の許容摂取量。食品または飲料水に含まれる農薬の量の尺度で、相当な健康リスクを伴わず に生涯にわたって日常的に(経口的に)摂取することができる。
- ADME 薬理学(及び毒物学)で使用される略語(体内動態)で、化学物質の吸収、分布、代謝及び排泄 のために使用され、生物体内でのその処理を示す。
- AOP Adverse Outcome Pathway(有害性転帰経路)。リスク評価に関連する有害な影響につながる生物学的事象 を構造的に表現したもの。
- ARfD 急性参照用量(Acute Reference Dose)。食品または飲料水に含まれる農薬の量(通常は体重べ ースで表される)の推定値で、評価時に知られているすべての事実に基づいて、24時間以内に消 費者が健康上のリスクを認めずに摂取できる量。
- バイオマーカー 「生物学的マーカー」とも呼ばれる。正常な生物学的プロセス、病原性プロセス、または治療的介 入に対する薬理学的反応の指標として客観的に測定され、評価される特性。
- BMD ベンチマークドーズ。バックグラウンドと比較して有害な影響の反応率(ベンチマーク反応または BMR)に所定の変化をもたらす閾値の用量または濃度。95%の下限値(BMDL)が計算され、健 康に基づいた参照値を導き出すための出発点としてさらに使用される。
- HBM ヒューマンバイオモニタリング(Human biomonitoring)。ヒトの生物学的体液または組織におけ る化学物質及び/またはその代謝物の測定。また、すべてのばく露経路からの総合的なばく露か ら得られる化学物質の内部ばく露量とも呼ばれる。
- ヒトデータ 研究者が研究参加者に働きかけることなく、要因と健康影響との間の自然な関係を観察する観察

BMD	Benchmark Dose. A threshold dose or concentration that produces a predetermined change in response rate of an adverse effect (the benchmark response or BMR) compared to background. The lower 95% confidence limit is calculated (BMDL) to be further used as a point of departure to derive health-
НВМ	based reference values. Human biomonitoring. The measurement of a chemical and/or its metabolites in human biological fluids or tissues. Also referred as to the internal dose of a chemical resulting from integrated exposures from all exposure routes.
Human data	They include observational studies (also called epidemiological studies) where the researcher is observing natural relationships between factors and health outcomes without acting upon study participants. Vigilance data also fall under this concept. In contrast, interventional studies (also called experimental studies or randomised clinical trials), where the researcher intercedes as part of the study design, are outside the scope of this opinion.
IARC	International Agency for Research on Cancer. An agency of the World Health Organization whose role is to conduct and coordinate research into the causes and occurrence of cancer worldwide.
LOAEL	Lowest-observed-adverse-effect level. The lowest concentration or amount of a chemical stressor evaluated in a toxicity test that shows harmful effects (e.g. an adverse alteration of morphology, biochemistry, function, or lifespan of a target organism).
NOAEL	No observed-adverse-effect level. Highest dose at which there was not an observed toxic or adverse effect.
OR	Odds ratio. A measure of association between an exposure and an outcome. The
PBTK-TD	OR represents the odds that an outcome will occur given a particular exposure, compared to the odds of the outcome occurring in the absence of that exposure. Physiologically based toxicokinetic/toxicodynamic modelling is a mathematical modelling approach aimed at integrating <i>a priori</i> knowledge of physiological processes with other known/observed information to mimic the fates and effects of compounds in the bodies of humans, preclinical species and/or other
PPP	organisms. Plant Protection Product. The term 'pesticide' is often used interchangeably with 'plant protection product', however, pesticide is a broader term that also covers
RR	non plant/crop uses, for example biocides. Relative risk. Ratio of the probability of an event (e.g. developing a disease) occurring in an exposed group to the probability of the event occurring in a
RMS	comparison, non-exposed group. Rapporteur member state. The member state of the European Union initially in charge of assessing and evaluating a dossier on a pesticide active substance
Sensitivity	toxicological assessment. The ability of a test to correctly classify an individual as 'diseased'. Probability of
Specificity	being test positive when disease present. The ability of a test to correctly classify an individual as disease-free. Probability
Surrogate endpoint	of being test negative when disease absent. A biomarker intended to substitute for a clinical endpoint

# Annex A – Pesticide epidemiological studies reviewed in the EFSA External Scientific Report and other reviews

The extensive evidence gathered by the EFSA External Scientific Report (Ntzani et al., 2013) highlights that there is a considerable amount of information available on pesticide exposure and health outcomes from epidemiological studies. Nonetheless, the quality of this evidence is usually low and many biases are likely to affect the results to an extent that firm conclusions cannot be made. In particular, exposure epidemiology has long suffered from poor measurement and definition and in particular for pesticides this has always been exceptionally difficult to assess and define.

# A.1. The EFSA External scientific report

### A.1.1. Methodological quality assessment

The External Scientific Report consists of a comprehensive systematic review of all the epidemiological studies published between 1 January 2006 and 30 September 2012, investigating the association between pesticide exposure and the occurrence of any human health-related outcomes.

The methodological assessment of eligible studies (to evaluate risk of bias associated with each study) was focused on: study design, study population, level of details in exposure definition and the methods of exposure measurement and the specificity of the measurement. Efforts undertaken to account for confounders through matching or multivariable models, blinded exposure assessment and well-defined and valid outcome assessment were considered.

The elements of the methodological appraisal were considered from the Research Triangle Institute (RTI; Research Triangle Park, NC, USA) item bank, a practical and validated tool for evaluating the risk of bias and precision of observational studies. Those elements are described below (Table A.1).

Table A.1:	Elements from the Research Triangle Institute (RTI; Research Triangle Park, NC, USA)
	item bank for methodological appraisal of epidemiological studies

Question	High risk	Low risk
Study design (prospective, retrospective, mixed, NA)	Retrospective, mixed, NA	Prospective
Inclusion/exclusion criteria clearly stated (yes, partially, no)	No	Yes
Authors mention power calculations (yes, no)		Yes
Level of detail in describing exposure (high, medium, low)	Low	High
Robust measurement of exposure. (biomarker (yes): small area ecological measures, job titles, questionnaire (partial); was based on large area ecological measures (no)	No	Yes
Were measures of exposure specific? yes; based on broader, chemically- related groups (partial); based on broad groupings of diverse chemical and toxicological properties (no)	No	Yes
Attempt to balance the allocation between the groups (e.g., through stratification, matching)	No	Yes
Adjustment performed for potential confounders (yes, some, no)	No	Yes
Assessors blinded to exposure status (for cohort studies)	No	Yes
Outcomes assessed using valid and reliable measures, implemented	ed fr	
consistently across all study participants?	No	Yes
Sample size	Low	Тор
Rough quality assessment	>6 answers high risk	>6 asnwers low risk

Quantitative synthesis of the results was attempted when there were 5 or more eligible studies per examined outcome and when there was no substantial heterogeneity among the published evidence. Publication bias was assessed using funnel plots which allowed to visually inspect asymmetry when more than 10 studies were included in the meta-analysis.

Toxicological data was not reviewed or discussed in the External Scientific Report.

#### A.1.2. Inclusion/exclusion criteria

All types of pesticides, including those banned in the EU, were considered to enhance the totality of the epidemiological evidence available at the time of the review.

# 付属書A-EFSAの外部科学報告書でレビューされた農薬疫学研究及びその他のレビュー

EFSA 外部科学報告書(Ntzani ら、2013 年)によって収集された広範なエビデンスは、疫学研究からの農薬ばく 露と健康影響に関するかなりの量の情報が利用可能であることを強調している。それにもかかわらず、このエビデンス の質は通常低く、多くのバイアスが結果に影響を与え、結論を出すことができない可能性が高い。特に、ばく露疫学は 長い間、測定と定義の貧弱さに悩まされてきたが、特に農薬に関しては、これは常に評価と定義が非常に難しいもので あった。

# A.1. EFSA の外部研究報告書 A.1.1. 方法論的品質評価

外部研究報告書は、2006年1月1日から2012年9月30日までに発表されたすべての疫学研究の包括的なシ ステマティックレビューから構成されており、農薬ばく露ととト健康関連影響の発生との関連性を調査している。

対象となる研究の方法論的評価(各研究に関連するバイアスのリスクを評価する)は、研究デザイン、研究対象集団、 ばく露の定義の詳細度、ばく露の測定方法、測定の特殊性に焦点を当てた。マッチングモデルや多変量モデル、盲検 化されたばく露評価、十分に説明された有効な結果評価を通じた交絡因子の説明などの取り組みが検討された。

方法論的評価の要素は、Research Triangle Institute (RTI; Research Triangle Park, NC, USA)の項目バンク で検討されたもので、観察による研究の偏りのリスクと精度を評価するための実用的で検証済みのツールである。これ らの要素を以下に示す(表 A.1)。

# 表 A.1: Research Triangle Institute (RTI; Research Triangle Park, NC, USA)の疫学研究の方法論的評価のための項目バンクの要素

賞問	高リスク	低リスク

# ejusanos

#### Exclusion criteria:

- Studies without control populations (case reports, case series) and ecological studies
- Pesticide poisoning or accidental high dose exposure
- Studies with no quantitative information on effect estimates
- Studies with different follow-up periods and examining the same outcome, only the one with the longest follow-up was retained to avoid data duplication.
- Studies referred to the adverse effects of substances used as therapy for various medical conditions (e.g. warfarin-based anticoagulants)
- Studies on solvents and other non-active ingredients (e.g. co-formulants) in pesticides
- Studies examining the association between exposure and biomarkers of exposure were not considered eligible as they do not examine health outcomes
- Studies/analyses investigating exposure to pesticides: arsenic, hexachlorocyclohexane (HCH)  $\alpha$  or  $\beta$ , lead, dioxins and dioxin-like compounds including polychlorinated biphenyls (PCBs) were not considered
- Narrative reviews were excluded but not systematic reviews or meta-analyses.

Publications reporting series of acute poisonings or clinical cases, biomonitoring studies unrelated to health effects, or studies conducted on animals or human cell systems were not included; only epidemiological studies addressing human health effects were selected. Publications that lacked quantitative data for measuring associations were also excluded.

Cohort studies, case-control studies and cross-sectional studies were included. Each study underwent an assessment of its eligibility based on a method including 12 criteria such as study design, precise description of the inclusion/exclusion criteria, level of detail in describing exposure, robustness in the measurement of exposure, adjustment for potential confounding factors, method of assessment of the health outcome, sample size, etc. Among these 12 criteria, three were related to the degree of precision in the description/measurement of exposure, which may explain why a large number of epidemiological studies were not selected.

#### A.1.3. Results

Overall, 602 individual publications were included in the scientific review. These 602 publications corresponded to 6,479 different analyses. The overwhelming majority of evidence comes from retrospective or cross-sectional studies (38% and 32%, respectively) and only 30% of studies had a prospective design. Exposure assessment varied widely between studies and overall 46% measured biomarkers of pesticides exposure and another 46% used questionnaires to estimate exposure to pesticides. Almost half of the studies (49%) were based in America. Most studies examined associations between occupational exposure to pesticides and health effects. The entire spectrum of diseases associated with pesticides has not been studies before. The report examined a wide variety of outcomes (Figure A.1). The largest proportion of studies pertains to cancer outcomes (N = 164) and outcomes related to child health (N = 84).

69

#### Epidemiological studies and pesticides

- ・ 対照集団のない研究(症例報告、症例シリーズ)及び生態学的研究
- ・ 農薬中毒または偶発的な高用量ばく露
- 影響の推定に関する定量的な情報がない研究
- データの重複を避けるために、追跡期間が異なり、同じ健康影響(アウトカム)を調査している研究については、
   追跡期間が最も長いもののみを残した。
- ・様々な病状の治療に使用される物質の有害影響について言及した研究(例:ワルファリンをベースとした抗凝固 薬)。
- ・ 農薬中の溶剤やその他の非有効成分(補助剤など)の研究
- ・ ばく露とばく露のバイオマーカーとの関連性を検討した研究は、健康影響を調べないため対象外とされた。
- ・ 農薬へのばく露を調査した研究/解析:ヒ素、ヘキサクロロシクロヘキサン(HCH)aまたはb、鉛、ダイオキシン 類及びポリ塩化ビフェニル(PCB)を含むダイオキシン様化合物は考慮されなかった。
- ・ナラティブレビューは除外したが、システマティックレビューやメタアナリシスは除外しなかった。

急性中毒または臨床症例のシリーズである出版物、健康影響とは無関係のバイオモニタリング研究、または動物また はヒトの細胞システムで実施された研究は含まれず、ヒトの健康影響を扱った疫学的研究のみが選ばれた。また、関連 性を測定するための定量的データを欠く出版物も除外した。

コホート研究、症例対照研究及び横断研究が含まれた。各研究は、研究デザイン、除外・包含基準の正確な記述、 ばく露の記述の詳細度、ばく露の測定の強固性、潜在的な交絡因子の調整、健康影響の評価方法、サンプルサイズ 等の12の基準を含む方法に基づいて適格性の評価を受けた。これら12の基準のうち、3つの基準はばく露の記述・ 測定の精度に関連しており、多くの疫学研究が選ばれなかった理由を説明することができるかもしれない。

## A.1.3. 結果

全体では、602 の個別の論文が科学的レビューに含まれている。これら 602 の出版物は、6,479 の異なる解析に対応していた。エビデンスの圧倒的多数は後ろ向きまたは横断研究(それぞれ 38%と 32%)であり、前向きな研究は 30%のみであった。ばく露評価は研究によって大きく異なり、全体の 46%が農薬ばく露のバイオマーカーを測定し、さらに46%が農薬ばく露を推定するためにアンケートを使用していた。研究のほぼ半数(49%)がアメリカを拠点としていた。ほとんどの研究では、農薬への職業性ばく露と健康影響との関連性が調査されていた。農薬に関連する疾患の全領域を対象とした研究はこれまで行われていなかった。報告書では、さまざまなアウトカムを調査している(図 A.1)。最も多いのは、がんのアウトカム(N=164)と子どもの健康に関するアウトカム(N=84)である。

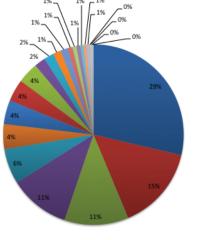

Figure A.1: Major outcome categories and corresponding percentage of studies examining those outcomes among the publications reviewed by the EFSA external scientific report (Ntzani et al., 2013)

Despite the large volume of available data and the large number (> 6.000) of analyses available. firm conclusions were not made for the majority of the outcomes studied. This was due to several limitations of the data collected as well as to inherent limitations of the review itself. As mentioned above, the review studied the whole range of outcomes examined in relation to pesticides during an approximately 5 years' period. Thus, only recent evidence was reviewed and the results of the metaanalyses performed should be cautiously interpreted as they do not include all the available evidence. It is therefore capable of highlighting outcomes which merit further in-depth analysis in relation to pesticides by looking at the entire literature (beyond 5 years) and by focusing on appraising the credibility of evidence selected. The limitations of the studies itself are in line with other field of environmental epidemiology and focus around the exposure assessment, the study design, the statistical analysis and reporting. In particular:

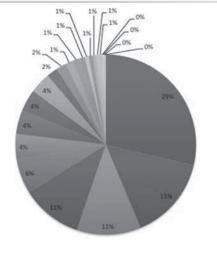

a) Exposure assessment: The assessment of exposure is perhaps the most important methodological limitation of the studies reviewed in the ESR. Studies used different methods for exposure assessment and assignment. Most studies were based on self-reported exposure to pesticides, defined as 'ever versus never' use or as 'regular versus non-regular' use. Such methods suffer from high misclassification rates and do not allow for dose-response analysis. This is especially the case for retrospective studies where misclassification would be differential with higher exposures reported in participants with disease (recall bias) (Raphael, 1987). While questionnaires might be capable of differentiating subjects with very high and very low exposure levels, they are not capable of valid exposure classification across an exposure gradient, thus not allowing the study of dose-response relationships. Also, questionnaire for exposure assessment need to be validated for use in epidemiological studies. Nonetheless, a vast proportion of studies use in house version of non-validated questionnaires which may suffer from content (the questionnaire does not cover all sources of exposure to the hazard of interest) or criterion validity (e.g. through inaccurate recall or misunderstanding of questions) (Coggon, 1995).

Although the range of categories of pesticide studied is wide, studies very often concentrate on a broadly defined pesticide category, so that it is difficult to know what type of pesticide the population is exposed to.

### 図 A.1:EFSA の外部科学研究報告書でレビューされた出版物のうち、主要な健康影響のカテゴリーと、その健康影 響を調査した研究の割合(Ntzaniら、2013年)

利用可能な大量のデータと大量の分析(>6,000 件)にもかかわらず、研究されたアウトカムの大部分については確 固たる結論が出ていない。これは、収集したデータのいくつかの限界と、レビュー自体の固有の限界によるものである。 上述したように、レビューでは約5年間に農薬に関連して検討されたアウトカムの全範囲が調査された。したがって、最 近のエビデンスのみがレビューされ、実施されたメタアナリシスの結果は、利用可能なすべてのエビデンスを含んでい るわけではないため、慎重に解釈されるべきである。したがって、文献全体(5年以上)をみて、選択したエビデンスの 信頼性を評価することに焦点を当てることで、農薬に関連してさらに詳細な解析を行う価値のある結果を浮き彫りにす ることができる。研究自体の限界は、環境疫学の他の分野と一致しており、ばく露評価、研究デザイン、統計解析、報 告に焦点を当てている。特に以下の点が挙げられる:

a) ばく (標評価: ばく 露の評価は、おそらく ESR でレビューされた研究の中で最も重要な方法論的限界である。 研究 では、ばく露の評価と割り付けにさまざまな方法が用いられている。ほとんどの研究では、「これまでに使用したこと があるかないか」または「定期的に使用したことがあるかないか」という自己申告による農薬へのばく露に基づいて いた。このような方法では、高い誤分類率に悩まされ、用量反応分析を行うことができない。これは特に後ろ向き研 究の場合で、病気のある参加者で報告されるより高いばく露量の差が誤分類を生じる(想起バイアス)(Raphael、 1987年)。アンケートは非常に高いばく露レベルと非常に低いばく露レベルの被験者を区別することができるかも しれないが、ばく露濃度による有効な分類を行うことはできず、その結果、用量反応関係の研究を行うことができな い。また、ばく露評価のためのアンケートは、疫学研究で使用するために検証される必要がある。それにもかかわ らず、多くの研究では検証されていないアンケートを使用しているが、これには内容(アンケートが対象とする有害 なばく露源をすべて網羅していない)や基準妥当性(例えば、不正確な想起や質問の誤解)に問題があるかもしれ ない(Coggon、1995年)。

調査対象とした農薬のカテゴリーの範囲は広いが、研究では多くの場合、広く定義された農薬のカテゴリーに集中し ているため、対象集団がどのような種類の農薬にばく露されているのかを知ることは困難である。

農薬へのばく露は、研究参加者による農薬の使用報告または政府の登録データとして定義された。これらのデータ EESA Journal 2017:15(10):5007 www.efsa.europa.eu/efsajourna 70

Exposure to pesticides was defined as reported use of pesticides by the study participant or by government registry data. These derive from self-administered questionnaires, interviewer administrated questionnaires, job exposure matrices (JEM), by residential status (proximity to pesticide exposure), by detecting biomarkers associated with pesticide exposure or by other means as defined by each study.

Studies often examine pesticides that have already been banned in western populations and the EU. The use of biomarkers as means of exposure assessment is infrequent, but still available in almost half of the studies.

b) Study design: As mentioned above, the majority of evidence comes form case-control studies and cross-sectional studies. Cross-sectional, and in part also case-control studies, cannot fully assess the temporal relationships and thus are less able to provide support regarding the causality of associations.

c) Outcomes examined: The definition of clinical outcomes displayed large variability in eligible epidemiological studies, which can further cause the variability in results. Perhaps most important in this setting is the use of a great number of surrogate outcomes examined. Surrogate outcomes are biomarkers or physical measures that are generally accepted as substitutes for, or predictors of, specific clinical outcomes. However, often these surrogate outcomes are not validated and do not meet the strict definitions of surrogate outcomes. Such outcomes can be defined as possible predictors of clinical outcomes but do not fulfil the criteria for a surrogate outcome. It is essential to appraise the evidence around non-validated surrogate outcomes by taking into account the implicit assumptions of these outcomes.

A great variety of assessed outcomes covering a wide range of pathophysiologies was observed. 'Hard' clinical outcomes as well as many surrogate outcomes included in the database reflect the different methodologies endorsed to approach the assessed clinical research questions. The different outcomes were divided into 23 major disease categories, with the largest proportion of studies addressing cancer and child health outcomes.

The adverse health effects assessed included:

- a) major clinical outcomes, such as cancer, respiratory (allergy), reproductive (decreased fertility, birth defects) and neurodegenerative (Parkinson's disease);
- b) clinical surrogate outcomes, e.g. neurodevelopmental impairment (assessed by neurocognitive scales);
- c) laboratory surrogate outcomes (e.g. liver enzyme changes).

For many adverse health effects attributed to pesticide exposure, there exist contradictory or ambiguous studies. Whether this results from lack of consistency or real heterogeneity warrants further clarification.

#### d) Statistical analysis:

Simultaneous exposure to multiple agents (heavy metals, solvents, suspended particulate matter etc.) from different sources is common. It may introduce further bias in the results as all of them may produce adverse health outcomes. Thus, it is essential to account for confounding from exposure to multiple agents in order to delineate true associations but this has not been possible in the overwhelming majority of evidence assessed in the EFSA external scientific report.

In addition, the evidence collected and appraised in the EFSA external scientific report (Ntzani et al., 2013) is likely to suffer from selective reporting and multiple testing. The studies reported a very wide range of analyses; 602 publications resulted in 6,000 analyses. The amount of multiple hypothesis testing is enormous. These analyses need to be adjusted for multiple hypothesis testing else, otherwise the results suffer from high false positive rate. Even when studies present only one analysis, selective reporting is always a possibility as has been shown in other epidemiological fields as well. In addition, when interpreting results one should also take into account that, especially for certain outcomes (e.g. cancers), the majority of evidence comes from single study populations and the Agricultural Health Study in particular.

### A.1.4. Conclusion of the EFSA External Scientific Report

Regardless of the limitations highlighted above, the External Scientific Report (Ntzani et al., 2013) showed consistent evidence of a link between exposure to pesticides and Parkinson's disease and childhood leukaemia, which was also supported by previous meta-analyses. In addition, an increased risk was also found for diverse health outcomes less well studied to date, such as liver cancer, breast cancer and type II diabetes. Effects on other outcomes, such as endocrine disorders, asthma and allergies, diabetes and obesity showed increased risks and should be explored further.

71

www.efsa.europa.eu	/efsajournal
--------------------	--------------

EFSA Journal 2017;15(10):5007

el usa muni

は、自己記入式アンケート、質問者が管理するアンケート、職業性ばく露マトリックス(JEM)、居住状況(農薬ばく露に 近接しているかどうか)、農薬ばく露に関連するバイオマーカーの検出、または各研究によって定められたその他の方 法から得られたものである。

研究では、欧米の集団や EU ですでに禁止されている農薬を調査することが多い。ばく露評価の手段としてバイオ マーカーを使用することはまれであるが、ほぼ半数の研究ではまだ利用可能である。

- b) 研究デザイン:上述したように、エビデンスの大部分は症例対照研究と横断研究から得られている。横断研究や一部の症例対照研究では、時間的関係を完全に評価することができないため、関連性の因果関係に関する裏付けを提供することができない。
- c)調査された健康影響:臨床健康影響の定義は、適格な疫学研究において大きなばらつきを示しており、これが結果のばらつきの原因となっている。おそらくこのような状況において最も重要なのは、調査された多数の代替健康影響の使用である。代替健康影響とは、特定の臨床転帰の代替または予測因子として一般的に受け入れられているバイオマーカーまたは身体測定値のことである。しかし、多くの場合、これらの代替健康影響は検証されておらず、代替健康影響の厳密な定義を満たしていない。このような健康影響は、臨床健康影響の予測因子の可能性があるとされているが、代替健康影響の基準を満たしていない。これらの健康影響の暗黙の仮定を考慮に入れることにより、検証されていない代替健康影響に関するエビデンスを評価することが不可欠である。

広範囲の病態生理をカバーすると評価されたアウトカムは非常に多様だった。データベースに含まれる多くの代替 健康影響と同様に「ハード」な臨床健康影響は、評価された臨床研究の課題にアプローチするために支持された異な る方法論を反映している。さまざまな健康影響は 23 の主要な疾患カテゴリーに分類されており、がんと小児の健康影 響を扱った研究が最も多くを占めている。

評価された健康への悪影響には以下のものが含まれる。

- a)がん、呼吸器(アレルギー)、生殖(受精率低下、先天性疾患)、神経変性(パーキンソン病)などの主要な臨床転帰;
- b)神経発達障害(神経認知スケールで評価)などの臨床代替健康影響;

c)検査での代替健康影響(例:肝酵素の変化)。

農薬ばく露に起因する多くの有害な健康影響については、矛盾した、あるいは曖昧な研究が存在する。この結果が 一貫性の欠如からくるものなのか、真の不均一性からくるものなのかは、さらなる解明が必要である。

#### d) 統計的解析。

異なる供給源からの複数の物質(重金属、溶剤、浮遊粒子状物質など)への同時ばく露は一般的である。それらの すべてが有害な健康影響をもたらす可能性があるため、結果にさらなるバイアスがかかる可能性がある。したがって、 真の関連性を明らかにするためには、複数の物質へのばく露による交絡を考慮することが不可欠であるが、EFSAの 外部科学研究報告書で評価された圧倒的多数のエビデンスでは、これは不可能であった。

さらに、EFSA の外部科学研究報告書(Ntzani ら、2013 年)で収集・評価されたエビデンスは、都合の良い報告と 複数の試験に悩まされる可能性が高い。研究は非常に広範な解析を報告しており、602 の出版物で 6,000 の解析が 行われた。多重仮説検定の量は膨大である。これらの解析は、複数の仮説検定のために調整されていなければならず、 そうでなければ結果は高い偽陽性率に悩まされる。研究が1つの解析しか行われていない場合でも、他の疫学的研究 でも示されているように、都合の良い報告の可能性が常にある。さらに、結果を解釈する際には、特に特定の健康影響 (がんなど)については、エビデンスの大部分が単一の研究集団そして特に農業健康調査から得られていることも考慮 に入れるべきである。

### A.1.4. EFSA 外部科学研究報告書の結論

上記で強調された限界にもかかわらず、外部科学研究報告書(Ntzani 6、2013 年)では農薬ばく露とパーキンソン 病及び小児の白血病との関連、これらは先行するメタアナリシスでも裏付けられている、について首尾一貫したエビデ ンスを示した。さらに、肝臓がん、乳がん、Ⅱ型糖尿病など、これまであまり研究されてこなかった多様な健康影響につ

www.efsa.europa.eu/efsajourna

Childhood leukaemia and Parkinson's disease are the two outcomes for which a meta-analysis after 2006 was found consistently showing an increased risk associated with pesticide exposure. Nonetheless, the exposure needs to be better studied to disentangle the effect of specific pesticide classes or even individual pesticides. Significant summary estimates have also been reported for other outcomes (summarised in Table A.2). However, as they represent studies from 2006 onwards results should be regarded as suggestive of associations only and limitations especially regarding the heterogeneity of exposure should always been taken into consideration. Data synthesis and statistical tools should be applied to these data in relation to specific outcomes, after the update of the results to include publications before 2006, in order to quantify the amount of bias that could exist and isolate outcomes where the association with pesticides is well supported even when estimates of bias are taken into account. Similarly, outcomes where further evidence is needed to draw firm conclusions need to be highlighted.

#### **Table A.2:** Summary of meta-analyses performed in the report

Health outcome	N studies	Meta-analysis results	I <sup>2</sup>
Leukaemia	6	1.26 (0.93; 1.71)	59.4%
Hodgkin lymphoma	7	1.29 (0.81-2.06)	81.6%
Childhood leukaemia (exposure to pesticides during pregnancy)	6	1.67 (1.25-2.23)	81.2%
Childhood leukaemia (exposure to insecticides during pregnancy)	5	1.55 (1.14–2.11)	65%
Childhood leukaemia (exposure to insecticides during pregnancy $-$ update Turner, 2010)	9	1.69 (1.35–2.11)	49.8%
Childhood leukaemia (exposure to unspecified pesticides during pregnancy)	5	2.00 (1.73–2.30)	39.6%
Childhood leukaemia (exposure to unspecified pesticides during pregnancy – update Turner, 2010)	11	1.30 (1.06–1.26)	26.5%
Childhood leukaemia (exposure to pesticides during childhood)	7	1.27 (0.96-1.69)	61.1%
Childhood leukaemia (exposure to insecticides during childhood – update Turner, 2010)	8	1.51 (1.28–1.78)	0%
Childhood leukaemia (exposure to unspecified pesticides during childhood – update Turner, 2010)	11	1.36 (1.19–1.55)	0%
Breast cancer (DDE exposure)	5	1.13 (0.81–1.57)	0%
Breast cancer	11	1.24 (1.08–1.43)	0%
Testicular cancer (DDE exposure)	5	1.40 (0.82–2.39)	59.5%
Stomach cancer	6	1.79 (1.30–2.47)	0%
Liver cancer	5	2.50 (1.57–3.98)	25.4%
Cryptorchidism	8	1.19 (0.96–1.49)	23.9%
Cryptorchidism (DDT exposure)	4	1.47 (0.98-2.20)	51%
Hypospadias (general pesticide exposure)	6	1.01 (0.74–1.39)	71.5%
Hypospadias (exposure to specific pesticides)	9	1.00 (0.84–1.18)	65.9%
Abortion	6	1.52 (1.09–2.13)	63.1%
Parkinson's disease	26	1.49 (1.28–1.73)	54.6%
Parkinson's disease (DDT exposure)	5	1.01 (0.78-1.30)	0%
Parkinson's disease (paraquat exposure)	9	1.32 (1.09–1.60)	34.1%
Amyotrophic lateral sclerosis	6	1.58 (1.31-1.90)	10%
Asthma (DDT exposure)	5	1.29 (1.14–1.45)	0%
Asthma (paraquat exposure)	6	1.40 (0.95-2.06)	53.3%
Asthma (chlorpyrifos exposure)	5	1.03 (0.82–1.28)	0%
Type 1 diabetes (DDE exposure)	8	1.89 (1.25–2.86)	49%
Type 1 diabetes (DDT exposure)	6	1.76 (1.20–2.59)	76.3%
Type 2 diabetes (DDE exposure)	4	1.29 (1.13–1.48)	0%

N = number of studies considered for the meta-analysis; in the column of meta-analysis results, the numbers represent the statistical estimate for the size of effect (odds ratio (OR), or relative risk (RR)) with the corresponding 95% confidence interval (CI). I<sup>2</sup> represents the percentage of total variation across studies that is due to heterogeneity.

#### Epidemiological studies and pesticides

いてもリスクの増加が認められた。内分泌疾患、喘息、アレルギー、糖尿病、肥満などの他の健康影響への影響は、リ スクの増加を示しており、今後さらに調査が必要である。

小児白血病とパーキンソン病は、2006 年以降のメタアナリシスで一貫して農薬ばく露に関連したリスクの増加を示した2 つの健康影響である。それにもかかわらず、特定の農薬クラスや個々の農薬の影響を解きほどくためには、ばく露をよりよく研究する必要がある。他の健康影響についても、有意な要約推定値が報告されている(表 A.2 に要約)。しかし、これらは2006 年以降の研究であるため、結果は関連性を示唆するものとみなすべきであり、特にばく露の不均一性に関する限界は常に考慮されるべきである。存在しうるバイアスの量を定量化し、バイアスの推定値を考慮に入れても農薬との関連性が十分に支持される結果を分離するために、2006 年以前の出版物を含むように結果を更新した後、特定の健康影響に関連してこれらのデータにデータ統合と統計ツールを適用すべきである。同様に、結論を出すためにさらなるエビデンスが必要な健康影響は、強調される必要がある。

#### 表 A.2:報告書で実施されたメタアナリシスの概要

健康面での成果		メタアナリシスの	<sup>2</sup>

#### A.2. The INSERM report

In September 2013, the French National Institute of Health and Medical Research (INSERM) released a literature review carried out with a group of experts on the human health effects of exposure to pesticides.<sup>22</sup> Epidemiological or experimental data published in the scientific literature up to June 2012 were analysed. The report was accompanied by a summary outlining the literature analysis and highlighting the main findings and policy lines, as well as the recommendations.

CI USA INVITA

The INSERM report is composed of four parts: (1) exposure assessment, with a detailed description of direct and indirect methods to assess exposure in epidemiological studies; (2) epidemiology, with an inventory and analysis of epidemiological studies available in the literature up to 2012, and a scoring system to assess the strength of presumed association; (3) toxicology, with a review of toxicological data (metabolism, mode of action and molecular pathway) of some substances and assessment of biological plausibility; (4) recommendations.

The vast majority of substances identified by the INSERM report as having a presumed moderate or strong association with the occurrence of health effects are chemicals that are now prohibited. This is mainly driven by the fact that the majority of the diseases examined are diseases of the elderly; therefore, the studies performed to date are based on persons who were old at the time of the study and exposed many years ago. By definition, it is not yet possible to investigate the potential long term effects of many of the more recent products.

These substances belong to the group of organochlorine insecticides, such as DDT or toxaphene, or insecticides with cholinesterase-inhibiting properties, such as terbufos or propoxur.

Of the seven approved active substances identified by the INSERM expert appraisal report (the herbicides 2,4-D, MCPA, mecoprop, glyphosate, the insecticide chlorpyrifos, and the foliar fungicides mancozeb and maneb), all had a presumed moderate or weak association with haematopoietic cancers. Two of them (the foliar fungicides mancozeb and maneb) had a presumed weak association with Parkinson's disease and two (chlorpyrifos and glyphosate) had a presumed association with developmental impairment identified as weak or moderate in the expert appraisal.

#### A.2.1. Description of methods to assess exposure in epidemiological studies

Different methods (direct and indirect) have been developed to assess exposure, such as biological or environmental monitoring data, ad hoc questionnaires, job- or crop-exposure matrices, analysis of professional calendars, sales data, land use data, etc. According to the authors, these various tools can be combined with each other but, to date none has been validated as a reference method for estimating exposure in the context of occupational pesticide exposure assessment.

#### A.2.2. Epidemiology

The group of experts from INSERM carried out an inventory and analysis of epidemiological studies available in the literature, examining the possible association between pesticide exposure and health outcomes: eight cancer sites (non-Hodgkin lymphoma, leukaemia, lymphoma, multiple myeloma, prostate, testis, brain, melanoma), three neurodegenerative diseases (Parkinson's disease, Alzheimer's disease, amyotrophic lateral sclerosis), cognitive or depressive disorders, effects on reproductive function (fertility, pregnancy and child development) and childhood cancers. These are health outcomes that have been identified in previous studies as potentially related to pesticide exposure.

Epidemiological studies addressing primarily farmers, pesticide applicators and workers of the pesticide manufacturing industries, as well as the general population when it was relevant, were selected.

The INSERM group of experts established a hierarchy in the relevance of the studies, placing the meta-analysis at the top, then the systematic review, then the cohort study, and finally, the case-control study. Based on this hierarchy, a scoring system was defined to assess the strength of presumption of the association between exposure and the occurrence of health outcomes from the analysis of the study results; for each disease or pathological condition investigated, this score may vary depending on the quality, type and number of available studies, as, for example:

(++): strong presumption: based on the results of a meta-analysis, or several cohort studies or at least one cohort study and two case–control studies, or more than two case–control studies;

#### A.2. INSERIM レポート

2013 年 9 月、フランス国立保健医療研究所(INSERM)は、農薬へのばく露によるとト健康影響について専門家グ ループと共に実施した文献レビューを発表した22。2012 年 6 月までの科学文献に発表された疫学的または実験的デ ータが解析された。報告書には、文献的解析を概説し、主要な結論と政策及び勧告を強調した要約が添付されている。

INSERM の報告書は 4 つの部分から構成されている。(1) ばく露評価、疫学研究におけるばく露を評価するための 直接的及び間接的な方法の詳細な説明、(2) 疫学、2012 年までの文献で利用可能な疫学研究のインベントリと解析 及び推定される関連性の強さを評価するためのスコアリングシステム、(3) 毒性学、いくつかの物質の毒性学的データ (代謝、作用機序、分子経路)のレビューと生物学的妥当性の評価、(4) 推奨事項。

健康影響の発生と推定される中等度または強い関連性を持つと INSERM の報告書で特定された物質の大部分は、 現在禁止されている化学物質である。これは主に、調査された疾患の大部分が高齢者の疾患であるという事実によっ て推進されている。したがって、これまでに実施された研究は、研究の時点で高齢であり、何年も前にばく露された人に 基づいている。結論から言うと、最近の製品の多くの潜在的な長期的影響を調査することはまだ可能ではない。

これらの物質は、DDT やトキサフェンのような有機塩素系殺虫剤や、テルブフォスやプロポキサーのようなコリンエス テラーゼ阻害作用を持つ殺虫剤のグループに属している。

INSERM の専門家評価報告書で確認された 7 つの承認された有効成分(除草剤 2,4-D、MCPA、メコプロップ、グ リホサート、殺虫剤クロルビリホス、葉の殺菌剤マンコゼブとマネブ)のうち、すべてが造血器がんとの中等度または弱い 関連性があると推定されていた。そのうち 2 つ(葉状殺菌剤マンコゼブとマネブ)はパーキンソン病との関連性が弱いと 推定され、2 つ(クロルビリホスとグリホサート)は専門家の評価で弱い、または中等度とされた発達障害との関連性があ ると推定された。

### A.2.1. 疫学研究におけるばく露評価方法の説明

ばく露を評価するために、生物学的または環境モニタリングデータ、その場しのぎのアンケート、職業別または作物 別のばく露マトリクス、専門家のカレンダーの分析、販売データ、土地利用データなど、さまざまな方法(直接的及び間 接的)が開発されてきた。著者らによると、これらの様々なツールは互いに組み合わせることができるが、現在までのとこ ろ、職業性農薬ばく露評価の背景でばく露を推定するための基準となる方法として有効性が確認されていない。

#### A.2.2. 疫学

INSERMの専門家グループは、文献で入手可能な疫学研究の目録作成と解析を行い、農薬ばく露と健康影響との 関連性の可能性を検討した。8 つのがん部位(非ホジキンリンパ腫、白血病、リンパ腫、多発性骨髄腫、前立腺、精巣、 脳、メラノーマ)、3 つの神経変性疾患(パーキンソン病、アルツハイマー病、筋萎縮性側索硬化症)、認知・抑うつ障害、 生殖能への影響(受胎性、胎児と出生児の発生)、小児がんである。これらは、以前の研究で農薬ばく露に関連する可 能性があるとして同定されている健康影響である。

主に農家、農薬散布者、農薬製造業の労働者を対象とした疫学的研究と、関連性がある場合には一般集団を対象 とした研究が選ばれた。

INSERM の専門家グループは、研究の関連性における階層を設定し、メタアナリシスを最上位に置き、次にシステ マティックレビュー、コホート研究、そして最終的には症例対照研究とした。この階層に基づいて、研究結果の解析から、 ばく露と健康影響の発生との間の関連性の推定の強さを評価するためにスコアリングシステムが定義された;調査され た各疾患や病態について、このスコアは、例えば、利用可能な研究の質、種類、数によって異なる。

(++):強い推定:メタアナリシスの結果に基づく、または複数のコホート研究、または少なくとも 1 つのコホート研究と 2 つの症例対照研究、または 2 つ以上の症例対照研究。

(+):中程度の推定:コホート研究または入れ子になった症例対照研究または2つの症例対照研究の結果に基づ

<sup>&</sup>lt;sup>22</sup> INSERM. Pesticides. Effets sur la santé. Collection expertise collective, Inserm, Paris, 2013.

<sup>&</sup>lt;sup>22</sup> INSERM. 農薬。 sante への影響。 Collection expertise collective, Inserm, Paris, 2013.

(+): moderate presumption: based on the results of a cohort study or a nested case–control study or two case–control studies;

 $(\pm):$  weak presumption: based on the results of one case–control study. This synthesis takes the work beyond the status of a simple mapping exercise.

#### A.2.3. Toxicological data

Toxicological data that were considered in the literature review were mainly those regarding metabolism, mode of action and molecular pathways. None of the studies provided as part of the procedures for placing products on the market were considered except if they were published in the open literature.

When substances were clearly identified in the epidemiological studies, a scoring system was defined to assess the biological plausibility from the study results: coherence with pathophysiological data and occurrence of health outcome.

(++): hypothesis supported by 3 mechanisms of toxicity;

(+): hypothesis supported by at least one mechanism of toxicity.

#### A.2.4. Findings

The major results of the INSERM report are summarised in Tables A.3-A.6.

Table A.3:	Statistically significant associations between occupational exposure to pesticides and	
	health outcomes in adults (health outcomes that were analysed in the review)	

Health outcome	Type of population with significant risk excess	Strength of presumption <sup>(a)</sup>
NHL	Farmers, operators, manufacturing plant personnel	++
Prostate cancer	Farmers, operators, manufacturing plant personnel	++
Multiple myeloma	Farmers, operators	++
Parkinson's disease	Occupational and non-occupational exposure	++
Leukaemia	Farmers, operators, manufacturing plant personnel	+
Alzheimer's disease	Farmers	+
Cognitive disorders <sup>(b)</sup>	Farmers	+
Fertility and fecundability disorders	Occupational exposure	+
Hodgkin lymphoma	Agricultural workers	±
Testicular cancer	Agricultural workers	±
Brain cancer (glioma, meningioma)	Agricultural workers	±
Melanoma	Agricultural workers	±
Amyotrophic lateral sclerosis	Farmers	±
Anxiety, depression <sup>(b)</sup>	Farmers, farmers with a history of acute poisoning, operators	±

74

(a): Scoring system: strong presumption (++), moderate presumption (+), weak presumption ( $\pm$ ). (b): Almost all pesticides were organophosphates.

Epidemiological studies and pesticides

### $<_{\circ}$

(±):弱い推定:1件の症例対照研究の結果に基づく。この統合により、この作業は単純なマッピング作業の状態を 超えたものとなった。

### A.2.3. 毒性学的データ

文献レビューで検討した毒性データは、主に代謝、作用機序、分子経路に関するものであった。製品を上市するための手続きの一部として提供された研究は、公表された文献で発表された場合を除き、考慮されなかった。

疫学研究で物質が明らかに同定された場合には、研究結果から生物学的に妥当であるかどうかを評価するためのス コアリングシステムを設定した:病態生理学的データとの整合性と健康影響の発生。

(++):3つの毒性メカニズムで支持された仮説。

(+):少なくとも1つの毒性メカニズムによって支持された仮説。

#### A.2.4. 所見

INSERM 報告書の主な結果は、表 A.3-A.6 にまとめられている。

#### 表 A.3:農薬への職業上ばく露と成人の健康影響との間の統計的に有意な関連(レビューで解析された健康影響)

#### A.2.5. Recommendations

The analysis of the available epidemiological and mechanistic data on some active substances suggests several recommendations for developing further research:

a) Knowledge on population exposure to pesticides should be improved

- 1) Collect information about use of active substances by farmers
- 2) Conduct field studies to measure actual levels of exposure
- 3) Monitor exposure during the full occupational life span
- 4) Measure exposure levels in air (outdoor and indoor), water, food, soil
- 5) Collect information on acute poisonings
- 6) Improve analytical methods for biomonitoring and external measurements
- 7) Allow researchers to have access to extensive formulation data (solvents, co-formulants, etc.).

b) Research potential links between exposure and health outcomes

- 1) Characterise substances or groups of substances causing health outcomes
- 2) Focus on susceptible individuals or groups of individuals (gene polymorphism of enzymes, etc.)
- 3) Focus on exposure windows and susceptibility (pregnancy, development)
- 4) Bridge the gap between epidemiology and toxicology (mode of action)
- 5) Improve knowledge on mixture toxicity

6) Foster new approaches of research (in vitro and in silico models, omics, etc.).

#### A.3. Similarities and differences between the EFSA External Scientific Report and the INSERM report

The two reports discussed herein have used different methodologies. Yet, their results and conclusions in many cases agree. The INSERM report is limited to predefined outcomes and it attempted to investigate the biological plausibility of epidemiological studies by reviewing toxicological data as well, meanwhile the EFSA report is a comprehensive systematic review of all available epidemiological studies that were published during an approximately 5 year window.

The differences between the reports are shown in Table A.7 and are related to the time period of search (i.e. both reports did not assess the same body of published data), different criteria for eligibility of studies and different approaches to summarising the evidence across and within outcomes.

### A.2.5. 推奨事項

いくつかの有効成分に関する利用可能な疫学的・機序学的データを解析した結果、さらなる研究開発のためのいく つかの推奨事項が示唆された。

a) 農薬への集団ばく露に関する知識は改善されるべきである。

- 1) 農家の有効成分使用に関する情報収集
- 2)実際のばく露レベルを測定するための農地での研究の実施
- 3) 生涯労働期間のばく露を監視すること
- 4)空気(屋外・屋内)、水、食品、土壌中のばく露レベルの測定
- 5) 急性中毒に関する情報収集
- 6) バイオモニタリングや外部ばく露量測定のための解析方法の改善
- 7)研究者が広範な製剤データ(溶剤、共配合製剤など)にアクセスできるようにする。
- b)ばく露と健康影響との間の潜在的な関連性を研究する。
- 1)健康影響をもたらす物質または物質群の特性を把握する
- 2) 影響を受けやすい個人または集団に焦点を当てる(酵素の遺伝子多型など)
- 3) ばく露枠と感受性(妊娠期間、発育期間)に焦点を当てた研究
- 4) 疫学と毒物学のギャップを埋める(作用機序)
- 5) 混合物の毒性に関する知識の向上
- 6)研究の新しいアプローチ(in vitro や in silico モデル、オミクスなど)を育成する。

#### A.3. EFSA 外部科学研究報告書と INSERM 報告書の類似点と相違点

ここで議論されている2つの報告書は、異なる方法論を使用している。しかし、多くの場合、それらの結果と結論は一 致している。INSERMの報告書は、事前に調査された結果に限定されており、毒物学的データもレビューすることで疫 学研究の生物学的妥当性を調査しようとしているのに対し、EFSA の報告書は、約5年の期間に発表されたすべての 利用可能な疫学研究の包括的なシステマティックレビューである。

両報告書の違いは表A.7に示されており、検索期間(すなわち、両報告書は同じ出版データを評価していない)、研 究の適格性の基準の違い、健康影響全体と健康影響内のエビデンスを要約するアプローチの違いに関連している。

全体的に、INSERM の報告書は EFSA の報告書よりも多くの健康被害との関連を特定している。しかし、同じ健康 影響(小児白血病、パーキンソン病)については、両方の報告書で農薬ばく露との関連性が十分に証明されていると主 張されている。

Overall, the INSERM report identified a greater number of associations with adverse health effects than the EFSA report. However, a well-documented association with pesticide exposure was claimed by both reports for the same health outcomes (childhood leukaemia, Parkinson's disease).

A.4. The Ontario College of Family Physicians Literature review (OCFPLR)

In 2004, the Ontario College of Family Physicians (Ontario, Canada) reviewed the literature published between 1992 and 2003 on major health effects associated with pesticide exposure. The authors concluded that positive associations exist between solid tumours and pesticide exposures as shown in Table A.8. They noted that in large well-designed cohort studies these associations were consistently statistically significant, and the relationships were most consistent for high exposure levels. They also noted that dose–response relationships were often observed, and they considered the quality of studies to be generally good.

#### A.4. The Ontario College of Family Physicians の文献レビュー(OCFPLR)

2004 年、カナダの The Ontario College of Family Physicians は、1992 年から 2003 年の間に発表された、農 薬ばく露に関連した主要な健康影響に関する文献をレビューした。著者らは、表 A.8 に示すように充実性腫瘍と農薬 ばく露との間には正の関連が存在すると結論づけた。著者らは、よく計画された大規模コホート研究では、これらの関 連性は一貫して統計的に有意であり、その関係は高ばく露レベルで最も一貫していたと指摘している。また、用量反応 関係がしばしば観察され、研究の質は概ね良好であるとした。

Functional nervous system impact	+ ve organophosphate/carbamate poisoning					
Neurodegenerative impacts (PD)	+ve cohort (4/4) +ve case_control (2/2) +ve ecological (1/1)					

+ve: positive; -ve: negative.

The report concluded that there was compelling evidence of a link between pesticide exposure and the development of non-Hodgkin's lymphoma (NHL), and also clear evidence of a positive association between pesticide exposure and leukaemia. The authors also claimed to have found consistent findings of a number of nervous system effects, arising from a range of exposure time courses.

報告書は、農薬ばく露と非ホジキンリンパ腫(NHL)の発症との関連性を示す説得力のあるエビデンスがあり、また農 薬ばく露と白血病との間に正の関連性があるという明確なエビデンスがあると結論づけている。著者らはまた、様々な ばく露時間の経過から生じる多くの神経系への影響についても一貫した結果が得られたと主張している。

このような断定された結論は、非政府組織(NGO)の支持を得て、いくつかの規制当局の間で疑問が生じた。当時の

Such strong conclusions found favour with Non-Governmental organisations (NGOs) and raised questions among some Regulatory Authorities. The Advisory Committee on Pesticides (ACP), at that time an UK government independent advisory committee, was asked to provide an evaluation of the outcome of the Ontario College review. The committee membership included one epidemiologist and the committee consulted five other epidemiologists involved in providing independent advice to other government committees. They all agreed that the review had major shortcomings (e.g. exact search strategy and selection criteria not specified, selective reporting of results, inadequate understanding and consideration of relevant toxicology, insufficient attention to routes and levels of exposure, not justified conclusions, etc.). Overall, the conclusions of the Ontario College review were considered not to be supported by the analysis presented. In 2012, the Ontario review authors published an update of their evaluation; in their second report they used a very similar approach but offered more detail concerning the inclusion criteria used. This example is a reminder of the risk of over interpretation of epidemiological studies. In particular, a causal inference between exposure and the occurrence of adverse health effects is often made, but this represents an association that should be further assessed.

80

#### Epidemiological studies and pesticides

英国政府の独立諮問委員会である農薬諮問委員会(ACP)は、オンタリオ大学レビューの結果の評価を依頼された。 委員会のメンバーには1人の疫学者が含まれており、委員会は、他の政府の委員会に独立した助言を提供することに 関与している他の5人の疫学者に相談した。彼らはすべてのレビューが主要な欠点を持っていたことに同意した(例え ば、正確な検索戦略と特定されていない選択基準、結果の選択的な報告、不適切な理解と関連する毒性学の考慮、 ばく露のルートとレベルへの不十分な注意、正当化された結論、等)。全体的に、オンタリオ大学レビューの結論は、提 示された解析によってサポートされていないと考えられた。2012年には、オンタリオ大学レビューの著者は、彼らの評 価の更新を発表した;彼らの2番目の報告書では、彼らは非常に似たようなアプローチを使用したが、使用される包含 基準に関するより詳細を提供した。この例は、疫学研究の過剰解釈のリスクを思い起こさせるものである。特に、ばく露 と有害な性健康影響の発生との間の因果関係を推論することはよくあるが、これはさらに評価されるべき関連性を示し ている。

### Annex B – Human biomonitoring project outsourced by EFSA<sup>23</sup>

In 2015, EFSA outsourced a project to further investigate the role of HBM in occupational health and safety strategies as a tool for refined exposure assessment in epidemiological studies and to contribute to the evaluation of potential health risks from occupational exposure to pesticides. It was in fact recognised that exposure assessment is a key part of all epidemiological studies and misclassification of exposure and use of simple categorical methods are known to weaken the ability of a study to determine whether an association between contact and ill-health outcome exists; at present, this limits integration of epidemiological findings into regulatory risk assessment.

The consortium formed by Risk & Policy Analysts Limited (RPA), IEH Consulting Limited (IEH) and the Health&Safety Laboratory (HSL) carried out a systematic literature review for the period 1990–2015 with the aim to provide an overview on the use of HBM as a tool for occupational exposure assessment refinement, identifying advantages, disadvantages and needs for further development (first objective). The search identified 2096 publications relating to the use of HBM to assess occupational exposure to pesticides (or metabolites). The outcome of the search (Bevan et al., 2017) indicated that over the past 10–20 years there has been an expansion in the use of HBM, especially into the field of environmental and consumer exposure analysis. However, further improvement of the use of HBM for pesticide exposure assessment is needed, in particular with regards to: development of strategies to improve or standardise analytical quality, improvement of the availability of reference material for metabolites, integration of HBM data into mathematical modelling, exposure reconstruction, improvements in analytical instrumentation and increased availability of human toxicology data.

The contractors performed a review of available HBM studies/surveillance programmes conducted in EU/US occupational settings to identify pesticides (or metabolites) both persistent and not persistent, for which biomarkers of exposure (and possibly effect) were available and validated (second objective). A two-tiered screening process that included quality scoring for HBM, epidemiological and toxicological aspects, was utilised to identify the most relevant studies, resulting in 178 studies for critical review. In parallel with the screening of identified studies, a Master Spreadsheet was designed to collate data from these papers, which contained information relating to: study type; study participants; chemicals under investigation; biomarker quality check; analytical methodology; exposure assessment; health outcome/toxicological endpoint; period of follow-up; narrative of results; risk of bias and other comments.

HBM has been extensively used for monitoring worker exposure to a variety of pesticides. Epidemiological studies of occupational pesticide use were seen to be limited by inadequate or retrospective exposure information, typically obtained through self-reported questionnaires, which can potentially lead to exposure misclassification. Some examples of the use of job exposure or crop exposure matrices were reported. However, little validation of these matrix studies against actual exposure data had been carried out. Very limited data was identified that examined seasonal exposures and the impact of PPE, and many of the studies used HBM to only assess one or two specific compounds. A wide variety of exposure models are currently employed for health risk assessments and biomarkers have also often been used to evaluate exposure estimates predicted by a model.

From the 178 publications identified to be of relevance, 41 individual studies included herbicides, and of these, 34 separate herbicides were identified, 15 of which currently have approved for use in the EU. Similarly, of the 90 individual studies that included insecticides, 79 separate insecticides were identified, of which 18 currently have approved for use in the EU. Twenty individual studies studies that EU. Twenty individual studies in the EU. The most studied herbicides (in order) were shown to be: 2,4-D > atrazine > metolachlor = MCPA > alachlor = glyphosate. Similarly, the most studied insecticides (in order) were: chlorpyrifos > permethrin > cypermethrin = deltamethrin > malathion, and the most studied fungicides were: captan > mancozeb > folpet.

Current limitations comprised the limited number of kinetic data from humans, particularly with respect to the ADME of individual pesticides in human subjects, which would allow more accurate HBM sampling for all routes of exposure. A wider impact of this is on the development of PBPK models for the risk assessment of pesticides, which rely on toxicokinetic data, and on validation of currently used exposure assessment models. Further limitations currently impacting on the use of HBM in this field are a lack of large prospective cohort studies to assess long term exposure to currently used pesticides.

CI USA INVITA

### 付属書 B-EFSA が委託したヒト・バイオモニタリング・プロジェクト<sup>23</sup>

2015 年、EFSA は、疫学研究におけるばく露評価のためのツールとして、また、農薬への職業上ばく露による潜在 的な健康リスク評価に貢献するために、労働安全衛生戦略における HBM の役割をさらに調査するためのプロジェクト を外部委託した。実際、ばく露評価はすべての疫学研究の重要な部分であり、ばく露の誤分類や単純な分類法の使用 は、接触と健康被害の結果との間に関連性があるかどうかを判断する研究の能力を弱めてしまうことが知られている。

Risk & Policy Analysts Limited (RPA)、IEH Consulting Limited (IEH)、Health & Safety Laboratory (HSL)からなるコンソーシアムは、1990 年から 2015 年までの期間、系統的な文献レビューを実施した。その目的は、 作業ばく露評価の再開発のためのツールとしての HBM の使用に関する概要を提供し、長所、短所、さらなる開発の 必要性を特定することであった (第一の目的)。検索では、農薬(またはその代謝物)への職業上ばく露を評価するため の HBM の使用に関連する 2096 の文献を特定した。検索の結果(Bevan 6、2017 年)は、過去 10~20 年の間に HBM の使用が拡大してきたこと、特に環境や消費者のばく露分析の分野にまで拡大してきたことを示している。しかし、 農薬ばく露評価のための HBM の使用については、特に、分析品質の向上や標準化のための戦略の開発、代謝物の ための標準物質の利用可能性の向上、数学的モデリングへの HBM データの統合、ばく露の再構築、分析機器の改 善、ヒト毒性データの利用可能性の向上など、さらなる改善が必要とされている。

請負業者は、EU/米国の作業環境で実施された利用可能な HBM 研究/サーベイランスプログラムのレビューを 実施し、残留性のあるものと残留性のないものの両方の農薬(または代謝物)を特定した。最も関連性の高い研究を特 定するために、HBM、疫学的、毒性学的側面の品質スコアリングを含む 2 段階のスクリーニングプロセスを利用し、 178 件の研究をクリティカルレビューの対象とした。特定された研究のスクリーニングと並行して、これらの文献からのデ ータを照合するためにマスタースプレッドシートが計画され、その中には、研究タイプ、研究参加者、調査対象の化学 物質、バイオマーカーの品質チェック、分析方法、ばく露評価、健康影響/毒性エンドポイント、追跡期間、結果の説 明、バイアスのリスク、その他のコメントに関する情報が含まれている。

HBM は、様々な農薬への作業者のばく露を監視するために広く使用されている。職業上の農薬の使用に関する疫 学的研究では、不十分なばく露情報や後ろ向きなばく露情報が制限されていることが見受けられる。職業別または作 物別のばく露マトリックスの使用例も報告されている。しかし、実際のばく露データに対するこれらのマトリックス研究の 検証はほとんど行われていない。季節的なばく露と PPE の影響を調査したデータは非常に限られており、多くの研究 では、1 つまたは 2 つの特定化合物のみを評価するために HBM を使用している。現在、健康リスク評価には多種多 様なばく露モデルが採用されており、モデルによって予測されたばく露推定値を評価するためにバイオマーカーもしば しば使用されている。

関連性があると判断された 178 の出版物から、41 の個別研究が除草剤を含み、そのうち 34 の個別除草剤が同定さ れ、そのうちの 15 が現在 EU での使用が承認されている。同様に、殺虫剤を含む 90 件の個別研究のうち、79 件の殺 虫剤が同定され、そのうち 18 件は現在 EU での使用が承認されている。20 の個別研究には殺菌剤が含まれており、 34 種類の殺菌剤が確認され、そのうち 22 種類が現在 EU での使用が承認されている。最も研究された除草剤は(順 に)、2,4-D>アトラジン>メトラクロール=MCPA>アラクロール=グリホサートであることが示されている。同様に、最も研究 された殺虫剤(順に)は、クロルビリホス>ペルメトリン>シペルメトリン=デルタメトリン>マラチオンであり、最も研究された 殺菌剤は、キャブタン>マンコゼプ>フォルペットであった。

現在の限界は、特にとトを対象とした個々の農薬の ADME に関して、とトからの動特性データの数が限られているこ とに起因しており、これにより、すべてのばく露経路についてより正確な HBM サンプリングが可能になる。このことは、 毒物動態データに依存する農薬のリスク評価のための PBPK モデルの開発や、現在使用されているばく露評価モデ ルのパリデーションにも影響を及ぼす。現在、この分野での HBM の使用に影響を与えているさらなる限界は、現在使 用されている農薬への長期ばく露を評価するための大規模な前向きコホート研究が不足していることである。

特定されたエビデンスは、ヨーロッパにおける農薬の労働衛生サーベイランスの一環としての HBM の実施に関する

<sup>&</sup>lt;sup>23</sup> Bevan et al. (2017).

<sup>23</sup> Bevan S

The evidence identified has been used to help formulate recommendations on the implementation of HBM as part of the occupational health surveillance for pesticides in Europe. Some key issues were considered that would need to be overcome to enable implementation. These included the setting of priorities for the development of new specific and sensitive biomarkers, the derivation and adoption of health-based guidance values, development of QA schemes to validate inter-laboratory measurements, good practice in field work and questionnaire design, extension of the use of biobanking and the use of HBM for post-approval monitoring of pesticide safety.

#### Epidemiological studies and pesticides

推奨事項を策定するために使用されている。実施を可能にするために克服しなければならないいくつかの重要な問題 が検討された。その中には、新しいスペックや感度の高いバイオマーカーの開発の優先順位の設定、健康に基づいた ガイダンス値の導入と採用、研究間の計測値を検証するための QA スキームの開発、野外作業やアンケートの作成に おける良好な実施、バイオバンキングの使用範囲の拡大、農薬の安全性の承認後のモニタリングにおける HBM の使 用などが含まれている。

Annex C – Experience of international regulatory agencies in regards to the integration of epidemiological studies for hazard identification

#### C.1. WHO-International Agency for Research on Cancer (IARC)

The IARC Monographs on the Evaluation of Carcinogenic Risks to Humans of the International Agency for Research on Cancer (IARC) is a programme established four decades ago to assess environmental exposures that can increase the risk of human cancer. These include individual chemicals and chemical mixtures, occupational exposures, physical agents, biological agents and lifestyle factors.

IARC assembles international interdisciplinary Working Groups of scientists to review and assess the quality and strength of evidence from scientific publications and perform a hazard evaluation to assess the likelihood that the agents of concern pose a cancer risk to humans. In particular, the tasks of IARC Working Group Members include the evaluation of the results of epidemiological and other experimental studies on cancer, to evaluate data on the mechanisms of carcinogenesis and to make an overall evaluation of the carcinogenicity of the exposure to humans.

The Monographs are widely used and referenced by governments, organisations, and the public around the world to set preventive and control public health measures.

The Preamble<sup>24</sup> to the IARC Monographs explains the scope of the programme, the scientific principles and procedures used in developing a Monograph, the types of evidence considered and the scientific criteria that guide the evaluations. The scope of the monographs broadened to include not only single chemicals but also groups of related chemicals, complex mixtures, occupational exposures, physical and biological agents and lifestyle factors. Thus, the title of the monographs reads 'Evaluation of carcinogenic risks to humans'.

Relevant epidemiological studies, cancer bioassays in experimental animals, mechanistic data, as well as exposure data are critically reviewed. Only reports that have been published or accepted for publication in the openly available scientific literature are included. However, the inclusion of a study does not imply acceptance of the adequacy of the study design or of the analysis and interpretation of the results. Qualitative aspects of the available studies are carefully scrutinised.

Although the Monographs have emphasised hazard identification, the same epidemiological and experimental studies used to evaluate a cancer hazard can also be used to estimate a dose-response relationship. A Monograph may undertake to estimate dose-response relationships within the range of the available epidemiological data, or it may compare the dose-response information from experimental and epidemiological studies.

The structure of a Monograph includes the following sections:

- 1) Exposure data
- 2) Studies of cancer in humans
- 3) Studies of cancer in experimental animals
- 4) Mechanistic and other relevant data
- 5) Summary
- 6) Evaluation and rationale.

Human epidemiological data are addressed in point 2, where all pertinent epidemiological studies are assessed. Studies of biomarkers are included when they are relevant to an evaluation of carcinogenicity to humans.

The IARC evaluation of epidemiological studies includes an assessment of the following criteria: types of studies considered (e.g. cohort studies, case-control studies, correlation (or ecological) studies and intervention studies, case reports), quality of the study (e.g. bias, confounding, biological variability and the influence of sample size on the precision of estimates of effect), meta analysis and pooled analyses, temporal effects (e.g. temporal variables, such as age at first exposure, time since first exposure, duration of exposure, cumulative exposure, peak exposure), use of biomarkers in epidemiological studies (e.g. evidence of exposure, of early effects, of cellular, tissue or organism responses), and criteria for causality.

With specific reference to causality, a judgement is made concerning the strength of evidence that the agent in question is carcinogenic to humans. In making its judgement, the Working Group

CI USA INFO

### 付属書 C-ハザードの特定のための疫学研究の統合に関する国際規制機関の経験 C.1. WHO-国際がん研究機関(IARC)

国際がん研究機関(IARC)の「ヒトに対する発がん性リスク評価に関する IARC モノグラフ」は、ヒトのがんリスクを増加させる可能性のある環境ばく露を評価するために 40 年前に設立されたプログラムである。これらには、個々の化学物質や化学物質の混合物、職業上ばく露、物理的要因、生物学的要因、生活様式の要因が含まれる。

IARC は、科学者からなる国際的な学際的作業部会を組織し、科学的出版物からのエビデンスの質と強度をレビューして評価し、懸念される物質がヒトに発がんリスクをもたらす可能性を評価するためのハザード評価を実施している。 特に、IARC ワーキンググループのメンバーの役割は、がんに関する疫学的研究やその他の実験的研究の結果の評価、発がんのメカニズムに関するデータの評価、ヒトへのばく露による発がん性の総合的な評価を行うことである。

モノグラフは、世界中の政府、組織、公衆衛生の予防・管理措置を設定するために広く利用され、参照されている。

IARC モノグラフの前文<sup>24</sup>は、プログラムの範囲、モノグラフの開発に使用される科学的原理と手順、考慮されるエビ デンスの種類、評価の指針となる科学的基準を説明している。モノグラフの範囲は、単一の化学物質だけでなく、関連 する化学物質のグループ、複雑な混合物、職業上ばく露、物理的・生物学的物質、生活様式の要因を含むように拡大 された。そのため、モノグラフのタイトルは「ヒトに対する発がん性リスクの評価」となっている。

関連する疫学研究、実験動物を用いた発がんバイオアッセイ、メカニズムデータ、ばく露データなどが批判的にレビューされている。公表されている科学文献に掲載された、または掲載が認められた報告書のみが含まれる。しかし、研究を含めることは、研究デザインの妥当性や結果の分析と解釈を受け入れることを意味するものではない。利用可能な研究の質的側面は慎重に精査されている。

モノグラフではハザードの特定を強調しているが、がんのハザードを評価するために用いられた疫学研究や実験研 究と同じものを、用量反応関係を推定するためにも用いることができる。モノグラフは、利用可能な疫学データの範囲内 で用量反応関係を推定することもあれば、実験研究と疫学研究の用量反応情報を比較することもある。

モノグラフの構成は以下のようになっている。

- 1)ばく露データ
- 2) ヒトにおけるがんの研究
- 3)実験動物を用いたがんの研究
- 4)メカニズム等の関連データ
- 5)まとめ
- 6)評価と根拠

ヒトの疫学的データは、関連するすべての疫学的研究が評価されている 2)に記載されている。バイオマーカーの研究は、ヒトに対する発がん性の評価に関連する場合に含まれる。

疫学研究の IARC 評価には、以下の基準の評価が含まれる:検討された研究の種類(例:コホート研究、症例対照 研究、相関(または生態学的)研究及び介入研究、症例報告)、研究の質(例:バイアス、交絡、生物学的変動及び影響の推定精度に対するサンプルサイズの影響)、メタアナリシス及びプール分析、時間的影響。例えば、最初のばく露 時の年齢、最初のばく露からの時間、ばく露の期間、累積ばく露、ピークばく露などの時間的変数)、疫学研究におけ るバイオマーカーの使用(例えば、ばく露のエビデンス、初期効果のエビデンス、細胞、組織または生物の反応のエビ デンス)、因果関係の基準。

因果関係に関する特定の基準では、問題の薬剤がヒトに対して発がん性があるというエビデンスの強さに関して判断 がなされる。

判断を下す際に、作業部会は因果関係についていくつかの基準を考慮している(Hill、1965年)。強い関連性(例 えば、大きな相対リスク)は因果関係を示す可能性が高い。しかし、疾患やばく露が一般的な場合には、弱い関連性が 重要であることが認識されている。異なるばく露条件で計画の異なる複数の研究で再現された関連性は、単一の研究

<sup>24</sup> http://monographs.iarc.fr/ENG/Preamble/CurrentPreamble.pdf

www.efsa.europa.eu/efsajournal

<sup>&</sup>lt;sup>24</sup> http://monographs.iarc.fr/ENG/Preamble/CurrentPreamble.pdf

considers several criteria for causality (Hill, 1965). A strong association (e.g. a large relative risk) is more likely to indicate causality. However, it is recognised that weak associations may be important when the disease or exposure is common. Associations that are replicated in several studies of different design under different exposure conditions are more likely to represent a causal relationship than isolated observations from single studies. In case of inconsistent results among different investigations, possible reasons (e.g. differences in exposure) are sought, and high quality studies are given more weight compared to less methodologically sound ones. Risk increasing with the exposure is considered to be a strong indication of causality, although the absence of a clear dose-response effect is not necessarily evidence against a causal relationship. The demonstration of a decline in risk after cessation of or reduction in exposure also supports a causal interpretation of the findings. Temporality, precision of estimates of effect, biological plausibility and coherence of the overall data are considered. Biomarkers information may be used in an assessment of the biological plausibility of epidemiological observations. Randomised trials showing different rates of cancer among exposed and unexposed individuals provide particularly strong evidence for causality.

When epidemiological studies show little or no indication of an association between an exposure and cancer, a judgement of lack of carcinogenicity can be made. In those cases, studies are scrutinised to assess the standards of design and analysis described above, including the possibility of bias, confounding or misclassification of exposure. In addition, methodologically sound studies should be consistent with an estimate of effect of unity for any observed level of exposure, provide a pooled estimate of relative risk near to unity, and have a narrow confidence interval. Moreover, no individual study nor the pooled results of all the studies should show any increasing risk with increasing level of exposure. Evidence of lack of carcinogenicity can apply only to the type(s) of cancer studied, to the dose levels reported, and to the intervals between first exposure and disease onset observed in these studies. Experience with human cancer indicates that the period from first exposure to the development of clinical cancer is sometimes longer than 20 years, and latent periods substantially shorter than 30 years cannot provide evidence for lack of carcinogenicity.

Finally, the body of evidence is considered as a whole, in order to reach an overall evaluation which summarises the results of epidemiological studies, the target organs or tissues, dose-response associations, evaluations of the strength of the evidence for human and animal data, and the strength of the mechanistic evidence.

At the end of the overall evaluation, the agent is assigned to one of the following groups: Group 1, the agent is carcinogenic to humans; Group 2A, the agent is probably carcinogenic to humans; Group 2B, the agent is possibly carcinogenic to humans; Group 3, the agent is not classifiable as to its carcinogenicity to humans; Group 4, the agent is probably not carcinogenic to humans.

The categorisation of an agent is a matter of scientific judgement that reflects the strength of the evidence derived from studies in humans and in experimental animals and from mechanistic and other relevant data. These categories refer only to the strength of the evidence that an exposure is carcinogenic and not to the extent of its carcinogenic activity (potency).

For example, Group 1: The agent is carcinogenic to humans. This category is used when there is sufficient evidence of carcinogenicity in humans. Exceptionally, an agent may be placed in this category when evidence of carcinogenicity in humans is less than sufficient but there is sufficient evidence of carcinogenicity in experimental animals and strong evidence in exposed humans that the agent acts through a relevant mechanism of carcinogenicity.

Although widely accepted internationally, there have been criticisms of the classification of particular agents in the past, and more recent criticisms have been directed at the general approach adopted by IARC for such evaluations possibly motivating publication of a rebuttal (Pearce et al., 2015).

#### C.2. The experience of US-EPA in regards to the integration of epidemiological studies in risk assessment

The US Environmental Protection Agency's Office of Pesticide Programs (OPP) is the governmental organisation in the US responsible for registering and regulating pesticide products.<sup>25</sup> As part of this activity and prior to any permitted use of a pesticide, OPP evaluates the effects of pesticides on human health and the environment. EPA receives extensive hazard and exposure information to characterise

el usa muni

#### Epidemiological studies and pesticides

からの孤立した観察よりも因果関係を示す可能性が高い。異なる研究間で一貫性のない結果が得られた場合には、考 えられる理由(例えば、ばく露の違い)を探り、方法論的に健全でない研究よりも質の高い研究の方が重要視される。明 確な用量反応効果がないからといって必ずしも因果関係を否定するエビデンスにはならないが、ばく露に伴ってリスク が増加することは因果関係を示す強いエビデンスと考えられている。ばく露の停止または減少後にリスクが低下してい ることが示された場合も、結果の因果関係の解釈を支持するものである。時間性、影響の推定精度、生物学的妥当性、 全体的なデータの一貫性が考慮される。バイオマーカー情報は、疫学的観察の生物学的妥当性の評価に使用される ことがある。被験者と非被験者でがんの発生率が異なることを示している無作為試験は、特に因果関係を示す強力な エビデンスとなる。

疫学的研究でばく露とがんとの間の関連性がほとんど、または全く示されない場合には、発がん性がないと判断する ことができる。このような場合、研究は、バイアスの可能性、交絡の可能性、またはばく露の誤分類を含めて、上述の計 画と解析の基準を評価するために精査される。さらに、方法論的に健全な研究は、観察されたばく露レベルのどのよう なばく露についても、影響の推定値が一致していること、相対リスクのプール推定値がほぼ一致すること、そして狭い信 頼性間隔を持つことに一貫性があるべきである。さらに、個々の研究も、すべての研究のプール結果も、ばく露レベル の増加に伴うリスクの増加を示すべきではない。発がん性がないというエビデンスは、研究されたがんの種類、報告され たばく露量及びこれらの研究で観察された最初のばく露と疾患発症の間の期間にのみ適用できる。ヒトのがんの経験 から、最初のばく露から臨床症状のがんの発生までの期間が20年よりも長いことがあり、30年よりも実質的に短い潜伏 期間は、発がん性の欠如のエビデンスを提供できないことが示されている。

最後に、疫学研究の結果、標的臓器または組織、用量反応関連、ヒト及び動物のデータのエビデンスの強固さの評 価、メカニズムのエビデンスの強固さをまとめた総合評価に到達するために、エビデンスの全体像を検討する。

総合評価の最後に、以下のいずれかのグループに分類される。グループ 1、その薬剤はヒトに対して発がん性があ る:グループ 2A、その薬剤はおそらくヒトに対して発がん性がある:グループ 2B、その薬剤はヒトに対する発がん性が 疑われる:グループ 3、その薬剤はヒトに対する発がん性に関して分類できない:グループ 4、その薬剤はおそらくヒトに 対して発がん性がない。

薬剤の分類は、ヒト及び実験動物での研究、ならびにメカニズム及びその他の関連データから得られたエビデンスの 強固さを反映する科学的判断の問題である。これらの分類は、ばく露が発がん性であるというエビデンスの強固さにの み言及しており、発がん性(可能性)の程度には言及していない。

例えば、グループ 1:その薬剤はヒトに対して発がん性がある。このカテゴリーは、ヒトにおける発がん性の十分なエビ デンスがある場合に使用される。例外的に、ヒトにおける発がん性のエビデンスが十分ではないが、実験動物における 発がん性の十分なエビデンスがあり、ばく露されたヒトにおいて、その薬剤が発がん性の関連メカニズムを介して作用 するという強いエビデンスがある場合には、薬剤はこのカテゴリーに分類される。国際的に広く受け入れられているが、 過去には特定の薬剤の分類に対する批判があり、より最近の批判は、そのような評価のために IARC が採用した一般 的なアプローチに向けられており、反論の発表を動機づける可能性がある(Pearce ら、2015年)。

### C.2. リスク評価における疫学的研究の統合に関する US-EPA の経験

米国環境保護庁の農薬プログラム(OPP)は、農薬製品の登録と規制を担当する米国の政府機関である25。この活 動の一環として、また農薬の使用が許可される前に、OPP は農薬がヒト健康と環境に及ぼす影響を評価している。

EPAは、連邦殺虫剤・殺菌剤・殺鼠剤法(FIFRA)及び連邦食品・医薬品・化粧品法(FFDCA)を通じて、農薬製品 のリスクを特性評価するための広範なハザード及びばく露情報を入手している。農薬の毒性影響に関する情報は、一 般的に、農薬登録者が実施し、EPA に提出する実験動物を用いた研究から得られている。

これまでは、農薬へのばく露に関連する可能性のある潜在的なリスクを EPA が評価するための情報として、農薬に 関する十分に計画された疫学研究から得られた情報は一般的には得られていなかった。農薬へのばく露と健康影響と

<sup>&</sup>lt;sup>25</sup> See https://www.epa.gov/pesticide-science-and-assessing-pesticide-risks for general information on pesticide science and assessing pesticide risks. 84

<sup>25</sup> 農薬科学及び農薬リスクの評価に関する一般的な情報については、https://www.epa.gov/pesticide-science-and-assessing-pesticide-risks を参昭のこと

el usa muni

the risks of pesticide products through the Federal Insecticide, Fungicide, and Rodenticide Act (FIFRA) and the Federal Food, Drug, and Cosmetic Act (FFDCA). Information on the toxic effects of pesticides is generally derived from studies with laboratory animals conducted by pesticide registrants and submitted to EPA.

In the past, information from well-designed epidemiology studies on pesticides has not been typically available to inform EPA's evaluations of potential risks that might be associated with exposure to pesticides. With an increasing number of epidemiology studies entering the literature which explore the putative associations between pesticides exposure and health outcomes, EPA is putting additional emphases on this source of information. This is especially true for the wealth of studies deriving from the Agricultural Health Study<sup>26</sup> (AHS), a large, well-conducted prospective cohort study following close to 90,000 individuals over more than 20 years and from the Children's Environmental Health and Disease Prevention Research Centers.<sup>27</sup> EPA intends to make increasing use of these epidemiology studies in its human health risk assessment with the goal of using such epidemiological information in the most scientifically robust and transparent way.

#### C.2.1. OPP Epidemiological Framework Document

As an early first step in this process, EPA-OPP developed a proposed epidemiological framework document released as a draft in 2010, 'Framework for Incorporating Human Epidemiologic and Incident Data in Health Risk Assessment' (US-EPA, 2010a). The 2010 draft framework was reviewed favourably by the FIFRA Scientific Advisory Panel (SAP) in February, 2010 (US-EPA, 2010b). This document was recently updated in 2016 to the 'Office of Pesticide Programs' Framework Document for Incorporating Human Epidemiology and Incident Data in Risk Assessments for Pesticides' (US-EPA, 2016). The revised and updated 2016 Framework document proposes that human information like that found in epidemiology studies (in addition to human incident databases, and biomonitoring studies) along with experimental toxicological information play a significant role in this new approach by providing insight into the effects caused by actual chemical exposures. In addition, epidemiological/ molecular epidemiological data can guide additional analyses, identify potentially susceptible populations and new health effects and potentially confirming existing toxicological observations. The concepts in the 2016 Framework are based on peer-reviewed robust principles and tools and rely on many existing guidance documents and frameworks (Table C.1) for reviewing and evaluating epidemiology data. It is also consistent with updates to the World Health Organization/International Programme on Chemical Safety mode of action (MoA)/human relevance framework which highlight the importance of problem formulation and the need to integrate information at different levels of biological organisation (Meek et al., 2014). Furthermore, it is consistent with recommendations by the National Academy of Sciences' National Research Council (NAS/NRC) in its 2009 report Science and Decisions (NRC, 2009) in that the framework describes the importance of using problem formulation at the beginning of a complex scientific analysis. The problem formulation stage is envisioned as starting with a planning dialogue with risk managers to identify goals for the analysis and possible risk management strategies. This initial dialogue provides the regulatory context for the scientific analysis and helps define the scope of such an analysis. The problem formulation stage also involves consideration of the available information regarding the pesticide use/usage, toxicological effects of concern, exposure pathways, and duration along with key gaps in data or scientific information.

#### Epidemiological studies and pesticides

の間に考えられる関連性を調査する疫学研究が文献に掲載されることが増えてきたため、EPA はこの情報源をさらに 重視している。これは、20年以上にわたって9万人近くの個人を追跡した大規模でよく実施された前向きなコホート研 究である農業健康調査(Agricultural Health Study<sup>26</sup>(AHS)や、小児環境保健・疾病予防研究センターから得られ た豊富な研究に特に当てはまる。EPA27は、このような疫学的情報を最も科学的に強固で明白性の高い方法で利用す ることを目標に、ヒトの健康リスク評価においてこれらの疫学的研究をより多く利用することを意図している。

### C.2.1. OPP 疫学的フレームワーク文書

このプロセスの初期段階として、EPA-OPPは、2010年に「健康リスク評価にヒトの疫学的データ及びインシデントデ ータを組み込むためのフレームワーク(Framework for incorporated human Epidemiologic and Incident Data in Health Risk Assessment) (US-EPA、2010 年 a)という疫学的枠組み文書案を作成した。2010 年のフレームワ ーク草案は、2010年2月にFIFRA科学諮問委員会(SAP)によって好意的にレビューされた(US-EPA、2010年b)。 この文書は最近、2016 年に「Office of Pesticide Programs' Framework Document for Incorporating Human Epidemiology and Incident Data in Risk Assessments for Pesticides | (US-EPA, 2016 年)に更新された。改訂 及び更新された2016年のフレームワーク文書は、疫学研究(ヒト事例データベース、バイオモニタリング研究に加えて) でみられるようなヒトの情報が、実験的な毒性学的情報とともに、実際の化学物質ばく露によって引き起こされる影響に ついての予測を提供することで、この新しいアプローチにおいて重要な役割を果たすことが提案されている。さらに、疫 学的/分子疫学的データは、追加解析の指針となり、潜在的に影響を受けやすい集団や新たな健康影響を特定し、 既存の毒物学的観測を補完する可能性がある。2016年版フレームワークの概念は、専門家の査読を経た強固な原則 とツールに基づいており、疫学データのレビューと評価のための多くの既存のガイダンス文書とフレームワーク(表 C.1) に依存している。また、問題設定の重要性と生物学的組織の異なるレベルでの情報統合の必要性を強調した世界保 健機関/国際化学安全計画(MOA)/ヒト関連性フレームワークの更新とも一致している(Meek ら、2014 年)。さらに、 このフレームワークは、2009年の報告書「Science and Decisions (NRC、2009年)」の中で、複雑な科学的分析の最 初に問題の定式化を使用することの重要性を説明しているという点で、全米科学アカデミーの全米研究評議会(NAS /NRC)の勧告と一致している。問題の定式化の段階は、解析の目標と可能なリスク管理戦略を特定するためのリスク 管理者との計画的な対話から始まると想定されている。この最初の対話は、科学的解析のための規制の背景を提供し、 そのような解析の範囲を明確にするのに役立つ。問題設定の段階では、農薬の使用/使用、懸念される毒性学的影 響、ばく露経路、持続時間、データや科学的情報の主要なギャップに関する利用可能な情報を考慮することも含まれ ている。

OECD	2013	Organisation for Economic Co-operation and Development Guidance Document on Developing and Assessing Adverse Outcome Pathways				

Briefly, this EPA Framework document describes the scientific considerations that the Agency will weigh in evaluating how such epidemiological studies and scientific information can be integrated into risk assessments of pesticide chemicals and also in providing the foundation for evaluating multiple lines of scientific evidence in the context of the understanding of the adverse outcome pathway (or MoA). The framework relies on and espouses standard practices in epidemiology, toxicology and risk assessment, but allows for the flexibility to incorporate information from new or additional sources. One of the key components of the Agency's framework is the use the MoA framework/adverse outcome pathway concept as a tool for organising and integrating information from different sources to inform the causal nature of links observed in both experimental and observational studies. MoA (Boobis et al., 2008; Simon et al., 2014; Meek et al., 2014) and adverse outcome pathway (Ankley et al., 2010) provide important concepts in the integrative analysis discussed in the Framework document. Both a MoA and an adverse outcome pathway are based on the premise that an adverse effect caused by exposure to a compound can be described by a series of causally linked biological key events that result in an adverse human health outcome, and have as their goal a determination of how exposure to environmental agents can perturb these pathways, thereby causing a cascade of subsequent key events leading to adverse health effects.

A number of concepts in the Framework are taken from two reports from the National Academies, *Science and Decisions: Advancing Risk Assessment* (NAS 2009) and *Toxicity Testing on the 21st Century* (NAS 2007). These two NRC reports advocate substantial changes in how toxicity testing is performed, how such data are interpreted, and ultimately how regulatory decisions are made. In particular, the 2007 report on 21st century toxicity testing advocates a decided shift away from the current focus of using apical toxicity endpoints to using toxicity pathways to better inform toxicity testing, risk assessment, and decision-making.

The MoA framework begins with the identification of the series of key events that are along the causal path and established on weight of evidence using criteria based on those described by Bradford Hill taking into account factors such as dose-response, temporal concordance, biological plausibility, coherence and consistency. Specifically, the modified Bradford Hill Criteria (Hill, 1965) are used to evaluate the experimental support that establishes key events within a MoA or an adverse outcome pathway, and explicitly considers such concepts as strength, consistency, dose response, temporal

OECD	2013	経済協力開発機構 (Organisation for Economic Co-operation and Development) 有害性転帰経路の開発と評価に関するガイダンス文書

EPA フレームワーク文書は、このような疫学的研究及び科学的情報を農薬化学物質のリスク評価にどのように組み 込むことができるかを評価する際に、また、有害性転帰経路(または MOA)の理解との関連で複数の科学的エビデン スを評価するための基盤を提供する際に、EPA が考慮する科学的考察を記述している。このフレームワークは、疫学、 毒性学、リスク評価の標準的な手法に依存し、それを支持しているが、新しい情報源や追加の情報源からの情報を取り 入れることも可能である。この機関のフレームワークの重要な構成要素の一つは、実験研究と観察研究の両方で観察 された因果関係の特性を知るために、異なる情報源からの情報を整理して統合するためのツールとして、MOA フレー ムワーク/有害性転帰経路の概念を使用することである。MOA(Boobis 6、2008 年;Simon 6、2014 年;Meek 6、 2014 年)と有害性転帰経路(Ankley 6、2010 年)は、フレームワーク文書で議論されている統合解析において重要な 概念を提供する。MOA と有害性転帰経路の両方とも、化合物へのばく露によって引き起こされる毒性影響は、ヒトの毒 性影響をもたらす一連の因果関係のある生物学的重要事象によって記述できるという前提に基づいており、その目的 は、環境物質へのばく露がこれらのパスウェイをどのようにかく乱させ、それによって毒性影響につながる後続の重要事 象のカスケードを引き起こすかを決定することである。

フレームワークの多くの概念は、全米科学アカデミー(National Academies, Science and Decisions)の2つの報 告書:「リスクアセスメントの進展」(Advancing Risk Assessment:NAS 2009 年)と「21 世紀の毒性試験」(Toxicity Testing on the 21st Century: NAS 2007 年)から引用されている。これら2つのNRC報告書は、毒性試験の実施 方法、データの解釈方法、そして最終的に規制上の政策決定の方法を大幅に変更することを提唱している。特に、21 世紀の毒性試験に関する2007 年の報告書では、毒性試験、リスク評価、政策決定をより良く伝えるために、現在の先 毒性エンドポイントの頂点の使用に焦点を当てたものから、毒性経路を使用することへの決定的な変化を提唱している。 MOA のフレームワークは、原因経路に沿って、そして用量反応、時間的一致、生物学的妥当性、一貫性 などの要素を考慮に入れ、Bradford Hill によって記述されたものに基づいた基準を使用して、エビデンスの重み付け concordance, and biological plausibility in a weight of evidence analysis. Using this analytic approach, epidemiological findings can be evaluated in the context of other human information and experimental studies to evaluate consistency, reproducibility, and biological plausibility of reported outcomes and to identify areas of uncertainty and future research. Figure C.1 below (adapted from NRC, 2007) suggests how different types of information relate to each other across multiple levels of biological organisation (ranging from the molecular level up to population-based surveillance) and is based on the rapidly evolving scientific understanding of how genes, proteins, and small molecules interact to form molecular pathways that maintain cell function in humans.

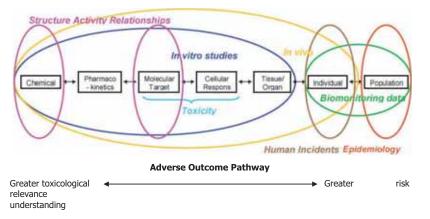

Figure C.1: Source to Outcome Pathway: Chemical effects across levels of biological organisation (adapted from NRC, 2007)

#### C.2.2. Systematic reviews: Fit for purpose

The National Academies' National Research Council (NRC) in its review of EPA's IRIS program defines systematic review as 'a scientific investigation that focuses on a specific question and uses explicit, prespecified scientific methods to identify, select, assess, and summarise the findings of similar but separate studies'.<sup>28</sup> In recent years, the NRC has encouraged the agency to move towards systematic review processes to enhance the transparency of scientific literature reviews that support chemical-specific risk assessments to inform regulatory decision-making.<sup>29</sup>

Consistent with NRC's recommendations, EPA-OPP employs fit-for-purpose systematic reviews that rely on transparent methods for collecting, evaluating and integrating the scientific data supporting its decisions. As such, the complexity and scope of each systematic review will vary among risk assessments. EPA-OPP starts with scoping/problem formulation followed by data collection, data evaluation, data integration and summary findings with critical data gaps identified.

Systematic reviews often use statistical (e.g. meta-analysis) and other quantitative techniques to combine results of the eligible studies, and can use a semi-quantitative scoring system to evaluate the levels of evidence available or the degree of bias that might be present. For EPA's Office of Pesticide Programs, such a Tier III (systematic review) assessment conducted as part of its regulatory review process would involve review of the pesticide chemical undergoing review and a specific associated suspected health outcome (as suggested by the initial Tier II assessment).

A number of federal and other organisations in the US are evaluating or have issued guidance documents for methods to conduct such systematic reviews and a number of frameworks have been

87

#### Epidemiological studies and pesticides

に基づいて確立された一連の重要事象を特定することから始まる。特に、修正された Bradford Hill 基準(Hill、1965年)は、MOA または有害な影響の現経路内の重要事象を立証する実験的支持を評価するために使用され、エビデンスの重み付け分析において、強度、一貫性、用量反応、時間的一致、生物学的妥当性などの概念を明示的に考慮している。この分析的アプローチを用いることで、疫学的結果は、報告された結果の一貫性、再現性、生物学的妥当性を評価し、不確実性の領域と将来の研究を特定するために、他のヒト情報との関連で評価することができる。以下の図C.1(NRC、2007年より引用)は、異なるタイプの情報が生物学的組織の複数のレベル(分子レベルから集団ベースのサーベイランスに至るまで)でどのように相互に関連しているかを示唆しており、遺伝子、タンパク質、低分子がヒトの細胞機能を維持する分子経路を形成するためにどのように相互作用するかという急速に発展している科学的理解に基づいている。

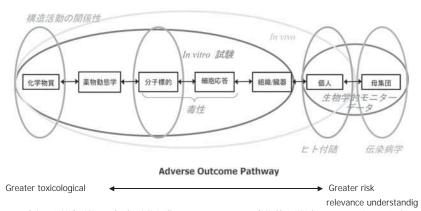

図 C.1:起源から健康影響への経路。生物組織のレベルにまたがる化学物質の影響(NRC、2007年より引用)

### C.2.2. システマティックレビュー:目的にかなった

全米アカデミーの全米研究評議会(NRC)は、EPA の IRIS プログラムのレビューにおいて、システマティックレビュ ーを「特定の問題に焦点を当て、明確かつ事前に特定された科学的方法を用いて、類似しているが別個の研究の結 果を特定、選択、評価、要約する科学的調査」と定義している<sup>28</sup>。近年、NRC は、規制上の政策決定に情報を提供す るために化学的特異性リスク評価をサポートする科学的な文献レビューの明白性を高めるシステマティックレビュープロ セスに移行することを EPA に勧めている<sup>6</sup>。

NRC の勧告に沿って、EPA-OPP は、政策決定を支える科学的データの収集、評価、統合のための明白性の高い 方法に依拠した、目的にかなったシステマティックレビューを採用している。そのため、各システマティックレビューの複 雑さと範囲はリスク評価ごとに異なる。EPA-OPP は、対象範囲/問題策定から始まり、データ収集、データ評価、デー タ統合及び重要なデータギャップが特定された結果の要約が行われる。

システマティックレビューでは、対象となる研究の結果をまとめるために統計的手法(メタアナリシスなど)やその他の 定量的手法を使用することが多く、利用可能なエビデンスのレベルや存在する可能性のあるバイアスの程度を評価す るために半定量的な採点システムを使用することができる。EPAの農薬プログラム管理局の場合、規制審査プロセスの 一環として実施されるこのような Tier III(システマティックレビュー)評価には、審査中の農薬化学物質と、(最初の Tier II評価で示唆されたように)特定の関連する健康影響が疑われる農薬化学物質の審査が含まれることになる。

米国の多くの連邦政府やその他の組織が、このようなシステマティックレビューの実施方法を評価したり、ガイダンス

developed. These include the EPA IRIS programs' approach,<sup>30</sup> the National Toxicology Programs' Office of Health Assessment and Translation (NTP/OHAT) approach<sup>31</sup> the Cochran Collaboration's approach,<sup>32</sup> the Campbell Collaboration and the Navigation Guide,<sup>33</sup> with this latter described in a series of articles in the journal *Environmental Health Perspectives*. Each broadly shares four defined steps: data collection, data evaluation, data integration, and summary/update. For example, The Cochrane Collaboration in its Cochrane Handbook for Systematic Reviews of Interventions for evidence-based medicine lists a number of the important key characteristics of a systematic review to be (from US-EPA, 2016):

- a clearly stated set of objectives with predefined eligibility criteria for studies;
- an explicit, reproducible methodology;
- a systematic search that attempts to identify all studies that would meet the eligibility criteria;
- · an assessment of the validity of the findings from the identified studies;
- a systematic presentation and synthesis of the characteristics and findings of the included studies.

As described and elaborated in the following sections of this Annex, OPP's approach to review and integration of epidemiological data into pesticide risk assessments takes a tiered approach which each tier appropriately fit-for-purpose in the sense that is considers 'the usefulness of the assessment for its intended purpose, to ensure that the assessment produced is suitable and useful for informing the needed decisions (US-EPA, 2012) and that required resources are matched or balanced against any projected or anticipated information gain from further more in-depth research. A Tier 1 assessment is either a scoping exercise or an update to a scoping exercise in which a research and evaluation is limited to studies derived from the AHS. A Tier II assessment involves a broader search of the epidemiological literature, comprehensive data collection, and a deeper, more involved data evaluation and is more extensive but is generally limited in scope to epidemiology and stops short of multidisciplinary integration across epidemiology, human poisoning events, animal toxicology and adverse outcome pathways. A Tier III assessment is a complete systematic review with data integration and more extensive data evaluation and extraction and may involve more sophisticated epidemiological methods such as meta-analysis and meta-regression, causal inference/causal diagrams, and quantitative bias and sensitivity analyses, among others.

- C.2.3. Current and Anticipated Future EPA Epidemiology Review Practices
- C.2.3.1. Tier I (Scoping & Problem Formulation) and Tier II (more extensive literature search)

Currently at EPA, epidemiology review of pesticides is conducted in a tiered process as the risk assessment develops, as briefly described above. The purpose of this early Tier I/scoping epidemiology report is to ensure that highly relevant epidemiology studies are considered in the problem formulation/scoping phase of the process and, if appropriate, fully reviewed in the (later) risk assessment phase of the process. In Tier I, EPA-OPP focuses on well-known high quality cohort studies which focus on pesticide issues, particularly the Agricultural Health Study (AHS). The AHS is a federally funded study that evaluates associations between pesticide exposures and cancer and other health outcomes and represents a collaborative effort between the US National Institute of Occupational Safety and Health (NIOSH) and the US EPA. The AHS participant cohort includes more than 89,000 licensed commercial and private pesticide applicators and their spouses from Iowa and North Carolina. Enrolment occurred from 1993 to 1997, and data collection is ongoing. The AHS maintains on its website a list of publications associated with and using the AHS cohort (see https://aghealth.nih.gov/ news/publications.html).

If the pesticide of interest has been investigated as part of the AHS (www.aghealth.org), a preliminary (Tier I/scoping) review of these studies is performed early on in the evaluation as the

#### Epidemiological studies and pesticides

文書を発行したりしており、多くのフレームワークが開発されている。これらには、EPA IRIS プログラムのアプローチ<sup>29</sup>、 National Toxicology Programs'Office of Health Assessment and Translation (NTP/OHAT) アプローチ<sup>30</sup>、 Cochran Collaboration のアプローチ<sup>31</sup>、Campbell Collaboration 及び Navigation Guide<sup>32</sup>が含まれ、後者につ いては Environmental Health Perspectives 誌の一連の記事で説明されている。それぞれのアプローチは、データ 収集、データ評価、データ統合、要約/更新という 4 つのステップを大まかに共有している。例えば、The Cochrane Collaboration は、The Cochrane Handbook for Systematic Reviews of Interventions for evidence-based medicine の中で、システマティックレビューの重要な主要特性の多くをリストアップしている(US-EPA、2016 年)。

- 目的が明確に示されており、研究の適格性基準があらかじめ定義されていること
- 明示的で再現性のある方法論
- 適格性基準を満たすすべての研究を特定するための系統的な検索
- 特定された研究から得られた知見の妥当性の評価
- 収録された研究の特性と知見を体系的に提示し、総合的にまとめたもの。

この付属書の以下のセクションで説明・詳述されているように、農薬リスク評価への疫学的データのレビューと統合に 対する OPP のアプローチは、「作成された評価が必要な政策決定を報告するのに適しており有用であることを確認し (US-EPA、2012 年)、必要な供給源が、より詳細な研究から得られる予測または予測される情報と一致しているか、バ ランスが取れていることを確認する」という意味で、各段階が目的に応じて適切に実施される段階的なアプローチを採 用している。Tier I 評価は、調査及び評価が AHS に由来する研究に限定されている場合の、調査実施または調査実 施の更新のいずれかである。Tier II 評価では、疫学的文献の広範な検索、包括的なデータ収集、より深く、より関与し たデータ評価が行われ、より広範であるが、一般的には範囲が疫学に限定されており、疫学、ヒト中毒事例、動物毒物 学、有害な影響経路を横断した学際的な統合には至らない。Tier III 評価は、データ統合とより広範なデータ評価と抽 出を伴う完全なシステマティックレビューであり、メタアナリシスやメタ回帰、因果関係推論/因果関係図、定量的バイア ス解析や感度分析などのより高度な疫学的手法を含むことがある。

### C.2.3. 現在及び将来予想される EPA 疫学レビューの実施 C.2.3.1. Tier I (scoping と問題の定式化)と Tier II (より広範な文献検索)

現在 EPA では、農薬の疫学的レビューは、上述の通り、リスク評価の進展に応じて段階的なプロセスで実施されて いる。この初期段階の Tier I/scoping 疫学報告書の目的は、プロセスの問題の定式化/scoping 段階で関連性の高い 疫学研究が検討され、適切な場合には、プロセスの(後期の)リスク評価段階で十分に検討されるようにすることである。 Tier I 段階では、EPA-OPP は、農薬問題に焦点を当てた質の高い有名なコホート研究、特に農業健康調査 (Agricultural Health Study: AHS)に焦点を当てている。AHS は、農薬ばく露とがん及びその他の健康影響との関 連を評価する連邦政府出資の研究であり、米国国立がん研究所(NCI)、国立環境衛生科学研究所(NIEHS)、CDC の国立労働安全衛生研究所(NIOSH)及び米国環境保護庁との共同研究を代表するものである。AHS 参加者コホー トには、アイオワ州とノースカロライナ州の 89,000 人以上の免許を持つ商業及び民間の農薬散布者とその配偶者が含 まれている。登録は 1993 年から 1997 年まで行われ、データ収集は現在も継続中である。AHS は、AHS コホートに 関 連 し た 、ま た そ れ を 利 用 し た 出 版 物 の リ スト を ウ ェ ブ サ イト に 掲 載 し て い る (https://aghealth.nih.gov/news/publications.html を参照)。

対象となる農薬がAHS(www.aghealth.org)の一部として調査されている場合、EPAの「scoping」解析の一環として内容摘要(または「調査資料」)が公表されるため、評価の早い段階でこれらの研究の予備的な(Tier I/scoping)レビ

www.efsa.europa.eu/efsajourna

docket (or 'dossier') is opened as part of EPA's 'Scoping' analysis. In this early Tier I/scoping phase, basic epidemiological findings and conclusions from the Agricultural Health Study are described in a Tier I/scoping document which is designed to simply summarise in brief form the pertinent conclusions of various AHS study authors if there are AHS findings relevant to a the pesticide undergoing review; this Tier I scoping review is not designed to offer detailed content, critical evaluation, or evidence synthesis, and may only touch on summarised highlights of the relevant AHS -related journal articles. If other high-quality non-AHS studies are available like those from the Children's Environmental Health and Disease Prevention Research Centres, these may be similarly summarised in this Tier I/scoping epidemiological review as well. Again, no critique or synthesis of the literature is offered. In some cases, the Tier I/scoping review may conclude that no additional epidemiological review of available evidence is further required. Alternatively, it may recommend that further review is necessary as part of a more involved Tier I/update or Tier II assessment.

A <u>Tier I/update assessment</u> is generally completed 1" to 3 years following the completion of the Tier I/scoping assessment and is issued, like the Tier II discussed below, along with and as part of the Draft Human Health Risk Assessment. Tier I/update assessments perform a thorough review of the available literature in the AHS. A Tier I/update assessment reviews, summarises and evaluates in a qualitative, narrative summary (including reported measures of association), the applicable studies that are listed on the AHS website.<sup>34</sup> Reviews are generally in the form of a narrative, focusing on the key aspects of studies and their conclusions and include EPA OPP commentary along with summary EPA OPP conclusions and recommendations for further study, if necessary.

#### C.2.3.2. Tier II (more extensive literature search)

A Tier II assessment is a more complete review of the available epidemiological evidence and is generally done only if the earlier Tier I/scoping document suggests a potential for a specific concern (e.g. a specific and credible exposure-disease hypothesis has been advanced and needs to be further evaluated as part of a more detailed assessment). A Tier II epidemiology assessment, similar to the Tier I/update, is generally completed 1" to 3 years following the completion of the Tier I assessment and is issued along with and as part of OPP's Draft Human Health Risk Assessment; the Tier II evaluation is considered to be a qualitative narrative review that incorporates certain elements of a systematic review. For example, a Tier II assessment will include a thorough and complete literature search that is broader than that of the Tier I/update, including not only the AHS database, but also such databases as PubMed, Web of Science, Google Scholar and Science Direct, and sometimes others using standardised, transparent and reproducible query language for which specialised professional library and information science support is obtained.<sup>35</sup> Evidence synthesis by EPA – albeit generally in a qualitative and narrative form - also occurs in a Tier II assessment, and overall conclusions regarding the body of epidemiological literature are made. In addition, the Tier II assessment may indicate areas in which further epidemiological data and studies with respect to specific hypothesised exposure-health outcome is of interest for future work. The Tier II assessment document will not generally attempt to integrate the epidemiological findings with other lines of evidence such as that from animal toxicology studies or information from MoAs/AOPs which may be done (separately) to some degree as part of the risk assessment. To the extent that the Tier II assessment identifies specific health outcomes putatively associated with a given pesticide, further investigation and integration across disciplines can subsequently be done as part of a more comprehensive Tier III assessment (see below).

#### C.2.3.3. Tier III (Full Systematic Review with Data Integration)

While a Tier II assessment examines a wide range of health outcomes appearing in the epidemiological literature that are hypothesised to be associated with a given pesticide chemical, a Tier III assessment might encompass a broader (multidisciplinary) and sometimes more quantitative/statistical evaluation of at the epidemiological evidence for the association of interest, and it attempts to more

89

el usa muni

ューが実施される。この初期の段階では、AHS 研究の基本的な疫学的結果と結論は、審査中の農薬に関連するAHS 結果がある場合には、様々な AHS 研究の著者による適切な結論を簡潔に要約することを目的とした Tier I/scoping 文書に記載されている;この Tier I scoping レビューは詳細な内容、批判的な評価またはエビデンスの統合を提供す るようになっていなくて AHS に関連する学術論文の要約されたハイライトに触れる可能性があるだけである。子ども環 境保健・疾病予防研究センター (Children's Environmental Health and Disease Prevention Research Centres) の研究のように、AHS 以外の高品質な研究がある場合は、これらの研究も同様にこの Tier I/scoping 疫学レビューに 要約されているかもしれない。繰り返しになるが、文献の批評や統合は行われていない。場合によっては、Tier I/scoping レビューでは、利用可能なエビデンスの追加的な疫学的レビューはこれ以上必要ないと結論付けられること がある。あるいは、より詳細な Tier I/update または Tier II 評価の一部として、更なるレビューが必要であると勧告する 場合もある。

Tier I/update 評価は通常、Tier I/scoping 評価の完了から1年から3年後に完了し、後述するTier IIと同様に、 ヒト健康リスクアセスメント案(Draft Human Health Risk Assessment)と一緒に、またその一部として発行される。 Tier I/update アセスメントでは、AHS で利用可能な文献の徹底的なレビューが行われる。Tier I/update 評価では、 AHS のウェブサイトに掲載されている該当する研究を質的、叙述的な要約(報告された関連性の尺度を含む)でレビュ ーし、要約し、評価する<sup>33</sup>。レビューは一般的に叙述の形式で行われ、研究の主要な側面とその結論に焦点を当て、必 要に応じて EPA OPP の結論の要約及び更なる研究のための勧告に加えて EPA OPP の解説を含む。

#### C.2.3.2. Tier II(より広範な文献検索)

Tier II 評価は、利用可能な疫学的証拠のより完全なレビューであり、一般的には、初期の Tier I/scoping 文書が特定の懸念の可能性を示唆している場合にのみ実施される(例えば、特定で信頼できるばく露・疾病仮説が進められており、より詳細な評価の一部としてさらに評価する必要がある)。Tier II 疫学評価は、Tier I/update と同様に、一般的に Tier I 評価の完了から 1 年から 3 年後に完了し、OPP のヒトの健康リスク評価案(Draft Human Health Risk Assessment)と一緒に、またその一部として発行される;Tier II 評価はシステマティックレビューの特定の要素を組み込む定性的で叙述的なレビューだと考えられる。例えば、Tier II 評価では、AHS データベースだけでなく、PubMed、 Web of Science、Google Scholar、Science Direct などのデータベースや、場合によっては標準化された明白で再現性のある照会言語を使用して、専門の図書館や情報科学の支援を得て、Tier I 評価よりも広範囲に及ぶ徹底した完全な文献検索が含まれている<sup>34</sup>。EPA によるエビデンス統合(一般的には定性的かつ叙述的な形式で行われるが)も Tier II 評価では行われ、疫学的文献に関する全体的な結論が出されている。さらに、Tier II 評価は、特別な仮説としてばく露・健康影響に関する更なる疫学的データや研究が将来の研究のための興味深い分野を示す可能性がある。 Tier II 評価文書は一般的に、疫学的知見を、動物毒性試験や、リスク評価の一部としてある程度(別個にに)行われる MOAs/AOPs からの情報などの他のエビデンスと統合しようとはしない。特定の農薬に関連すると考えられる特定の健康影響が特定される範囲までの Tier II 評価に対して、その後のより包括的な Tier III 評価では、分野を超えた更なる調査及び統合を行うことができる(下記参照)。

### C.2.3.3. Tier 3(データ統合を伴う完全なシステマティックレビュー)

Tier II 評価では、ある農薬化学物質との関連性があると仮説が立てられている疫学的文献に現れる広範な健康影響を検討するが、Tier III 評価では、より広範な(学際的な)疫学的根拠に基づく、時にはより定量的/統計学的な評

<sup>34</sup> https://aghealth.nih.gov/news/publications.html

formally integrate this with animal toxicology and MoA/AOP information. Such a Tier III assessment could take the form of a systematic review of the epidemiological literature which would be performed together with evaluation of toxicity and adverse outcome pathways. For pesticide chemicals from AHS, a Tier III analysis would also ideally incorporate the results of evaluations from other high-quality epidemiological investigations and incorporate 'Weight of the Evidence' to a greater degree to reflect a more diverse set of information sources. Results from these investigations would be used to evaluate replication and consistency with results from the AHS. Early AHS findings in a number of cases were based on only a small number of participants that had developed specific outcomes or a relatively few number of years over which the participants have been followed. As the AHS cohort ages, the release of second evaluations of some chemicals from AHS will be based on additional years of follow-up and a greater number of cases that are expected to provide a more robust basis for interpreting positive and negative associations between exposure and outcome. In addition, the AHS is increasingly generating a substantial amount of biochemical, genetic marker, and molecular data to help interpret results from the epidemiological studies. Such results may further clarify AHS findings, provide evidence for a biological basis linking exposures to outcomes, or suggest additional laboratory and observational research that might strengthen evidence for mechanisms underlying causal pathways. In addition, Tier III analyses also may take advantage of efforts to bring together information and results from international cohort studies in the International Agricultural Cohort Consortium (AgriCOH) in which AHS is a member. AgriCOH is actively working to identify opportunities and approaches for pooling data across studies, and the availability of these other cohort data should aid in assessing reproducibility and replication of exposure-outcome relationships as EPA considers, evaluates and weighs the epidemiological data.

#### C.2.4. OPP's open literature searching strategies and evaluation of study quality

An important aspect of the systematic review approach is the thorough, systematic, and reproducible searching of the open epidemiological literature such that much of the literature that meets the established eligibility criteria can be located.<sup>36</sup> OPP uses specific databases as part of their literature search and has specific guidance on their conduct (for example, OPP's open literature search guidance for human health risk assessments<sup>37</sup>). Evaluation of all relevant literature, application of a standardised approach for grading the strength of evidence, and clear and consistent summative language will typically be important components (NRC, 2011). In addition, a high quality exposure assessment is particularly important for environmental and occupational epidemiology studies.

A second important component of the above systematic review approach is the assessment of the validity of the findings from the identified studies. Generally speaking, the quality of epidemiological research, sufficiency of documentation of the study (study design and results), and relevance to risk assessment will be considered when evaluating epidemiology studies from the open literature for use in agency risk assessments. When considering individual study quality, various aspects of the design, conduct, analysis and interpretation of the epidemiology studies are important. These include (from US-EPA, 2016):

- clear articulation of the hypothesis, or a clear articulation of the research objectives if the study is hypothesis-generating in nature;
- adequate assessment of exposure for the relevant critical windows of the health effects, the range of exposure of interest for the risk assessment target population, and the availability of a dose/exposure-response trend from the study, among other qualities of exposure assessment;
- reasonably valid and reliable outcome ascertainment (the correct identification of those with and without the health effect in the study population);
- appropriate inclusion and exclusion criteria that result in a sample population representative of the target population, and absent systematic bias;
- adequate measurement and analysis of potentially confounding variables, including measurement or discussion of the role of multiple pesticide exposure, or mixtures exposure in the risk estimates observed.

CI USA INVIS

価を行い、これを動物毒性学や MOA/AOP 情報とより正式に統合しようとするものである。このような Tier III 評価は、 疫学的文献のシステマティックレビューの形をとり、毒性及び有害な転帰の経路の評価と併せて実施される。

AHS 由来の農薬化学物質については、Tier III 解析では、他の質の高い疫学調査の評価結果を取り入れ、より多 様な情報源を再調査するために「エビデンスの重み付け」をより多く取り入れることが理想的である。これらの調査の結 果は、AHS の結果との再現性と一貫性を評価するために使用される。多くのケースにおける初期の AHS の結果は、 特定の健康影響を示した少数の参加者、または参加者を追跡した年数が比較的少ない参加者に基づいている。AHS コホートの高齢化に伴い、AHS からのいくつかの化学物質の 2 回目の評価の発表は、さらなる追跡調査の年数と、ば く露と健康影響の間の正負の関連を解釈するためのより強固な根拠となると期待されるより多くの症例数に基づいて行 われることになるであろう。さらに、AHS では、疫学研究の結果の解釈を助けるために、かなりの量の生化学的、遺伝 的マーカー及び分子データの生成が増加している。このような結果は、AHS の結果をさらに明確にしたり、ばく露と健 康影響を結びつける生物学的基盤のエビデンスを提供したり、あるいは因果関係の経路の基礎となるメカニズムのエビ デンスを強化する可能性のある追加の実験研究や観察研究を示唆したりする可能性がある。さらに Tier III 解析では、 AHS がメンバーである国際農業コホートコンソーシアム(AgriCOH)の国際的なコホート研究からの情報と結果をまと める努力を利用することもできる。AgriCOH は、研究間のデータを蓄積するための機会と方法を特定するために積極 的に取り組んでおり、これらの他のコホートデータの利用可能性は、EPA が疫学的データを検討、評価、重み付けする 際に、ばく露ー健康影響の関係の再現性と反復を評価するのに役立つはずである。

#### C.2.4. OPP の公表文献検索戦略及び研究の質の評価

システマティックレビューアプローチの重要な側面は、確立された適格基準を満たす多くの文献をみつけることがで きるように、公表されている疫学的文献を徹底的に、体系的に、再現可能に検索することである<sup>35</sup>。OPP は文献検索の 一部として特定のデータベースを使用しており、その実施に関する特定のガイダンスがある(例えば、ヒト健康リスク評価 に関する OPP の公表文献検索ガイダンス<sup>36</sup>)。すべての関連文献の評価、エビデンスの強固さを評価するための標準 化されたアプローチの適用、明確で一貫性のある総括的表現は、一般的に重要な要素となる(NRC、2011 年)。さらに、 質の高いばく露評価は、環境疫学研究や職域疫学研究において特に重要である。

上記のシステマティックレビューのアプローチの第二の重要な要素は、同定された研究から得られた結果の妥当性 の評価である。一般的に言えば、疫学研究の質、研究の文書化の妥当性(研究の計画と結果)、リスク評価との関連性 は、政府機関のリスク評価に使用するために公表されている文献から疫学研究を評価する際に考慮される。個々の研 究の質を検討する際には、疫学研究の計画、実施、解析、解釈の様々な側面が重要である。これらには以下が含まれ る(US-EPA、2016年より)。

- 1) 仮説を明確に明示することで、たとえその研究が本質的に仮説生成的なものであったとしても、その仮説を明確に 示されていること。
- 2)健康影響の関連する臨界期、リスク評価対象集団の関係あるばく露範囲、試験から得られる用量/ばく露反応の 傾向の入手可能性など、ばく露評価の資質の中で、適切なばく露評価が十分であること。
- 3)合理的に有効で信頼性の高い結果の確認(研究集団における健康影響の有無を正しく識別されていること)。
   4)対象集団を代表するサンプル集団となり、系統的な偏りがない適切な組み入れ基準と除外基準。
- 5) 観察されたリスク推定値における複数の農薬ばく露、または混合物ばく露の役割の評価または考察を含む、潜在 的な交絡変数の適切な評価及び解析。

#### Annex D – Effect size magnification/inflation

As described in the main text of this document, a potential source of bias may result if a study has low power. This lesser known type of bias is known 'effect size magnification'. While it is as widely known that, generally small, low-powered studies can result in false negatives since the study power is inadequate to reliably detect a meaningful effect size, it is less well known that these studies can result in inflation of effect sizes if those estimated effects are required to pass a statistical threshold (e.g. the common p < 0.05 threshold used for statistical significance) to be judged important, relevant, or 'discovered'. This effect – variously known as effect size magnification, the 'winners curse', truth inflation, or effect size inflation – is a phenomenon by which a 'discovered' association (i.e. one that has passed a given threshold of statistical significance to be judged meaningful) from a study with suboptimal power to make that discovery will produce an observed effect size that is artificially and systematically inflated.

Such truth inflation manifests itself as (systematic) bias away from the null in studies that achieve statistical significance in instances where studies are underpowered (Reinhart, 2015). This is because low-powered (and thus generally smaller) studies are more likely to have widely varying results and thus be more likely to be affected by random variation among individuals than larger ones. More specifically, the degree of effect size magnification that may be observed in any study depends, in part, on how widely varying the results of a study is expected to be and this depends on the power of the study; low powered studies tend to produce greater degrees of effect size magnification in results that are found to be statistically significant (or pass other threshold criteria) than higher powered studies.

As an example of this 'effect size magnification' concept and why it may come about, it is useful to imagine a trial run thousands of times with variable sample sizes. In this case, there will be a broad distribution of observed effect sizes. While the observed medians of these estimated effect sizes are expected to be close to the true effect size, the smaller trials will necessarily systematically produce a wider variation in observed effect sizes than larger trials. However, in low powered studies, only a small proportion of observed effects will pass any given (high) statistical threshold of significance and these will be only the ones with the greatest of effect sizes. Thus, when these generally smaller, low powered studies with greater random variation do indeed find a significance-triggered association as a result of passing a given statistical threshold, they are more likely to overestimate the size of that effect. What this means is that research findings of low-powered and statistically significant studies are biased in favour of finding inflated effects. As summarised by Gelman and Carlin (2014): 'when researchers use small *[underpowered]*<sup>38</sup> samples and noisy measurements to study small effects..., a significant result is often surprisingly likely to be in the wrong direction and to greatly overestimate an effect'. In general, it can be shown that low background (or control or natural) rates, low effect sizes of interest, and smaller sample sizes in the study end to produce lower power in the study and this leads to a greater tendency towards and magnitude of (any) inflated effect sizes.

It is important to note that the effect size inflation phenomenon is a general principle applicable to discovery science in general and is not a specific affliction or malady of epidemiology (Ioannidis, 2005; Lehrer, 2010; Button, 2013; Button et al., 2013; Gelman and Carlin, 2014; Reinhart, 2015). It is often seen in studies in pharmacology, in gene studies, in psychological studies, and in much of the most-often cited medical literature. When researchers have limited ability to increase the sample size such as in most epidemiological studies, effect size magnification is not a function or fault of the research or research design, but rather a function of how that the results of that research are interpreted by the user community. Thus, unlike other possible biases such as selection or information bias in epidemiology studies, the bias is not intrinsic to the study or its design, but rather characteristic of how that study is interpreted.

In order to determine (and quantify) the potential degree of effect size magnification for any given study that produces a statistically significant result, the reviewer must perform various power calculations. More specifically, when the association between a chemical exposure and a disease is found to be statistically significant, a power analysis can be done to determine the degree to which the statistically significant effect size estimate (e.g. odds ratio, relative risk or rate ratio) may be artificially inflated.

Epidemiological studies and pesticides

#### 付属書 D-影響量の拡大/膨張

この文書の本文で説明されているように、研究の検出力が低い場合には、バイアスの潜在的な原因が生じる可能性 がある。このあまり知られていないタイプのバイアスは、「影響量の規模」として知られています。一般的に、小規模で検 出力の低い研究では、研究の検出力が意味のある影響量を確実に検出するには不十分であるため、偽陰性が生じる 可能性があることは広く知られているが、推定された影響が重要、関連性がある、または「発見された」と判断されるため に、統計的閾値(例えば、統計的有意性に使用される一般的な p<0.05 の閾値)を通過する必要がある場合、これらの 研究が影響量の膨張をもたらす可能性があることはあまり知られていない。この影響は、影響量の拡大、「勝者の呪い」、 真実の膨張、または影響量の膨張として様々に知られているが、これは、「発見された」関連性(すなわち、意味がある と判断されるために統計的有意性の所定の閾値を通過した関連性)が、その発見を行うために最適ではない検出力を 持つ研究から得られる現象であり、その結果、意図的かつ体系的に膨張した影響量が生じることになる。

このような真偽の不明確化は、検出力の低い研究で統計的有意差を達成する研究では、帰無値から離れる(系統的 な)バイアスとして現れる(Reinhart、2015年)。これは、検出力の低い(したがって一般的には小さい)研究は、結果が 大きく変動する可能性が高く、大規模な研究よりも個人の間のランダムな変動の影響を受けやすいからである。より具 体的には、どのような研究でも観察されるかもしれない影響量の拡大の変化の程度は、研究の結果がどの程度広く変 化すると予想されるかに部分的に依存しており、これは研究の検出力に依存する;検出力の低い研究は影響量の拡大 の程度を大きくする傾向があり、その結果検出力の高い研究よりも統計的有意性(または他の閾値基準をパスする)を 見出す。

この「影響量の拡大」の概念とその理由の例として、可変のサンプルサイズで何千回も試験を実施した場合を想像す ると便利である。この場合、観察された影響量の広い分布がある。これらの推定影響量の観察された中央値は、真の影 響量に近いと予想されるが、小規模な試験では、大規模な試験に比べて、観察された影響量のばらつきが必然的に大 きくなる。しかし、低検出力の研究では、観察された影響のうち、統計的に有意な(高い)関値を通過するのはごく一部 であり、これらの影響は最大の影響量を持つものだけである。このように、一般的に小規模で、ランダム変動が大きい低 検出力の研究では、与えられた統計的関値を通過した結果、実際に有意性起因の関連を発見した場合、その影響の 大きさを過大評価する可能性が高くなる。これが意味するのは、低検出力で統計的に有意な研究の結果は、膨張効果 となるように偏っているということである。Gelman 及び Carlin(2014 年)が要約しているように、「研究者が小さな影響 を研究するために小さな[検出力不足]<sup>37</sup>サンプルとノイズの多い測定を使用した場合、有意な結果はしばしば驚くほど 間違った方向に行き、影響を大幅に過大評価する可能性が高い」のである。一般的に、バックグラウンド(または対照ま たは無処置)率が低い、対象となる影響量が小さい、研究中のサンプルサイズが小さいと、研究の検出力が低下し、そ の結果、(あらゆる)膨張した影響量の傾向と規模が大きくなることが示されている。

影響量の膨張現象は、発見科学全般に適用される一般的な原則であり、疫学の特殊な現象や弊害ではないことに 注意することが重要である(Ioannidis, 2005 年; Lehrer, 2010 年; Button, 2013 年; Button ら、2013 年; Gelman 及び Carlin, 2014 年; Reinhart, 2015 年)。これは、薬理学の研究、遺伝子研究、心理学の研究、そして最もよく引 用される医学文献の多くでよくみられる。ほとんどの疫学研究のように、研究者がサンプルサイズを増加させる能力が限 られている場合、影響効果量の拡大は、研究や研究デザインの機能や欠陥ではなく、むしろ、その研究の結果がユー ザーコミュニティによってどのように解釈されるかという機能である。したがって、疫学研究における選択や情報バイアス のような他のバイアスの可能性とは異なり、バイアスは研究やその計画に内在するものではなく、むしろその研究がどの ように解釈されるかに特徴がある。

統計的に有意な結果をもたらす研究について、影響量の規模の潜在的な程度を決定(定量化)するために、査読者 は様々な検出力の計算を実行しなければならない。より具体的には、化学物質ばく露と疾患との間の関連が統計的に 有意であることが判明した場合、検出力解析は、統計的に有意な影響量の推定値(例えば、オッズ比、相対リスクまた は率比)がどの程度人工的に膨張しているかを決定するために行われる。

<sup>&</sup>lt;sup>38</sup> [italics added]

<sup>37 [</sup>斜体を付けた]

www.efsa.europa.eu/efsajourna

In order to perform the requisite power calculation, the reviewer must know or obtain four values:

- 1) the number of subjects in non-exposed group;
- 2) the number of subjects in the exposed group;
- the number of <u>individuals with the disease of interest (or cases)</u> in the <u>non-exposed</u> group; and
- a target value of interest to detect a difference of a given (predetermined) size in a comparison of two groups (e.g. exposed vs. not exposed)

The first three listed values are provided in or must be obtained from the publication while the target value of interest (typically an OR or RR in epidemiology studies) is selected by the risk managers (and is ultimately a policy decision).<sup>39</sup> This Annex examines this effect size inflation phenomenon in a quantitative way using simulations. The annex uses two example published studies and simulations of hundreds of trials to evaluate the degree to which effect size magnification may play a role in producing biased effect sizes (such as odds ratios, rate ratios or relative risks) due to low power.

The first example uses data from Agricultural Health Study prospective cohort publication examining diazinon exposure and lung cancer and illustrates the effect size magnification issue for a calculated RR. The second example uses ever-never data from a case–control study studying malathion exposure and NHL and illustrates the effect size magnification concept from the point of view of an estimated OR.

#### An Example Illustrating Effect Size Magnification and Relative Risk (Jones et al. (2015))

The power associated with a comparison between those that are not exposed to diazinon to those that are exposed at the highest tertile (T) can be computed from the information provided in the AHS study publication 'Incidence of solid tumours among pesticide applicators exposed to the organophosphate insecticide diazinon in the Agricultural Health Study - an updated analysis' by Jones et al. (2015) for lung cancer. The number of subjects at each exposure level was provided in the article (non-exposed group: N = 17710, and T(ertile)1, T2 and T3 were categorised based on exposure distribution; specifically: N of each tertile = (2,350 + 2,770)/3 = 1,710 from the publication's Table 1 where: (a) the value of 2,350 represents the number in the lowest exposed *level* and (b) the value of 2,770 represents the number of the two highest exposed levels when the exposed subjects were dichotomously categorised. Since we have (i) the number of subjects in the reference non-exposed group = 17,710; (ii) the number of subjects in each of the exposed groups (tertiles) = 1710; and (iii) the number of diseased individuals (lung cancer) in the reference non-exposed group = 199 (from Table 3 of the cited publication), we can calculate the power of the comparisons between T1 vs non-exposed, T2 vs non-exposed and T3 vs non-exposed that were presented in the article, given the assumption that any true Rate Ratio = 1.2, 1.5, or 2.0, etc.

Here, we are interested in evaluating the power associated with the estimated background rate of 199/17710 (= 0.011237), and, as a form of sensitivity analysis, one half of this background rate (or 0.005617), and twice this rate (0.022473) for detecting (admittedly arbitrary) relative rates of (possible regulatory interest of) 1.2, 1.5, 2.0 and 3.0 among the subjects in each tertile of the diazinon exposed individuals. This analysis was performed using Stata statistical software and is shown below in both tabular and graphical format for true Rate Ratios of 1.2, 1.5, 2.0 and 3.0 for

93

必要な検出力計算を行うために	、査読者は以下の4	つの値を知っているか、	または得なければならない。
1) 非ばく 露 起の 被 験 者 数 .			

2)ばく露群の被験者数。

3)非ばく露群の対象疾患を持つ個人の数(または症例数)及び

4)2 つのグループ(例えば、ばく露群 vs.非ばく露群)の比較において、所定の(事前決定の)量の差を検出するための対象となる目標値。

最初の3 つの値は文献に記載されているか、文献から入手しなければならないが、対象となる目標値(一般的に疫 学研究ではORまたはRR)はリスク管理者によって選択される(最終的には政策決定である)<sup>38</sup>。本付属書では、シミュ レーションを用いて、この影響量の膨張現象を定量的に検討する。本付属書では、2 つの公表された研究例と数百件 の試験のシミュレーションを用いて、検出力が低いために偏った影響量(オッズ比、率比、相対リスクなど)を生み出す のに影響量の拡大がどの程度の役割を果たしているかを評価している。

最初の例では、ダイアジノンばく露と肺がんを調査した Agricultural Health Study の前向きコホート出版物からの データを使用し、計算された RR の影響量の偏りの問題を説明している。2番目の例は、マラチオンばく露とNHLを研 究した症例対照研究からの ever-never データを使用して、推定 OR の観点から影響量の拡大の概念を説明する。

#### 影響量の拡大の説明と相対リスクを説明する例(Jones ら、2015 年)

ダイアジノンにばく露されていないものと、最も高い三分位(T)でばく露されているものとの間の比較に関連した検出 力は、肺がんに対する Jones ら(2015 年)の AHS 研究発表「Incidence of solid tumours among pesticide applicators exposed to the organophosphate insecticide diazinon in the Agricultural Health Study - an updated analysis」で提供された情報から計算することができる。各ばく露量での被験者数は文献中に記載されてい た(非ばく露群。N=17710 及び T(ertile) 1, T2 及び T3 は、ばく露分布に基づいて分類された;具体的には、各三分 位の N=(2,350 + 2,770)/3=1,710 文献の表 1 から。(a) 2,350 の値は最も低いばく露量を表し、(b) 2,770 の値は、 ばく露された被験者を二分法で分類したときの、2 つの最も高いばく露量を表している。(i)参照非ばく露群の被験者数 =17,710; (ii) ばく露群(三分位)のそれぞれの被験者数=1710; (iii)参照非ばく露群の罹患者数(肺がん)=199 人 (引用文献の表 3 より)とすると、真の率比=1.2、1.5、または 2.0 と仮定すると、文献に示された T1 対非ばく露群、T2 対非ばく露群、T3 対非ばく露群の比較の検出力を計算することができる。

ここで、我々は、199/17710(=0.011237)の推定バックグラウンド率及び感度分析の形態として、このバックグラウン ド率の1/2(または0.005617)及びダイアジノンにばく露された個人の各三分位の被験者の間で1.2、1.5、2.0及び3.0 の(可能な規制関係の)相対率を検出するためのこの率の2倍(0.022473)に関連する検出力を評価することに注目し ている。この解析はStata統計ソフトウェアを使用して行われ、1.2、1.5、2.0及び3.0の真の率比について、199人の 罹患者/17,710人のバックグラウンド率に対して1/2x・、1x・(太字/網掛けで以下に示す)及び

<sup>&</sup>lt;sup>39</sup> This target value is an effect size of interest, often expressed as either a relative risk (for cohort studies) or an odds rate (for case control studies). That is, the target value is generally an OR or RR of a given magnitude that the risk manager desires to detect with a given degree of confidence. The higher the OR or RR, the greater the magnitude of the estimated association between exposure and the health outcome. While there are not strict guidelines about what constitutes a 'weak' association vs a 'strong' one - and it undoubtedly can be very context-dependent - values less than or equal to about 1 (or sometimes  $\leq$  1.2) are considered to be 'null' or 'essentially null' (this ignores the possibility of a protective effect which in some contexts – for example, vaccination efficacy - may be appropriate to consider). Values less than 2 or 3 are often considered by some as 'weak'. Values greater than 2 (or 3) and up to about 5 might be considered 'moderate', and values greater than 5 are considered by some to be 'large'. Monson (1990) describes as a guide to the strength of association a rate ratio of 1.0-1.2 as 'None', of from 1.2 to 1.5 as 'Weak', of from 1.5 to 3.0 as 'Moderate', and of 3.0-10.0 as 'Strong'. Other authors use Cohen's criteria to describe ORs of 1.5 as 'small' and 5 as 'large', with 3.5 as 'medium' in epidemiology (Cohen and Chen, 2010). Others describe 1.5 as 'small', 2.5 as 'medium' or 'moderate', 4 as 'large' or 'strong' and 10 as 'very large' or 'very strong' (Rosenthal, 1996) Taube (1995) discusses some of the limitations of environmental epidemiology in detecting weak associations (also see invited commentary illustrating counter-arguments in Wynder (1997). It should be recognized that none of the demarcation lines are 'hard' and there can be legitimate disagreements about where these are drawn and how these are considered and interpreted. Regardless, these can be very much context-dependent and the above demarcations should not be regarded as in any way official or definitive.

<sup>&</sup>lt;sup>38</sup> この目標値は対象となる効果量であり、相対リスク(コホート研究の場合)またはオッズ率(確例対照研究の場合)のいずれかで表されるとが多い、 すなわち、目標値は一般的に、リスク管理者が一定の確信度で検出したいと考えている一定の大きさのOR または RF である。OR または RF が 高ければあいほど、ばく驚と健康影響との間の推定関連性の規模が大きくなる。何が「弱い」関連性と「強い」関連性を構成するかについての厳密 なガイドラインはないが、約1以下(時には 1.2 以下)の値は「帰無」または「本質的に帰無」と考えられる(これは、いくつかの背景(例えば、ワクチ ン接種の有効性など)では考慮することが適切であるかもしれない保護効果の可能性を差視している)。2 または 3 未満の値は、しばしば「弱い」と 考えられていてる。2 (または 3) より大きく約5 までの値は「中等度」と考えられ、5 より大きい値は「大」であると考えられていて、 のmoson(1990)は、 関連性の強さの目安として、1.0~1.2 を「か」、5 を「中」と表現している)、2 または 3 未満の値は、しばしば「弱い」と 考えられていてる。2 (または 3) より大きく約5 までの値は「中等度」と考えられ、5 より大き、3 いであると考えられていて。 (なわれの方面では 5 いた、5 まで)、5 まで「明」と表見している(Cohen and Chen、2010)また、1.5 を「小」、5 まで」」またば「中 程度」、4 を「大」またば「強てに大きい」または「非常に強い」と表現する人もいる(Rosenthal, 1996年)、 Tabuら(P5年)は、弱い関 連性を検出する上での環境疫学の限界について議論している(Wynder(1997年)の反論を示す招待解説も参照のこと)。これらの境界線はどれ も「軽しい」ものではなく、どこに線が引かれ、どのように解釈されるかについては、正当な意見の相違があり得ることを認識す べきである。それにもかかわらず、これらの境界線は背景に大きく依存するものであり、上記のような境界線は、いかなる意味でも、公式なものでも、 次定的なためのでもあると考えるべきではない。

(b): Jones ら(2015)の 199/17710 の肺がんの観察されたバックグラウンド率を 1/2 倍-、1 倍-、2 倍-を表す。

上表の強調表示/太字の領域は、引用研究における肺がんのこの 1x 観測されたバックグラウンド率に関連した検出力を表している。

これらの値は以下のようにグラフ化することができる40。

<sup>&</sup>lt;sup>30</sup> 1.2、1.5、2.0、3.0の RRは、リスク管理者や意思決定者が関心を持ちそうな一連の相対リスクに関連する検出力検出力を示すために、やや态意的に選択されたものである。RR または OR=2.0 と 3.0 の値は、弱い影響量の大きさと強い影響量の間の境界線であると考えられている。RR 値 1.2 は、一部の人が「帰無に近い、または本質的に帰無」と考えるものであり、RR 値 1.5 はこれらの間の中間値である。疫学的証拠がばく露と健康影響との間の関係を示唆しているかどうかを判断する際に、リスク管理者は、許容可能な統計力(一般的には 80-90%と考えられている)を持つ強固な研究から得られた「本質的には帰無」RR1.2 を、関連性を見いだせなかったことを示サト分なエビデンスであり、事実上、ばく露と健康影響との間に観察可能な関連性がないという結論を支持するエビデンスを提供していると判断されることがあるかもしれない。

<sup>&</sup>lt;sup>40</sup> The RRs of 1.2, 1.5, 2.0 and 3.0 were selected somewhat arbitrarily to illustrate the power associated with a series of relative risks that might be of interest to the risk manager/decision-maker. The values of RR or OR = 2.0 and 3.0 are considered by some to be a demarcation between weaker effect sizes and stronger effect sizes. The RR value of 1.2 is what some consider 'near to or essentially null', and the RR of 1.5 is an intermediate value between these. In determining whether the epidemiological evidence suggests a relationship between an exposure and a health outcome, a risk manager might consider the 'essentially null' RR of 1.2 from a robust study with acceptable statistical power (generally considered 80-90%) as sufficient evidence for failing to find an association and, in effect, may provide supporting evidence for a conclusion of no observable association between the exposure and the outcome.

<sup>&</sup>lt;sup>41</sup> State code for generating the above graph: power twoproportions (' = 0.5 \* 199/17710'(0.0001) '= 2 \* 199/17710'), test(chi2) rrisk(1.2 1.5 2.0 3.0) n1(17710) n2(1710) graph (recast(line) xline('= 0.5 \* 199/17710' '=199/17710' '= 2 \* 199/17710', lpattern (dash)) legend(rows(l)size(small)) ylabel(0.2(0.2)1.0)) one sided.

<sup>&</sup>lt;sup>40</sup> 上のグラフを生成するための Stata コード:乗2 比例(' = 0.5 \* 199/17710'(0.0001) '= 2 \* 199/17710'), test(chi2) rrisk(1.2 1.5 2.0 3.0) n1(17710) 0n 1(17710) n2(1710) グラフ(recast(line) xline('= 0.5 \* 199/17710" '= 199/17710" '= 2 \* 199/17710', lpattern(dash)) legend(rows(1)size(small)) ylabel(0.20.21).0)/F(周/ダラフである。

As can be seen in the above table and graph, this study had a power of about 23% at 1x the background rate (control-group proportion, equal to 199 diseased individuals/17,710 subjects = 0.011237) to detect a RR of 1.2. To detect an RR of 1.5, there is about 64% power. If the true background rate were in reality twice the observed background rate  $(2 \times 0.011237 = 0.022473)$ , we would have about 86% power to be able to detect a RR of 1.5 and essentially 100% power to detect an RR of 2.0.42

Given the above. SAS was used to simulate the degree to which there may be effect size magnification (aka effect size inflation) given true relative risks of 1.2, 1.5, 2.0 and 3.0. The table below illustrates the power analysis for diazinon and lung cancer which shows the extent of the effect size magnification from the simulation results. The analysis presented in the table below parallels that done by Ioannidis (2008) and presented in his Table 2 for a set of hypothetical results passing the threshold of formal statistical significance to illustrate the effect size magnification concept.

SAS simulation results illustrating effect size magnification given true odds ratios of 1.2, 1.5, 2.0 and 3.0<sup>(a)</sup>

True values				Distribution of observed significant RRs			
Proportion of diseased individuals in control	RR	N analysed data sets	Power <sup>(b)</sup>	N	10th percentile	Median (% inflation)	90th percentile

(1/2 $\times$ background)	1.5	1,000	0.40	401	1.6	1.8 (20)	2.3
	2	1,000	0.82	823	1.7	2.1 (5)	2.8
	3	1,000	1	997	2.3	3.0 (0)	3.9
0.011237	1.2	1,000	0.22	224	1.4	1.6 (33)	1.8
(1 $\times$ background)	1.5	1,000	0.63	627	1.4	1.6 (7)	2.0
	2	1,000	0.98	977	1.6	2.0 (0)	2.5
	3	1,000	1	1,000	2.5	3.0 (0)	3.6
0.022473	1.2	1,000	0.33	331	1.3	1.4 (17)	1.6
(2 $\times$ background)	1.5	1,000	0.87	871	1.3	1.5 (0)	1.8
	2	1,000	1	1,000	1.7	2.0 (0)	2.3
	3	1,000	1	1,000	2.6	3.0 (0)	3.4

Poisson regression model was used to compare the rate of (relative risks) between the groups. The EXACT Test was used in the analysis of some data sets when the generalised Hessian matrix is not positive definite (due to a zero cases in one of the groups). (a): One-sided test,  $\alpha = 0.05$ , N Controls = 17,710, N diazinon Exposed = 1,710, Number of iterations = 1,000 (data sets).

(b): The power resulting from this simulation may be close but not precisely match the power calculated from built-in procedures in statistical software such as SAS (PROC POWER) or Stata (power two-proportion). This may be due to the number of data sets simulated being of insufficient size. However, 1.000 iterations is sufficient to adequately estimate the power and to illustrate the degree of effect size magnification given a statistically significant result (here,  $\alpha \leq 0.05$ ).

Note that – given a statistically significant result at p < 0.05 – the percent effect size inflation at the median of the statistically significant results varies from 0% to 42% depending on both the rate of lung cancer among individuals not exposed to diazinon (i.e. proportion of diseased individuals in the non-exposed group) and the true relative risk (ranging from 1.2 to 3.0). For example, if the true RR of a tertile of exposed vs non-exposed were 1.2, where the non-exposed group has a rate of lung cancer of 0.011237 (bolded row in the above table), half of the observed statistically significant RRs would be above the median of 1.6 and half would be below 1.6; this represents a median inflation of 33% over the true RR of 1.2 used in the simulation.

For the background rate found in the Jones et al. (2015) study (0.011237), a true RR of 1.2 that was found to be statistically significant would instead were the study to be repeated be observed to vary from 1.4 (at the 10th percentile) to 1.8 (at the 90th percentile) with the aforementioned median of 1.6. When the true RR is 2 or 3, the power is greater than 80% (as seen in the above table) and the median of observed RR is close to the true RR and the range of observed RRs are narrow. As the true RR increases to 3, the study's power increases such that the effect size inflation disappears and the median from the simulations indeed reflects the true RR.

ボアソン回帰モデルが、グループ間の(相対リスク)率を比較するために使用された、EXACT 検定は、一般化ヘシアン行列が正のデ フィニートでない場合(グループの1つでゼロのケースがあるため)、いくつかのデータセットの解析に使用された。 (a): 片側検定, a=0.05, N コントロール=17.710, N ダイアジノンばく露者=1.710, 反復回数=1.000回(データセット)。 (b): このシミュレーションから得られた検出力は、SAS (PROC POWER)や Stata (power two-proportion)のような統計ソフトの組み 込まれた手順から計算された検出力に近いかもしれないが、正確には一致しないかもしれない。これは、シミュレーションされたデ ータセットの数が十分でないためかもしれない。しかし、1,000回の反復は、検出力を適切に推定し、統計的に有意な結果(ここで は、≤0.05)を与えられた影響量の拡大の程度を説明するのに十分である。

p<0.05 で統計的に有意な結果が得られた場合、統計的に有意な結果の中央値での影響量の拡大の変化率は、ダ イアジノンにばく露されていない個人の肺がんの割合(すなわち、非ばく露グループの罹患者の割合)と真の相対リスク (1.2 から 3.0 までの範囲)の両方に応じて 0%から 42%まで変化することに注意する。例えば、ばく露対非ばく露の三 分位の真のRRが1.2であった場合、非ばく露グループの肺がんの割合は0.011237(上記の表の太字の行)で、観察 された統計的に有意な RR の半分は 1.6 の中央値を超えており、半分は 1.6 以下になるだろう:これは、シミュレーショ ンで使用される 1.2 の真の RR の上に 33%の膨張があることを表している。

Jones ら(2015 年)の研究(0.011237)でみつかったバックグラウンド率については、統計的に有意であることが判明

<sup>&</sup>lt;sup>42</sup> Said another way, if the true (but unknown) background rate were actually twice the observed background rate, we could reasonably conclude (with 86% confidence) if no statistically significant relationship was found that the true OR did not exceed 1.5.

<sup>41</sup> 別の言い方をすると、真の(しかし未知の)バックグラウンド率が実際に観測されたバックグラウンド率の2倍であった場合、統計的に有意な関係 がみつからなかった場合、我々は合理的に(86%の信憑性で)真の OR が 1.5 を超えていないと結論付けることができる。 EFSA Journal 2017:15(10):5007

#### An Example Illustrating Effect Size Magnification and Odds Ratios in an Ever/Never Analysis (Waddell, et al. 2001)

Sometimes comparisons between exposed group vs non-exposed group are presented in an 'ever/never' comparison as opposed to a comparison based on some other categorisation or grouping such as terciles or quartiles. This exposure category-based analysis might be done because there are an insufficient number of cases to break the exposure categories into small (more homogenous) exposure classifications or groupings or because the measurements of exposure are not available or are less reliable (such as in case-control studies). In these situations, we similarly need (i) the total number of subjects in non-exposed group; (ii) the number of subjects in exposed group; (iii) the number of diseased individuals in the non-exposed group at some; (iv) given or preselected odds ratios.

To illustrate how a power and effect size magnification analysis might be done for a case-control study using ever-never exposure categorisations, a study investigating the association between malathion and NHL (Waddell et al., 2001) was selected. Here, we have (i) the number of subjects in the reference non-exposed group = 1,018 (from Table 1: non-farmers = 243 diseased individuals + 775 non-diseased individuals); (ii) the number of subjects in the exposed group = 238 (from Table 4: malathion exposed individuals = 91 exposed cases + 147 non-exposed controls); (iii) the number of diseased individuals in the reference non-exposed group = 243 (from Table 1: 243 diseased individuals in the non-farmer or non-exposed group), we can similarly calculate the power of the comparisons between the ever vs never exposed, given the assumption that any true OR = 1.2, 1.5, 2.0, etc.

As was described above for lung cancer and diazinon, we estimated a power of 30.5% to detect an OR of 1.2 at the study-estimated NHL proportion of 0.2387 among non-farmers (non-exposed), as illustrated in the table below:

Results of power analysis for a one-sided, two-sample proportions test ( $\alpha = 0.05$ ) <sup>(a)</sup>

Stata code used to generate the above results: power two-proportions ('= 0.5 \* 243/1018' '= 243/ 1018' '= 2 \* 243/1018'), test(chi2) OR (1.21.52.03.0) n1(1,018) n2(238) one-side table(N1: 'N control' N2: 'N exposed' p1: 'proportion control' p2' proportion exposed' OR: 'odds ratio' power: 'power').

(a). One-sided test  $\alpha = 0.05$  Ho: p2 = p1 vs Ha: p2 > p1;  $N_{controls} = 1,018$ ,  $N_{exposed} = 238$ , Number of iterations = 1,000 (data sets). (b): Representing  $1/2x_{-}$ ,  $1x_{-}$  and  $2x_{-}$  the observed background rate of lung cancer of 243/1018 in Waddell et al. (2001). Highlighted,

bolded region in table above represents power associated with this 1x observed background rate of NHL in cited study.

Such power relations for malathion and NHL are graphed below<sup>43</sup> – as was done in the above AHS prospective cohort study for diazinon and lung cancer – with the middle vertical dotted line in the graph showing power at the NHL proportion of 0.2387 among non-farmers/non-exposed and the lefthand and right-hand vertical dashed lines representing a form of sensitivity analysis at one-half and twice the NHL proportion among non-farmers/non-exposed, respectively.

CI USA INVITA

#### Epidemiological studies and pesticides

した真の RR の 1.2 は、前述の中央値 1.6 の代わりに 1.4(10%のパーセンタイルで)から 1.8(90%のパーセンタイル で)に変化することが観察される研究が繰り返されるだろう。真の RR が 2 または 3 のときには、検出力は 80%以上(上 記の表に見られるように)であり、観測された RR の中央値は真の RR に近く、観測された RR の範囲は狭い。真の RR が 3 になると、影響量の膨張がなくなり、シミュレーションの中央値が真の RR に回帰するように検出力が増加する。

エバー/ネバー解析における影響量の拡大とオッズ比を示す例(Waddellら、2001年)

ばく露群と非ばく露群の比較は、三分位や四分位などの他の分類やグループ分けに基づいた比較とは対照的に、 「これまでありと、決してない」の比較で示されることがある。このようなばく露カテゴリーベースの解析は、ばく露カテゴリ ーを小さな(より均質な)ばく露分類やグループに分けるには十分な数の症例数がないため、あるいはばく露の測定値 が利用できないか、あるいは信頼性が低いため(症例対照研究のような)に行われるかもしれない。これらの状況では、 (i)非ばく露群の被験者の総数、(ii)ばく露群の被験者の数、(iii)ばく露群と非ばく露群の間の比較の検出力を計算 するために、非ばく露群の罹患者の数、(iv)与えられた、または事前に選択されたオッズ比が同様に必要となる。

エバー/ネバー分類を用いた症例対照研究において、検出力と影響量の拡大の解析がどのように行われるかを説 明するために、マラチオンとNHLの関連性を調査した研究(Waddellら、2001)を選択した。ここでは、(i)基準非ばく 露群の被験者数=1,018人(表1より:非農家=243人の罹患者+775人の非罹患者)、(ii)ばく露群の被験者数=238 人(表4より:マラチオンばく露者=91人の非ばく露者+147人の非ばく露コントロール)、(iii)参照非ばく露群の罹患 者数=243人(表1より:非農家または非ばく露群の243人の罹患者)とすると、真の率比=1.2、1.5、または2.0と仮定 すると、「ばく露ありと、ばく露なし」の比較の検出力が計算できた。

肺がんとダイアジノンについて上述したように、非農家(非ばく露者)では、以下の表に示すように、研究で推定された NHL の割合が 0.2387 で 1.2 の OR を検出する検出力を 30.5%と推定した。

N <sub>control</sub>	N <sub>exposed</sub>	Proportion control <sup>(b)</sup>	Proportion exposed	Odds Ratio	Power
1,018	238	0.1194	0.1399	1.2	0.2279
1,018	238	0.1194	0.1689	1.5	0.647
1,018	238	0.1194	0.2133	2.0	0.9693
1,018	238	0.1194	0.2891	3.0	1
1,018	238	0.2387	0.2734	1.2	0.3047
1,018	238	0.2387	0.3199	1.5	0.8149
1,018	238	0.2387	0.3854	2.0	0.9971
1,018	238	0.2387	0.4847	3.0	1
1,018	238	0.4774	0.523	1.2	0.3522
1,018	238	0.4774	0.5781	1.5	0.8779

1,018	238	0.4774	0.7327	3.0	1

上記の結果を生成するために使用される Stata コード: 2 乗比例('= 0.5 \* 243/1018' '= 243/1018' '= 2 \* 243/1018'), test(chi2) OR (1.2 1.5 2.0 3.0) n1(1,018) n2(238) 片側

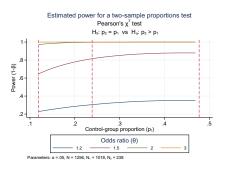

table(N1:"N コントロール" N2:"N ばく露" p1:"割合コントロール" p2"割合ばく露" OR:"オッズ比" power."検出力') (a): 片側検定 a = 0.05 Ho: p2 = p1 vs Ha: p2 > p1; Ncontrols = 1,018, Nexposed = 238、反復回数 = 1,000 回 (データセット)。 (b): Waddell ら (2001) の 243/1018 の肺がんの観察されたパックグラウンド率を 1/2 倍、1 倍、2 倍を表す。上表のハイライトされ 太字の領域は、引用された研究におけるこの 1 倍の NHL の観測されたパックグラウンド率に関連した検出力を表している。

このようなマラチオンとNHLの検出力関係は、上記のAHS前向きコホート研究(ダイアジノンと肺がん)と同様に以下のようにグラフ化されている42。グラフの中央縦点線は非農家/非ばく露群のNHL比が0.2387での検出力を示し、

<sup>42</sup> グラブを生成するための Stata コード・2 乗比例(= 0.5 \* 243/1018′(0.01) = 2 \* 243/1018′), test(chi2) OR (1.2 1.5 2.0 3.0) n1(1018) 0) n1(1018) n2(238)graph(再キャスト(線) ×line(= 0.5 \* 243/1018′' = 243/1018′' = 2 \* 243/1018′, lpattern(dash) legend(rows(1)size(small)) y-label(0.2(0.21).0))<sup>4</sup>側。

<sup>&</sup>lt;sup>43</sup> Stata code for generating the graph: power two proportions ('=0.5\*243/1018'(0.01) '=2\*243/1018'), test(chi2) OR (1.2 1.5 2.0 3.0) n1(1018) n2(238)graph(recast (line) x-line('=0.5\*243/1018' '=243/1018' '=2\*243/1018', lpattern(dash)) legend(rows(1)size(small)) y-label(0.2(0.2)1.0)) one sided.

Graph showing estimated power for a (one-sided) two-sample proportions test evaluating power as a function of control-group proportion at true RRs of 1.2-, 1.5-, 2.0- and 3.0. Dashed red vertical lines represent control group proportions at 1/2x of that observed, 1x of that observed and 2x of that observed and illustrates the sensitivity of the power to these background rate assumptions.

At the study-estimated NHL proportion of 0.2387 among non-farmers/non-exposed, the power (one-sided) to detect ORs of 1.2, 1.5, 2.0 and 3.0 is shown to be 30.5%, 81.5%, 99.7% and > 99.9%, respectively. Note that Waddell et al. (2001) reported an OR of 1.6 with a 95% CI of 1.2–2.2, based on 91 NHL cases who used malathion and 243 cases that were among non-farmers who did not.

Given the above, SAS was used to simulate the degree to which effect size magnification may exist given *true* odds ratios of 1.2, 1.5, 2.0 and 3.0. Below is a SAS-generated table for the power analysis for malathion and NHL showing the magnitude of the effect size magnification from the SAS-based simulation results.

SAS simulation results illustrating effect size magnification given true odds ratios	of 1.2, 1.5, 2.0,
and 3.0 <sup>(a)</sup>	

True values				Dist	Distribution of observed significant ORs			
Proportion of diseased individuals in non-exposed group	OR	N analysed data sets	Power <sup>(b)</sup>	N	10th percentile	Median (% inflation)	90th percentile	
0.1194 (1/2 background)	1.2	1,000	0.22	220	1.4	1.5 (25)	1.8	
	1.5	1,000	0.66	661	1.5	1.7 (13)	2.0	
	2	1,000	0.97	972	1.6	2.0 (0)	2.5	
	3	1,000	1.0	1,000	2.4	3.0 (0)	3.7	
0.2387 (1 $\times$ background)	1.2	1,000	0.32	323	1.3	1.4 (17)	1.6	
	1.5	1,000	0.81	812	1.4	1.6 (7)	1.8	
	2	1,000	1.0	997	1.6	2.0 (0)	2.4	
	3	1,000	1.0	1,000	2.5	3.0 (0)	3.6	
0.4774 (2× background)	1.2	1,000	0.34	337	1.3	1.4 (17)	1.6	
	1.5	1,000	0.87	872	1.3	1.5 (0)	1.8	
	2	1,000	1.0	1,000	1.6	2.0 (0)	2.5	
	3	1,000	1.0	1,000	2.4	3.0 (0)	3.7	

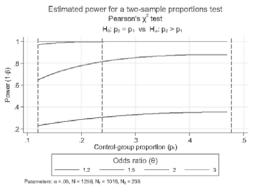

The logistic regression model was used to compute the odds ratios for the two groups. The EXACT Test was used in the analysis of some data sets when the maximum likelihood estimate did not exist (perhaps due to a zero cases in one of the groups). (a): One-side test,  $\alpha = 0.05$ , N non-exposed = 1,018, N malathino exposed = 238, N iterations = 1,000 (data sets).

(b): The power resulting from this simulation may be close but not match exactly with the power calculated from built-in procedures in statistical software such as SAS (PROC POWER) or Stata (power two-proportion). This may be due to number of data sets simulated being of insufficient size. However, 1,000 iterations are sufficient to adequately estimate the power and to illustrate the degree of effect size magnification given a statistically significant result (here, α ≤ 0.05).

左端と右端の縦点線は非農家/非ばく露群のNHL比が1/2と2倍での感度分析の枠を示している。

1.2・、1.5・、2.0・及び 3.0 の真の RR におけるコントロール群比率の関数としての検出力を評価する(片側)2 標本比 率検定の推定検出力を示すグラフ。赤い破線の縦線は、観測された比率の 1/2 倍、観測された比率の 1 倍及び観測 された比率の 2 倍におけるコントロールグループの比率を表し、これらのバックグラウンドレートの仮定に対する検出力 の感度を示している。

非農業者/非ばく露者の NHL 割合を 0.2387 と推定した場合、OR 1.2、1.5、2.0、3.0 を検出する検出力(片側) は、それぞれ 30.5%、81.5%、99.7%、99.9%以上となる。なお、Waddellら(2001 年)は、マラチオンを使用した NHL 症例 91 例と使用しなかった非農家 243 例を対象に、OR は 1.6、95%CI は 1.2-2.2 と報告している。

以上のことから、真のオッズ比が 1.2、1.5、2.0、3.0 の場合に、影響量の拡大の差がどの程度存在するかをシミュレ ーションするために SAS が使用された。以下は、マラチオンと NHL の検出力解析のために SAS で作成された表で、 SAS ベースのシミュレーション結果から、影響の拡大のマグニフィケーションの大きさを示している。

真値			観察された有意な OR の分布				
非ばく露群における罹 患者の割合	OR	N 個の解析 データセット	Power <sup>(b)</sup>	N	10%台	中央値 (%inflation)	90%台
0.1194 (1/2 background)	1.2	1,000	0.22	220	1.4	1.5 (25)	1.8
	1.5	1,000	0.66	661	1.5	1.7 (13)	2.0
	2	1,000	0.97	972	1.6	2.0 (0)	2.5
	3	1,000	1.0	1,000	2.4	3.0 (0)	3.7
0.2387 (19 background)	1.2	1,000	0.32	323	1.3	1.4 (17)	1.6
	1.5	1,000	0.81	812	1.4	1.6 (7)	1.8
	2	1,000	1.0	997	1.6	2.0 (0)	2.4
	3	1,000	1.0	1,000	2.5	3.0 (0)	3.6
0.4774 (29 background)	1.2	1,000	0.34	337	1.3	1.4 (17)	1.6
	1.5	1,000	0.87	872	1.3	1.5 (0)	1.8
	2	1,000	1.0	1,000	1.6	2.0 (0)	2.5
	3	1,000	1.0	1,000	2.4	3.0 (0)	3.7

ロジスティック回帰モデルが、2 つのグループのオッズ比を計算するために使用された。最尤推定値が存在しない場合(おそらくいずれ かのグループの症例がゼロであったため)、EXACT 検定をいくつかのデータセットの解析に使用した。

(a):片側検定、a = 0.05、非ばく露群=1,018、マラチオンばく露群=238、反復 N=1,000 (データセット)。(b):このシミュレーション から得られた検出力は近いかもしれないが、組み込みの SAS (PROC POWER)や Stata (power 2-proportion)のような統計ソフトウェア のブロシージャを使用している。これは、シミュレーションされたデータセットの数が十分でないためかもしれない。しかし、1,000 回 の反復は、検出力を十分に推定し、統計的に有意な結果(ここでは、≤0.05)が得られた場合の影響量の拡大を説明するのに十分である

www.efsa.europa.eu/efsajourna

Note that – given a statistically significant result at p < 0.05 – the median effect size varies from 1.4 to 3, depending on the NHL proportion in the non-exposed group, and the true odds ratio (ranging from 1.2 to 3.0). For example, if the true OR for a NHL proportion among non-farmers of 0.2387 was 1.2 (bolded row in the table), half of the *observed statistically significant* ORs would be above the median of 1.4 and half would be below. Further, most (90%) of the statistically significant ORs would be observed to be above 1.3, and a few (10%) would be observed even to be above 1.6.

In sum, then, the power of an epidemiological study is an important factor that should considered by regulators and others evaluating such studies. A study that is sufficiently powered will not only be more likely to detect a true effect of a given size if it is indeed present (the classic definition of power which relates to the issue of a Type II error or a false negative) but will also be less likely to magnify or exaggerate the effect if it is not there but (by chance) crosses a preselected threshold (such as the 0.05 level for statistical significance). If a study is suitably powered (say, 80% or more), the observed effect size is more likely to be a reflect a true effect size and any observed chance variation in this effect size will reflect a distribution symmetrically centred around the unknown true value. The take home message from these simulations and the original work by Ioannidis and extensions by Gelman and Carlin (2014) is that a study should be not only suitably powered to avoid a false negative (Type II error) but also suitably powered to avoid a magnification of the effect size for those effect sizes that are statistically significant (or pass some other threshold). Gelman and Carlin (2014) go further, stating that such 'retrospective design calculations may be more relevant for statistically significant findings than for nonsignificant findings. The interpretation of a statistically significant result can change drastically depending on the plausible size of the underlying effect'. Note that if a study is suitably powered, there is NO systematic risk inflation, but the effect estimates for underpowered studies that produce statistically significant effects are prone to what might be substantial risk inflation, the interpretation of which depends on realistic estimates of the true (underlying) effect.

Ideally, then, published literature studies should conduct and document power analyses. Short of that, published literature should provide adequate information for the reader to perform such power calculations (or, as Gelman and Carlin (2014) term them: (retrospective) design calculations). In the two examples provided above, the authors did provide sufficient information for the reader to calculate power and the potential for effect size magnification. This is not always the case. Sometimes information used for power calculations are only partially provided in the publications or provided information was structured in a way that does not permit such calculations.<sup>44,45</sup> For example, if authors use number of cases instead of level of exposure to determine tertiles or quartiles (which would be evidenced by a constant number of cases between groups) or if authors group multiple cancer outcomes together and use that number to determine tertiles, then the power (or design) calculations illustrated here are not possible since the required inputs are not able to be derived. Since the counts and data which are tabulated and reported are not necessarily standardised among authors and publications, one strong recommendation would be for publications to require reporting (even if in supplementary or online data) the necessary information to estimate power such that such evaluations can be done by both peer reviewers and interested readers.

98

CI USA INVIS

p<0.05 で統計的に有意な結果が得られた場合、影響量の中央値は、非ばく露群の NHL の割合と真のオッズ比 (1.2 から 3.0 まで)によって、1.4 から 3 まで変化することに注意する。例えば、非農家の NHL の割合が 0.2387 の場 合、真の OR が 1.2 (表中の太字の行)とすると、統計的に有意な OR の半分は中央値 1.4 を超え、半分は下回ってい ることになる。さらに、統計的に有意な OR の大部分 (90%)は 1.3 以上であることが観察され、少数 (10%)は 1.6 以上 であることさえ観察された。

まとめると、疫学研究の検出力は、規制当局や他の人がそのような研究を評価する際に考慮すべき重要な要素であ る。十分な検出力を持つ研究は、与えられた規模の真の効果が実際に存在する場合に検出する可能性が高くなるだ けでなく(検出力の古典的な定義は、II型エラーや偽陰性の問題に関連している)、影響が存在しないが(偶然にも) 事前に選択された閾値(統計的有意性の 0.05 レベルなど)を超えた場合に、影響を拡大したり誇張したりする可能性 が低くなるだろう。研究が適切な検出力を持っている場合(例えば、80%以上)、観察された影響量は真の影響量を再 現する可能性が高く、この影響量の観察された偶然の変動は、未知の真の値を中心に対称的に分布を再現する。これ らのシミュレーションと Ioannidis によるオリジナルの研究及び Gelman と Carlin(2014 年)による拡張研究から得ら れるメッセージは、研究は偽陰性(タイプ II エラー)を回避するために適切な検出力が必要であるだけでなく、統計的 に有意な(または他の閾値を通過した)影響量のために影響量の拡大を回避するために適切な検出力が必要であると いうことである。Gelman と Carlin(2014 年)はさらに進んで、そのような「後ろ向き計画の計算は、統計的に有意でな い影響量よりも統計的に有意な影響量に関連しているかもしれない。統計的に有意な結果の解釈は、基礎となる影響 のもっともらしい規模によって大きく変わる可能性がある」と述べている。研究が適切な検出力を持っていれば体系的な リスクの膨張は皆無であるが、統計的に有意な効果をもたらす検出力不足の研究の影響推定値は、実質的なリスク膨 張の可能性があり、その解釈は真の(基礎となる)影響の現実的な推定値に依存することに注意することである。

理想的には、公表されている文献研究は、検出力解析を実施し、文書化するべきである。それ以外にも、公表されて いる文献は、読者がこのような検出力計算(あるいは Gelman と Carlin(2014 年)が言うところの(後ろ向き)デザイン 計算)を行うのに十分な情報を提供すべきである。上記の2つの例では、著者は読者に検出力と影響量の拡大を計算 することができる十分な情報を提供していた。これは常にそうとは限らない。検出力の計算に使用された情報が文献に 部分的にしか提供されていなかったり、提供された情報がそのような計算ができない方法で構成されていたりすること がある<sup>43-44</sup>。例えば、著者が三分位または四分位を決定するためにばく露量の代わりに症例数を使用している場合(こ れはグループ間での症例数が一定であることから証明される)、または著者が複数のがん症例をまとめてグループ化し、 その数を使用して三分位を決定している場合、必要な入力が得られないため、ここに示されている検出力(またはデザ イン)の計算は不可能である。集積及び報告される数値及びデータは、著者及び文献の間で必ずしも標準化されてい るわけではないので、一つの強い推奨事項は、文献が(補足的またはオンラインデータであっても)検出力を推定する ために必要な情報を報告することを義務付けることであり、このような評価を査読者及び関心のある読者の両方ができ るようにすることであろう。

以上の解析から、影響量の膨張現象の潜在的な意味合いは、疫学研究を評価する上で重要な考慮事項であること が示唆されたが、この現象に関するいくつかの注意点を覚えておくことが重要であり、疫学研究の解釈にどのように考

<sup>&</sup>lt;sup>44</sup> For example, in the review of the association between malathion exposure vs aggressive prostate cancer presented in the publication 'Risk of Total and Aggressive Prostate Cancer and Pesticide Use in the Aggressive Prostate Cancer and Pesticide Use in the Aggressive Prostate Study' by Stella Koutros et al. (2012), the Panel was not able to calculate the power of the comparison between the malathion-exposed groups vs non-exposed group because critical information was not provided in the published article. From the publication and the supplemental document of the publication, we were able to easily find the number of <u>cases</u> in the non-exposed group (Table 2 in the main article), but the number of <u>subjects</u> in the non-exposed group or at <u>each</u> exposed level (i.e., quartile) appeared not to be available. We attempted to derive the number of <u>subjects</u> in the non-exposed group and number of <u>subjects</u> in each quartile from the information in Table 1 of the supplemental document of the article but were not able to do so since the information in Table 1 away that was not consistent with many other AHS publications in that the exposed subjects were categorized into groups based on the quartiles of number of cases.

<sup>&</sup>lt;sup>45</sup> Sometimes, information used for power calculations may have only been <u>partially</u> provided in the publications. For example, we calculated the powers associated with various thyroid cancer comparisons from the information provided in the AHS study publication in the AG cancer Incidence Among Pesticide Applicators in the Agricultural Health Study (1994-2007), by Laura Beane-Freeman et al. (2011). In this publication, the authors did not categorize the subjects into quartiles based on exposure but instead categorized or grouped the subjects based on the total number of all cancer cases combined. In this way, the number of sall cases of all types of cancer was the same between groups and thus both the number of subjects was not the same between groups. In this example, the publication provided (i) the reference Q11 N = 9,523, (ii) total subjects in Q2, Q3 and Q4: N = 26,834 (Table 1) and (iii) the number of thyroid cancer cases in the reference Q1 = 3 (Table 2). The exact number of subjects in each of the compared groups (Q2, Q3 or Q4) was, however, not available.

<sup>&</sup>lt;sup>45</sup> 例えば、Stella Koutros ら(2012 年)の出版物/Risk of Total and Aggressive Prostate Cancer and Pesticide Use in the Agricultural Health Study ごを基されたマラチオンは、2歳と良双性前立廠がんの関連性のレビューでは、発表された論文に重要な情報が提供されていなか ったため、バネルはマラチオンは、2歳能と非ばく2歳群しまは、2歳であった。文献及び文献の補足文書から、非ば、2歳群の症例表を容 易に把握することができたが(本文中の麦 2)、非ばく3歳群または各はく3歳量(四分位)の被験者数は入手できなかったようである。我々は、文献の 補足文書の表 1)の情報から非ばく3歳者能の被験者数及び各四分位の被験者数を導入したらしたが、表 1 の情報は、ばく3歳者を症例数の四分 位に基づいてグループに分類するという他の多くの AHS の出版物を一致しない方法で示されていたため、それを行うことができなかった。

<sup>44</sup> 検出力の計算に使用された情報は、文献では部分的にしか提供されていないことがある。例えば、我々は Laura Beane-Freeman ら(2011)に よる AHS 研究文紙「Atrazine and Cancer Incidence Among Pesticide Applicators in the Agricultural Health Study (1994-2007)」に記 載されている情報から、様々な甲状腺がんの比較に関連した検出力を計算した。この文献では、著者らは被験者をばく露に基づいて四分位に分 類するのではなく、その代わりに、すべてのがん症例を合わせた総症例数に基づいて被験者を分類またはグループ化した。このようにして、すべ てのタイプのがんの症例数は、分類されたグループ間で同じであり、したがって、対象となる任意の特定のがん(例えば、甲状腺、ここでは)の症例 数は、グループ間で同じではなく、被験者の数は、グループ間で同じではなかった。この例では、文献は、(i)参照 Q1:N=9,523、(ii) Q2、Q3 及 び Q4 の総被験者数を提供した。N=26,834 人(表 1) 及び(iii)参考 Q1 の甲状腺がん症例数=3 人(表 2)を提供した。しかし、比較詳(Q2,Q3 または Q4)のそれぞれの正確な披験者数は得られなかった。

While the above analysis suggests that potential implications of the effect size inflation phenomenon are important considerations in evaluating epidemiological studies, it is important to remember a number of caveats regarding the phenomenon and how its consideration should enter into any interpretation of epidemiological studies.

- First, while this phenomenon would tend to inflate effect sizes for underpowered studies for which the effect of interest passes a statistical (or other) threshold, there are other biases that may be present that bias estimates in the other direction, *towards* the null. This bias might be referred to as effect size *suppression*. Perhaps, the most well-known of these is non-differential misclassification bias discussed in the main body of the text. This can commonly (but not always) produce predictable biases towards the null, thereby systematically under-predicting the effect size. Recognising that this is not always true and there are potentially countervaling or counteracting factors like effect size magnification (at least for small underpowered studies) is an important step forward. Specifically, underpowered studies can result in biased estimates in a direction away from the null to a degree that that can potentially offset (and possibly more than offset) any biases towards the null that may result, for example, from non-differential misclassification bias. Regardless, what is of critical importance is to recognise that adequately powered studies are necessary to be able to have at least some minimal degree of confidence in the estimate of the effect size for a statistically significant result.
- Secondly and as stated in the main body of the text effect size magnification is linked to a focused effort on the part of the researcher (or regulators interpreting such a study) on identifying effects that pass a given threshold of significance (e.g. p < 0.05) or achieve a certain size (e.g. OR > 3) when that study is underpowered. This phenomenon, then, is of most concern when a 'pre-screening' for statistical significance (or effect size). To the extent that regulators, decision-makers and others avoid acting by focusing on only those associations that 'pass' some predetermined statistical threshold and then use that effect size to evaluate and judge the magnitude of the effect without acknowledging that it might be inflated if the study is underpowered, the phenomenon is of lesser concern. Note that effect size magnification is not a function or fault of the research or research design, **but rather a function of how that research is interpreted by the user community**.

Unfortunately, there is sometimes a tendency for attention to focus on effect sizes that are greater than a given size or that pass a certain statistical threshold and are as such 'discovered'. As recommended by Ioannidis with respect to how these 'discoveries' should be considered (Ioannidis, 2008):

'At the time of the first postulated discovery, we usually cannot tell whether an association exists at all, let alone judge its effect size. As a starting principle, one should be cautious about effect sizes. Uncertainty is not conveyed simply by CIs (no matter if these are 95%, 99% or 99.9%).

For a new proposed association, credibility and accuracy of the proposed effect varies depending on the case. One may ask the following questions: does the research community in the field adopt widely statistical significance or similar selection thresholds for claiming research findings? Did the discovery arise from a small study? Is there room for large flexibility in the analyses? Are we unprotected from selective reporting (e.g. was the protocol not fully available upfront?). Are there people or organisations interested in finding and promoting specific "positive" results? Finally, are the counteracting forces that would deflate effects minimal?'

 Thirdly, it should be remembered that the effect size inflation phenomenon is a general principle applicable to discovery science in general and is not a specific affliction or malady of epidemiology (Ioannidis, 2005; Lehrer, 2010; Button, 2013; Button et al., 2013; Reinhart, 2015). As indicated earlier, it is often seen in studies in pharmacology, in gene studies, in psychological studies, and in much of the most-often cited medical literature. Such truth inflation occurs in instances where studies are small and underpowered because such studies have widely varying results. It can be particularly problematic in instances where many researchers are performing similar studies and compete to publish 'new' or 'exciting' results (Reinhart, 2015).

#### **Summary and Conclusions**

Effect size magnification or 'truth inflation' is a phenomenon that can result in exaggerated estimates of odds ratios, relative risks or rate ratios in those instances in which these effect measures

99

Epidemiological studies and pesticides

慮すべきであるかについても留意すべきである。

- -第一に、この現象は、対象となる影響が統計的(またはその他の)閾値を通過するような検出力不足の研究では影響量が膨張する傾向があるが、他にも推定値を帰無に向かって逆方向に偏らせるバイアスが存在する可能性がある。このバイアスは、影響量抑制と呼ばれることがある。おそらく、これらのバイアスの中で最もよく知られているのは、本文で議論されている非差異的誤分類バイアスである。これは、一般的に(常にではないが)帰無値に向かって予測可能なバイアスを生じさせ、それによって影響量を体系的に過小予測する。これが常に正しいとは限らず、(少なくとも小規模の低い検出力の研究については)影響量の拡大のような対抗要因や相殺要因が存在する可能性があることを認識することは、重要な前進である。特に、検出力不足の研究では、例えば、非差異的誤分類バイアスから生じるかもしれない帰無値へのバイアスを潜在的に相殺する(そして、多分相殺以上に)ことができる程度に、帰無値から離れた方向に偏った推定値をもたらすことがある。いずれにしても、重要なことは、統計的に有意な結果を得るための影響量の推定値に少なくともいくつかの最低限の一致度を持たせることができるようにするためには、十分な検出力のある研究が必要であるということを認識することである。
- -第二に、そして本文で述べられているように、影響量の拡大は、研究者(またはそのような研究を解釈する規制者)の側で、その研究が検出力不足の場合に、与えられた有意性の閾値(例:p<0.05)を通過するか、または一定の大きさ(例:OR>3)を達成する影響を特定することに焦点を当てた努力に関連している。この現象は、統計的有意性(または影響量)の「事前スクリーニング」を行う際に最も懸念される現象である。規制者や政策決定者などが、事前に決められた統計的閾値を「通過」した関連性のみに焦点を当てて行動することを避け、研究が検出力不足の場合に効果量の拡大を評価して判断するためにその影響量を使用する場合、この現象はあまり懸念されない。影響量の拡大の決定は、研究や研究デザインの機能や欠陥ではなく、むしろその研究がユーザーコミュニティによってどのように解釈されるかの機能であることに注意する。

残念なことに、与えられた量よりも大きい、またはある統計的閾値を通過して「発見された」影響量に注目が集まる 傾向が時々ある。これらの「発見」がどのように考慮されるべきかに関しては Ioannidis によって推奨されている (Ioannidis, 2008 年)。

「最初に仮定された発見の時点では、影響量を判断することはおろか、関連性が全く存在するかどうかもわからないのが普通である。最初の原則として、影響量については慎重にならなければならない。不確実性は、単に CI (95%、99%、99.9%であるかどうかは関係ありません)だけでは伝わらない。

新たに提案された関連性については、提案された影響の信頼性と正確性はケースによって異なる。ヒトは次のよう な質問をするだろう:この分野の研究コミュニティは、研究成果を主張するために、広く統計的な有意性や同様の選 択の閾値を採用しているのか?発見は小規模な研究から生まれたのか?分析に大きな変動の余地があるか?選択 的な報告から保護されていないか(例:プロトコールが前もって完全に利用可能ではなかったか)?特定の「ポジティ ブな」結果を発見し、促進することに興味を持っている人や組織はあるか?最後に、影響を相殺する力は最小限に 抑えられているか?

-第三に、影響量の膨張現象は、発見科学全般に適用可能な一般的な原則であり、疫学の特異的悩みや弊害ではないことを覚えておくべきである(Ioannidis、2005年;Lehrer、2010年;Button、2013年;Buttonら、2013年;Reinhart、2015年)。先に示したように、これは薬理学、遺伝子研究、心理学研究、そして最も頻繁に引用される医学文献の多くでしばしば見られる。このような真実性の膨張は、研究の規模が小さく、検出力が不足している場合に起こり、そのような研究では結果に大きなばらつきがあるからである。これは、多くの研究者が同様の研究を行っており、「新しい」または「刺激的な」結果を発表するために競争している場合には特に問題となる(Reinhart、2015年)。

### まとめと結論

影響量の拡大または「真実の膨張」とは、影響を「発見」するために統計的またはその他の閾値を満たす必要がある www.efsa.europa.eu/efsalourna EFSA.Journal 2017;15(10):5007

are derived from underpowered studies in which statistical or other thresholds need to be met in order for effects to be 'discovered'. The phenomenon is not specific to epidemiology or epidemiological studies, but rather to any science in which studies tend to be small and predetermined thresholds such as those relating to effect sizes or statistical significance are used to determine whether an effect exists. As such, it is important that users of epidemiological studies recognise this issue and its potential interpretational consequences. Specifically, any discovered associations from an underpowered study that are highlighted or focused upon on the basis of passing a statistical or other similar threshold are systematically biased away from the null. While we cannot know if any specific observed effect size from a specific study is biased away from the null as a result of being a 'discovered' association that passes a statistical threshold (just as we can't say that a specific study showing non-differential misclassification will necessarily be biased towards the null), we do know that that chance favours such a bias to some degree as illustrated by the explications presented and simulations performed here. Said another way: by choosing to focus on, report, or act upon effect sizes on the basis of those effect sizes passing a statistical or other threshold, a bias is introduced since it is inevitably more likely to select those associations that are helped by chance rather than hurt by it (Yarkoni, 2009). Again, this is an issue related to how studies are interpreted by users, not one that is intrinsic to the study design nor one that is related to good scientific principles or practices.

One (partial) solution to the above issue is for the reader to cautiously interpret effect sizes in epidemiological studies that pass a prestated threshold or are statistically significant if they arise from an underpowered study, recognising that the observed effect sizes can be systematically biased away from the null. Such an approach would require that either the authors report the power of the study or that the authors provide sufficient information for the reader to do so. Effects sizes from studies with powers substantially less than 80% should be interpreted with an appropriate degree of scepticism, recognising that these may be inflated - perhaps substantially so (particularly if the power is less than 50%). The potential degree of this inflation will depend on a number of issues including background rate of the health outcome of interest, the sample size of the study and the effect size of interest. More specifically, when (a) the smaller the background rate of the health outcome of interest is low, (b) the sample size of the study is small and (c) the effect size of interest is weak, then the power of the study (to detect that effect size) will be low and the tendency towards inflated effect sizes in statistically significant results will be high. Low power studies investigating small or weak effects in populations that have a low background rate of the health outcome of interest will tend towards the greatest degree of effect size inflation. As a result, the PPR Panel recommends that epidemiological publications either incorporate such calculations or include key information such that those calculations can be performed by the reader. Specifically:

When the association between a given pesticide exposure and a disease is found to be statistically significant, particularly in (presumed) low powered studies, data user should perform various power calculations (or a power analysis) to determine the degree to which the statistically significant effect size estimate (OR or RR) may be artificially inflated or magnified. This requires three values to be clearly reported by epidemiological studies: (i) the number of subjects in the non-exposed group (including diseased and non-diseased individuals); (ii) the number of subjects in the exposed group (including diseased and non-diseased individuals); and (iii) the number of diseased subjects in the non-exposed group. Risk managers can then select the target value of interest (typically an OR or RR) to detect a difference of a given (predetermined) effect size between the exposed and non-exposed subjects, and evaluate the degree to which effect size magnification could potentially explain the effect size that was estimated in the study of interest.

Since it appears that (i) many epidemiological studies are frequently underpowered; (ii) it is not common for authors to provide either power calculations or (sometimes) the information in publications required to do them, and (iii) the phenomenon of effect size magnification generally appears to be little recognised in the epidemiological field, the above PPR Panel recommendation will require effort on the part of researchers/grantees, publishers, and study sponsors to implement. While the above suggests that the current state of practice in this area may leave one pessimistic, an opinion piece on this topic by researcher Kate Button (Button, 2013) describing her work in Nature Reviews Neuroscience (Button et al., 2013) offered guarded reasons for optimism:

'Awareness of these issues is growing and acknowledging the problem is the first step to improving current practices and identifying solutions. Although issues of publication bias are difficult to solve overnight, researchers can improve the reliability of their research by adopting well-established (but

#### Epidemiological studies and pesticides

検出力不足の研究から得られた効果測定値の場合に、オッズ比、相対リスク、または率比の推定値が誇張されることが ある現象である。この現象は、疫学や疫学研究に特有のものではなく、むしろ、影響が存在するかどうかを判断するた めに、影響量や統計的有意性に関連するような、研究の規模が小さく、事前に設定された閾値が使用される傾向にあ るあらゆる科学に見られる。このように、疫学研究の利用者がこの問題とその潜在的な解釈の結果を認識することが重 要である。特に、検出力不足の研究から発見された関連性は、統計的または他の同様の閾値を通過したことに基づい て強調されたり、注目されたりするが、それは帰無値から系統的にバイアスがかかっている。統計的閾値を通過した「発 見された」関連性の結果として、特定の研究で観測された影響量が帰無値から遠ざかるかどうかはわからないが(非差 異的な誤分類を示す特定の研究が必ずしも帰無値に向かって偏るとは言えないのと同じように)、ここで提示された説 明と実行されたシミュレーションによって説明されているように、偶然がそのような偏りをある程度有利にすることはわか っている。別の言い方をすると、統計的またはその他の閾値を通過した影響量に基づいて影響量に注目したり、報告し たり、行動したりすることを選択することで、バイアスが導入される(Yarkoni、2009 年)。繰り返しになるが、これは研究 がユーザーによってどのように解釈されるかに関連する問題であり、研究デザインに内在するものでもなければ、優れ た科学技術の原則や実践に関連するものでもない。

上記の問題に対する(部分的な)解決策の 1 つは、観察された影響量が帰無値から系統的に偏ってしまう可能性が あることを認識した上で、事前に定められた閾値を通過した疫学研究の影響量または検出力不足の研究から生じた場 合の統計的に有意な影響量を慎重に解釈することである。このようなアプローチでは、著者が研究の検出力を報告す るか、著者が読者に十分な情報を提供する必要がある。検出力が実質的に 80%未満の研究から得られた影響量は、 おそらく実質的に(特に検出力が 50%未満の場合)誇張する可能性があることを認識した上で、適切な程度の疑いを 持って解釈する必要がある。この誇張の潜在的な程度は、対象となる健康影響のバックグラウンド率、研究のサンプル サイズ、対象となる影響量など、多くの問題に依存する。より具体的には、(a)対象となる健康影響のバックグラウンド率 が低い場合、(b)研究のサンプルサイズが小さい場合、(c)対象となる影響量が弱い場合、研究の検出力(その影響量 を検出するための)は低く、統計的に有意な結果において影響量が誇張される傾向が高くなる。対象とする健康影響 のバックグラウンド率が低い集団で、小さな、または弱い影響を調査する低検出力研究では、影響量の誇張が最も大き くなる傾向がある。その結果、PPRパネルは、疫学的文献にこのような計算を組み込むか、または読者が計算を実行で きるような重要な情報を含めることを推奨している。具体的には以下の通り。

特定の農薬ばく露と疾病との間の関連が統計的に有意であることが判明した場合、特に(推定される)検出力の低い 研究では、データ利用者は、統計的に有意な影響量推定値(ORまたはRR)がどの程度人工的に拡大、または誇張さ れているかを判断するために、様々な検出力計算(または検出力解析)を実行すべきである。これは、疫学研究で明確 に報告される3つの値を必要とする。(i)非ばく露群の被験者数(罹患者と非罹患者を含む)、(ii)ばく露群の被験者数 (罹患者と非罹患者を含む)、(iii)非ばく露群の罹患者数である。リスク管理者は、次に、ばく露群と非ばく露群の間の 所定の(予め決められた)影響量の差を検出するために、対象となる目標値(典型的には、ORまたはRR)を選択でき、 影響量の規模が、対象となる研究で推定された影響量をどの程度説明できるかを評価することができる。

(i)多くの疫学研究はしばしば検出力不足であり、(ii)著者が検出力の計算や(場合によっては)計算に必要な情報 を文献の中で提供することは一般的ではなく、(iii)影響量の拡大の現象は一般的に疫学分野ではほとんど認識され ていないようであるため、上記の PPR パネルの勧告を実施するためには、研究者/助成機関、出版社、研究資金提 供者の側での努力が必要である。上記のように、この分野での実践の現状は悲観的になるかもしれないことを示唆して いるが、研究者である Kate Button(Button、2013 年)が Nature Reviews Neuroscience 誌に掲載したこのトピック に関するオピニオン・ピース(Button ら、2013 年)で、楽観について慎重な理由を提供した。

これらの問題に対する認識は高まっており、問題を認識することは、現在の実践を改善し、解決策を特定するための 第一歩である。出版バイアスの問題を一朝一夕に解決するのは難しいが、研究者は確立された(しかし、しばしば無視 される)科学技術の原則を採用することで、研究の信頼性を向上させることができる。また、研究者は、確立された(しか し無視されることが多い)科学技術の原則を採用することで、研究の有用性/信頼性を向上させることができる。

100

1)研究の計画や結果の解釈において、統計的な検出力を考慮する。

often ignored) scientific principles; Also, researchers can improve the usefulness/reliability of their research by adopting well-established (but often ignored) scientific principles:

1) Consider statistical power in the design of our studies, and in the interpretation of our results;

CI USA INFO

- 2) Increase the honesty with which we disclose our methods and results.
- 3) Make our study protocols, and analysis plans, and even our data, publically available; and
- 4) Work collaboratively to pool resources and increase our sample sizes and power to replicate findings."

Although the above set of recommendations and thoughts were set in the context of sample size and neurotoxicology, they have broad applicability to any discovery science, including epidemiology. In sum, while there is much room for improvement in the conduct and reporting of epidemiological studies for them to be useful to regulatory bodies in making public health-based choices, the issues are beginning to be better defined and recognised and - going forward - there is reason for optimism.

# ABSTRACT

We performed a systematic and extensive literature review of epidemiological studies examining the association between pesticide exposure and any health outcome published after 2006. We searched 43,259 citations and identified 603 published articles examining a very wide variety of outcomes and presenting over 6,000 analyses between pesticide exposure and health outcomes. We divided the different outcomes into 23 major disease categories. The largest proportion of studies pertains to cancer outcomes (N=164) and outcomes related to child health (N=84). The majority of studies were case-control studies and cross-sectional studies (N=222) and examined occupational exposure to pesticides (N=329). A wide and diverse range of pesticides was studied with studies using various definitions of pesticides; it is very hard to harmonise between studies this information. Despite the large volume of available data and the large number (>6,000) of analyses available, firm conclusions cannot be made for the majority of the outcomes studied. This observation is disappointing especially when one accounts for the large volume of research in the area. However, this observation is in line with previous studies on environmental epidemiology and in particular on pesticides which all acknowledge that such epidemiological studies suffer from many limitations and that the heterogeneity of data is such that does not allow firm conclusions to de made. We also performed updated metaanalysis for major outcomes and for those where a relevant meta-analysis published after 2006 was identified. This has only been possible for childhood leukaemia and for Parkinson's disease. For both these outcomes we found significant associations between pesticide exposure and disease in line with previous evidence.

The present document has been produced and adopted by the bodies identified above as author(s). This task has been carried out exclusively by the author(s) in the context of a contract between the European Food Safety Authority and the author(s), awarded following a tender procedure. The present document is published complying with the transparency principle to which the Authority is subject. It may not be considered as an output adopted by the Authority. The European Food Safety Authority reserves its rights, view and position as regards the issues addressed and the conclusions reached in the present document, without prejudice to the rights of the authors.

#### **BACKGROUND AND TERMS OF REFERENCE**

Over the last years an abundance of epidemiological studies investigating possible associations of pesticide exposure with adverse health effects on humans have become available. In these studies exposure to pesticides e.g. via inhalation, ingestion, dermal contact or across the placenta has been established as being, or suggested to be, causative for instance for cancer in various organs and tissues, disturbed neurodevelopment of children, allergies, decreased fertility (male and female), birth defects and Parkinson's disease.

However, for many adverse health effects that are attributed to pesticide exposure contradictive or ambiguous studies also exist. Studies vary generally greatly in design (e.g. case control versus cohort studies), sample size and in many cases exposures are rather estimated or assumed than actually determined.

A comprehensive up-to-date literature collection and review covering relevant publications from 1<sup>st</sup> January 2006 to 31<sup>st</sup> March 2012 should be carried out in which also the quality of these studies is evaluated.

The objectives of the contract resulting from the present procurement procedure are as follows:

Objective 1: To collect and compile scientific publications in which possible links between pesticide exposure and adverse human health effects have been investigated.

Objective 2: To review and evaluate each collected study in regard to its qualitative aspects (e.g. the corner points of the investigations).

Objective 3: Provision of a database and a report of epidemiological studies.

This contract was awarded by EFSA to: The Department of Hygiene and Epidemiology, University of Ioannina Medical School, Ioannina, Grecce.

Contractor: The Department of Hygiene and Epidemiology, University of Ioannina Medical School, Ioannina, Grecce.

Contract title: Literature review on epidemiological studies linking exposure to pesticides and health effects.

Contract number: CFT/EFSA/PRAS/2012/04 – CT 01.

EFSA supporting publication 2013:EN-497

The present document has been produced and adopted by the bodies identified above as author(s). This task has been carried out exclusively by the author(s) in the context of a contract between the European Food Safety Authority and the author(s), awarded following a tender procedure. The present document is published complying with the transparency principle to which the Authority is subject. It may not be considered as an output adopted by the Authority. The European Food Safety Authority reserves its rights, view and position as regards the issues addressed and the conclusions reached in the present document, without prejudice to the rights of the authors.

#### **INTRODUCTION AND OBJECTIVES**

This project aims to systematically collect, review and appraise epidemiological studies carried out to investigate possible links of pesticide exposure to health-related outcomes in order to improve understanding of already established or suggested associations with adverse effects in humans. The review focuses on all exposure types either through occupation or in general population with a particular focus on investigating sources of heterogeneity. In particular, we have collected scientific publications in which possible links between pesticide exposure and adverse human health effects have been investigated. The available evidence is under review and evaluation with regard to its qualitative aspects. Finally, a database of studies, which examine adverse health effect of pesticides, was compiled.

The final report is structured around health outcome categories and is linked to a *data extraction database*. In the methods we provide a detailed documentation of the search criteria and search strategy used for the literature review and the study selection process. This section also describes the analytical framework with the detailed documentation on the selected exposure and indicators of exposure and the surrogate and clinical outcomes examined. We present the results of the literature search with the full list of eligible studies and the contents of the *data extraction database*. We also present the results of the outcomes and pesticides examined and conclusions based on the literature review findings.

#### **BACKGROUND AND AIMS**

Pesticides have been widely used against pests that can damage crops such as insects, fungi, rodents, noxious, weeds, in order to prevent or reduce losses and improve product quality, for many years. Their use is very popular; in 2006 and 2007, the world used approximately 5.2 billion pounds of pesticides. However, despite their extensive use, and the associated benefits from pesticide use, there have been concerns on adverse effects in human health as these chemicals are designed to have adverse biological effects on target organisms. Indeed, there is evidence between pesticide use and adverse health outcomes such as cancers, neurodegenerative disease and birth defects; however, results so far have been inconsistent and firm conclusions cannot be drawn for several pesticides.

The aim of this review is to systematically collect, review and appraise epidemiological studies carried out to investigate possible links of pesticide exposure to health-related outcomes. This review includes all exposure types either through occupation or in the general population with a particular focus on investigating sources of heterogeneity. In particular, we have collected and compiled scientific publications in which possible links between pesticide exposure and adverse human health effects have been investigated. The available evidence has been reviewed and evaluated with regard to its qualitative aspects and data from each eligible study has been extracted. Finally, a database of studies, which examine adverse health effects of pesticides, has been compiled with the aim to facilitate the continuous update of results.

The aforementioned aims constitute a stimulating task due to the methodological challenges of environmental epidemiology and pesticide exposure in particular and the vast volume of the peer-reviewed literature.

EFSA supporting publication 2013:EN-497

The present document has been produced and adopted by the bodies identified above as author(s). This task has been carried out exclusively by the author(s) in the context of a contract between the European Food Safety Authority and the author(s), awarded following a tender procedure. The present document is published complying with the transparency principle to which the Authority is subject. It may not be considered as an output adopted by the Authority. The European Food Safety Authority reserves its rights, view and position as regards the issues addressed and the conclusions reached in the present document, without prejudice to the rights of the authors.

#### MATERIALS AND METHODS

#### 1. Search strategy

A comprehensive literature search was conducted of peer-reviewed original research pertaining to pesticide exposure and any health outcome. The search strategy was designed so as to identify observational epidemiologic studies published between 1<sup>st</sup> of January 2006 to 30<sup>th</sup> of September 2012 and examining the relationship between pesticide exposures during critical exposure time windows (preconception, pregnancy, childhood, adulthood) and any health-related outcome as discussed previously. The search strategy was developed to search primarily the MEDLINE (1950–to date), and EMBASE (Excerpta Medica Database; 1980 to-date) databases as well as TOXNET (Toxicology Data Network; U.S. National Library of Medicine 2012), OpenSigle (2012), and ProQuest Digital Dissertations and Theses (2012) as supplemental searches.

#### 2. Search algorithm for original studies in MEDLINE and EMBASE

This systematic review aimed to identify studies examining any clinical outcome or valid biomarker acting as surrogate for a clinical outcome that has been associated with exposure to pesticides. In order to achieve maximum sensitivity, we did not include any outcome-related search terms in the search algorithm that we developed. For the formation of the search algorithm, we concentrated on pesticides related terms, identified through the MEDLINEMESH terms and EMBASE classification trees on pesticides. In MEDLINE, the MESH terms of pesticides and pesticides (pharmacological action) were examined. Similarly, we examined the pesticide term in the EMBASE Emtree index. We have looked for pesticide categories (i.e. insecticides, herbicides, fungicide etc.) and for specific pesticide names as described in the literature or as pharmacological terms (e.g. DDT or Dichlorodiphenyltrichloroethane) in order to be comprehensive. We have also examined the search terms used in published systematic reviews on pesticide exposure during the past 10 years and looked for any additional terms.

Our first constructed algorithm was long including all aforementioned terms. We piloted different searches and shortened the search to improve the sensitivity of the algorithm with modest impact on the precision. All searches were limited to Humans and to publication date after 1<sup>st</sup> of January 2006.

The long list of pesticide names provided from the MESH database for pesticides pharmacological names only provided 2,270 citations on top of the pesticides related words search (pesticid\* OR pesticides"[MeSH Terms] OR "pesticides"[All Fields] OR "pesticide"[All Fields] OR "pesticides"[Pharmacological Action]) in MEDLINE. Examination of 200 from those 2,270 citations showed that these did not include epidemiological studies and referred to chemical studies on the substances and chemical formation of pesticides. We therefore adopted the search algorithm including the generic terms. The algorithm was constructed in EMBASE as the database provides a function to study MEDLINE and EMBASE simultaneously (see textbox below). The following algorithm was developed:

The present document has been produced and adopted by the bodies identified above as author(s). This task has been carried out exclusively by the author(s) in the context of a contract between the European Food Safety Authority and the author(s), awarded following a tender procedure. The present document is published complying with the transparency principle to which the Authority is subject. It may not be considered as an output adopted by the Authority. The European Food Safety Authority reserves its rights, view and position as regards the issues addressed and the conclusions reached in the present document, without prejudice to the rights of the authors.

# **Table 1:**Search algorithm for EMBASE and MEDLINE

pesticid\* OR 'pesticide'/exp OR 'chemical pest control'/exp OR fungicid\* OR 'fungicide'/exp OR herbicid\* OR 'herbicide'/exp OR insecticid\* OR 'insecticide'/exp OR molluscacid\* OR 'molluscacide'/exp OR molluscicid\* OR 'molluscicide'/exp OR rodenticid\* OR 'rodenticide'/exp OR carbamat\* OR 'carbamate'/exp OR pyrethroid\* OR 'pyrethroid'/exp OR 'chlorinated hydrocarbon'/exp OR 'agricultural chemical'/exp AND [humans]/lim AND [2006-2013]/py

The algorithm resulted in 43,259 citations in EMBASE and MEDLINE combined. Of those, 14,539 were unique to EMBASE. The algorithm includes all pesticides related terms and subcategories used either as emtree entries with the explode option and also as text words. The explode option ensures that when a term has any more specific, or narrower, index terms within the Emtree thesaurus, they are also automatically retrieved as part of the search. Terms such as organochlorine, glyphosate, paraquat and maneb were excluded as they are part of the pesticide tree of the explode option and are searched. Inclusion of these terms would lead to the same set of results. Figure 1 below shows examples of the indexing trees in EMBASE for some of our search terms.

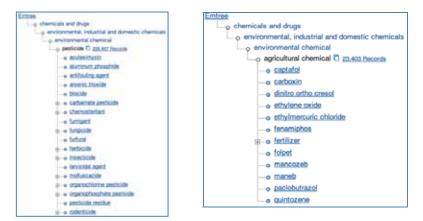

Figure 1: Examples of Emtree classification trees

#### **3.** Supplemental searches

The database of TOXNET, which lists databases on toxicology, hazardous chemicals, environmental health, and toxic releases, was also searched to identify any information missed from previous search in MEDLINE and EMBASE. We used only the Databases, which look for references in the biomedical literature (i.e. the Toxicology Literature Online (TOXLINE) and the Developmental Toxicology Literature (DART)). The remaining TOXNET databases provided summaries of Chemical, Toxicological, and Environmental Data per chemical substance and were not relevant to this search. For TOXLINE and DART, we used the generic terms "Pesticide OR Pesticides" as longer search algorithms with the inclusion of pesticides subcategories had only minor impact on the number of references identified. The searches were limited to publication dates after 2006, excluding references identified through MEDLINE. The function to identify chemical synonyms to the search term was enabled. Overall, 893 references were retrieved from TOXLINE and 34 from DART.

EFSA supporting publication 2013:EN-497

The present document has been produced and adopted by the bodies identified above as author(s). This task has been carried out exclusively by the author(s) in the context of a contract between the European Food Safety Authority and the author(s), awarded following a tender procedure. The present document is published complying with the transparency principle to which the Authority is subject. It may not be considered as an output adopted by the Authority. The European Food Safety Authority reserves its rights, view and position as regards the issues addressed and the conclusions reached in the present document, without prejudice to the rights of the authors.

We also looked into the System for Information on Grey Literature in Europe (OpenSigle), which includes 700.000 bibliographical references of grey literature (paper) produced in Europe. There were no bibliographical references on pesticides (search term pesticid\*) published after 2006.

We have also constructed a search algorithm to search the ProQuest Digital Dissertations and Theses database. We excluded from our search articles published in scholarly journals as those will have been identified through MEDLINE and EMBASE. We used the search term "pesticide\* AND health" and limited our search to specific subjects (environmental science OR public health OR environmental health OR epidemiology OR pesticides OR nutrition OR occupational health) and to publication dates between 2006 and 2012. This search strategy resulted in 1,713 results. Results were numerous when no subject limits were used (12,135) or when the term "health" was excluded from the initial algorithm (18,195).

Finally, the reference lists of all identified eligible studies and systematic reviews are scanned during data extraction for additional references.

### 4. Search for literature systematic reviews and meta-analysis

We also performed targeted searches for systematic reviews and meta-analysis in relation to specific outcomes. We restricted the search for reviews on those outcomes where more than 4 studies had been identified and we performed targeted searches in MEDLINE using the name of the outcome along with the keywords "systematic review OR meta-analysis" limited to the title or the abstract of the paper.

## 5. Structure of this report

This report is structured around health outcome categories and provides the results for each outcome group separately. A section on general conclusions is presented at the end. At the end of each section on outcomes and tables and figures are presented to allow ease of reading. Also, the ID numbers of each eligible article are referenced throughout the text. These correspond to the ID for each health outcome group in the *data extraction database* which has been provided as a separate file to this report. The ID is defined with an abbreviation for the specific health outcome and a study number.

The present document has been produced and adopted by the bodies identified above as author(s). This task has been carried out exclusively by the author(s) in the context of a contract between the European Food Safety Authority and the author(s), awarded following a tender procedure. #### 6. Selection of studies

All titles identified through the literature search of various databases were screened to identify studies, which evaluated the association between pesticides and health outcomes including any surrogate outcome. All abstracts of the selected titles are then screened in duplicate to identify epidemiological studies linking pesticide exposure to any health outcome including surrogate outcome. Both primary studies and systematic reviews or meta-analyses are selected. Articles that potentially meet eligibility criteria at the abstract screening stage have been retrieved and the full text articles have been reviewed in duplicate for eligibility. The reason for rejection of all full text articles has been recorded.

# 6.1. Eligibility criteria for full text articles

We included observational studies assessing the association between pesticide exposure and healthrelated outcomes. We included cohort, cross-sectional and case- control studies. We included studies performed in humans published from 1<sup>st</sup> of January 2006 to 30<sup>th</sup> of September 2012. Animal studies and studies performed in human cells have been excluded. We had no language, population or geographical restrictions. To enhance totality of the evidence, all types of pesticides have been considered. Exposure to pesticides was defined as reported use of pesticides by the study participant or by government registry data (self administrated questionnaires, interviewer administrated questionnaires, job exposure matrix (JEM)), by residential status (proximity to pesticide exposure), by detecting biomarkers associated with pesticide exposure or by any other means as defined by each study. Eligible health-related outcomes were "major" clinical outcomes, such as neoplasias or Parkinson's disease, clinical surrogate outcomes such as neurocognitive scales, or laboratory surrogate outcomes with an established association with clinical outcomes, such as liver enzymes.

Narrative reviews, case-series and case-reports (studies without control populations) are excluded. We also excluded studies assessing the health-related effect of pesticide poisoning or accidental high-dose pesticide exposure. We have excluded studies with no availability of sufficient quantitative information reported in the article (e.g. effect estimates) so that effect sizes or measures of associations can be calculated. Whenever reports pertained to the same study at different follow-up periods and examining the same outcome, we retained the one with the longer follow-up to avoid data duplication. We also excluded studies that referred to fertilizers (exploded from the algorithm term "agricultural chemical") as well as studies referred to the adverse effects of substances used as therapy for various medical conditions such as warfarin for anticoagulation or agents used in the treatment of scabies. Solvents and other non-active ingredients in pesticides/herbicides were not considered eligible. We excluded studies that investigate the various effects of Agent Orange on chemical warfare veterans as they represent cases of very high dose exposures. Finally, studies which examined the association between exposure and biomarkers of exposure were also not considered eligible as they do not examine health outcomes. Finally, following consultation with EFSA, we excluded studies/analyses investigating exposure to pesticides: arsenic,  $\alpha$ ,  $\beta$ , hexachlorocyclohexane (HCH), lead, dioxins and dioxin-like compounds including polychlorinated biphenyls (PCBs) as these chemicals were not considered relevant for the current project.

Regarding systematic reviews and meta-analyses, we considered all systematic reviews and metaanalyses that systematically assessed the effect of pesticide exposure to health-related outcomes, regardless of the pesticide, exposure window and outcome assessed. We included all publications where a systematic approach was endorsed (systematic literature search, assessment of methodological characteristics of the included studies and, if a meta-analysis was performed, the use of standard analytical tools including the use of a weighted summary estimate and a formal appraisal of heterogeneity). Narrative reviews are excluded.

The present document has been produced and adopted by the bodies identified above as author(s). This task has been carried out exclusively by the author(s) in the context of a contract between the European Food Safety Authority and the author(s), awarded following a tender procedure. The present document is published complying with the transparency principle to which the Authority is subject. It may not be considered as an output adopted by the Authority. The European Food Safety Authority reserves its rights, view and position as regards the issues addressed and the conclusions reached in the present document, without prejudice to the rights of the authors.

### 6.2. Quality control measures

The pilot literature searches have all been performed in duplicate. In addition, the first 500 results of all title searches were performed in duplicate and results were compared between investigators, which displayed high levels of agreement. The kappa statistic for agreement was 0.78. Two independent research group members performed in duplicate the abstract screening, the full text screening and the data extraction. All discrepancies are resolved by consensus or by a third arbitrator.

### 6.3. Data extraction database

We have constructed and tested the *data extraction database* with data extraction items and quality assessment items that were implemented through the whole process. The data extraction database has been structured in 7 domains: Reference, Time period, Study characteristics, Exposure assessment, Outcomes, Statistical analysis and Quality assessment (separate database file). The first 6 domains pertain to information directly extracted from the full-texts of eligible studies and would be primarily used to select studies for quantitative synthesis and aid quantitative synthesis. Studies contribute one row in the database for each outcome examined and for each exposure examined. When studies present various definitions of exposure we select for data extraction the most comprehensive definition of exposure and subsequently the one with the largest sample size. However when studies include any type of quantitative information for different biomarkers used for the identification of the same chemical substance e.g. p,p'-DDT and p,p'-DDE for dichlorodiphenyltrichloroethane (DDT), they are all reported in separate rows. When studies present data in subgroups (e.g. males and females) we extract only their main analysis (whole group) unless the data is only presented in subgroups in which case multiple rows are presented. Analyses regarding different pesticide classes and different health outcomes are extracted individually. Appendix II explains all the items used in the *data extraction* database.

The data extraction form was validated through a robust and systematic procedure. Specifically, various versions of the form were validated after blinded loops of extracting information for studies randomly selected from the database. We opted for the maximum agreement while preserving the comprehensiveness of the database. Two investigators extract each item independently and discrepancies are resolved with discussion.

# 6.4. Quality appraisal

The last part of the *data extraction database*, concerns the methodological appraisal of each eligible paper. The areas that we have focused are the study design, the study population, the level of details in exposure definition and the methods of exposure measurement and the specificity of the measurement. These are crucial questions to be asked in exposure assessment epidemiology. We have also focused on the efforts undertaken to account for confounders through matching or multivariable models, blinded exposure assessment and well-defined and valid outcome assessment. We have also looked at whether the source of funding was acknowledged. The elements of the methodological appraisal were considered from the RTI item bank. The RTI item bank is a practical and validated item bank for evaluating the risk of bias and precision of observational studies of interventions or exposures included in systematic evidence reviews. The questions were adapted to reflect exposure assessment. Across the quality appraisal questions we consistently coloured the responses to qualitative assessment in green, orange and red with green representing low risk of bias and red high risk of bias. Table 3

EFSA supporting publication 2013:EN-497

The present document has been produced and adopted by the bodies identified above as author(s). This task has been carried out exclusively by the author(s) in the context of a contract between the European Food Safety Authority and the author(s), awarded following a tender procedure. The present document is published complying with the transparency principle to which the Authority is subject. It may not be considered as an output adopted by the Authority. The European Food Safety Authority reserves its rights, view and position as regards the issues addressed and the conclusions reached in the present document, without prejudice to the rights of the authors.

below explains which answers were considered low and high risk respectively. However, the quality appraisal questions should be interpreted with caution, as they are only suggestive of the risk of bias associated with each study. There may be studies which score high in this quality assessment and still have a high risk of bias and vice versa. A final column was constructed to grade the overall quality of the studies in low, intermediate and high. This classification was based on the answers to the methodological assessment questions as explained in Table 3.

Table 3:	Methodological	assessment of eligible studies

Question	High risk	Low risk
Study design (prospective, retrospective, mixed, cross-sectional)	Retrospective, mixed, NA	Prospective
Inclusion/exclusion criteria clearly stated (yes, partially, no)	No	Yes
Authors mention power calculations (yes, no)		Yes
Level of detail in describing exposure (high, medium, low)	Low	High
Robust measurement of exposure. (biomarker (yes); small area ecological measures, job titles, questionnaire (partial); was based on large area ecological measures (no)	No	Yes
Were measures of exposure specific? yes; based on broader, chemically- related groups (partial); based on broad groupings of diverse chemical and toxicological properties (no)	No	Yes
Attempt to balance the allocation between the groups (e.g., through stratification, matching)	No	Yes
Adjustment performed for potential confounders (yes, some, no)	No	Yes
Assessors blinded to exposure status (for cohort studies)	No	Yes
Outcomes assessed using valid and reliable measures, implemented	N	-
consistently across all study participants?	No	Yes
Sample size	Low	Тор
Rough quality assessment	>6 answers high risk	>6 asnwers low risk

# 6.5. Quantitative synthesis

Quantitative synthesis of the results was only attempted when there were more than 4 studies per examined outcome and when there was no substantial heterogeneity among the published evidence. The presence and extent of heterogeneity was assessed by the  $I^2$  (ranging from 0% to 100%) (Ioannidis 2007). We have summarized the RR/OR estimates using fixed and random-effects models (Lau 1997). Fixed-effects models assume that there is a common underlying effect and the variability observed is attributed to chance alone; random effects models acknowledge that true between-study heterogeneity exists and take into account the presence of heterogeneity into their calculations. In the absence of heterogeneity, fixed-and random-effects models yield the same results. Publication bias was assessed using funnel plots and visual inspection of the results.

For each outcome with more than 5 eligible studies quantitative synthesis was attempted. We did not include data from the same cohort study; either presented in the same or in different publications in the same meta-analysis when the groups compared were not mutually exclusive. For each outcome with more than 4 studies, we also looked for previously published meta-analyses to compare results and to interpret our findings in the context of previous studies. Meta-analyses were found through a) systematic reviews and meta-analyses identified through our literature review and b) targeted searches in PUBMED to identify published meta-analyses for each outcome of interest. We attempted to update any previously published meta-analyses with our results when the meta-analysis a) included studies published by 2006 and b) when outcome and exposure definitions were comparable with the definitions used in this report. Finally, we also plotted funnel plots to visually inspect asymmetry when more than 10 studies were include in the meta-analysis.

# RESULTS

## 7. Overall results

This section focuses on the literature review results including flowcharts with number of studies screened and deemed eligible as well as number of excluded studies and corresponding reasons. It also provides an overview of the studies identified and their main characteristics.

# 7.1. Selection process for individual studies

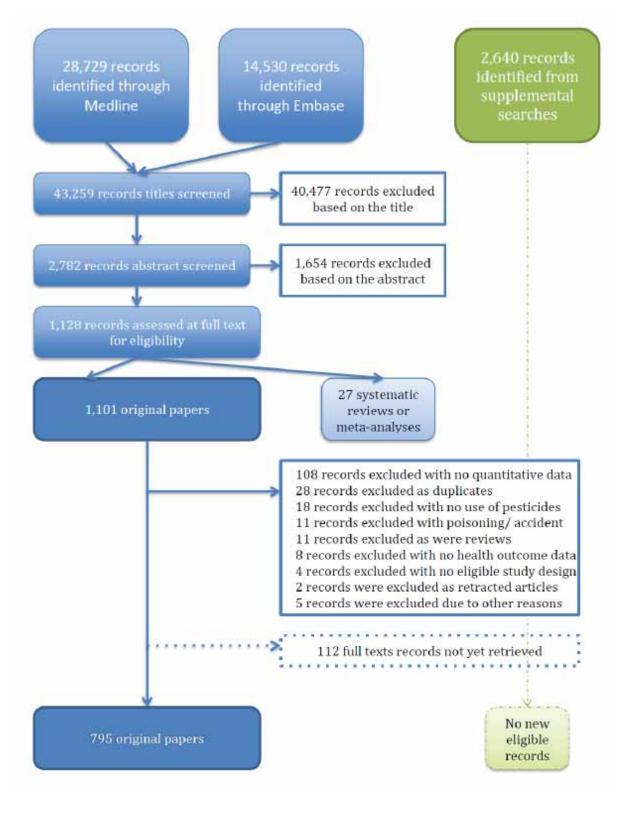

Of the 43,259 retrieved citations, 40,477 were excluded at the title screening level. Of the 2,782 remaining titles, a further 1,654 were excluded after the abstract screening. We thus deemed eligible, 1,128 citations to be scrutinized at the full-text level of which 1,101 were original research articles and 27 were systematic reviews or meta-analyses. Of the 1,101 original articles, 184 were excluded (Figure 2). For few (101) publications were the full text (or abstract for conference presentations) has not been found online, we sought the full text through letters to authors and investigations from our library. This has not been possible for 58 studies for which we extracted information from the abstract only.

Main reasons for exclusion at the full-text level pertained to: no quantitative information/ data (these were mainly abstract presentations or comments/ editorials which did not present any quantitative information for the association between pesticides and health outcomes, n=108); duplicate records (n=28), no implied use of pesticides (n=18), studies on poisoning or accidental very high doses (n=11), reviews with no primary data (n=11), no data on health outcomes (n=8). Supplemental searches did not succeed to provide additional references as they resulted in a large number of policy documents, grant applications documents and studies already retrieved. Supplemental searches through reference lists of identified studies and especially the reference lists of identified systematic reviews will continue during data extraction and any new identified studies will be added to the current list of eligible studies. During full text screening and data abstraction a further 301 studies were excluded. The main reason for exclusion was no eligible pesticide, such as Polychlorinated Biphenyls (PCBs) (Figure 2). Overall, 602 individual publications were eligible for inclusion in the present review. These 602 publications correspond to 6,479 different analyses, which are also present in the *data extraction database*.

#### 7.2. Evidence map tables and outcomes examined

We observed a great variety of assessed outcomes covering a wide range of pathophysiologies. "Hard" clinical outcomes as well as many surrogate outcomes are present in the database reflecting the different methodologies endorsed to approach the assessed clinical research questions. We divided the different outcomes into 23 major disease categories (Table 4 and Figure 3). The largest proportion of studies pertains to cancer outcomes (N=164) and outcomes related to child health (N=84). Table 4 corresponds to the Evidence map Table and shows the outcome mapping of the project describing all outcomes that have been associated with pesticide exposure between 2006 and 2012 and their frequency.

**Figure 3:** Major outcome categories and corresponding percentage of studies examining those outcomes among the eligible publications

# 7.3. Characteristics of eligible studies

The eligible studies were published from 2006 to 2012. The observed distribution of the publication year of the eligible studies indicates an approximately equal distribution of studies throughout the past 5 years (Figure 4). Of note, we expected a considerable presence of the results of the various reports of the Agricultural Health Study (AHS), the largest to-date observational study performed in the field. Indeed, the AHS publications (n=42) represent a recognizable proportion of the included studies (7%). Another 22 studies come form the cross-sectional National Health and Nutrition Examination Survey (NHANES) cohorts.

The majority of studies were case-control studies (N=222) and cross-sectional studies (Figure 5) and examined occupational exposure to pesticides (N=329). Almost half of the studies (N=285) were based in America (Figure 6). The most frequent method of pesticide assessment was measurement of biomarker or use of self reported questionnaire (Figure 7). Approximately half (N=261) studies were classified as 'high' in the methodological assessment.

EFSA supporting publication 2013:EN-497

The present document has been produced and adopted by the bodies identified above as author(s). The European Food Safety Authority reserves its rights, view and position as regards the issues addressed and the conclusions reached in the present document, without prejudice to the rights of the authors.

A wide and diverse range of pesticides was studied with studies using various definitions of pesticides; it is very hard to harmonise between studies this information. We also anticipated a considerable proportion of the published literature to be focusing on pesticides no longer approved for use in the European Union and in most of the developed countries. We acknowledge that this research lies on the rational of pesticide long-term residuals, as well as of the continuing use of these pesticides in developing countries. For example, studies focusing solely on DDT and its metabolites constitute almost 10% of the eligible studies.

## 7.4. Systematic literature review of systematic reviews and meta-analysis

Throughout our search strategy we also identified systematic reviews and meta-analyses. Overall, 21 different eligible reviews were identified published after 2006. The outcomes examined are shown in Table 5 below. Most reviews examined cancer related outcomes and some claimed positive associations between pesticides and examined outcome. The reviews are discussed in relevant outcome categories along with the individual studies.

### Table 5: List of systematic reviews and meta-analyses identified in the literature review

The present document has been produced and adopted by the bodies identified above as author(s). This task has been carried out exclusively by the author(s) in the context of a contract between the European Food Safety Authority and the author(s), awarded following a tender procedure. The present document is published complying with the transparency principle to which the Authority is subject. It may not be considered as an output adopted by the Authority. The European Food Safety Authority reserves its rights, view and position as regards the issues addressed and the conclusions reached in the present document, without prejudice to the rights of the authors.

#### 8. Cancer Outcomes

Overall, 164 publications examined the effect of pesticide exposure on cancer outcomes, contributing more than 2000 separate analyses. As seen with other outcomes, the diversity of exposure definition is remarkable and poses special challenges to data synthesis. Only 36 out of the 164 were prospective cohort studies and other 13 were nested case-controls; the overwhelming majority of evidence comes from retrospective case-control analyses, which are prone to recall bias in exposure measurement. Also, out of the 49 prospective analyses, 30 (61%) were from the same prospective study, the Agricultural Health Study (AHS) and evidence beyond this prospective cohort is limited. This is an important observation as it emphasizes the fact that 60% of the evidence for prospective associations comes from a single population. The sample size of the analyses was often small; it ranged between 24 and 82,596 participants (median 301). In addition, 33 studies had information on biomarkers of exposure and only 7 assessed occupational exposures through job exposure matrix (JEM). Common limitations in studies included small sample sizes, self-reported exposure, potential for high false positive rates due to multiple testing (studies test multiple hypothesis without adjusting for multiple testing and therefore results are likely to be false positives), and retrospective design. A wide variety or pesticides were assessed, with many studies examining organochlorine insecticides.

The different cancer categories examined are presented in Table 6 along with the number of studies contributing to each outcome category and a recommendation for quantitative synthesis. Due to heterogeneity of data and small number of studies identified, statistical synthesis of the data (meta-analysis) was only performed for some cancer subgroups.

#### 8.1. Hematological neoplasms

#### 8.1.1. Leukemias

Overall, 26 studies (and 2 abstracts) examined associations between pesticide exposure and various forms of leukaemia. Fourteen out of these 26 studies were reports from the AHS with some overlapping results and examination of different pesticide groups. Only 2 studies, both on DDE (ID CAN 063, ID CAN 064) examined residential exposure and all the remaining studies examined occupation exposure to pesticides. Twelve out of 99 different analyses were statistically significant with effect sizes across all studies ranging between 6.1 and 0.2. Statistically significant results come from 7 different studies; with the exception of the AHS all were of modest to low quality. Table 7 shows summarised results across studies that reported information on the same pesticide class. The vast majority of results are non-significant and of small effect sizes. Figure 8 shows random effect meta-analyses keeping analyses with largest sample size form each study. The meta-analysis resulted in a non-significant pooled effect (OR 1.26, 95% CI 0.93, 1.71) and had modest heterogeneity. Previous meta-analyses on occupational exposure to pesticides and leukaemia were published in 2008 and 2007 (Merhi 2007, Van Maele-Fabry 2008). The overall summary effect estimates from previous meta-analyses suggested that there is a significantly positive, albeit weak, association between occupational exposure to pesticides and all hematopoietic cancers. But both reports acknowledged a wide range of limitations including the lack of sufficient data about exposure information and other risk factors for hematopoietic cancer and unclear definition of exposure and of leukemia type.

The present document has been produced and adopted by the bodies identified above as author(s). This task has been carried out exclusively by the author(s) in the context of a contract between the European Food Safety Authority and the author(s), awarded following a tender procedure. The present document is published complying with the transparency principle to which the Authority is subject. It may not be considered as an output adopted by the Authority. The European Food Safety Authority reserves its rights, view and position as regards the issues addressed and the conclusions reached in the present document, without prejudice to the rights of the authors.

# 8.1.2. Hodgkin lymphoma

Seven studies examined the associations between pesticide exposure and Hodgkin lymphoma. All studies assessed exposure through questionnaires, one studies had large sample size and all studies were retrospective. A wide range of pesticides classes was examined which did not allow any meaningful synthesis of the results. Twelve out of 75 separate analyses were statistically significant with effect sizes ranging from 8.4 to 0.4 across all analyses. We attempted random effects meta-analysis keeping only the Agricultural Health Study (AHS) analysis with the largest sample size. The result was not statistically significant and had high heterogeneity which can be attributed to the range of different pesticide classes examined by each study (Figure 9).

# 8.1.3. Other lymphomas

A very wide variety of definitions of lymphomas other than Hodgkin lymphoma were used in 44 studies of which 21 were reports from the Agricultural Health Study (AHS) and 2 from the BC (British Columbia) sawmill workers cohort study. Studies examined broad definitions of lymphomas and lymphoproliferative syndromes (ID CAN\_047, ID CAN\_049, ID CAN\_074) and other examined more specific definitions of follicular lymphoma, diffuse large cell lymphoma and peripheral T-cell lymphoma. Twenty-one studies provided effect sizes between pesticide exposure and broad definitions of Non-Hodgkin lymphomas. Five of those studies were prospective (ID CAN\_063, ID CAN\_064, ID CAN\_067, ID CAN\_118, ID CAN\_121) and seven examined associations with biomarkers of exposure (ID CAN\_056, ID CAN\_057, ID CAN\_064, ID CAN\_065, ID CAN\_067, ID CAN\_060, ID CAN\_052). However, the later analyses were all on organochlorine pesticides with only few significant results (6 analyses among a total of 35 analyses) without any firm evidence for associations. In the AHS, large and significant effect size was observed between butylate use and Non-Hodgkin lymphomas (RR 2.94, 95% 1.49–5.96, p=0.002; high vs. no exposure). However, again the AHS in the same publication has examined ten different outcomes and results need adjustment for multiple testing.

# 8.1.4. Multiple myeloma

Also, 11 studies examined associations between pesticides and multiple myeloma, myelodysplastic syndromes and monoclonal gammopathy of undetermined significance. These studies were generally heterogeneous and no quantitative synthesis was suggested. Overall, some analyses were statistically significant, but those were mainly from the French case control study (ID CAN\_049) which presented overall 147 separate analyses and results are prone to bias. The AHS also reported significant associations between permethrin, dieldrin, Carbon-tetrachloride/carbon disulfide mix and Chlorthalonil but again these were amongst 52 other analyses and require cautious interpretation. One study, reported very high significant effect size of 7.3 for myelodysplastic syndrome (ID CAN\_070) but the quality of the study was poor and adjustment of covariates very limited and results were not replicated by other studies on the same phenotype.

# 8.2. Prostate cancer

Overall, 39 studies (in 260 analyses) examined the effects of pesticide exposure on prostate cancer. One study was a conference abstract which provided little data on methodology to allow meaningful appraisal of its results (ID CAN\_107). Also, 25 of those 39 studies were studies from the AHS population with some overlapping results. For example, two studies (ID CAN\_022, ID CAN\_106) examined interactions between pesticide exposure and genetic variants in relation to prostate cancer. These AHS studies presented the same main effects for pesticide exposure; effects were largely null and, if anything, significant inverse effects were found e.g. for carbaryl, chlordane, metalachlor and

EFSA supporting publication 2013:EN-497

The present document has been produced and adopted by the bodies identified above as author(s). This task has been carried out exclusively by the author(s) in the context of a contract between the European Food Safety Authority and the author(s), awarded following a tender procedure. The present document is published complying with the transparency principle to which the Authority is subject. It may not be considered as an output adopted by the Authority. The European Food Safety Authority reserves its rights, view and position as regards the issues addressed and the conclusions reached in the present document, without prejudice to the rights of the authors.

others. The remaining AHS studies, examined associations between specific pesticides, again showing no statistically significant associations between any of the examined pesticides and prostate cancer with the exception of a weak significant effect between butylate exposure and prostate cancer. The remaining evidence stems from, rather small and of modest quality, retrospective studies. Most studies (ID CAN 103, ID CAN 101, ID CAN 100, ID CAN 094, ID CAN 143, ID CAN 142) examined the effects of organochlorines with largely small and non-significant results. Two studies (IDs CAN 099, ID CAN 095) showed high significant increased risk associated with pesticide exposure and prostate cancer but both studies were of low quality, had very broad definitions of exposure and results need cautious interpretation and do not match with those reported from well conducted large prospective studies (e.g. AHS). Notably, one population-based case-control study (ID CAN 104) in a highly exposure area found strong association of ambient exposure to methyl bromide with prostate cancer risk, but the study did not observe evidence for exposure-response. In summary, most evidence for prostate cancer risk in relation to pesticide exposure concerns the effect of organoclorines with studies showing weak non-significant effects. A meta-analysis (Maele-Fabry 2003) on occupational exposure to pesticides and prostate cancer was also identified published. The pooled effect estimate, based on 22 epidemiological studies, was 1.13 (95% CI 1.04 to 1.22) with substantial heterogeneity across studies. In addition, the studies reviewed contained insufficient qualitative and quantitative information on exposure in order to distinguish the influence of pesticides from other occupational, environmental, and lifestyle factors (Maele-Fabry 2003). Overall, there is no evidence supporting an association between pesticide exposure and prostate cancer.

### 8.3. Lung cancer

Thirty studies contributing 45 analyses examined associations between pesticide exposure and lung cancer; previously published meta-analysis was not identified. Again, 23 out of 30 published studies and 30 of the 45 analyses were analyses of the AHS. Amongst the 50 different analyses of the AHS, only one statistically significant result was observed. Three studies examined broad pesticides definition as their exposure (ID CAN\_080, ID CAN\_082, ID CAN\_083), one studied mosquito coil burns (ID CAN\_081), while the remaining studies examined a range of different pesticides with an emphasis on organochlorine insecticides. The diversity of pesticide categories and the repeated use of the same cohort population (AHS) in more than half of the studies does not allow for quantitative synthesis. Notably, the association between mosquito coil burn and lung cancer was statistically significant with large effect size (3.78 (1.55, 6.90); yes vs. no use) but the study is relative small, retrospective with limited examination of confounders and of overall modest quality. Two case-control studies (ID CAN\_082, ID CAN\_082) reported over a two-fold increased risk of lung cancer for occupational exposure to pesticides but individual pesticides were not examined. Another case-control study (ID CAN\_080) failed to replicate these observations between pesticide exposure and lung cancer mortality. Overall, the evidence on pesticide exposure and lung cancer is limited and inconclusive.

#### 8.4. Childhood cancer

#### 8.4.1. Childhood hematological neoplasms

Overall, 17 studies (and one abstract) which examined childhood hematological neoplasms in relation to pesticide exposure were identified. All 17 studies examined childhood leukemia and 4 of them also included other hematological neoplasms.

Previous meta-analysis on childhood leukemia concentrated on studies which assessed residential exposure to pesticides only. All studies that were included in the meta-analyses and were published after 2006 have been identified by our search which confirms that we identified all available evidence.

23

EFSA supporting publication 2013:EN-497

The present document has been produced and adopted by the bodies identified above as author(s). This task has been carried out exclusively by the author(s) in the context of a contract between the European Food Safety Authority and the author(s), awarded following a tender procedure. The present document is published complying with the transparency principle to which the Authority is subject. It may not be considered as an output adopted by the Authority. The European Food Safety Authority reserves its rights, view and position as regards the issues addressed and the conclusions reached in the present document, without prejudice to the rights of the authors.

Identified studies were generally small with the exception of two studies on national registries, the Northern Region Young Persons' Malignant Disease Registry (ID CAN 120) and the national registry-based case-control study ESCALE (Etude sur les cancers de l'enfant) (ID CAN 073). Results from these studies should be cautiously interpreted, despite their large sample size, due to the large number of hypothesis examined (high false positive rate); each study reported 42 and 64 separate analysis respectively. All were case control studies and vast majority examined residential exposures with few studies on occupation exposure identified. Although most studies assessed use of, or exposure to, pesticides or pesticide subgroups (insecticides, herbicides, fungicides), some studies also attempted to collect information on specific pesticides (ID CAN 031, ID CAN 032) and one study (ID CAN 032) assessed biomarker levels. There were few data regarding frequency or duration of pesticide use, with most studies reporting only "ever/never" use of/exposure to the pesticide of interest. Although confounding is difficult to assess because there are few established risk factors for childhood hematological neoplasms, most studies examined or adjusted for at least a range of sociodemographic and maternal characteristics. Almost all studies assessed pesticide exposure separately for preconception, pregnancy, and childhood time windows. One study of very low quality and incomplete statistical analyses results examined all exposure time windows and other 2 (ID CAN 073, ID CAN 044) examined preconception and pregnancy jointly.

Three studies were excluded from further quantitative analyses: study ID CAN\_040 was excluded due to lack of CIs; study ID CAN\_030 due to duplicate data from Northern California Childhood Leukemia Study (duplicate with ID CAN\_031), and study ID CAN\_037 due to a unique study population (Down syndrome cases only). We divided the quantitative synthesis of results by the time period (window of exposure).

### 8.4.1.1. Exposure during pregnancy

Seven studies had information for pesticide exposures during pregnancy. Eleven out of 86 analyses were statistically significant corresponding to 5 studies which all examined acute leukaemia as outcome of interest. Largest effect estimates were reported from the national registry-based casecontrol study ESCALE (Etude sur les cancers de l'enfant). Insecticide use during pregnancy was significantly associated with childhood acute leukemia (OR = 2.1; 95% CI, 1.7-2.5) and paternal household use of pesticides was also related to acute leukemia (OR = 1.5; 95% CI, 1.2–1.8) in this study. We performed a series of quantitative synthesis of results. We first selected analyses with the largest sample size within each published report and synthesized results (Figure 10). This analysis was associated with large heterogeneity ( $I^2 > 80\%$ ) as each study had different exposure assessment (type of pesticide and parental route of exposure) and variability in outcome assessment. The remaining metaanalysis in Figure 10 show synthesis or results based on pesticide class examined in an effort to harmonize results with the previously published meta-analysis (Turner 2010) on 'Residential Pesticides and Childhood Leukemia'. We performed quantitative synthesis of all studies on insecticides and pesticides identified in this systematic review and subsequently we updated the previously published meta-analysis keeping only studies assessing residential exposure. Overall, the results show modest heterogeneity across studies, which can be attributed to variability in pesticide exposure definition, outcome definition, definition of exposure time windows etc. However, the metaanalysis show a consistent increased risk of childhood leukemia associated with exposure to unspecified pesticides and insecticide (Summary OR=1.69; 96% CI=1.35, 2.11). Our updated metaanalysis resulted in more conservative results compared to the meta-analysis published in 2010 but still supported an association between exposure to pesticides during pregnancy and childhood leukaemia. Still the evidence merits careful interpretation as there were concerns around publication bias in the original meta-analysis, the studies are typically small and the exposure is measured through non-validated self-reported questionnaires that are prone to misclassification. Funnel plot shows relative symmetry around studies of small size. Further evidence from large studies, using valid

EFSA supporting publication 2013:EN-497

The present document has been produced and adopted by the bodies identified above as author(s). This task has been carried out exclusively by the author(s) in the context of a contract between the European Food Safety Authority and the author(s), awarded following a tender procedure. The present document is published complying with the transparency principle to which the Authority is subject. It may not be considered as an output adopted by the Authority. The European Food Safety Authority reserves its rights, view and position as regards the issues addressed and the conclusions reached in the present document, without prejudice to the rights of the authors.

biomarkers of past exposure are needed to confirm whether there is public health merit in reducing prenatal exposure to residential pesticides.

# 8.4.1.2. Preconception

Four studies examined preconception as the time window of exposure (ID CAN\_032, ID CAN\_043, ID CAN\_073, ID CAN\_120) but none reported statistically significant results.

## 8.4.1.3. Childhood

Seven studies with information on exposure during childhood were identified (ID CAN\_031, ID CAN\_032, ID CAN\_035, ID CAN\_036, ID CAN\_041, ID CAN\_043, ID CAN\_133). One study examined Endosulfan, which is no longer in use; the study was of very low quality and was not considered further. Meta-analysis of these studies is shown in Figure 14 below. Two analyses are presented A) one on identified studies from 2006 onwards based on the analysis of the largest sample size in each report (any pesticide) and B) an update on the 2010 meta-analysis on pesticide exposure during childhood and childhood leukemia. The meta-analysis on any pesticides had modest heterogeneity whereas the updated meta-analysis, which was restricted to residential exposure and insecticides/ unspecified pesticides only, displayed no heterogeneity in its results. The results of the updated meta-analysis are more conservative than the original meta-analysis but still very close to the pooled estimates reported in 2010 (Figure 14). Funnel plots indicated considerable symmetry around results. Overall, there is some evidence for association between childhood exposure to pesticide and childhood leukemia but this is weaker than exposure during pregnancy and requires more evidence from well-conducted large birth cohorts to draw firm conclusions.

# 8.4.2. Lymphomas

Evidence beyond leukaemia for childhood hematological neoplasms comes only from 3 studies, which reported many analyses (IDs CAN\_073, ID CAN\_120, ID CAN\_133) among which analyses for Non-Hodgkin and Hodgkin lymphomas. All analyses were not statistically significant and had weak effect estimates.

# 8.4.3. Other childhood cancers

Seven studies on other childhood cancers were identified. Four studies examined brain cancer (ID CAN\_006, ID CAN\_011, ID CAN\_089, ID CAN\_133), one childhood germ cell tumor (ID CAN\_114) and two examined a range of childhood cancers (ID CAN\_120, ID CAN\_133). Significant associations were only observed for brain cancers but again these pertain to only a small subset of many analyses and cannot be informative at this stage.

# 8.5. Colorectal cancer

Overall, 26 identified studies examined associations between pesticide exposure and colorectal cancer in 207 analyses. Separate analyses for colon cancer and rectum cancer were available in 24 and 11 studies respectively. A very large body of evidence comes from the AHS study, which examined all these 3 outcomes for associations with 194 out of the 207 identified analyses on colorectal cancer examining 50 different pesticides with no adjustments for multiple testing. Out of these 194 analyses, only 7 were statistically significantly positively associated with the outcome (Carbaryl, Aldicarb,

EFSA supporting publication 2013:EN-497

The present document has been produced and adopted by the bodies identified above as author(s). This task has been carried out exclusively by the author(s) in the context of a contract between the European Food Safety Authority and the author(s), awarded following a tender procedure. The present document is published complying with the transparency principle to which the Authority is subject. It may not be considered as an output adopted by the Authority. The European Food Safety Authority reserves its rights, view and position as regards the issues addressed and the conclusions reached in the present document, without prejudice to the rights of the authors.

Toxaphene, Pendimethalin, S-Ethyl dipropylthiocarbamate (EPTC), imazethapyr and Fonofos) but need to be interpreted with caution due to high false positive probability. Despite the fact that 27 published studies were identified, overall the evidence comes from only 7 different populations. This fact along with the range of different pesticides analysed by each of these studies in relation to colon cancer does not allow meaningful quantitative synthesis of the results. Table 8 shows the extent of publication of duplicate data from one cohort in multiple papers and shows good consistency of results. Previous meta-analyses on colorectal cancer and pesticide exposure have not been identified. Overall, the evidence for pesticides and colorectal cancer is very limited and current state of the literature does not support associations between pesticides and colorectal cancer.

#### 8.6. Skin cancer

Seventeen studies examined associations between melanoma and pesticide exposure. The majority of studies assessed organochlorine pesticides. Again, 14 out of 17 studies on melanoma were results from the AHS examining in each paper different pesticides categories and different definitions of exposure with some supplication of results present. Of the 26 different analyses of the AHS, 8 were statistically significant and all stemming from the same publication (ID CAN\_085) on dose response relationships for 50 agricultural pesticides with cutaneous melanoma. The study reported significant associations between cutaneous melanoma and maneb/mancozeb ( $\geq$  63 exposure days: OR = 2.4; 95% CI, 1.2–4.9; trend *p* = 0.006), parathion ( $\geq$  56 exposure days: OR = 2.4; 95% CI, 1.3–4.4; trend *p* = 0.003), and carbaryl ( $\geq$  56 exposure days: OR = 1.7; 95% CI, 1.1–2.5; trend *p* = 0.013) (155). Other studies did not report results on these pesticides to allow examination of replication of results. One case-control study showed increased statistically significant risk between indoor pesticide exposure and melanoma whereas in the same study outdoors pesticide exposure was not associated with melanoma (106). The remaining studies on organochlorines showed heterogeneous results with few statistically significant results (Hexachlorobenzene (HCB), mirex), which do not provide evidence for an association between these pesticides and melanoma.

#### 8.7. Breast cancer

Overall, 14 studies (and 3 abstracts) after 2006 examined the relationship between pesticide exposure and breast cancer. The vast majority of studies and analyses concentrate on organochlorine pesticide, which they are assessed through biomarker analyses. Two previous meta-analyses on breast cancer and DDT exposure have been published (Khanjani 2007, López-Cervantes 2004). Overall, previous meta-analyses did not show a significant association between any cyclodiene chemical and breast cancer except for heptachlor, but that was based on only two studies. Meta-analysis on identified studies in this systematic review on Dichlorodiphenyldichloroethylene (DDE) and breast cancer (5 studies) also shows no evidence for association. We have also performed a meta-analysis across all identified studies on breast cancer, selecting each time the analysis within each study with the largest sample size. Studies ID CAN 019 and ID CAN 023 were excluded from synthesis, as effect sizes and confidence interval to allow synthesis were not provided and study ID CAN 022 was excluded as it reported very tight confidence intervals which did not were assumed to be reported incorrectly. The synthesis here involves the pooled effect of many different pesticides definitions and biomarkers (DDE, lindane, and broad pesticide definition) and is difficult to be interpreted. The pooled effect shows a statistically significant increased risk of breast cancer (1.07 (0.87 to 1.31)) but this result need cautious interpretation. The meta-analysis combines very different categories of pesticides and is largely dominated by one study (ID CAN 022), which assessed pesticide exposure by self-reported residential pesticide use and is therefore of modest quality compared to the rest of the studies which assessed pesticides via biomarkers.

## 8.8. Bladder cancer

Sixteen studies examining bladder cancer in relation to pesticide exposure were identified; however, 13 were studies from the same population the AHS as previously observed for other cancer outcomes. Among the 25 different analyses presented, only one provided statistically significant results for occupational exposure to imazethapyr in the AHS. However, due to multiple testing the results need cautious interpretation and based on the evidence reviewed in this report there is no suggestion for an association between pesticide exposure and bladder cancer.

# 8.9. Kidney cancer

Ten studies examined kidney cancer in relation to pesticide exposure; however, data from two populations only, the AHS and the BC (British Columbia) sawmill workers cohort study. Results form the BC sawmill workers cohort study (ID CAN\_129 and ID CAN\_125) were both on occupational exposure to pentachlorophenol and tetrachlorophenol but examining different approaches to statistical analyses. Results from the AHS were on different pesticide classes. Overall, no statistically significant results were observed and the limited number of contributing populations (n=2) does not allow further quantitative synthesis.

# 8.10. Pancreatic cancer

Seven studies examined pancreatic cancer in relation to pesticide exposure; 4 were reports from the AHS. The overwhelming majority of analyses considered organochlorine pesticides. In a small casecontrol study of modest quality significantly increased concentrations of hexachlorobenzene (HCB), sum of chlordanes and polybrominated diphenylethers (PBDEs) were found in the pancreatic cancer cases compared to healthy controls (ID CAN\_090). In the AHS, among 46 different analyses, significant associations were reported for Pendimethalin and S-Ethyl dipropylthiocarbamate (EPTC). Applicators in the top half of lifetime pendimethalin use had a 3.0-fold (95% CI 1.3–7.2, p-trend 5 0.01) risk compared with never users, and those in the top half of lifetime EPTC use had a 2.56-fold (95% CI 5 1.1–5.4, p-trend=0.01) risk compared with never users. Organochlorines were not associated with an excess risk of pancreatic cancer in the AHS. These findings suggest that herbicides may be associated with pancreatic cancer but require replication by future studies as they all come from a single population without adjustments for multiple testing.

# 8.11. Testicular cancer

Overall, 8 studies examined testicular cancer. Two studies also reported outcomes for seminoma cancer. All but one study assessed biomarker levels and concentrated on organochlorine pesticides with a range of different biomarkers assessed and studies showing a weak effect for an association with testicular cancer. However, information on more than 4 studies was available for p-p'DDE only and quantitative synthesis showed a non-significant effect and modest heterogeneity (Figure 20). Quantitative synthesis across any pesticide was not performed due to heterogeneity of biomarkers assessed in each study. Overall, there is no evidence to support an association between pesticide exposure and testicular cancer based on evidence reviewed herein.

# 8.12. Stomach cancer

Six studies examined association between pesticide exposure and stomach cancer. All studies examined occupational exposure to pesticides, a range of pesticide classes was studies; 2 studies had a prospective design but all had modest to small sample sizes. In agreement with previous meta-analysis

on farmers (Saphir 1998), studies reported weak and mainly non-significant results. A nested casecontrol study (ID CAN 028) of gastric cancer embedded in the United Farm Workers of America (UFW) cohort reported significant associations: working in areas with high use of the phenoxyacetic acid herbicide 2,4-dichlorophenoxyacetic acid (2,4-D) was associated with gastric cancer (OR 1.85; 95% CI 1.05-3.25); use of the organochlorine insecticide chlordane was also associated with the disease (OR 2.96; 95% CI 1.48-5.94). Gastric cancer was associated with use of the acaricide propargite (OR 2.86; 95% CI 1.56-5.23). Nonetheless, the study is limited by a relatively small number of cases and controls, multiple testing and exposure misclassification, as assessment was ecological in nature. In the AHS, based on 15 exposed cases, stomach cancer risk increased monotonically with increasing methyl bromide use (RR = 3.13; 95 % CI, 1.25-7.80 for high use compared with no use; p for trend = 0.02). However, again the associations suffer from multiple testing as all other cancer subtypes have been associated with methyl bromide use in this study (ID CAN 147). Meta-analysis selecting the analysis with largest sample size is shown in Figure 21 but results require careful consideration. Despite a statistical significant pooled large effect size, this is dominated by two studies (ID CAN 125, ID CAN 147), which examine pentachlorophenol and methyl bromide; two compounds that are not approved in the European Union.

### 8.13. Liver cancer

Five studies (including 11 separate analyses) and one conference abstract examined associations between pesticide exposure and liver cancer. The majority of analyses examined exposure to organochlorine pesticides and all studies examined occupational exposure to pesticides. Both studies on DDT (IDs CAN\_076 and ID CAN\_079) reported statistically significant associations with liver cancer; the remaining analyses were non-statistically significant. These two studies largely dominate the meta-analysis on liver cancer, which shows a statistically significant pooled result largely driven by the DDT studies.

#### 8.14. Cancer subgroups with few studies

As illustrated in Table 6, for a large number of individual cancers only very few studies are available to allow synthesis of evidence for each cancer subgroup. Our systematic review did not identify any previously published meta-analyses on these cancer subtypes to allow for comparisons with previously published evidence (prior to 2006). Generally the results on these cancer subtypes were of small effect and not statistically significant with few exceptions concerning occupational exposure only. Given the large number of analyses within each study, these results need cautious interpretation and, based on these data, there is no evidence to suggest association between pesticide exposure and these cancer subtypes.

There were also a large number of studies examining all cancers (composite cancer outcome) in relation to pesticide. Cancers represent a very heterogeneous group of disorders and simultaneous examination of all cancer subtypes may introduce bias in the associations. Overall, 30 analyses examining "all cancers" were identified and 28 of them were analyses of the same cohort, the AHS, not allowing further synthesis of the results. Only 4 results out of 31 were statistically significant were associated with poor quality of studies and therefore do not merit interpretation at this stage.
