Risk Assessment Report

Sedaxane (Pesticides)

Food Safety Commission of Japan (FSCJ) December 2014

ABSTRACT

FSCJ conducted a risk assessment of sedaxane (CAS No.87497-67-6), a pyrazole carboxamide fungicide, based on results from various studies.

The data used in the assessment include fate in animals (rats, goats and chikens), fate in plants (spring wheat and soybeans), residues in crops, subacute toxicity (rats, mice and dogs), subacute neurotoxicity (rats), chronic toxicity (dogs), combined chronic toxicity/carcinogenicity (rats), carcinogenicity (mice), two-generation reproductive toxicity (rats), developmental toxicity (rats and rabbits), and genotoxicity.

Major adverse effects of sedaxane observed are decreased body weight gain, decrease in food intake, and centrilobular hepatocellular hypertrophy. Sedaxane did not show any neurotoxicity, teratogenicity, reproductivity toxicity, genotoxicity and immunotoxicity.

In a two-year combined chronic toxicity/carcinogenicity study in ras, increased incidence of uterine adenocarcinomas was observed. Increased incidence of hepatocellular tumors was also observed in an 80-week carcinogenicity test in mice. However, a genotoxic mechanism was unlikely to be involved in the tumor induction. It was thus considered possible to establish a threshold in the assessment.

Based on the above results, only sedaxane (parent compound) was identified as the residue definition for dietary risk assessment in agricultural products.

The lowest no-observed-adverse-effect level (NOAEL) in the toxicological studies was 11 mg/kg bw/day in a combined two-year chronic toxicity/carcinogenicity study in rats. Applying a safety factor of 100 to the NOAEL, FSCJ specified the acceptable daily intake (ADI) of 0.11 mg/kg bw/day.

The lowest NOAEL for potential adverse effects of a single oral administration of sedaxane was 30 mg/kg bw in an acute neurotoxicity study in rats. Applying a safety factor of 100 to the NOAEL, FSCJ specified the acute reference dose (ARfD) of 0.3 mg/kg bw.
