統合_0001	M. Zuo, I. Gamache, K. Fagbemi, F. R. Day, K. K. Ong and D. Manousaki	2025	The causal role of endocrine disrupting chemicals in pubertal timing: a Mendelian randomization study	OBJECTIVES: Endocrine disrupting chemicals (EDCs) interfere with hormonal homeostasis, and have been observationally linked to altered pubertal timing, defined by the age at menarche (AAM) in girls and the age at voice change (VAC) in boys. However, the causality of these associations remains unclear. We used Mendelian randomization (MR) to investigate if genetically altered serum EDC levels affect pubertal timing. METHODS: We selected genetic instruments for 11 EDCs (bisphenol A (BPA), BP-3, BP-8, BP-1, BP-2, BP-4, BP-5, BP-6, BP-9, BP-10, and BP-12) from a GWAS of 1,720 children. Two-sample MR was conducted to examine mediating effects of body mass index (BMI). RESULTS: We found causal MR associations with AAM for three phenol-containing EDCs: BPA (-0.10 SD [-0.19,-0.01], 95% CI 0.9 [0.83, 0.99], p=0.03), PCR (-0.11 SD [-0.20, -0.03], 95% CI 0.9 [0.82, 0.97], p=0.01), and PCR (-0.10 SD [-0.19, -0.01], 95% CI 0.9 [0.83, 0.99], p=0.03). See MR association was found with AAC for bisphenol A (BPA, -0.11 SD [-0.20, -0.02], 95% CI 0.9 [0.82, 0.98], p=0.02) and for dibutyl phthalate (DBP, -

統合_0014	R. Zhou, Z. Chen, T. Yang, H. Gu, X. Yang and S. Cheng	2024	Vitamin D Deficiency Exacerbates Poor Sleep Outcomes with Endocrine-Disrupting Chemicals Exposure: A Large American Population Study	Phthalate and bisphenol A are recognized as the predominant endocrine-disrupting substances (EDCs) in the environment, but their impact on sleep health remains unclear. Vitamin D has often been reported to play a role in sleep regulation. However, the interaction between vitamin D and EDCs on sleep health remains unexplored. This study aimed to investigate the associations between environmental EDCs and sleep duration through modeling various exposures. Furthermore, it emphasizes the importance of vitamin D in this present scenario. Preliminary analyses suggested that vitamin D-deficient individuals generally slept shorter than individuals with normal vitamin D (p < 0.05). Exposure to three vinyl phthalate (MEP), mixtures (TPH), and three benzyl phthalate (BCPP), either alone or in combination, was associated with reduced sleep duration and a greater risk of vitamin D deficiency. Individuals with low vitamin D levels exposed to TPH experienced shorter sleep duration than those with normal vitamin D levels (p < 0.05). TPH and BCPP were identified as crucial factors in patient outcomes, where evaluating mixed exposures (p < 0.05). The results provide new data supporting a link between exposure to EDCs and insufficient sleep length. Additionally, they imply that a vitamin D shortage may worsen the sleep problems induced by EDCs. 統合_0015	Y. Zhou, Z. Jin, L. Zhu, F. Huang, A. Ye and C. Hou	2022	A preliminary study on the relationship between environmental endocrine disruptors and precocious puberty in girls	OBJECTIVES: To explore the associations of environmental endocrine disruptors on precocious puberty in girls. METHODS: This was a case-control study in which 30 girls with precocious puberty and 30 age- and sex-matched controls were enrolled. The concentrations of 20 environment endocrine disruptors (bisphenol A, bisphenol B, bisphenol S, propylparaben, butylparaben, methyl paraben, mono-2-ethylhexyl phthalate, monoethyl phthalate, and monomethyl phthalate) in urine and 10 steroid hormones (dihydrotestosterone, androstenedione, hydrocortisone, 11-deoxycortisol, 17-α-hydroxyprogesterone, 4-androstenedione, testosterone, progesterone, and estradiol) in serum were measured by ultra-performance liquid chromatography-tandem mass spectrometry. The associations of maternal urinary BPA, BPF, and BPS, urinary levels of bisphenol A, monobutyl phthalate, and monoisononyl phthalate were significantly higher in the precocious group than in the prepubertal group. As to blood hormones, 11-deoxycortisol, corticosterone, deoxycorticosterone, and progesterone were significantly lower in the precocious group than in the prepubertal group (p<0.05, VIP>1). CONCLUSIONS: Our findings confirm the association between phthalate exposure and the incidence of precocious puberty in girls. Control and reduction of children exposure to phthalate esters should be considered as a health priority. 統合_0016	B. Zhou, P. Yang, Y. L. Deng, Q. Zeng, W. Q. Luo and S. R. Mei	2020	Prenatal exposure to bisphenol a and its analogues (bisphenol F and S) and ultrasound parameters of fetal growth	BACKGROUND: Bisphenol A (BPA) has been shown to affect normal fetal growth, but human evidence on its analogues, BPF and BPS, is limited. OBJECT: To examine the associations between prenatal exposure to BPA and its analogues, BPF and BPS, and ultrasound parameters of fetal growth. METHODS: We measured urinary BPA, BPF, and BPS concentrations among 321 pregnant women during late pregnancy from a cohort study in Wuhan, China. Fetal biparietal diameter (BPD), head circumference (HC), femur length (FL), and abdominal circumference (AC) were measured by ultrasonography. The associations of maternal urinary BPA, BPF, and BPS concentrations with fetal ultrasound parameters were examined using linear regression models. RESULTS: Maternal urinary BPA concentrations were associated with a decrease of 0.20 mm (95%CI: -0.39, -0.01) in HC (p for interaction = 0.003), such as with increase in maternal urinary BPA concentrations was associated with a mean decrease of 0.20 mm (95%CI: -0.39, -0.01) among boys and a mean increase of 0.21 mm (95%CI: 0.03, 0.39) among girls for HC. The associations were robust for urinary BPA concentrations modelled as tertiles or including urinary BPA, BPF, and BPS into mutual adjustment models. We did not observe robust associations between maternal urinary BPF and BPS concentrations and ultrasound parameters of fetal growth. Though in inverse association with HC and a positive association with FL were estimated for maternal urinary BPF concentrations modelled as continuous variables. CONCLUSIONS: Prenatal exposure to BPA but not BPF and BPS was sex-specifically associated with certain fetal growth parameters. 統合_0017	R. Zhang, H. Ma, M. Jin, Z. Lu, Y. Deng, C. Liu, N. Shen, J. Li, H. Wang, P. Ying, B. Li, Q. Zeng, Q. Lu, L. Cheng, Y. Zhu, X. Miao and J. Tian	2022	Genome-wide gene–bisphenol A, F and triclosan interaction analyses on urinary oxidative stress markers	BACKGROUND: Bisphenols and triclosan (TCS) are common endocrine disruptors (EDCs) that may induce oxidative stress. However, there is limited information as to whether these EDCs, indexed with genetic variants, modify the levels of oxidative stress on a genome-wide scale. METHODS: We first performed a genome-wide scan among a Chinese population and also measured three urinary EDCs, including bisphenol A (BPA), bisphenol F (BPF), and TCS, and 8-hydroxy-2′-deoxyguanosine (8-OHdG), a biomarker of oxidative stress. Then, we validated the significant findings in a Taiwanese population. RESULTS: Unfortunately, we examined interactions between three urinary EDCs and nearly 0.8 million genetic variants on three urinary oxidative stress markers by the improved linear mixed (ILM) models. Only urinary BPA, BPF, and TCS were positively associated with 8-OHdG (β, 95% CI: 0.0252, 0.0123, 0.0377; p = 0.0001, 0.0001, 0.0001, respectively). We identified 2 SNPs, rs1229984 (ADH1B) and rs4988235 (MCM6), showing significant gene-TCS interactions on 8-OHdG (all P < 5 × 10−8). The gene-level analysis found significant interactions between SNUH1 and TCS for 8-oxoPG (all P values (P = 2.02 × 10−6). CONCLUSION: Our results identify several gene–EDCs interactions for oxidative stress, highlighting that EDCs may modify the effect of genetic variants on oxidative stress.	Sci Total Environ. 2022 Feb 10;807(Pt 1):150753.	10.1016/j.scitotenv.2021.150753	34619205	ヒト	その他(酸化ストレス)	-	-	-	-	-	-	横断研究	1	1	-	-	-	1	1	1	-	-	-	-	-	-	-	-	-	-	-	-
統合_0018	Q. Zhong, M. Peng, J. He, W. Yang and F. Huang	2020	Association of prenatal exposure to phenols and parabens with birth size: A systematic review and meta-analysis	Phenols and parabens are endocrine-disrupting chemicals and are widely used in daily life products due to their antibacterial action. Previous studies suggest associations of prenatal exposure to phenols and parabens with fetal development; however, such findings are not well-summarized. The aim of this review and meta-analysis is to summarize the associations between maternal exposure to phenols and parabens and birth size. We identified 21 relevant studies that met the inclusion criteria through databases of PubMed, Cochrane, EMBASE and QuickMedian. The last search was in July 2, 2019. The heterogeneity and possibility of publication bias among included studies were examined by Q-statistic and Begg's tests, respectively. Meta-analysis revealed that prenatal exposure to mixed phenols (β = 0.08, 95% confidence interval (CI): -0.138, 0.301), benzophenone-3 (β = -16, β = -0.052, 95% CI: -0.833, 0.023), bisphenol A (n = 9, β = -0.004 g, 95% CI: -0.191, 0.102), 2-4-dichlorophenols (n = 6, β = -12.126 g, 95% CI: -29.071, 4.819), methyl paraben (n = 4, β = -0.004 g, 95% CI: -0.191, 0.102), and propyl paraben (n = 4, β = -0.004 g, 95% CI: -0.191, 0.102) were not associated with birth size. However, prenatal exposure to triclosan (n = 5, β = -0.001 g, 95% CI: -0.002, 0.000) was associated with decreased birth size. Subgroup analysis suggested that heterogeneity in our meta-analysis was mainly attributable to the studies conducted in developed countries and samples collected in the second trimester. Insignificant and controversial associations of maternal exposure to phenols and parabens with birth size were observed in our study. The study design and methods of the included studies are inconsistent, and the effects of environmental pollutants on human health are complex. Further cohort studies with large samples and a consistent approach are thus required to evaluate the associations of maternal exposure to phenols and parabens with birth size.	Sci Total Environ. 2020 Feb 10:703:134720.	10.1016/j.scitotenv.2019.134720	31731171	ヒト	生殖発生/メタアナリシス	-	-	-	-	-	-	メタアナリシス	1	1	-	-	-	1	1	1	-	1	-	-	-	-	-	-	-	-	-	-
統合_0019	J. Zheng, J. E. Reynolds, M. Long, C. Ostertag, T. Pollock, M. Hamilton, J. F. Dunn, J. Liu, J. Martin, M. Gibbs, B. Landman, Y. Huo, D. Dewey, O. Kurmasch and C. Lebel	2022	The effects of prenatal bisphenol A exposure on brain volume of children and young mice	Bisphenol A (BPA) is a synthetic chemical used for the manufacturing of plastics, epoxy resin, and many personal care products. This ubiquitous endocrine disruptor is detectable in the urine of over 80% of North Americans. Although adverse neurodevelopmental outcomes have been observed in children with high prenatal and postnatal exposure to BPA, the effects of prenatal BPA on brain structure are unclear. Here, using magnetic resonance imaging (MRI), we studied the associations of maternal BPA exposure with children's brain structure, as well as the impact of comparable BPA levels in a mouse model. Our human data showed that most maternal BPA exposure effects on brain volume outcomes occurred, with the largest effects observed in the caudate region of the inferior frontal gyrus (p = 0.016), superior occipital gyrus (p = 0.006), and paracentral gyrus (p = 0.080). In mice, gestational exposure to an equivalent level of BPA (2.25 μg BPA/kg body/day) induced structural alterations in brain regions including the superior olivary complex (SOC) and bed nucleus of the stria terminalis (BNST). Behavioral tests revealed that BPA-exposed mice displayed hyperactivity and impaired sensorimotor gating. We performed the primary endpoint analysis. Combined, these human and mouse data suggest that gestational exposure to low levels of BPA may have some impacts on the developing brain at the resolution of MRI.	Environ Res. 2022 Nov;214(Pt 3):114040.	10.1016/j.envres.2022.114040	35952745	ヒト、動物	発達神経	1	不明	1	不明	0	2.25 μg BPA/kg体重/日	コホート研究	1	1	-	-	-	1	1	1	-	-	-	-	-	-	-	-	-	-	-	-
統合_0020	Y. Zhao, Y. Yu, H. Liu, X. Ruan, Y. Guo and J. Wu	2025	Infant urinary bisphenol A concentrations in relation to child neurodevelopment at 2 years of age	Prenatal and childhood bisphenol A (BPA) exposures are known to negatively affect neurodevelopment, but the impact of exposure during the infancy period remains unclear. This study aimed to investigate BPA exposure in infancy and its association with neurodevelopment at 2 years of age. A total of 1,000 mother-infant pairs were recruited from Ma'anshan Maternal and Child Health Hospital between 2021 and 2023. Urine samples were collected from infants at 1 and 6 months, followed by neurodevelopmental assessments at 2 years of age. Of the 748 and 732 urine samples collected at 1 and 6 months, unconjugated BPA was detected via liquid chromatography-tandem mass spectrometry in 57.7 and 90.8%, with median concentrations of 2.79 and 6.61 μg/L, respectively. At the 1 month assessment, no statistically significant associations were observed between urinary BPA concentrations and any neurodevelopmental outcomes in either male or female infants (all adjusted P > 0.05). However, at the 6 month assessment, female infants' receptive language abilities were identified exclusively in female infants. Specifically, higher urinary BPA concentrations at 6 months were independently associated with lower scores in the gross motor domain (adjusted β = -3.32; 95 % CI: -6.16, -0.48; P = 0.022) and the total score (adjusted β = -3.32; 95 % CI: -6.16, -0.48; P = 0.022). Additionally, a 10-fold increase in urinary BPA concentration was associated with a 3.32-point decrease in the total score (adjusted β = -3.32; 95 % CI: -6.16, -0.48; P = 0.022) after controlling for relevant confounders. In contrast, no significant associations were detected between 6-month BPA concentrations and neurobehavioral outcomes in male infants (all adjusted P > 0.05). Our study identified neurodevelopmental effects of BPA as specific to both exposure timing and infant sex, highlighting for the finding that exposure at 6 months was negatively associated with neurobehavioral scores in females. 統合_0021	Y. Zhang, Z. Zhang, F. Zhou, G. Xu, W. Huang, M. Wang, Y. Lan, W. Zhang, Z. Liu, S. Cheng, S. Qiu, F. Qi and Z. Wei	2025	Association between endocrine disrupting chemicals exposure and the risk of all-cause mortality in individuals with diabetes mellitus or its complications: A prospective cohort study	OBJECTIVE: To investigate the association between exposure to endocrine-disrupting chemicals (EDCs) and all-cause mortality in individuals with diabetes mellitus (DM) in U.S., including those with diabetic complications. METHODS: This prospective cohort study included participants with DM in the 1999-2018 National Health and Nutritional Examination Survey. Data on mortality were obtained from the National Death records up to December 31, 2019. Cox regression, WQS regression and g-BKMR regression were constructed to examine the associations between EDCs and all-cause mortality in individuals with DM or its complications, adjusted for potential confounders. Restricted cubic spline analysis was used to investigate linear relationships. Subgroup analyses were also tested to pinpoint high-risk populations. RESULTS: The study included 2,265 participants. Mean (7 of) of 9 (ethylhexyl) phthalate (MEHHP), mono (2-ethyl-5-oxohexyl) phthalate (MEOHP), and mono (7-ethyl-5-carboxyheptyl) phthalate (MECPP) showed positive associations with all-cause mortality in the WQS regression model (HR 1.24 (95 % CI: 1.08, 1.42), HR 1.24 (95 % CI: 1.08, 1.42), and HR 1.24 (95 % CI: 1.08, 1.42), respectively). Similar results were observed in the g-BKMR model (HR 1.24 (95 % CI: 1.08, 1.42), HR 1.24 (95 % CI: 1.08, 1.42), and HR 1.24 (95 % CI: 1.08, 1.42), respectively). Bayesian kernel machine regression (BKMR) models revealed a similar relative contribution of optimal MEHHP, MEOHP, and mono (7-ethyl-5-carboxyheptyl) phthalate (MECPP) toward positive associations with all-cause mortality in the diabetic population. Stratified analyses revealed that the associations between EDCs and all-cause mortality in individuals with DM or its complications were significantly stronger among those with female infants only. Preterm birth risk may be compound, sex, and window-specific. Given the limited sample size of this cohort, results should be confirmed in larger studies, including birth populations.	Environ Int. 2025 Jun;200:109556.	10.1016/j.envint.2025.109556	40446755	ヒト	その他(死亡率)	-	-	-	-	-	-	コホート研究	1	1	-	-	-	1	1	1	-	-	-	-	-	-	-	-	-	-	-	-
統合_0022	Y. Zhang, V. Mustieles, P. L. Williams, J. Yland, J. Souter, J. M. Braun, A. M. Calafat, R. Hauser and C. Messerlian	2021	Prenatal urinary concentrations of phenols and risk of preterm birth: exploring windows of vulnerability	OBJECTIVE: To explore windows of vulnerability to prenatal urinary phenol concentrations and preterm birth. DESIGN: Prospective cohort. SETTING: A large fertility center in Boston, Massachusetts. PATIENT(S): A total of 586 mothers who sought fertility treatment and gave birth to a singleton between 2005 and 2018. INTERVENTION(S): None. MAIN OUTCOME MEASURE(S): Gestational age at birth and preterm birth (<37 completed weeks). RESULT(S): Compared with women with term preterm births, urinary bisphenol A (BPA) concentrations were higher among preterm births (including early and late preterm), and among those with female infants. Second-trimester BPA concentrations were associated with preterm birth (Risk Ratio [RR] 1.23; 95%CI: 0.92, 1.65), which was primarily driven by female RR 1.65; 95%CI: 1.03, 1.89). Second-trimester BPA concentrations were associated with early preterm birth (RR 1.61; 95%CI: 1.01, 2.56) and late preterm birth (RR 1.66; 95%CI: 1.01, 2.73) among female infants only. Second-trimester bisphenol S concentrations showed a suggestive risk of preterm birth (RR 1.26; 95%CI: 0.82, 1.95), although the small case numbers precluded sex-specific examination. CONCLUSION(S): We found preliminary evidence of associations between mid-to-late pregnancy BPA and early pregnancy paraben concentrations with preterm birth among those with female infants only. Preterm birth risk may be compound, sex, and window-specific. Given the limited sample size of this cohort, results should be confirmed in larger studies, including birth populations.	Fertil Steril. 2021 Sep;116(3):820-832.	10.1016/j.fertnstert.2021.03.053	34238571	ヒト	生殖発生	-	-	-	-	-	-	コホート研究	1	1	-	-	-	1	1	1	-	-	-	-	-	-	-	-	-	-	-	-
統合_0023	Y. Zhang, V. Mustieles, P. L. Williams, B. J. Wylie, I. Souter, A. M. Calafat, M. Danielsboiku, A. Lee, S. Vagios, R. Hauser and C. Messerlian	2021	Parental preconception exposure to phenol and phthalate mixtures and the risk of preterm birth	BACKGROUND: Parental preconception exposure to select phenols and phthalates was previously associated with increased risk of preterm birth in single chemical analyses. However, the joint effect of phenol and phthalate mixtures on preterm birth is unknown. METHODS: We included 380 female and 211 male (383 couples) participants seeking infertility treatment in the Environment and Reproductive Health (EARTH) Study who gave birth to 386 singleton infants between 2005 and 2016. Nine preconception urinary concentrations of bisphenol A (BPA), parabens, and seven phthalate biomarkers, including di-2-ethylhexyl phthalate (DEHP) metabolites, were examined. We used principal component analysis (PCA) with log-Poisson regression and Probit-Bayesian Kernel Machine Regression (BKMR) with hierarchical variable selection to examine maternal and paternal preconception mixtures and preterm birth (<37 completed weeks of gestation). We also examined couple-level exposure to mixtures of BPA, parabens, and DEHP metabolites. RESULTS: In maternal and paternal preconception mixtures, PCA1 was positively associated with preterm birth. Maternal PCA1 scores (adjusted Risk Ratio (aRR): 1.16; 95%CI: 1.08, 1.24) and paternal (aRR: 1.17; 95%CI: 1.08, 1.27) preconception DEHP-BPA factor was positively associated with preterm birth. Maternal and paternal BKMR models consistently presented the DEHP-BPA factor with the highest group Posterior Inclusion Probability (PIP). BKMR models further showed that maternal DEHP-BPA mixtures were linearly associated with increased preterm birth risk when all exposures were above the 60th percentile. Maternal DEHP metabolites were the largest contributors, with BPA and paraben metabolites contributing little to the mixture effect. Couple-based BKMR models showed a similar relative contribution of paternal DEHP-BPA and maternal DEHP-BPA preconception mixtures on preterm birth. We found a positive joint effect on preterm birth across increasing quantiles of couples' total mixture concentrations. CONCLUSION: In this prospective cohort of subfertile couples, maternal DEHP and DEHP- and paternal DEHP-exposure before conception were positively associated with preterm birth. Both parental windows jointly contributed to the outcome. These results suggest that preterm birth may be a couple-based pregnancy outcome.	Environ Int. 2021 Jun;151:106440.	10.1016/j.envint.2021.106440	33640694	ヒト	生殖発生	-	-	-	-	-	-	コホート研究	1	1	-	-	-	1	1	1	-	1	-	-	-	-	-	-	-	-	-	-
統合_0024	Y. Zhang, V. Mustieles, P. L. Williams, I. Souter, A. M. Calafat, M. Danielsboiku, A. Lee, S. Vagios, R. Hauser and C. Messerlian	2022	Association of preconception mixtures of phenol and phthalate metabolites with birthweight among subfertile couples	Although parental preconception exposure to some phenols and phthalates have been associated with reduced birthweight, few studies have examined those chemicals as complex mixtures. METHODS: We included 386 mothers and 211 fathers (383 couples) who gave birth to 386 singletons from a prospective cohort of couples seeking fertility evaluation. Urinary concentrations of bisphenol A (BPA), parabens, and 11 phthalate metabolites, including those of di(2-ethylhexyl) phthalate (DEHP) were examined. Birthweight was abstracted from delivery records. We used principal component analysis and Bayesian Kernel Machine Regression (BKMR) with hierarchical variable selection to examine maternal and paternal preconception mixtures and birthweight. We also examined couple-level exposure to mixtures of BPA, parabens, and DEHP metabolites. RESULTS: In maternal and paternal preconception mixtures, PCA1 scores were positively associated with birthweight. In BKMR models, the DEHP-BPA factor had the highest group Posterior Inclusion Probability (PIP). BKMR models further showed that maternal preconception mono(2-ethyl-5-carboxypentyl) phthalate (MECPP), a DEHP metabolite, and paternal preconception mono-n-butyl phthalate concentrations were inversely associated with birthweight when the remaining mixture components were held at their median concentrations. In couple-based BKMR models, paternal preconception parabens contributed more to couples' joint effect on birthweight compared to maternal preconception biomarkers. A decreasing trend of birthweight was observed across quantiles of maternal, paternal, and couples' total preconception mixture concentrations, respectively. CONCLUSION: Results suggest that preconception exposure to mixtures of DEHP metabolites in couples suggest a complex interplay between paternal and maternal preconception exposure to mixtures of nonpersistent chemicals, with both parental windows of exposure jointly contributing to reduced birthweight. Zhou	2023	Design, methodology, and baseline of eastern China student health and wellbeing cohort study	PURPOSE: To describe the study design, methodology, and cohort profile of the Eastern China Student Health and Wellbeing Cohort Study. The cohort baseline includes 1) targeted disease (myopia, obesity, elevated blood pressure, and dental caries) and 2) lifestyle behaviors (physical activity, sedentary behavior, and sleep). PARTICIPANTS: Primary and secondary schools in Shandong province, China, have been recruited and conducted annual health examinations and questionnaire surveys. Data collection and monitoring have been carried out in the study population in the first stage (2020-2021), a total of 6,588 students in primary schools are enrolled in the cohort study. FINDINGS TO DATE: Of all the cohort participants, the ratio of male to female is 1.16 among a total of 6,588 students participants, of which 2,728 (41.4%) students are from developed regions and 3,778 (58.1%) students are from developing regions. The initial age of participants ranges from 6 to 15 years old, with a mean age of 10.2 ± 2.4 years old. The prevalence of myopia, obesity, elevated blood pressure, and dental caries in developed regions and in developing regions, the prevalence of myopia, obesity, and elevated blood pressure is 39.7%, 17.9%, and 12.9% in the first three, respectively. The corresponding prevalence in developing regions is 21.6 ± 9.6 in developed regions, 11.6 ± 9.0 in developed regions, 10 Exposures: 11 The first aspect of individual behaviors in the questionnaire survey includes diet, physical exercise, bullying, and family. 2) The second aspect of environment and metabolomics. the average time (hours/day) is 1.03 (0.58-1.61) (41.1%), and the average likelihood (hours/week) is 3.61 (0.138-10.5) (42.1.5%). Metabolomics. Xiao bisphenol A in the urine is 0.750 ng/ml. 2) The third aspect of gene and epigenetics. 100% (rs420345, rs2350823, rs2350824, rs2350825, rs2350826, rs2350827, rs2350828, rs2350829, rs2350830, Jia	2024	Urinary concentrations of bisphenol A and its alternatives: Potential predictors of and associations with antral follicle count among women from an infertility clinic in Northern China	BACKGROUND: Experimental studies have suggested exposure to bisphenol A (BPA) and its alternatives, such as bisphenol F (BPF) and bisphenol S (BPS), may exert adverse effects on ovarian reserve, but human evidence is limited. Moreover, the potential predictors of exposure to bisphenols among women seeking infertility treatment have not been reported. OBJECTIVE: To explore whether individual or mixture of BPA, BPF, and BPS exposure is associated with antral follicle count (AFC) and to identify potential predictors of exposure to bisphenols. METHODS: A total of 1,...	Environ Res. 2024 May 15:249:118433.	10.1016/j.envres.2024.118433	38331151	ヒト	-	-	-	-	-	-	-	-	-	-	横断研究	1	1	-	-	-	1	1	1	-	-	-	-	-	-	-	-	-	-	-	-	-
統合_0030	N. Zhang, Y. Zhao, L. Zhai, Y. Bai and L. Jia	2023	Urinary bisphenol A and S are associated with diminished ovarian reserve in women from an infertility clinic in Northern China	Bisphenol A (BPA) has been demonstrated to cause ovarian toxicity including disruption of steroidogenesis and inhibition of follicle growth. Still, human evidence is lacking on its analogs, such as bisphenol F (BPF) and bisphenol S (BPS). In this study, we aimed to investigate the associations between exposure to BPA, BPF, and BPS with ovarian reserve in women of childbearing age. We recruited 311 women from an infertility clinic in Northern China between 2019 and 2020. Urinary concentrations of BPA, BPF, and BPS were measured using high-performance liquid chromatography-tandem mass spectrometry (HPLC-MS/MS). Antral follicle count (AFC) was used to assess the associations between urinary BPA, BPF, and BPS levels and indicators of ovarian reserve and DOR, respectively. Restricted cubic spline (RCS) models were further utilized to explore potential non-linear associations. Our results showed that urinary BPS concentrations were negatively associated with AFC (β = -0.083; 95%CI: -0.172, -0.005). Analysis of their dual-high urinary concentrations of BPF, BPS, and total bisphenols (2 BPs) from women who did not, and age was related to increased urinary BPF concentrations. CONCLUSION: Our findings indicated that exposure to individual BPA, BPF, BPS and bisphenols mixtures were associated with impaired ovarian reserve. Furthermore, the intake of fried food, as identified in this study, could serve as an important bisphenols exposure route for reproductive-aged women. 統合_0031	L. Zhang, J. Zhang, S. Fan, Y. Zhang, J. Li, Y. Zhao, S. Ni, J. Liu and Y. Wu	2023	A case-control study of urinary concentrations of bisphenol A, bisphenol F, and bisphenol S and the risk of papillary thyroid cancer	The incidence of thyroid cancer (TC), especially papillary thyroid cancer (PTC), has dramatically increased globally. Whereas some endocrine disruptors have been linked to neoplastic processes, the associations between human exposure to bisphenol analogs and the risk of TC remain unclear. This present case-control study examined the associations between the urinary concentrations of BPA and other bisphenol analogs, namely bisphenol F (BPF) and bisphenol S (BPS), and the risk of PTC. After adjusting for confounders and creatinine standardization, significantly positive associations were observed for BPF (odds ratio [OR] = 1.80, 95% confidence interval [CI]: 1.27-2.56), but negative associations were observed for BPS (OR = 0.58, 95% CI: 0.41-0.83) and total bisphenols (OR = 0.72, 95% CI: 0.52-0.99). Moreover, the significant associations remained robust in the stratified analyses by sex, age, and body mass index. Additionally, additional significance was observed only in non-smoking women, suggesting the inherent effects of BPF exposure on PTC risk, especially in women. These findings require replication and confirmation in further research.	Chemosphere. 2023 Jan;312(Pt 1):137162.	10.1016/j.chemosphere.2022.137162	36347349	ヒト	-	-	-	-	-	-	-	-	-	-	症例対照研究	1	1	-	-	-	1	1	1	-	-	-	-	-	-	-	-	-	-	-	-	-
統合_0032	J. Zhang, M. Yuan, Y. Liu, X. Zhong, J. Wu and W. Chen	2025	Bisphenol A exposure and neurodevelopmental disorders and problems in children under 12 years of age: A systematic review and meta-analysis	BACKGROUND: Bisphenol A (BPA) exposure may lead to neurodevelopmental disorders, and problems (NDPs) in children under 12 years old. In recent years, the number of relevant studies has increased, but the evidence remains inconsistent. OBJECTIVES: To systematically review and meta-analyze the associations between BPA exposure and NDPs in children under 12 years old. METHODS: A systematic search was conducted in eight bibliographic databases for peer-reviewed research articles published from database inception to October 31, 2024. Eligible studies were epidemiological observational studies in children under 12 years old, which evaluated the associations between BPA of biosamples and NDPs. The converted effect sizes were synthesized using multilevel random-effects meta-analysis models. Meta-regression analysis, sensitivity analysis, unmeasured confounding bias, and publication bias tests were examined to substantiate the results. RESULTS: The search identified 1880 unique studies, 32 of which met the criteria including 25,880 participants were finally included in the meta-analysis. The meta-analysis showed that BPA exposure was associated with intellectual disability (Cohen's d = 0.14, 95 %CI = 0.06-0.22), autism spectrum disorder (ASD, Cohen's d = 0.12, 95 %CI = 0.04-0.20), and attention-deficit/hyperactivity disorder (ADHD, Cohen's d = 0.10, 95 %CI = 0.03-0.17). Subgroup analyses revealed that the associations between urine BPA was associated with intellectual disability, ASD, ADHD, and motor disorders. Urine, and with intellectual disability and ADHD in girls. CONCLUSION: This study indicated that BPA exposure was associated with an increased risk of NDPs. In children, particularly in boys, underscoring the importance of considering BPA exposure as a potential risk factor for children's brain health. 統合_0033	H. Zhang, S. Feng, S. Song, Q. Zhao, Y. Gao and T. Zhang	2025	First evidence in the association of phenolic endocrine-disrupting chemicals with secondary non-alcoholic fatty liver disease: A case-control study in South China	The presence of phenolic endocrine-disrupting chemicals (EDCs) in patients with secondary non-alcoholic fatty liver disease (S-NAFLD) and their associations with S-NAFLD incidence have not been previously documented. In this study, serum concentrations of 12 phenolic EDCs, including parabens, benzophenone-type (2-) EDCs, bisphenols, and bisphenol A diglycidyl ether derivatives, were detected in patients with S-NAFLD (n = 100) and healthy controls (n = 100) from South China. Bisphenol A (BPA) was the predominant phenolic EDC in both groups, with significantly higher concentrations in patients with S-NAFLD compared to those in the healthy population. Through multiple modeling analyses, we observed that parabens and bisphenols, which are commonly associated with S-NAFLD incidence. A risk of high-risk EDCs for S-NAFLD-related diseases was identified, including propyl paraben (PrP), butyl paraben (BuP), bisphenol S (BPS), and bisphenol AF (BPAF). Furthermore, significant positive correlations were found between the serum levels of these high-risk analytes and liver clinic indices. To the best of our knowledge, this study firstly examined the serum levels of multiple phenolic EDCs in patients with S-NAFLD, aiming to provide novel insights into high-risk EDCs associated with S-NAFLD incidence and their associations with clinic liver indices. 統合_0034	D. Zhang, K. Zhao, T. Han, X. Zhang, X. Xu, Z. Liu, X. Ren, X. Zhang, Z. Lu and C. Qin	2024	Bisphenol A promote the cell proliferation and invasion ability of prostate cancer cells via regulating the androgen receptor	A synthetic organic substance called bisphenol A (BPA) is used to make polycarbo- nate resin, polysulfate, and polyurethane plastic. BPA exposure via regular basis has increased the risk of developing cancer. Recent study has found that BPA exposure is linked to the development of prostate cancer (PCa). Androgen receptor (AR) is a crucial factor in the development of PCa. The purpose of this study was to investigate the prostate cancer cohort were obtained using the cBioPortal algorithm. The analysis of Gene Ontology (GO) and Kyoto Encyclopedia of Genes and Genomes (KEGG) enrichment was used to investigate probable pathways that are closely related to the genes. Additionally, the BPA-based risk model was built using regression analysis. Additionally, the molecular docking method was employed to assess BPA's capacity to attach to important genes. Finally, our team was able to successfully pair the BPA cohort settings for prostate cancer patients. Additionally, the KEGG enrichment study showed that of the neighbors related to BPA, prostate cancer is the most highly enriched. In a group of men with prostate cancer, the BPA-related prognostic prediction model exhibits good predictive value. The BPA demonstrated strong and efficient binding to the androgen receptor, according to the molecular docking studies. According to cell proliferation and invasion experiments, exposing prostate cancer cells to BPA at a dosage of 10(-7) mM could greatly enhance their ability to proliferate and invade. Lu	2024	Co-Exposure to Bisphenols, Parabens, and Antimicrobials and Association with Coronary Heart Disease: Oxidative Stress as a Potential Mediating Factor?	Coronary heart disease (CHD) is the leading cause of global mortality, but the effects of plasticizers and antimicrobial additives on CHD is unknown. Here, we conducted a case-control study to investigate the mediating role of oxidative stress. In the association between co-exposure to seven bisphenols, four parabens, triclocarban (TCC), triclosan (TCS), triclocarbon, and CHD risk in Guangzhou, China. Generalized linear models and weighted quantile sum regression were used to analyze mixture outcome associations. Quantile-based g-computation showed a positive joint effect of a decile increase in exposure to all examined pollutants on CHD risk (OR: 1.62; 95% CI: 1.08, 2.43). Bisphenol A (BPA) (OR: 1.49; 95% CI: 1.01, 2.20) and TCC (OR: 1.49; 95% CI: 1.01, 2.20) were the major contributors. Urinary BPA concentrations were positively correlated with a 2,3-hydroxybutyl BPA (1.1-1.1) ng/mL) elevation of 8-hydroxy-2′-deoxyguanosine (8-OHdG), a pro-BuP, TCC, bisphenol AP (BPAP), and BPP contributed to increased 8-OHdG. Mediation analysis revealed that 8-OHdG mediated the relationship between BPA, BPP, BPAP, and TCS, and CHD risk. Moreover, the mediating role of high-density lipoprotein (HDL) between several bisphenols and CHD was also identified. It is yet to be verified, but bisphenols may elevate CHD risk by reducing HDL values and increasing oxidative stress.	Environ Sci Technol. 2023 Jan 10;57(1):531-538.	10.1021/acs.est.2c06488	36534741	ヒト	-	-	-	-	-	-	-	-	-	-	症例対照研究	1	1	-	-	-	1	1	1	-	-	-	-	-	-	-	-	-	-	-	-	-

Wei	2022	Associations between urinary concentrations of bisphenols and serum concentrations of sex hormones among US. Males	BACKGROUND: Bisphenol A (BPA) exposure and its structural analogs (BPS and BPF) might cause endocrine alterations and adverse physiological effects. Few studies to date have directly explored the association between BPA and its analogs and sex hormones in males. METHODS: We included 2,569 participants (aged 20-80 years) with available information on urinary bisphenols and sex hormones from the U.S. National Health and Nutrition Examination Survey 2011-2016. We included participants without data available on sex hormones and urinary bisphenols. Furthermore, participants consuming sex hormone medications were excluded. Multivariable regression models were performed to assess the association between bisphenols and sex hormones. RESULTS: In this study, 2387 participants were included. Of 2387 participants, 1,194 were males. Urinary BPA was detected in 92.7% of participants, BPS in 52.1%, and BPF in 39.2%. Urinary BPA was positively associated with total testosterone (TT) (β = 0.062, 95% CI: 0.016, 0.108, P = 0.011) and free testosterone (FT) (β = 0.062, 95% CI: 0.016, 0.108, P = 0.011) in males. However, no associations were observed between BPA and TT in females. Furthermore, increased BPA and BPF levels were associated with higher levels of sex hormone binding globulin (SHBG) (Model 2: β = 0.062, 95% CI: 0.016, 0.108, P = 0.011; β = 0.05, 95% CI: 0.015, 0.085, respectively). Additionally, participants in the highest BPA exposure quartile (quartile 4) had 0.833 nmol/L higher levels of SHBG than those in quartile 1 (Model 2: 95% CI: 0.156, 1.507, P = 0.021). Prior-level (0.085). Both BPA and BPS were negatively associated with free testosterone (FT, nmol/L) after full adjustment (Model 2: β = -0.015, P = 0.011; Model 2: β = -0.014, P = 0.008, respectively). However, BPF was positively associated with FT (Model 2: β = 0.02095, P = 0.018). CONCLUSION: Our study indicated that exposure to both BPA and its substitutions could alter sex hormone levels. This finding supports the possibility that human exposure to bisphenols at environmental levels might affect the endogenous hormone balance.	Environ Health Vol.21 Issue 1 Pages 135	10.1186/s12940-022-00949-6	36550468	ヒト	-	-	-	-	-	-	-	-	-	-	横断研究	1	1	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-
統合_0037	B. Zhang, Y. He, H. Zhu, X. Huang, X. Bai, K. Kannan and T. Zhang	2020	Concentrations of bisphenol A and its alternatives in paired maternal-fetal urine, serum and amniotic fluid from an e-waste dismantling area in China	Bisphenol A (BPA) and its alternatives are suspected endocrine disruptors. However, prenatal exposure and transplacental transfer of bisphenols (BPs) is still limited. Therefore, BPA and its six alternatives in maternal serum (MS), maternal urine (MU), cord serum (CS), and amniotic fluid (AF) samples collected from 305 maternal-fetal pairs in an e-waste dismantling site in Southern China were determined. Bisphenol AF (BPAF) and bisphenol S (BPS) were the dominant BPA alternatives detected in MS and CS, and the geometric mean (GM) concentration of BPAF (0.02 ng/mL) in MS, 0.097 ng/mL in CS and BPS (0.09 ng/mL in MU, 0.08 ng/mL in CS) in MS and CS was lower than that of BPA (0.6 ng/mL in MS, 0.05 ng/mL in CS). The ratios of BPA concentrations between MU and MS (MU/MS ratio) were over three times higher than those of AF and CS. GM CS-AF concentration ratios between bisphenols were similar to those in MS and CS. The GM CS-AF concentration ratio of BPA (1.4) was significantly lower than that of BPAF (2.9), BPS (1.9), and BPB (1.5). Results suggest that BPs and its alternatives can pass through the placental barrier. The placental transfer rates of BPs are partially related to molecular weight or log K(ow) values. This finding indicates that structure transport is responsible for the placental transfer of BPs.	Environ Int Vol.136 Pages 105407	10.1016/j.envint.2019.105407	31955035	ヒト	-	-	-	-	-	-	-	-	-	-	バイオモニタリング	1	1	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-
統合_0038	W. Zhao, H. Yang, J. Zhang and Q. Chen	2022	Association between co-exposure to phenols and phthalates mixture and infertility risk in women	BACKGROUND: Exposure to phenols and phthalates has been separately linked to increased risks of infertility in women of reproductive age. However, the combined effect of phenols and phthalates exposure on infertility has not been explored. METHODS: Data from the National Health and Nutrition Examination Survey (NHANES) were used. A total of 897 women of reproductive age (18-45 years) with available information on urinary phenol and phthalate metabolites, reproductive questionnaires, and covariates were included in the present study. The definition of infertility was based on self-reports. Multivariable logistic regression, principal component analysis (PCA), and weighted quantile sum (WQS) regression were used to assess the associations between co-exposure to phenols and phthalates mixture and risk of infertility among women of reproductive age. RESULTS: The PCA results for urinary concentrations of phenols and phthalates revealed that bisphenol A (BPA), mono(3-carboxypropyl) phthalate (MCPP), and monoethyl phthalate (MEP) metabolites, [mono(2-ethylhexyl) phthalate (MEHP), mono(2-ethyl-5-hydroxyhexyl) phthalate (MEHHP), mono(2-ethyl-5-oxohexyl) phthalate (MEOHP) and mono(2-ethyl-5-carboxypentyl) phthalate (MECPP)] were positively associated with infertility. PCA revealed that the DEHP-MPB factor (-97, none was significantly positively related to the likelihood of infertility [adjusted odds ratio (aOR) = 1.05; 1.00, 1.10]. The DEHP-MPB component consistently had the highest group posterior inclusion probability (PIP) in BKMR models. The BKMR model also found that MEOHP, MEHHP, and BPA were positively associated with infertility risk when the remaining combination concentrations were held at their median values. In addition, we observed that the probability of infertility increased dramatically as the quantile of total mixture concentration increased. CONCLUSION: Our findings indicate that a combination of phenol and phthalate metabolites is linked to infertility among reproductive-age women. BPA and DEHP, in particular, are significantly related to the risk of infertility. 統合_0039	W. Zhao, W. Tang, X. Shen, H. Xu and J. Zhang	2023	Exposure to bisphenol A and its analogs and polycystic ovarian syndrome in women of childbearing age: A multicenter case-control study	BACKGROUND/OBJECTIVES: In recent years, the reproductive toxicity of new bisphenol analogs has garnered much interest, but it remains to be determined whether bisphenol analogs affect polycystic ovarian syndrome (PCOS). We investigated the associations between urinary concentrations of bisphenol A (BPA) and its analogs and PCOS in women of childbearing age. METHODS: A total of 1,000 PCOS cases and 1,0 controls were included in the current analysis. We quantified seven bisphenol analogs in urine samples, including bisphenol S (BPS), bisphenol AF (BPAF), bisphenol AP (BPAP), bisphenol B (BPB), bisphenol F (BPF), and bisphenol Z (BPZ). Spearman correlation and generalized linear regression were used to assessing the relationship between bisphenol analogs and hormonal parameters. To examine the associations of bisphenol analogs with odds of PCOS, multiple logistic regression, and two multi-pollutant models [quantile-based g-computation (QGC) and extreme gradient boosting (XGBoost) methods] were used. RESULTS: After covariates adjustment, BPA, BPS, and BPAP were positively correlated with testosterone (T) in the control group (P < 0.05). Dose–response relationships were observed between BPA, BPS, BPAP, and T (P-nonlinear < 0.05). Compared with the lowest quartile, the highest quartile of BPA (OR = 1.52, 95% CI: 1.16, 1.99), BPS (OR = 1.34, 95% CI: 1.03, 1.75), and BPAP (OR = 1.32, 95% CI: 1.01, 1.72) were associated with higher odds of PCOS. The QGC index was also positively related to PCOS (OR = 1.27, 95% CI: 1.03, 1.57), with BPA (weight = 0.52), BPS (weight = 0.28), and BPAP (weight = 0.20) likewise, the same overweight or obese tended to have a stronger association between bisphenol analogs and PCOS than normal-weight women. CONCLUSIONS: Environmental exposure to bisphenol analogs was associated with increased odds of PCOS in this case-control study. This association was stronger among obese and overweight women. Zeng	2024	Prenatal exposures to phthalates and bisphenols in relation to oxidative stress: single pollutant and mixtures analyses	Prenatal exposures to phthalates and bisphenols have been shown to be linked with adverse birth outcomes. Oxidative stress (OS) is considered a potential mechanism. The objective of this study was to explore the individual and mixtures of prenatal exposures to phthalates and bisphenols in associations with OS biomarkers. We measured eight phthalate metabolites and three bisphenols in the urine samples from 335 pregnant women in the Wuhan-Zhuhan cohort. Urinary concentrations of 8-hydroxy-2'-deoxyguanosine (8-OHdG) and 8-iso-prostaglandin F2α (8-iso-PGF2α) were measured as OS biomarkers. In associations with the individual chemicals, we estimated by linear regression models and restricted cubic spline (RCS) models, and their associations with the chemical mixtures were explored by quantile g-computation (qg-comp) models. In single pollutant analyses, five phthalate metabolites including monoethyl phthalate (MEP), monoethyl phthalate (MEP), mono (2-ethylhexyl) phthalate (MEHP), (2-ethyl-5-hydroxyhexyl) phthalate (MEHHP), and (2-ethyl-5-oxohexyl) phthalate (MEOHP) and three bisphenols including monomethyl phthalate (MMP), monoethyl phthalate (MEP), mono (2-ethylhexyl) phthalate (MEHP), (2-ethyl-5-hydroxyhexyl) phthalate (MEHHP), (2-ethyl-5-oxohexyl) phthalate (MEOHP) and monobenzyl phthalate (MBzP) were positively associated with 8-OHdG levels in the fully adjusted models and were risen 3% in overall association in GLM and P for non-linear association (P-NL) in restricted cubic spline (RCS) models. In mixture analyses, qg-comp models showed that a one-quartile increase in the chemical mixtures of phthalate metabolites and bisphenols was positively associated with urinary levels of 8-OHdG and 8-iso-PGF2α (+), and bisphenol A (BPA) and bisphenol F (BPF) were the most contributing chemicals, respectively. Prenatal exposures to individual phthalates and mixtures of phthalates and bisphenols were associated with higher OS levels. 統合_0041	J. Y. Zeng, P. P. Chen, C. Liu, Y. L. Deng, Y. Miao, M. Zhang, F. P. Cui, T. T. Lu, T. Shi, K. D. Yang, C. J. Liu and Q. Zeng	2022	Bisphenol A analogues in associations with serum hormone levels among reproductive-aged Chinese men	BACKGROUND: Bisphenol A (BPA) as an endocrine disrupting chemical has been shown to alter reproductive endocrine function, but little is known on its analogues such as bisphenol F (BPF) and bisphenol S (BPS) with increasing usage and exposure. OBJECTIVE: To explore the associations between exposure to BPA, BPF and BPS and serum reproductive hormones among reproductive-aged Chinese men. METHODS: We measured BPA, BPF and BPS concentrations in urine samples from 335 reproductive-aged men in the Wuhan-Zhuhan cohort. Serum hormone levels including testosterone (T), estradiol (E2), follicle-stimulating hormone (FSH), luteinizing hormone (LH) and sex hormone-binding globulin (SHBG) were detected in serums. We used restricted cubic spline (RCS) models and multivariate linear regression models to examine the associations between exposure to BPA, BPF and BPS and serum hormone levels, and mixed linear regression models were utilized to explore associations between these associations. We also examined potential modifying effects by age and body mass index (BMI). RESULTS: There was little evidence of associations between BPA exposure and altered reproductive hormones. However, we found that elevated BPF and BPS exposures were in negative associations with estrogen (E2) levels and E2/T level (estradiol/testosterone ratio) (all P for trends < 0.05), and that elevated BPS exposure was negatively associated with SHBG levels (P for trend = 0.09). Based on the RCS models, these linear negative associations mixed that between BPS exposure and E2/T ratio were further confirmed. In stratified analyses, BPA exposure was positively associated with T levels among men with BMI < 24 kg/m2 (P for interaction = 0.02). CONCLUSIONS: Our findings suggested that BPA exposure was not associated with reproductive hormones. Elevated BPF and BPS exposures were negatively associated with male serum E2/T ratio and SHBG levels, and these associations varied by age and BMI. 統合_0042	M. Zbucka-Krętowska, U. Lisowek, W. Miltyk, I. Sidakiewicz, P. Pierzyński, B. Mikwski, S. Wal czyński and J. Ciesiacki	2019	Simultaneous analysis of bisphenol A fractions in maternal and fetal compartments in early second trimester of pregnancy	Background:Bisphenol A (BPA) is an estrogenic, endocrine disrupting compound widely used in the industry. It is also a ubiquitous environmental pollutant. Its presence was confirmed in human fetuses, which results from maternal exposure during pregnancy. The mechanisms behind maternal-fetal transfer, and relationships between pregnant women and fetal exposures remain unclear. The aim of this study was to assess the impact of maternal exposure to BPA on the exposure of the fetus. Methods:Maternal plasma and amniotic fluid samples were collected from 52 pregnant women undergoing amniocentesis for prenatal diagnosis of chromosomal aberrations in the 15th-18th gestational week. Concentrations of BPA in the samples were measured by high-performance liquid chromatography with fluorescence detection. Results:The number of BPA-positive samples in amniotic fluid was 42 (81%) and in maternal plasma 41 (79%). The median concentration of maternal plasma BPA was 8 times higher than the total BPA concentration in the amniotic fluid (0.69 ng/mL, range 0.05-49.76 ng/mL vs. median 0.08 ng/mL, range 0.3 ng/mL - 0.61 ng/mL). There was no direct relationship between the levels of BPA in maternal plasma and amniotic fluid levels. The permeability factor, in turn, negatively correlated with fetal development (body weight: P = 0.03, P = 0.001). Conclusions:Our results suggest that the risk of fetal BPA exposure depends on placental BPA permeability, rather than the levels of maternal BPA plasma concentration and support general recommendations to become aware and avoid BPA-containing products. Peterson	2022	Trimester two gestational exposure to bisphenol A and adherence to mediterranean diet are associated with adolescent offspring oxidative stress and metabolic syndrome risk in a sex-specific manner	BACKGROUND: Exposure to prenatal bisphenol A (BPA) and Mediterranean Diet Score (MDS) has been linked to metabolic risk in child offspring. It remains unclear if independent and interactive effects persist in adolescence. METHODS: We examined prenatal BPA and MDS on adolescent offspring metabolic syndrome risk score (MRS) and 8-isoprostane (8-iso), a biomarker of oxidative stress. Data from maternal adolescent pairs (n = 148) in the Programming Research in Obesity, Growth, Environment and Social Stressors (PROGRESS) cohort in Mexico City were used. Second trimester urine BPA and first trimester MDS were measured during pregnancy. MRS and 8-iso were obtained during adolescence. We used linear regression models to examine associations between maternal-specific BPA, MDS, and MRS and offspring 8-iso outcomes. We then stratified analyses by sex. We identified a significant association between MDS with increased 8-iso (β = -0.066, p = 0.05), and a marginal association between trimester two BPA with increased 8-iso (β = 0.215, p=0.06). MDS modified the marginal association between BPA and 8-iso in females (β = 0.060). A negative, marginal association was observed between trimester two BPA and MRS (β = -0.106) while BPA*T1 MDS was significantly positively associated with MRS (β = 0.102 × males. CONCLUSIONS: Study findings indicate that trimester two prenatal BPA and maternal adherence to a Mediterranean diet may have sexually dimorphic effects on adolescent offspring oxidative stress, and metabolic syndrome risk. Peterson	2023	Cross-sectional associations between phthalates, phenols, and parabens with metabolic syndrome risk during early-to-mid adolescence among a cohort of Mexican youth	BACKGROUND: Epidemiological studies on children and adults have linked exposures from plastics and personal care products to metabolic disruption. Yet, the impact of endocrine disrupting chemicals (EDCs) on adolescent metabolic syndrome (MetS) risk during early and mid-adolescence is unclear. METHODS: To examine the link between exposure to EDCs and MetS risk in this transitional window, cross-sectional data from 505 Mexican youth in early to mid-adolescence (10-12 years) were analyzed. Urinary biomarker concentrations of phthalates, phenol, and paraben analytes were measured from a single spot-urine sample collected in 2019, study personnel obtained anthropometric and metabolic measures. We examined associations between exposure to phthalates and metabolites, phenol, and paraben analytes with MetS scores using linear regression adjusted for specific gravity, sex, age, pubertal status, smoking, alcohol intake, physical activity level, and screen time. As a secondary aim, mediation analysis was conducted to evaluate the role of hormones in the relationship between EDC exposure and MetS risk. RESULTS: Of the 505 youth, 11.3% (n = 57) had MetS. Urinary concentrations of 2,5-dichlorophenol (2,5-DCP), 2,4-dichlorophenol (2,4-DCP), phthalates/base analytes were, including 3- (MHP) (β = 0.23 (95% CI: 0.06, 0.37), p = 0.01), phthalates/base analytes (mono-2-ethylhexyl phthalate (MEHP), mono-(2-ethyl-5-hydroxyhexyl) phthalate (MEHHP), mono-(2-ethyl-5-oxohexyl) phthalate (MEOHP), and mono-(2-ethyl-5-carboxypentyl) phthalate (MECPP)) among males. Among females, BPA (β = 0.26 (95% CI: 0.03, 0.49), p = 0.03) was positively associated with MetS risk-a score and was placed 2.5 DCP (β = 0.09 (95% CI: 0.02, 0.16), p = 0.01) was associated with increased waist circumference z-score. Results showed no evidence of mediation by hormone concentrations in the association between summary phthalates with lipids, ratio or MetS risk z-scores. CONCLUSION: Higher EDC exposure was positively associated with serum lipids during adolescence, particularly among males. 統合_0045	Ö. Yuruker, C. Dalkan, M. Uccu, Ö. Yetkin, A. Bahaygül and N. N. Bahcecilar	2023	High fetal bisphenol A exposure enhances IL22 secretion: A proinflammatory cytokine	BACKGROUND: Bisphenol A (BPA) is an industrial product, widely used in human-consumed types of equipment that can be transmitted orally, by inhalation or through dermal absorption and is detectable in nearly body fluids including umbilical. A correlation between BPA concentration in maternal serum and cord blood has been demonstrated previously, suggesting a possible transfer of BPA from the hemoplacental unit. OBJECTIVE: Our objective is to determine the impact of cord blood BPA level on cytokine responses. METHODS: In this cross-sectional study, healthy pregnant women who delivered healthy newborns followed by the Obstetrics and Gynecology Department of Ankara Yildirim Beyazit University between January 2019 and January 2020 were included in the study. Cord blood samples were collected from 100 healthy newborns. For cytokine examination, cord blood cells (PBMC) were isolated by Ficoll-Hypaque density gradient centrifugation. Cells were cultured in the presence or absence of phytohemagglutinin (PHA) (5 μg/mL) for 48 hours. Cytokine concentrations in the supernatants were determined by ELISA. RESULTS: Among 107 deliveries, 7 (6.5%) were excluded in the study, due to lack of cut-off value. BPA levels were classified as percentiles. No statistically significant difference was detected in the comparison of cytokine levels based on BPA concentrations below and above the 25th and 50th percentile. Significantly higher IL22 levels (p = 0.007) and lower IL-17/IL-22 (p = 0.01) were detected in those with BPA level above 75th percentile (> 0.51 ng/ml) compared to the below group. CONCLUSIONS: This is the real life study demonstrated that very high BPA levels in cord blood of expectant mothers enhances IL22 secretion in cord blood which is a proinflammatory cytokine. Studies evaluating long-term immunological effects on these highly exposed newborns are recommended.	Asian Pac J Allergy Immunol Vol.41 Issue 4 Pages 396-400	10.12932/ap-020320-0778	33386784	ヒト	-	-	-	-	-	-	横断研究	1	1	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-
統合_0046	B. Yue, S. Ning, H. Miao, C. Fang, J. Li, L. Zhang, Y. Bao, S. Fan, Y. Zhao and Y. Wu	2023	Human exposure to a mixture of endocrine disruptors and serum levels of thyroid hormones: A cross-sectional study	Exposure to endocrine disrupters (EDCs) could disrupt thyroid hormone homeostasis. However, human epidemiological studies reported inconsistent observations, and scarce information on the effect of a mixture of chemicals. The aim of the present study was to examine the associations of multiple chemicals with thyroid hormones among adults from China. We measured seven kinds of thyroid hormones and urinary levels of 11 EDCs, including six phthalate metabolites, bisphenol A (BPA), bisphenol F (BPF), bisphenol S (BPS), para-hydroxybenzoic, and triclosan among 1717 healthy adults without occupational exposure. Associations of multiple urinary EDCs with thyroid hormones were assessed by multivariate linear regression models and Bayesian kernel machine regression (BKMR) models. Multivariate linear regression models showed that for all free hormones, an interquartile range (IQR) significantly associated with lower thyroxine (T4) (β = -0.27, 95% confidence interval (CI) (-0.41, -0.13)), total triiodothyronine (TT3) (β = -0.03, 95% CI (-0.05, -0.01)), free T4 (FT4) (β = -0.02, 95% CI (-0.03, -0.01)), and free T3 FT3 (β = -0.04, 95% CI (-0.07, -0.02)), and mono (2-ethyl-5-oxohexyl) phthalate (MEOHP) and monoethyl phthalate (MEP) positively associated with FT4 (β = 0.01, 95% CI (0.01, 0.02)) and FT3 (β = 0.02, 95% CI (0.01, 0.03)), respectively. Moreover, we observed significant dose-response relationships between FT3 and the mixture of 11 EDCs, and MEP was the main contributor to the mixture effect, suggesting the priority of potential effect of MEP on disrupting thyroid function under a real scenario of human exposure to multiple EDCs. Our findings supported the hypothesis that human exposure to low levels of EDCs could alter thyroid hormones homeostasis, among non-occupational healthy adults. 統合_0047	Y. Yuan, Q. Chen, X. Ding, Q. Zhang and X. Zhong	2024	Endocrine disrupting chemical Bisphenol A and its association with cancer mortality: a prospective cohort study of NHANES	INTRODUCTION: There is evidence suggesting that Bisphenol A (BPA) is associated with increased all-cause mortality in adults. However, the specific causes of the relationship between BPA exposure and cause-specific mortality remain unclear. METHODS: Bisphenol A (BPA) was measured in urine samples from participants in the National Health and Nutrition Examination Survey (NHANES) using high-performance liquid chromatography-mass spectrometry (LC-MS). Through the use of multivariable Cox proportional hazard regression and restricted cubic splines, the relationships between urine BPA and death from all causes and cancer were investigated. RESULTS: This study has a total of 8,836 participants, and 337 died from cancers after a 7.5-year follow-up. The median level of BPA was 2.8 ng/mL. Urinary BPA levels were not independently associated with all-cause mortality. For cancer mortality, the second quartile, multivariable-adjusted hazard ratio was 0.52 (95% confidence interval: 0.30 to 0.88; p = 0.02) compared to the lowest quartile. The restricted cubic spline, showed that the association was nonlinear (p for nonlinearity = 0.028) and the inflection point was 5.49 ng/mL. CONCLUSION: Urinary BPA exposure was U-shaped associated with the risk of cancer mortality, and a lower level of BPA less than 5.49 ng/mL was associated with a higher risk of cancer mortality.	Front Public Health. 2024 Feb 23:12:1341789.	10.3389/fpubh.2024.1341789	38584917	ヒト	-	-	-	-	-	-	コホート研究	1	1	-	-	-	1	1	1	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-
統合_0048	S. Yuan, K. Du, H. Liu, X. Guo, B. Zhang, Y. Wang, B. Wang, H. Zhang and H. Guo	2023	Association between bisphenol A exposure and thyroid dysfunction in adults: a systematic review and meta-analysis	The occurrence of thyroid dysfunction is affected by environmental factors, and BPA is a ubiquitous environmental pollutant with the potential to cause thyroid dysfunction. However, the limited epidemiological evidence shows an inconsistent association between BPA exposure and thyroid dysfunction. Therefore, the literature on the impact of BPA on thyroid was sorted and analyzed to study the relationship between BPA and adult thyroid function. The studies published as or before 23rd May 2022 from PubMed, Web of Science, and Scopus were collected and pooling the association between BPA exposure and the levels of thyroid hormones. The methodological quality of each study was assessed, the sensitivity analysis and subgroup analysis based on study population and gender were also performed, and publication bias was evaluated. A total of 2988 literatures were identified, and 14 studies were included in the meta-analysis. The pooled results showed that BPA exposure was positively correlated with TSH (β = 0.03, 95% confidence interval (CI): 0.01, 0.05), and the coefficients between BPA and FT3/FT4 were -0.01 (95%CI: -0.03 ~ 0.00) and -0.00 (95%CI: -0.11 ~ 0.10), BPA concentration was positively correlated with TSH in females, and the pooled correlation coefficient was 0.08 (95%CI: 0.02–0.08). The effects of BPA on thyroid hormone levels were significantly different between males and females. BPA may significantly decrease the levels of FT3 and TSH in males but increase the levels of FT3 in females. Considering the high heterogeneity among studies and the limited investigations, the subgroups, the relationship between BPA exposure and thyroid dysfunction needs to be further investigated. 統合_0049	N. Yuan, J. Sun, X. Zhao and W. Li	2024	Relationship between bisphenol A and autoimmune thyroid disease in women of childbearing age	BACKGROUND: Autoimmune thyroid disease (AITD) is the main cause of hypothyroidism in women of childbearing age. Bisphenol A (BPA) is an environmental factor affecting AITD. This study aims to investigate relationship between BPA and AITD in women of childbearing age, thereby providing a reference for the prevention of hypothyroidism in this specific demographic. METHODS: A total of 330 women of childbearing age were enrolled in this study, including the euthyroid group (matched 90 women with euthyroidism and thyroid autoantibodies negativity) and the AITD group (matched 90 women with euthyroidism and at least one thyroid autoantibody positivity). Urinary BPA concentrations were measured by high-performance liquid chromatography-tandem mass spectrometry (HPLC-MS/MS). Thyroid autoantibodies and BPA's endocrine were detected. The difference of BPA levels between the two groups was compared. Logistic regression was used to analyze the correlation between BPA and AITD. RESULTS: The proportion of multivariate and serum thyroid-stimulating hormone levels were significantly higher in the AITD group compared to the euthyroid group. Logistic regression analysis revealed that BPA levels did not exhibit a statistically significant association with AITD. Spearman correlation analysis revealed a statistically significant correlation between BPA and urinary iodine levels (r = 0.16, P < 0.05), as well as a correlation between urinary BPA and free triiodothyronine (FT3) levels (r = 0.29, P < 0.05). CONCLUSION: This study revealed a correlation between urinary BPA levels and FT3 levels. However, it did not establish a relationship between BPA and AITD in women of childbearing age. 統合_0050	K. Y. Yuan, Y. H. Gu, Y. H. Pei, S. Y. Yu, T. Z. Li, T. Feng, Y. Liu, J. Tian, X. Miao, J. Kong, M. Hu and B. F. Yuan	2025	Comprehensive analysis of transplacental transfer of environmental pollutants detected in paired maternal and cord serums	Prenatal exposure to hazardous environmental pollutants is a critical global concern due to their confirmed presence in umbilical cord blood, indicating the ability of pollutants to cross the placental barrier and expose the fetus to harmful compounds. However, the transplacental transfer efficiencies (TTEs) of many pollutants remain underexplored. Herein, we developed a liquid chromatography-tandem mass spectrometry (LC-MS/MS) method to quantitatively analyze 95 environmental pollutants, including 13 bisphenols (BPs), 18 organophosphorus flame retardants (OPFRs), 7 brominated and other flame retardants (BFRs), 36 phthalates (PAEs), and 11 per- and polyfluoroalkyl substances (PFASs), in paired maternal serum and cord serum samples from 100 mother-infant pairs in Tianjin, China. The TTEs of pollutants ranged from 0.01 (bisphenol A (BPA) and bisphenol S (BPS)) to the highest concentration (500–8,000 pg/mL in maternal serums and 12.66 ng/mL in cord serums), followed by 4-cumyl-2,6-di-tert-butylphenol (TTCDTBP) (median TTE = 0.93) and 3,3′,5,5′-tetrachloro-4,4′-biphenol bisphenol (BPHC). The exposure concentrations of the same type of pollutants were highly correlated between maternal and cord serums. Perfluorohexanoic acid (PFHxA) had the highest TTE value (0.59), while perfluorooctane sulfonic acid (PFOS) had the lowest (0.28). TTEs of PFOS and perfluorooctanoic acid (PFOA) were higher for linear isomers, whereas TTEs of perfluoroalkanesulfonic acid (PFHxS) and perfluorodecane sulfonic acid (PFDS) were higher for male newborns. Moreover, the expression levels of the transplacental transporters ABCA1, ABCC1, ABCC3, ABCC4, ABCG1, SLCO2B1, and SLCO4A1 were significantly correlated with the TTEs of pollutants. Molecular docking revealed that pollutants with higher TTEs exhibited stronger binding affinities to ABCC4 and SLCO4A1. Further research is essential to unveil the mechanisms involved in the transplacental transfer of environmental pollutants, ultimately fostering our comprehension of their impact on fetal health and child outcomes. Porucznik	2019	Association between peri-conceptional bisphenol A exposure in women and men and time to pregnancy- The HOPE study	BACKGROUND: Bisphenol A (BPA) is a non-persistent endocrine disrupting chemical with nearly ubiquitous, involuntary exposure. Previous studies have shown that BPA causes reproductive dysfunction in animal models, but there are limited data regarding the effects of BPA exposure on time to pregnancy (TTP) in humans. OBJECTIVE: To evaluate whether peri-conceptional BPA exposure of women and men is associated with couples' TTP. METHODS: The Home Observation for Pregnancy Environment (HOPE) study is a prospective pregnancy cohort study of couples trying to conceive in Utah. Urine samples were collected and were followed up to 12 months. Women collected first morning urine samples starting at the beginning of the fertile window and continued until the result of menses or 35 days after the estimated date of ovulation (EDO-35 days). The time to pregnancy (TTP) after the enrollment was self-reported and used for the analysis. Discrete time Cox proportional hazards models were performed to generate fecundability odds ratio (FOR) between BPA and TTP after adjusting for education and age, accounting for right-censoring and prior number of cycles trying to conceive. RESULTS: Among 344 couples, 125 couples became pregnant during the study. There was no association between TTP and peri-conceptional BPA exposure for both men (FOR 1.02, 95% CI: 0.72, 1.47) and women (FOR 1.07, 95% CI: 0.76, 1.52) after adjusting for education and age. CONCLUSIONS: No association was found between peri-conceptional BPA exposure and fecundability in this peri-conception cohort of relatively young, healthy pregnancy planners. Erkekoglu	2024	Estimated exposure to bisphenol A in breastfed and breastfed plus formula-fed infants in Turkey: a comparison study	This study aimed to estimate and compare dietary exposure to bisphenol A (BPA) in exclusively breastfed (EBF) and breastfed plus formula-fed (BF + FF) infants. A total of 70 mothers and their 0.5-month-old infants (35 EBF and 35 BF + FF) were recruited. Breast milk samples were collected from mothers, and urine samples were collected from infants. Breast milk samples were collected in polypropylene tubes and stored at -20 °C until analysis. Urine samples were collected in sterile polypropylene cups and stored at -80 °C until analysis. Total BPA levels in breast milk, infant formula, and infant urine samples were analyzed by the liquid chromatography (HPLC). While BPA was detected in 42.5% of the breast milk samples, it was in the BF group (mean ± SD = 0.09 ± 0.29 ng/mL). BPA was detected in all of the breast milk samples in the BF + FF group (mean ± SD= 0.72 ± 0.72 ng/mL) (p< 0.05). Similarly, 100% of the infant formula samples in the BF + FF group had detectable levels of BPA (mean ± SD = 1.10 ± 1.17 ng/g formula). The mean urinary BPA levels in the EBF infants (3.31 ± 1.08 µg/L creatinine) were not significantly different from the BF + FF infants (3.83 ± 0.3 µg/g creatinine) (p = 0.23). The average daily BPA intake in EBF infants (0.18 ± 0.11 µg/kg body weight (bw)/day) was found to be significantly higher than in BF + FF infants (0.12 ± 0.09 µg/kg bw/day) (p = 0.05). The estimated daily BPA intake for infants in both groups were below the temporary tolerable daily intake (t-TDI: 4 µg/kg bw/day). Consequently, BPA intake of EBF and BF + FF infants were within safe daily limits during the first six months of life. 統合_0055	K. E. Yeo, S. Lim, A. Kim, Y. B. Lim, C. R. Lee, J. J. Kim and B. N. Kim	2025	Association Between Endocrine-Disrupting Chemicals Exposure and Attention-Deficit/Hyperactivity Disorder Symptoms in Children With Attention-Deficit/Hyperactivity Disorder	OBJECTIVES: This study investigated the relationship between exposure to endocrine-disrupting chemicals (EDCs), specifically phthalates, bisphenol A, bisphenol F, and bisphenol S, and the severity of attention-deficit/hyperactivity disorder (ADHD) symptoms using neuropsychological tests in children diagnosed with ADHD. METHODS: This study included 87 medication-naive children with ADHD aged 6-16 years. The urinary concentrations of EDCs were measured, and ADHD symptom severity was evaluated using neuropsychological tests and clinical symptom scale measurements. The Jonckheere Terpstra test, Pearson and Spearman correlation analyses, linear regression models, and multiple regression models were used to examine the relationships between EDC exposure and ADHD symptoms. RESULTS: A significant correlation was observed between urinary phthalate metabolite concentrations and commission error T scores in the visual Advanced Test of Attention test. No significant associations were found with other neuropsychological indicators or bisphenol levels. CONCLUSIONS: Phthalate exposure affects impulsivity in children with ADHD, which is consistent with the results of previous studies that used parental surveys. However, bisphenols are not clearly associated with ADHD symptoms, which is consistent with the results of previous studies. Mosalioğlu Yaklı	2021	The effect of plastic bottled water consumption on outcomes of ICSI cycles undertaken for unexplained infertility	RESEARCH QUESTION: Do bisphenol A (BPA) levels in maternal urine, serum and follicular fluid affect embryo quality and intracytoplasmic sperm injection (ICSI) cycle outcomes in women with unexplained infertility? DESIGN: Prospective study conducted between 1 April 2019 and 30 September 2020. The study cohort consisted of 92 women aged between 23 and 37 years who underwent intracytoplasmic sperm injection owing to unexplained infertility. Urine samples were collected on the day of oocyte retrieval, and serum and follicular fluid samples were collected during oocyte retrieval. Demographic features and IVF outcomes of the patients were collected. RESULTS: Among the 92 women who underwent ICSI, 50 (54.3%) patients drank only bottled water and 42 (45.7%) patients drank other tap water/boiled water/filtered water/mineral water. Only water consumption was defined as bottled water consumption. Patients who consumed tap water had statistically significantly lower BPA values in their body fluids compared with patients who consumed plastic bottled water (all P < 0.001). Women who had given birth (1 embryo transferred had lower serum BPA values than women who had given birth (2 embryos transferred (3.02 ± 1.17 versus 26.9 ± 37 ng/ml, P = 0.001). Serum and follicular fluid BPA levels were statistically significantly higher in women who failed to achieve clinical pregnancy (P < 0.001, P = 0.008, respectively) and values of a live birth (both P < 0.001). CONCLUSIONS: A negative relationship was found between serum and follicular fluid BPA levels and embryo quality, clinical pregnancy and live birth in these women. In addition, the BPA levels of women who consume tap water at home were lower than those who use plastic bottled water. 統合_0057	J. F. Yap, K. S. Wan, M. F. M. Yusoff, Y. C. Lim and R. K. Supramani	2025	Challenges in diagnosing occupational allergic contact dermatitis: a case report	BACKGROUND: In Malaysia, occupational allergic contact dermatitis (OCD) is often under-reported. This case report describes a chemical engineer who developed possible ACD, likely due to workplace allergen exposure. CASE PRESENTATION: A 30-year-old male chemical engineer presented with a 3-month history of recurrent, pruritic, erythematous rashes on his hands and forearms. He had worked at his current workplace for eight months. A clinical and occupational history was taken, including fragrance use, and a comprehensive physical examination was conducted. Skin testing was not performed. However, among these, only 'bisphenol A diglycidyl ether', a component of 'epoxy resin,' was listed in the safety data sheet as a confirmed occupational exposure. In accordance with its local regulations, this case was reported as an occupational dermatitis' to the Department of Occupational Safety and Health. The patient was prescribed symptomatic topical treatments, including emollients and topical steroids. Additionally, he was advised to switch to hypoallergenic products. On follow-up, his chronic inflammatory skin lesions showed improvement. CONCLUSIONS: Through occupational history taking and patch testing are successful for diagnosing ACD. Personalized health education and regular follow-ups, is crucial in monitoring lesion resolution and evaluating the effectiveness of preventive measures. In workplace settings. 統合_0058	J. Yao, F. Wang, Y. Zhang, Z. Zhang, J. Bi, J. Ha, P. Li, X. Han, Y. Wei, X. Zhang, H. Guo and M. Ha	2022	Association of serum BPA levels with changes in lipid levels and dyslipidemia risk in middle-aged and elderly Chinese	Previous evidences exploring the associations of BPA with lipid changes and dyslipidemia did not obtain consistent results. To evaluate whether serum BPA concentration was associated with changes in blood lipid levels and incident dyslipidemia risk in middle-elderly Chinese adults, we conducted a prospective study with 1880 participants (average 62.65 years old) derived from the Dongfeng-Tongji cohort which was founded in 2008 and followed up each 3 years. Serum BPA levels were measured by high-performance liquid chromatography-tandem mass spectrometry (HPLC-MS/MS). Changes in lipid levels were calculated as Δ (wide which equal to 1 and 2013) - 1 and 2008). The diagnosis of dyslipidemia was according to Chinese Guidelines on Prevention and Treatment of Dyslipidemia in 2016. We used multivariable linear regression and Logistic regression to explore the associations of serum BPA with changes in lipid levels and incident dyslipidemia risk, respectively. Restricted cubic spline was performed to model the dose-response relationship. Results: 1880 individuals developed with hypercholesterolemia, 87 with hypertriglyceridemia, 30 with high-LDL-cholesterolemia, 76 with low-HDL-cholesterolemia, and 1196 with dyslipidemia. Serum BPA levels were significantly related to TC, LDL-c, and Non-HDL-c levels. In the prospective study, each ln-BPA increase was associated with 0.05 (95% CI: 0.02, 0.08) mmol/L increase in TC, 0.07 (95% CI:0.03, 0.11) mmol/L increase in Non-HDL-c, 0.05 (95% CI: 0.01, 0.08) increase in lg TC/HDL-c, and 0.04 (95% CI: 0.00, 0.08) increase in lg Non-HDL-c (P < 0.05). We only observed significant associations in females but not in males. Besides, serum BPA levels were positively associated with hypercholesterolemia (OR=1.2, 95% CI: 1.01, 1.43). The restricted cubic splines showed similar results. In conclusion, serum BPA was associated TC and Non-HDL-c changes, and BPA was also associated with increased risk of hypercholesterolemia. Further prospective studies with large sample size are warranted to validate our findings. 統合_0059	Z. Yang, H. Liu, J. Wei, R. Liu, J. Zhang, M. Sun, C. Shen, J. Liu, K. Mao, Y. Chen, X. Yang, P. Yu, L. Chen and N. J. Tang	2024	Bisphenol mixtures, metal mixtures and type 2 diabetes mellitus: Insights from metabolite profiling	BACKGROUND: Little is known about the combined effect of bisphenol mixtures and metal mixtures on type 2 diabetes mellitus (T2DM) risk, and the mediating roles of metabolites. METHODS: The study included 886 participants from the Dongfeng-Tongji cohort. Urinary bisphenols and metals were measured by ultra-performance liquid chromatography-tandem mass spectrometry (UPLC-MS/MS) and inductively coupled plasma mass spectrometry (ICP-MS), respectively. Widely targeted metabolomics was employed to obtain the serum metabolomic profiles. Conditional logistic regression models were used to assess the single associations of bisphenols and metals with T2DM risk after multivariable adjustment. Additionally, the joint effects of bisphenol mixtures and metal mixtures were examined using quantile-based g-computation (QG-C) models. Furthermore, differential metabolites associated with T2DM were identified, and metabolic analyses were performed to explore the role of metabolites in the associations of bisphenols and metals with T2DM risk. RESULTS: The results showed bisphenol mixtures were associated with an increased T2DM risk, with bisphenol S (BPS) contributing the most. Metal mixtures were also associated with an increased T2DM risk, with cobalt (Co) contributing the most. Moreover, 42 differential metabolites were screened between the T2DM cases and controls. Mediation analyses indicated that 9 metabolites mediated the association between BPS and T2DM, while 1 alone mediated the association between Co and T2DM risk. CONCLUSIONS: The study indicated that BPS, Co, Fe, and Zn were the primary contributors to increased T2DM risk, and metabolites played a mediating role in the associations of BPS and Co with the risk of T2DM. Our findings contribute to a better understanding of the mechanisms underlying the associations of bisphenols and metals with T2DM.	Environ Int. 2024 Aug:190:108921.	10.1016/j.envint.2024.108921	39098088	ヒト	代謝	-	-	-	-	-	-	症例対照研究	1	1	-	-	-	1	1	1	-	1	-	-	-	-	-	-	-	-	-	-	-	-
統合_0060	Y. Yang, X. Bai, J. Lu, R. Zou, R. Ding and X. Hu	2023	Assessment of five typical environmental endocrine disruptors and thyroid cancer risk: a meta-analysis	INTRODUCTION: There are conflicting results on the association between environmental endocrine disruptors (EEDs) and thyroid cancer. This meta-analysis aimed to elucidate the relationship between EEDs and thyroid cancer. METHODS: We searched for epidemiological studies on EEDs and thyroid cancer published in PubMed and Web of Science up to December 2022. We then screened the studies that could extract data on EEDs concentration levels in both thyroid cancer patients and healthy controls. We excluded articles that could not calculate effect sizes, focused on other thyroid diseases, or lacked controls. Standardized mean difference (SMD) was calculated to analyze the association between EEDs and thyroid cancer. We measured the heterogeneity among the included studies using Q- and I-squared (I2) tests and Begg's test, and evaluated article quality using the Newcastle-Ottawa Quality Score (NOS). In the end, fifteen eligible case-control studies were included. RESULTS: Our comprehensive analysis revealed that polychlorinated biphenyls (PCBs) (SMD = 0.61, 95%CI = 0.34, 0.87, P < 0.001), polybrominated diphenyl ethers (PBDEs) (SMD = 0.49, 95%CI = 0.22, 0.76, P < 0.001), and bisphenol A (BPA) (SMD = 0.21, 95%CI = 0.01, 0.41, P = 0.042) were significantly associated with thyroid cancer.PFASs (SMD = -0.22, 95%CI = -0.50, 0.07, P = 0.137) and PAHs (SMD = -0.08, 95%CI = -0.50, 0.33, P = 0.693) had no significant association with thyroid cancer. Sensitivity analysis indicated that the findings were stable. Publication bias was found for PCBs (Egger's test, P = 0.041), but not for BPA (P = 0.602). The study also found that exposure to certain EEDs, such as PBDEs, PAHs, and heavy metals, increases the risk of thyroid cancer. However, further large-scale epidemiological studies and mechanism studies are needed to verify these potential relationships and understand the underlying biological mechanisms. 統合_0061	P. Yang, B. G. Liu, B. Zhou, W. C. Cao, P. P. Chen, Y. L. Deng, J. Hou, S. Z. Sun, T. Z. Zhang, W. Q. Lu, L. M. Cheng, W. J. Zeng and Q. Zeng	2021	Sex-specific associations of prenatal exposure to bisphenol A and its alternatives with fetal growth parameters and gestational age	BACKGROUND: Bisphenol A (BPA) can cause detrimental effects on fetal growth. However, the effects of BPA alternatives, such as bisphenol F (BPF) and bisphenol S (BPS), on fetal growth are less known. OBJECTIVE: To investigate the relationships of prenatal BPA, BPF, and BPS exposures with fetal growth parameters and gestational age. METHODS: Urinary BPA, BPF, and BPS were measured in 1,347 pregnant women before delivery in a Chinese cohort. The associations of prenatal exposure to BPA, BPF, and BPS with fetal growth parameters and gestational age were examined, and covariates stratified by fetal sex were also considered. We used a restricted cubic splines (RCS) model to examine the dose-response associations between exposures and outcomes. RESULTS: Maternal urinary BPA and BPF were negatively related to birth length (-0.50 cm, 95% CI: -0.97, -0.03 comparing the extreme exposure groups, p for trend = 0.03) and ponderal index (-0.08 kg/m3, 95% CI: -0.15, -0.01, p for trend = 0.03), respectively. Maternal urinary BPA was positively related to gestational age (0.28 weeks, 95% CI: 0.03, 0.53, p for trend = 0.03). Dose-response relationships were nonlinear for BPA and BPS, but linear for BPF. Maternal urinary BPA and BPF were also positively related to birth weight (-102.99 g, 95% CI: -203.98, -2.00 comparing the extreme exposure groups, p for trend = 0.05) and ponderal index (-0.29 kg/m3, 95% CI: -0.57, -0.01 comparing the extreme exposure groups, p for trend = 0.04), respectively, both p for trends < 0.05), and maternal urinary BPS was associated with shorter gestational age (-0.35 weeks, 95% CI: -0.67, -0.03 comparing the extreme exposure groups, p for trend = 0.03). These associations were only observed in girls and exhibited a linear dose-response relationship. CONCLUSIONS: Prenatal BPA, BPF, and BPS exposures were associated with detrimental effects on fetal growth parameters, and stronger effects were noted in female infants.	Environ Int. 2021 Jan:146:106305.	10.1016/j.envint.2020.106305	33395947	ヒト	生殖発生	-	-	-	-	-	-	コホート研究	1	1	-	-	-	1	1	1	-	1	-	-	-	-	-	-	-	-	-	-	-	-
統合_0062	L. Yang, Y. Liu, H. Zhang, Y. Zhao, G. Zhang, Y. Cao, Z. Wang, H. Liang, M. Miao, T. Zhang and J. Xue	2025	Interpretable machine learning-based insights into early-life endocrine disruptor exposure and small vulnerable newborns	Early life exposure to endocrine disrupting chemicals (EDCs) may contribute to small vulnerable newborns, including conditions such as being small for gestational age (SGA) and preterm birth (PTB), yet evidence remains limited. This study, within it, based on 735 mother-infant pairs in the Chinese Jiaozuo Birth Cohort (2018–2020), including 78 SGA and 56 PTB cases, employed interpretable machine learning to elucidate isolated effects of 36 EDCs on SGA and PTB risk and sex interactions in a multi-substance exposure context. Extra Trees and CatBoost classifiers performed best for SGA and PTB, respectively, achieving sensitivities of 0.667 and 0.750 and AUC-ROC values of 0.747 and 0.824. Bisphenol A (BPA), bisphenol S (BPS), and 2,4-dichlorophenol (2,4-DCP) were identified as key contributors to SGA risk, while BPA, BPS, and 2,5-dichlorophenol (2,5-DCP) were linked to PTB. Sex-specific effects were evident, with BPA and BPS associated with increased SGA risk in females (SHAP values: 0.0028 and 0.0026, respectively), while 2,5-DCP and 2,4-DCP showed stronger associations with PTB in males (SHAP values: 0.0022 and 0.0020). Dose–response relationships revealed nonlinear patterns, with BPA and BPS exceeding 2.0 ng/mL increasing SGA risk by 1.8- and 1.6-fold, respectively, and 2,5-DCP and 2,4-DCP above 0.5 ng/mL raising PTB risk by 2.1- and 1.9-fold, respectively. Co-exposure to BPA and BPS further amplified SGA risk (OR = 2.3), while 2,5-DCP and 2,4-DCP co-exposure increased PTB risk (OR = 2.5). Mediation analysis revealed that BPA and BPS partially mediated the effects of 2,5-DCP and 2,4-DCP on PTB, with mediation proportions ranging from 12% to 18%. These findings underscore the critical role of early-life exposure to EDC mixtures in adverse birth outcomes and highlight the sex-specific vulnerabilities of newborns. The integration of interpretable machine learning with traditional epidemiological approaches offers a powerful framework for identifying high-risk exposure patterns and informing targeted public health interventions.	J Hazard Mater. 2025 Jul 15:492:138067.	10.1016/j.jhazmat.2025.138067	40158502	ヒト	生殖発生	-	-	-	-	-	-	コホート研究	1	1	-	-	-	1	1	1	-	1	-	-	-	-	-	-	-	-	-	-	-	-
統合_0063	J. Yang, H. Wang, H. Du, L. Xu, S. Liu, J. Yi, Y. Chen, Q. Jiang and G. He	2021	Serum Bisphenol A, glucose homeostasis, and gestational diabetes mellitus in Chinese pregnant women: a prospective study	Lab studies have suggested that exposure to Bisphenol A (BPA) could disturb glucose homeostasis, but epidemiologic studies are limited and show inconsistent results. For pregnant women. For this, 338 pregnant women were selected from a pregnant women cohort established in Tangshan City in North China between 2013 and 2014. Serum concentrations of BPA were measured in the early terms of pregnancy, and testing glucose and lipid levels were also measured in the same period. Gestational diabetes mellitus (GDM) was diagnosed between 24 and 28 weeks of gestation. Logistic regression was used to estimate the risk of GDM in terms of pregnancy. BPA was detected in 47.63% of pregnant women with a median of 0.49 ng/mL. Natural log-transformed BPA (Ln-BPA) was positively associated with fasting blood glucose (0.039; 95% CI: 0.003, 0.076) and triglycerides (0.099; 0.009–0.222), and homeostasis model insulin resistance index (HOMA-IR) (0.226; 0.087–0.365) in the middle term of pregnancy by multiple linear regression model after adjusting for potential confounders. After serum BPA levels were divided into three groups (low, middle, and high), BPA showed a positive dose–response relationship with fasting glucose, insulin, and HOMA-IR in the middle term of pregnancy. Increased BPA concentration tended to increase the RR of GDM although not statistically significant (risk ratio: 2.10; 95% CI: 0.88–5.00 for high vs. low tertile of BPA concentrations). These findings suggested that exposure to BPA might affect glucose homeostasis and the middle term of pregnancy was a potentially sensitive period.	Environ Sci Pollut Res Int. 2021 Mar;28(10):12546-12554.	10.1007/s11356-020-11263-4	33083951	ヒト	生殖発生(妊娠糖尿病)	-	-	-	-	-	-	コホート研究	1	1	-	-	-	1	1	1	-	1	-	-	-	-	-	-	-	-	-	-	-	-
統合_0064	C. F. Yang, W. J. J. Kamsaun, C. C. Yang, M. L. Chan and J. I. Wang	2020	Bisphenol a Exposure, DNA Methylation, and Asthma in Children	Epidemiological studies have reported the relationship between bisphenol A (BPA) exposure and increased prevalence of asthma, but the mechanisms remain unclear. Here, we investigated whether BPA exposure and DNA methylation related to asthma in children. We collected urinary and blood samples from 226 children (Childhood Environment and Allergic Diseases Study cohort aged 5 years. Thirty-three candidate genes potentially related to asthma were selected for methylation analysis. Urinary BPA was measured by high-performance liquid chromatography-tandem mass spectrometry (HPLC-MS/MS). Genome-wide DNA methylation levels were analyzed by Infinium MethylationEPIC BeadChip. Multivariate linear regression was used to examine the relationship between DNA methylation and BPA exposure and asthma risk. Associations between the methylation percentage and BPA exposure were also examined. Accordingly to our findings, MAPK1 showed differential methylation and was further investigated in 226 children. Adjusting for confounders, urinary BPA glucuronide (BPAG) had inversely correlated with MAPK1 promoter methylation (β = -0.08, p = 0.003). For the logistic regression analysis, MAPK1 methylation status was dichotomized into higher methylated and lower methylated groups with cut-off values of the median methylation percentage (78%) while performing the analysis. MAPK1 methylation was lower in children with asthma than in children without asthma (mean ± SD, 84.82 ± 1.68% vs. 79.82 ± 5.96%) (p = 0.001). Mediation analysis suggested that MAPK1 methylation acts as a mediation variable between BPA exposure and asthma. The mechanism of BPA exposure on childhood asthma might, therefore, be through the alteration of MAPK1 methylation. The mechanism of BPA exposure on childhood asthma might, therefore, be through the alteration of MAPK1 methylation. 統合_0065	S. S. Yalçın, E. Okmen, B. B. Kuykınmaz, S. Yalçın, O. Aykut and D. U. Gel-Nkaya	2025	Engraftment after pediatric hematopoietic stem cell transplantation and its association with recipient and donor phthalate and bisphenol A exposure levels: A cohort study	Phthalates and bisphenols, ubiquitous compounds found in various everyday products, have garnered attention due to their potential health-disrupting effects. This study aimed to (1) investigate urinary phthalate metabolite and bisphenol A (BPA) levels in pediatric hematopoietic stem cell transplantation (HSCT) recipients and their donors before and after transplantation, and (2) examine their time-dependent changes. Spot urine samples, collected before the conditioning regimen (day 0), day 5, day 7, day 14, day 21, day 42, and 12 months after transplantation, were analyzed for phthalate metabolites and BPA using high-performance liquid chromatography-tandem mass spectrometry (HPLC-MS/MS). Urine samples from patients' recipients and donors were collected for analysis of phthalate metabolites and BPA in 30 donor-recipient pairs. Monoethyl phthalate metabolite was not detectable in any of the urine samples. A notable increase in phthalate metabolites and BPA levels was observed in recipients starting from day 28. Granulocyte engraftment time showed a positive correlation with donor urinary levels of mono-n-butyl phthalate (MBP), mono-(2-ethylhexyl) phthalate (MEHP), and monobenzyl phthalate metabolites, with recipient MBP levels measured on day 0. Moreover, donor urinary MBP and MEHP levels were also linked to delayed platelet engraftment. No relationship was observed between engraftment timing and the urine levels of neonatal/infantile/childhood exposure to phthalates and BPA. Overall, this study suggests that HSCT may increase exposure to phthalates and BPA in recipients, and that the timing of engraftment may be influenced by the urine levels of phthalate metabolites and the levels of urine phthalate metabolites or BPA. These findings highlight the potential role of preclinician exposure in influencing engraftment outcomes, although no significant associations were found between MBP or BPA levels and engraftment. Ozcova	2022	Association of urine phthalate metabolites, bisphenol A levels and serum electrolytes with 24-h blood pressure profile in adolescents	BACKGROUND: Among the possible causes of hypertension in adolescence, electrolyte imbalances and environmental pollutants are drawing increasing attention. We aimed to examine the relationship between bisphenol A (BPA), phthalate metabolites, and serum electrolytes and blood pressure. METHODS: Eighty-six participants aged 12–16 years were included in the study. Body mass index (BMI), office blood pressure and 24-h ambulatory blood pressure measurements (ABPM), and carotid intima-media thickness were determined. Blood samples were taken for hemogram, renal function tests, and serum electrolytes. Urine and total BPA and phthalate metabolites were measured by LC-MS/MS. RESULTS: Mean age was 14.2 ± 1.4 years, and 52.3% were girls. Mean BMI was 21.2 ± 4.3 kg/m2. Forty-two (48.8%) adolescents in ABPM hypertension groups had higher BMI standard deviation score (SDS), glucose, cholesterol, insulin, fat mass/ lean mass ratio, compared to the normal blood pressure profile group. The percentage of adolescents with abnormal urinary mono- benzyl phthalate (MBzP) was higher in ABPM hypertensive (32.1%) and MCHT groups (33.3%), compared to the normal blood pressure profile group (6.9%, p = 0.002). Urinary BPA was detected in 72.1% of the participants. Urinary BPA concentrations were significantly higher in the ABPM hypertensive group (p = 0.001). Urinary mono-benzyl phthalate and 'albumin-corrected calcium-corrected per product' compared to others. Adolescents with abnormally urinary MBzP levels had higher blood pressure profiles, systolic blood pressure (SBP) daytime hypotatic blood pressure (SDS), and night-time/ linear arterial pressure SDS, systolic blood pressure SDS, and diastolic blood pressure (DBP) measurements, compared to others. MCHT was found to be associated negatively with incrementally phthalate and the sum of dibutyl phthalate metabolites and ABPM HT with BCPM. There was no significant association between blood pressure profiles and liver- and total BPA status. CONCLUSION: MBzP was associated with adverse blood pressure profiles. In adolescence. Additive follow- up studies are necessary for cause-effect relations. Xue	2021	Urinary levels of dimethoate, bisphenol A and benzo[a]pyrene in first-year students of Hohai University from different geographical regions	BACKGROUND: The objective of this study was to detect the urinary levels of dimethoate, benzo[a] pyrene (BaP), and bisphenol A (BPA) in first-year Hohai University students with different geographic origins. METHODS: First-morning urine samples were collected from 569 freshmen aged 16–19 years. Considering their living environment, 31 glucuronidase/sulfatase was combined with solid-phase extraction and liquid chromatography tandem mass spectrometry based method. Geometric means (GMs) of these three chemicals are presented by body mass index (BMI) and location in a volume based and creatinine-standardized way. RESULTS: The detection frequencies of dimethoate, BaP, and BPA were 100%, 100%, and 99.8%, respectively. The GMs of dimethoate, BaP, and BPA were 0.5, 0.2, and 1.3 μg/L, respectively. The GM of dimethoate in males was significantly higher than that in females. The individuals born in 2001 had higher GM concentrations of dimethoate, BPA, and 3-OHBaP. The individuals of Southwest China had significantly lower GM concentrations of dimethoate, BPA, and 3-OHBaP than those who lived in other locations in China. CONCLUSION: The average level of environmental chemical accumulation in freshmen is lower in Southwest China and differs in youth who live in different regions. In addition, obesity is correlated with higher toxic levels in youth. 統合_0068	Y. Xu, H. Gao, Z. Du, H. Liu, Q. Cheng, F. Zhang, J. Yu, A. Wang, Y. Dou, B. Ma, N. Zhao, F. Zhu, X. Xu, N. Shen, J. Wu and B. Xue	2022	A new approach for reducing pollutants level: a longitudinal cohort study of physical exercises in young people	BACKGROUND: The present study aimed to evaluate the elimination of three common pollutants (dimethoate, benzo[a]pyrene (BaP) and bisphenol A (BPA)) by different physical exercises and to assess the possible factors which could affect the pollutants elimination. METHODS: A total of 282 individuals who chose different kinds of exercises in accordance to their own wish were recruited. The levels of urinary pollutants were measured using β-glucuronidase/sulfatase hydrolysis followed by a high-performance liquid chromatography tandem mass spectrometry based method. RESULTS: Totally, the levels of dimethoate, BaP and BPA were reduced after physical exercises (all p < 0.05). Among the three pollutants, the elimination of BPA was the most significant (p < 0.001). Multivariate linear regression analysis showed that the level and BMI change was associated factor affecting the improvement effect of dimethoate, BaP and BPA while BMI (body mass index) was a risk factor. Nonetheless, the duration of Southwest China had significantly lower GM concentrations of dimethoate, BPA, and 3-OHBaP than those who lived in other locations in China. CONCLUSION: The present findings indicate that physical exercises can be considered as a novel approach to eliminate pollutants level in human body and can also give suggestions for choosing specific physical exercises to male and female individuals. Moreover, those who are with higher BMI need to lose weight before eliminating pollutant level through physical exercises. 統合_0069	S. Xu, X. Yuan, Y. Wang, Z. Fu, K. Chen, Z. Cui, L. Xu, H. Zhang, D. Xia and Y. Wu	2025	Bisphenols exposure at environmentally relevant dose promoted ovarian cancer progression and modulated tumor microenvironment through β-catenin/SPP1 axis	Bisphenol A (BPA) and its substitute, Bisphenol S (BPS) are typical endocrine-disrupting chemicals used in plastics, but their cancer-promoting effects has remained controversial. Here, we investigated the effects of environmentally relevant doses of BPA/BPS exposure on the tumor microenvironment (TME) in ovarian cancer. BPA exposure boosts was exhibiting a declining trend and BPS showing an ascending trend in the female population. Moreover, BPA and BPS exposure (0.5 μg/L, 5 μg/L, 50 μg/L) significantly promoted ovarian cancer progression in vivo and in vitro. Mechanistically, BPA and BPS activated the Wnt/β-catenin signaling pathway, thereby both inducing the SPP1 gene transcription. Notably, low dose BPA/BPS facilitated ovarian cancer cells to secrete SPP1 protein to adapt to the TME growth, subsequently fostering the transformation of fibroblasts into cancer-associated fibroblasts (CAFs), which could reshape the TME of ovarian cancer. Two in vivo experiments established with nude mice and SPP1(-/-) mice respectively, both confirmed that low dose BPA/BPS exposure increased the incidence of tumor metastasis accompanied by CAF infiltration, while administration of SPP1-neutralizing antibodies effectively blocked these effects. Our results indicated that exposure to either BPA or its substitute BPS could promote the release of secreted protein SPP1 into the β-catenin/SPP1 axis, ultimately modulating the TME and enhancing the progression of ovarian cancer, providing new evidence and potential intervention strategies for the toxicological assessment and management of bisphenols. 統合_0070	Y. Xiong, S. Xu, Z. Wang, Z. Wang, S. Li, M. Zhang and Y. Zhang	2024	BPA-free? Exploring the reproductive toxicity of BPA substitutes BPS and BPF on endometrial decidualization	Bisphenol A (BPA) exposure is linked to multiple adverse health outcomes, prompting the rise of "BPA-free" products. However, substitutes like Bisphenol S (BPS) and Bisphenol F (BPF) are equally prevalent, with detection frequencies and concentrations rivaling BPA. Our research previously identified BPS as an endocrine disruptor affecting reproductive and developmental systems. This study explores the impact of BPS, BPF, and BPF on endometrial decidualization and receptivity. We detected these bisphenols in serum samples from infertile women undergoing assisted reproductive technology (ART) treatment whose average age was 31.58 years. Human endometrial stromal cells were exposed to varying concentrations (1, 10, 50, 100, 500, and 1,000 μM) of BPA, BPS, and BPF, following hormonal induction of decidualization (0.5 mM 8-bromo-cAMP (8-Br-cAMP) and 10 μM medroxyprogesterone acetate) for 6 days). Methods including CCK-8, EdU, qPCR, untargeted metabolomics, and transcriptome sequencing assessed cell proliferation, decidualization markers, and metabolic changes. Results indicated that BPS and BPF exposure significantly reduced cell proliferation (p < 0.05) and impaired decidualization. Differential cell proliferation and reduced decidualization markers. Differential metabolites (FC, 1.5; 1.5) and gene expression (GSE6, NAB1, LEF1) were observed with BPS, BPF, and BPE exposure, respectively. Enriched pathways included glutathione metabolism, arginine biosynthesis, ABC transporters, cAMP signaling, and glycogen signaling. Metabolomics and transcriptome analyses unveiled the reproductive toxic effects of BPS and its substitutes, suggesting significant impacts on endometrial decidualization through diverse signaling pathways. 統合_0071	Y. Xiong, Z. Li, X. Xiong, Z. Luo, K. Zhong, J. Hu, S. Sun and C. Chen	2025	Associations between phenol and paraben exposure and the risk of developing breast cancer in adult women: a cross-sectional study	Increasing evidence suggests that endocrine-disrupting chemicals (EDCs) have adverse effects on breast cancer (BC). The aim of this study was to assess the association between exposure to prevalent EDCs (phenol, paraben) and the risk of developing BC in adult women. Data from 2,000 female participants aged ≥ 20 years with BC information in the National Health and Nutrition Examination Survey (NHANES) database were obtained from the 2005–2018 National Health and Nutrition Examination Survey. A total of 4,000 subjects were included in this cross-sectional study. The researchers first employed multivariable regression models to indicated that exposure to elevated concentrations of TRS increased the risk of developing BC by 2.32 (OR 95% CI = 1.05–5.76, p = 0.032) and 3.56 times (OR 95% CI = 1.23–10.86, p = 0.006), respectively. The nonlinear association between TRS concentrations and the risk of developing BC was statistically significant (P nonlinear = 0.007), and this nonlinear dose–response relationship was examined using restricted cubic splines (RCS) curve modeling on the natural log-transformed TRS concentrations. The association between TRS concentrations and the risk of developing BC was more pronounced among overweight individuals (BMI ≥ 25 kg/m2), those aged ≥ 60 years, and white individuals. Weighted quantile sum (WQS) and quantile-based g-computation (qgcomp) models revealed that exposure to TRS was significantly positively associated with BC risk (OR 95% CI = 1.19–1.68, p < 0.001). Furthermore, in the WQS model, 3,4-dichlorophenol, a chlorinated phenol, exhibited the highest weight (0.61). Sensitivity analyses confirmed that TRS, particularly in overweight individuals (BMI ≥ 25 kg/m2), those aged ≥ 60 years, and white individuals. 統合_0072	C. Xiong, L. Xu, X. Dong, Z. Cao, Y. Wang, K. Chen, M. Gao, S. Xu, Y. Li, W. Xia and A. Zhou	2023	Trimester-specific associations of maternal exposure to bisphenols with neonatal thyroid stimulating hormone levels: A birth cohort study	BACKGROUND: Growing evidence suggests that exposure to bisphenol A (BPA) during pregnancy could interfere with neonatal thyroid function. Bisphenol F (BPF) and bisphenol S (BPS) are increasingly used as the substitutes for BPA, but little is known about their potential thyroid disrupting effects. METHODS: We measured the urinary levels of BPA, BPF, and BPS in both maternal samples in the first, second, and third trimesters for bisphenol exposure assessment, and neonatal heel prick blood samples for TSH measurement. Multiple informant model and quantile g-computation were used to evaluate the trimester-specific associations of bisphenols individually and mixture with TSH, respectively. RESULTS: The Each doubling concentration increase of maternal urinary BPA in the first trimester was significantly related to a 3.58 % (95% CI: 0.58 %, 6.72 %) increment in neonatal TSH. Each doubling concentration increase of BPS in the first, second and third trimesters were associated with 3.58 % (95% CI: 0.58 %, 6.72 %), 3.58 % (95% CI: 0.58 %, 6.72 %), and 3.58 % (95% CI: 0.58 %, 6.72 %) increment in neonatal TSH, respectively. The concentration and TSH was observed. The relationship between exposure to BPA/BPS and neonatal TSH were more evident in female infants. Quantile g-computation indicated that maternal co-exposure to bisphenols in the first trimester was significantly associated with neonatal TSH levels in a non-linear fashion. CONCLUSIONS: Maternal exposure to BPA and BPS were positively associated with neonatal TSH levels. The results indicated the endocrine disrupting effect of prenatal exposure to BPS and BPA, which should be of particular concern. Zhou	2024	Associations of prenatal exposure to bisphenols with BMI growth trajectories in offspring within the first two years: evidence from a birth cohort study in China	BACKGROUND: Prenatal bisphenol exposure has been reported to be associated with lower birth weight and obesity-related indications in early childhood. These findings warrant an investigation of the relationship between prenatal bisphenol exposure and BMI growth trajectories in offspring within the first two years. METHODS: Maternal urine samples were collected during the first, second, and third trimesters. A total of 1,000 pairs of children aged up to two years and its identify the critical exposure periods. METHODS: A total of 850 mother-offspring pairs were recruited from Wuhan Children's Hospital between December 2013 and March 2016. Maternal urine samples collected during the first, second, and third trimesters were analyzed for bisphenol A (BPA), bisphenol S, and bisphenol F (BPF) concentrations. Measurements of height and weight were taken at 0, 1, 6, 8, 12, 18, or 24 months. Children's BMI was assessed according to the World Health Organization criteria, and group-based trajectory modeling was used to identify BMI growth trajectories. The associations between prenatal bisphenol exposure and BMI growth trajectory patterns were assessed using multinomial logistic regression models. RESULTS: The BMI growth trajectories of the 826 children were categorized into three groups: "Low-stable" (n = 413, 50.0%), "Medium-increasing" (n = 330, 40.0%), and "High-increasing" (n = 83, 10.0%). Children in the "High-increasing" group had the highest prenatal exposure to BPA during the second trimester (odds ratio (OR) = 2.38, 95% confidence interval (CI) = 1.09–5.22) and BPF during the third trimester (OR = 1.59, 95% CI: 1.03–2.47) of the children's quartile concentration were associated with an increased likelihood of the low-increasing BMI trajectory. Furthermore, in the subgroup analysis by infant sex, the positive association between the highest quartile of prenatal exposure to BPA and BPF concentration during the whole pregnancy and the low-increasing BMI trajectory was found only in girls (OR = 2.42, 95% CI = 1.02–5.68). CONCLUSIONS: Our study findings suggest that prenatal exposure to BPA and BPF is commonly and substitute for BPA is associated with BMI growth trajectories in offspring during the first two years, increasing the likelihood of the low-increasing pattern. 統合_0074	T. Xiao, Z. Huang, C. Zhang, B. Quach, Y. Zhu, F. Li, W. Liang, J. Baker, C. Reichetzeder, B. Hocher and Y. Yang	2024	Associations of bisphenol A exposure with metabolic syndrome and its components: A systematic review and meta-analysis	Mounting evidence shows that bisphenol A (BPA) is associated with metabolic risk factors. The aim of this study was to review related epidemiologic studies and conduct a meta-analysis to quantitatively estimate the association between BPA and metabolic syndrome. Four electronic databases were systematically searched to identify suitable articles. A total of 47 published studies were finally included. Two studies involved metabolic syndrome (N for 17, 11 16, and 13 studies on the relationship between BPA with abdominal obesity, blood pressure, fasting plasma glucose, and dyslipidemia, 31, 6, 5, and 6 studies were included in the meta-analysis, respectively. Pooled odds ratios (ORs) with 95% confidence intervals (CIs) were calculated using random-effects models. Higher BPA exposure was associated with MetS (OR = 1.46, 95%CI: 1.31–1.63; I2 = 0%), abdominal obesity (OR = 1.53, 95%CI: 1.33, 1.76; I2 = 0%), hypertension (OR = 1.16, 95%CI: 1.01, 1.33; I2 = 0%), fasting plasma glucose (OR = 1.22, 95%CI: 1.03–1.44; I2 = 0%), and dyslipidemia (OR = 1.16, 95%CI: 1.01, 1.33; I2 = 0%). However, there was no significant association between BPA exposure and metabolic syndrome components including hypertension, abnormal fasting plasma glucose, and dyslipidemia. The present study found that BPA exposure is significantly associated with a higher risk of abdominal obesity. However, the relationship between BPA with metabolic syndrome and its other components needs further longitudinal studies to verify. 統合_0075	L. Xiao, X. Wen, L. Li and Y. Li	2024	Correlation of bisphenol A and bisphenol S exposure with the metabolic parameters on FDG PET/CT image	PURPOSE: Bisphenol A (BPA) and its analogs have been proved to be harmful to human health. This study aimed to assess the correlation of BPA and its major analog, Bisphenol S (BPS), with metabolic parameters within main organs using 18F-fluorodeoxyglucose positron emission tomography/computed tomography (18F-FDG PET/CT) imaging. METHODS: A retrospective analysis was conducted on patients who had undergone FDG PET/CT imaging and urine was examined for BPA and BPS levels. Urine samples were collected for detection of BPA and BPS. Standardized uptake values (SUVmean) and SUV(mean) of main organ tissues including liver (SUVliver), fat (SUVfat), and muscle (SUVmuscle) were measured. Pearson correlation analysis was used to assess the correlation between BPA and BPS levels and SUVmean. RESULTS: A total of 100 patients were included. Urine samples revealed detectable BPA and BPS concentrations in 67.0 % (67/100) and 11.0 % (11/100), respectively. Urine BPA exhibited a moderate positive correlation with liver SUVmean (r = 0.381, p < 0.001) and SUVmuscle (r = 0.362, p < 0.001). Urine BPS showed a weak positive correlation with liver SUVmean (r = 0.222, p = 0.027). Conversely, urine BPS demonstrated a negative correlation with thyroid SUVmean (r = -0.413, p < 0.001) and SUVmuscle (r = -0.332, p < 0.001), while a positive correlation was observed between BPS and cerebral cortex SUV(mean) (r = 0.386, p < 0.001). CONCLUSIONS: Urinary levels of BPA and BPS exerted distinct influences on tissue metabolic parameters observed via FDG PET/CT imaging, particularly affecting the liver, thyroid, and cerebral cortex. 統合_0076	Z. Xiang, H. Wang, K. Zhu, R. Liu, S. Zhao, H. Fan, Q. Chen, B. Zhu and R. Song	2025	Phenol exposure, polygenic risk score, and dyslexia in Chinese children: Gene-environment interaction	Phenols, widespread environmental chemicals, may influence neurodevelopment, but their association with dyslexia remains poorly understood. This case-control study, part of the Tongji Reading Environment and Dyslexia Research Project, included 1282 children. We measured urinary levels of three bisphenols, three benzophenones, and two antimicrobials, and constructed a dyslexia-specific polygenic risk score (PRS) using genome-wide association study data. Conditional logistic regression assessed the relationship between phenol exposure and dyslexia risk. Participants were stratified by low or high PRS, and multiplicative and additive models were used to examine the modifying role of genetic susceptibility. Phenol compounds were detected in most urine samples. Elevated urinary bisphenol A (BPA) levels were significantly associated with increased dyslexia risk (OR = 1.39, 95% CI: 1.03–1.87, p = 0.029), and this association was more pronounced among children with high genetic susceptibility (OR = 1.75, 95% CI: 1.22–2.51). Compared to those with low PRS and low BPA exposure, those with high PRS and high BPA exposure had a substantially higher dyslexia risk (OR = 1.75, 95% CI: 1.22–2.51). No significant interaction was observed between PRS and BPA exposure. These findings underscore the importance of reducing BPA exposure as a potential preventive measure and highlight the need for further research to elucidate causal pathways and mechanisms underlying these associations. 統合_0077	Z. Xia, C. Lu, Y. Zhang, R. Shi, Q. Lu, Y. Tian, X. Lei and Y. Gao	2023	Associations of exposure to bisphenol A and its substitutes with neurodevelopmental outcomes among infants at 12 months of age: A cross-sectional study	BACKGROUND: Bisphenol A (BPA) exposure has been linked to adverse childhood neurodevelopment, but little is known about whether BPA substitutes exposures are also related to childhood neurodevelopment. OBJECTIVES: To investigate the associations of exposure to BPA and its substitutes with infant neurodevelopment at 12 months. METHODS: A total of 320 infants at 12 months were included from the Laizhou Wan Baseline Cohort Study. Urinary concentrations of BPA, bisphenol S (BPS), bisphenol F (BPF), and bisphenol AF (BPAF) were measured by ultra-performance liquid chromatography-tandem mass spectrometry. Infant neurodevelopment was measured by Ages and Stages Questionnaires, Third Edition (ASQ-3). Five domain scores measured: Developmental quotient (DQ) scores based on the Gesell Development Schedules (GDS) were used to evaluate infant neurodevelopment. The multivariable linear regression and weighted quantile sum (WQS) regression were applied to estimate the associations of exposure to individual bisphenols and their mixtures with DQ scores, respectively. Dose-stratified analyses were also performed. RESULTS: BPA was detected in 99.4% of urine samples, followed by BPS (93.8%), BPF (83.8%), and BPAF (58.1%). Urinary concentrations of BPA, BPS, BPF, and BPAF were 1.10 ng/mL, 0.14 ng/mL, 0.10 ng/mL, and 0.03 ng/mL, respectively. BPA was positively associated with social DQ scores among all infants (β = 0.59; 95% CI: 0.002, 0.09). After sex stratification, this inverse association was significant in girls (β = 0.085; 95% CI: -0.002, 0.180). Besides, BPA exposure was negatively related to gross motor DQ scores in boys (β = -0.065; 95% CI: -0.078, -0.005). WQS analyses confirmed these results. CONCLUSIONS: Our study suggests that bisphenol exposure during infancy may be associated with poor infant neurodevelopment, and BPAF as a commonly used BPA substitute contributing the most to this adverse association deserves more attention. 統合_0078	J. Xi, X. Su, Z. Wang, H. Ji, Y. Chen, X. Liu, M. Miao, H. Liang and W. Yuan	2023	The associations between concentrations of gestational bisphenol analogues and thyroid related hormones in cord blood: A prospective cohort study	Human studies indicated that Bisphenol analogues (BPs) exhibited potential thyroid toxicity. However, little is known of the associations between maternal BPs exposure and offspring's thyroid related hormones in humen. On the basis of Shanghai Minhang Birth Cohort study, we analyzed BPs in maternal urine collected at the third trimester of pregnancy. Thyroid related hormones (TRs), including total triiodothyronine (TT3), free triiodothyronine (FT3), total thyroxine (TT4), free thyroxine (FT4) and thyroid stimulating hormone (TSH) were measured in cord blood samples. We performed multiple linear regression and Bayesian kernel machine regression (BKMR) models to explore the associations between BPs and TRs. Generalized additive models (GAM) were used to explore the nonlinear dose-response relationships. Stratified analyses by infant sex were conducted. Results showed that the detection frequencies of BPs were all above 80%. Compared to the first quartile group, the third quartile group of BPA was associated with 7.7% increment in FT4 and the fourth quartile group of BPA was associated with 6.2% increment in FT3 (all p < 0.05). Meanwhile, we observed that BPA exposure was associated with 7.7% increment in FT4 and 6.2% increment in FT3 in female infants, but not in male infants. Exposure to BPA and BPAF might have sex-specific associations with thyroid hormones in cord blood. A prospective cohort study was conducted to explore the associations between maternal BPs exposure and offspring's thyroid related hormones in cord blood. We found that BPA exposure was associated with increased FT3 and FT4 levels in cord blood, and the effects were more pronounced in female infants. Our findings suggested that BPA might have sex-specific associations with thyroid hormones in cord blood. 統合_0092	J. B. Ward, S. S. Casagrande and C. C. Cowie	2020	Urinary phenols and parabens and diabetes among US adults, NHANES 2005-2014	BACKGROUND AND AIMS: Phenols and parabens are ubiquitous and have been associated with markers of cardiovascular health. However, the literature lacks population-based studies examining the link between these endocrine disruptors and diabetes. We examined the association between paraben/phenol concentrations and diabetes among a nationally representative sample of US adults. METHODS AND RESULTS: We utilized data from the National Health and Nutrition Examination Survey (NHANES) 2005-2014. Urinary concentrations of 2 parabens and 5 phenols were measured in a subsample of participants selected during the examination session. Diabetes status was based on self-report of a previous diagnosis or HbA1c ≥6.5%. We used logistic regression to estimate odds ratios (ORs) and 95% confidence intervals. ß-S associated with the difference in log-transformed values of the 75th and 25th percentiles for each phenol/paraben, adjusting for potential confounders. The adjusted ORs (95% CI) of diabetes comparing the 75th to 25th percentiles were 1.13 (1.04, 1.23) for methyl paraben, 1.10 (1.01, 1.20) for propyl paraben, 1.06 (0.96, 1.17) for 2,5-dichlorophenol, 1.08 (0.98, 1.19) for BP-3, 0.95 (0.82, 1.09) for BP-1, 0.73 (0.62, 0.87) for triclosan, 0.89 (0.82, 0.97) for BP-8, 0.72 (0.62, 0.83) for propyl paraben, and 0.79 (0.68, 0.91) for methyl paraben. CONCLUSIONS: Higher concentrations of triclosan, BP-3, and propyl, butyl, ethyl, and methyl parabens were associated with lower odds of diabetes. These findings suggest further investigation into the potential mechanisms behind the observed associations and the temporal direction of the associations, given that we cannot rule out reverse causation. Future studies of these endocrine disruptors may improve the understanding of their relationship with diabetes. 統合_0093	Z. Wang, Y. Zhou, H. Liang, M. Miao, Y. Chen, X. Zhang, X. Song and W. Yuan	2021	Prenatal exposure to bisphenol analogues and digit ratio in children at ages 4 and 6 years: A birth cohort study	Bisphenol analogues (BPs), including bisphenol A (BPA), have been shown to exhibit similar endocrine disrupting activities. However, epidemiological evidence on the reproductive and developmental toxicities of BPs other than BPA is scarce. The second-to-fourth digit ratio (2D:4D), an endocrine-sensitive endpoint, has been suggested to be a biomarker of prenatal sex steroid exposure and associated with reproductive outcomes in later life. Using the data of 585 mother-child pairs from the Shanghai Maternal-Infant Nutrition and Health Cohort Study, we prospectively assessed the effects of prenatal exposure to BPs, among 8 BPs mother's third urine samples were collected in the third trimester and analyzed for BPs. Digit lengths were measured using a vernier caliper in children at ages 4 and 6 years, and the 2D:4D values for both hands were calculated. A multivariate linear regression model was applied to estimate the associations between maternal BPs and 2D:4D values in children at ages 4 and 6 years, respectively. Maternal BPA was detected in 100% of the samples with repeated 2D:4D measures, determined at ages 4 and 6 years. We found that prenatal exposure to BPA, alternatives including BPF, BPS, and MHPP, was associated with higher digit ratio (2D:4D) and in girls (increasing 2D:4D) in children. In contrast, TCBPA was suggestively associated with higher 2D:4D in boys. Interestingly, These associations were more pronounced at 6 years of age, and tended to remain after further considering the potential confounding from prenatal co-exposure to other BPs and childhood BPs exposure. Our study provides epidemiological evidence that BPs exposure during pregnancy may alter the digit development in children, indicative of disrupted reproductive development in later life. Given these new findings, further studies are needed to corroborate our results. 統合_0094	Z. Wang, M. Miao, J. Xu, Y. Chen, H. Liang, L. Yang, X. Liu, S. Wan, X. Tu and W. Yuan	2022	Gestational exposure to bisphenol analogues and kisspeptin levels in pregnant women and their children: A pregnancy-birth cohort study	Gestational exposure to bisphenol analogues (BPs), , especially bisphenol A (BPA), has been associated with adverse pregnancy-related outcomes and altered reproductive development of offspring, but the underlying mechanisms are not well documented. Kisspeptin, a key regulator of reproductive health, could be the potential target for endocrine-disrupting compounds. Six BPs, among BPA-mother-child pairs, we investigated the associations of gestational BPs exposure with kisspeptin levels in two critical life stages, pregnancy and per-puberty. Maternal BPs and kisspeptin concentrations were measured in urine samples collected in the third trimester. Children's urine samples were collected at 9 years old and analyzed for kisspeptin levels. Associations were observed between BPS and its alternatives and maternal kisspeptin in pregnant women but higher kisspeptin in their children. In contrast, TCBPA was suggestively associated with higher kisspeptin in pregnant women but lower kisspeptin in children. Our study provides the first epidemiologic evidence that gestational exposure to substituted BPs may be associated with altered kisspeptin system in both pregnant women and their children, sheds some light on the potential mechanisms underlying the various reproductive health outcomes following gestational BPA exposure, and suggests potential reproductive toxicities of other BPs in humans.	Sci Total Environ. 2022 Nov 20:848:157720.	10.1016/j.scitotenv.2022.157720	35914601	ヒト	-	-	-	-	-	-	コホート研究	1	1	-	-	-	1	1	1	-	-	-	-	-	-	-	-	-	-	-	-	-	-
統合_0095	Y. Wang, H. Wu, K. Li, R. Huang, J. Liu, Z. Lu, Y. Wang, J. Wang, Y. Du, X. Jin, Y. Xu and B. Li	2024	Environmental triggers of autoimmunity: The association between bisphenol analogues and systemic lupus erythematosus	The aim of this research was to examine the correlation between the exposure to bisphenol analogues (BPAs), such as bisphenol A (BPA), bisphenol F (BPF), and bisphenol S (BPS), and the risk of developing systemic lupus erythematosus (SLE). Ultra-performance liquid chromatography/tandem mass spectrometry (UPLC-MS/MS) was utilized to measure the levels of BPS, BPF, and BPA in the urine of 168 female participants diagnosed with SLE and 175 female participants who were deemed healthy controls. Logistic regression models were utilized to assess the connections between levels of bisphenol and the risk of SLE. The findings indicated that levels of BPA and BPF in the urine of individuals with SLE were markedly elevated compared to those in the control group. Higher exposure to BPA and BPF individually or their mixtures was associated with increased SLE risk. No significant associations were identified between BPS and the risk of SLE. These findings suggest exposure to BPA and BPF may be implicated as novel environmental triggers in the development of autoimmunity. The study's cross-sectional design limits causal inferences, and the relatively small sample size may affect the generalizability of the results. Elevated BPA and BPF levels, coupled with increased SLE risk, underscore crucial criteria for comprehending how endocrine-disrupting substances contribute to the genesis of autoimmune illnesses. Further research using robust longitudinal assessments of bisphenol analogue exposures is warranted to corroborate these epidemiological findings. Overall, this study highlights potential environmental risk factors for SLE while calling for additional investigation into the impact of bisphenol exposures on autoimmunity development. 統合_0096	Y. Wang, R. Aimuzi, M. Nian, Y. Zhang, K. Luo and J. Zhang	2021	Bisphenol A substitutes and sex hormones in children and adolescents	Bisphenol F (BPF) and bisphenol S (BPS) are increasingly used as bisphenol A (BPA) substitutes in consumer products. Little is known about the effects of BPA substitutes on reproductive endocrine function in children and adolescents. Thus, we conducted a cross-sectional study to examine the associations of BPA, BPF, and BPS with sex steroid hormones among 6-19 year-old participants. Included were 1017 participants with information on BPA, BPF, BPS, and serum sex hormones (total testosterone (TT), estradiol (E2), and sex hormone-binding globulin (SHBG)). Multiple linear regression models were used to assess the association between bisphenols and sex hormones by sex age groups. Bisphenol-response (DR) relationships were examined via restricted cubic splines. Significant association with BPF or BPS was generally observed among males. Urinary BPF was positively associated with TT in 6-11 year-old males (β = 0.10; 95% CI: 0.01, 0.19) and 12-19 year-old males (β = 0.08; 95% CI: 0.01, 0.15). Urinary BPS was positively associated with TT among pre-pregnancy BMI < 25 kg/m2), with adjustment for maternal age, maternal education, gestational diabetes mellitus, SHBG, isolated smoking during pregnancy, and gestational age at hospital presentation, measured, but no association was observed in pre-pregnancy BMI ≥ 18.5, or 18.5-23.9 kg/m2) stratum. No BPA- associated changes were observed in maternal FT3 level or odds of positive TPO-Ab in adult males or adult females among pre-pregnancy BMI < 18.5 kg/m2 stratum. No associations were observed between prenatal urinary BPA concentration and maternal FT4, FT3, TSH levels, and odds of positive TPO-Ab in both male and female mothers among pre-pregnancy BMI < 18.5, 18.5-23.9 or ≥ 24 kg/m2 stratum. In this study, prenatal urinary BPS concentration was associated with lower maternal TSH among women with overweight, but not associated with other maternal thyroid parameters. Associations of prenatal thyroid parameters across maternal BMI categories. More research on pregnant women and newborns cohort with BPS exposure are warranted. 統合_0097	X. Wang, N. Tang, S. F. Nakayama, P. Fan, Z. Liu, J. Zhang and F. Ouyang	2020	Maternal urinary bisphenol A concentration and thyroid hormone levels of Chinese mothers and newborns by maternal body mass index	Animal studies indicated that bisphenol A (BPA) exposure during pregnancy may disrupt thyroid function which is critical for fetal development. However, the epidemiological studies have examined this topic and the results were inconsistent. We aimed to evaluate whether prenatal BPA exposure is associated with thyroid hormone levels in Chinese mothers and newborns with overall cohort and by maternal body mass index (BMI). BPA concentrations were measured in urine samples collected from 559 women at late pregnancy and 559 newborns at birth. Maternal serum free thyroxin (FT4), thyroid-stimulating hormone (TSH) and thyroid peroxidase antibody (TPO-Ab) concentrations at the third trimester were abstracted from medical records. Cord serum free triiodothyronine (FT3), FT4, TSH, and TPO-Ab levels were measured in 386 newborns. Prenatal urinary BPA was detected in 97.3% of the samples with a median level of 2.1 μg/g Cr. Each 10-fold increase in maternal BPA was associated with a 0.19 (95% CI: 0.03, 0.35) ng/dL increase in FT4 and a 0.16 (95% CI: 0.01, 0.31) ng/dL increase in FT3 among pre-pregnancy BMI < 25 kg/m2), with adjustment for maternal age, maternal education, gestational diabetes mellitus, SHBG, isolated smoking during pregnancy, and gestational age at hospital presentation, measured, but no association was observed in pre-pregnancy BMI ≥ 18.5, or 18.5-23.9 kg/m2) stratum. No BPA- associated changes were observed in maternal FT3 level or odds of positive TPO-Ab in adult males or adult females among pre-pregnancy BMI < 18.5 kg/m2 stratum. No associations were observed between prenatal urinary BPA concentration and maternal FT4, FT3, TSH levels, and odds of positive TPO-Ab in both male and female mothers among pre-pregnancy BMI < 18.5, 18.5-23.9 or ≥ 24 kg/m2 stratum. In this study, prenatal urinary BPA concentration was associated with lower maternal FT4 among women with overweight, but not associated with other maternal thyroid parameters. Associations of prenatal thyroid parameters across maternal BMI categories. More research on pregnant women and newborns cohort with BPS exposure are warranted. 統合_0098	X. Wang, Z. C. Luo, O. Du, H. J. Zhang, P. Fan, R. Ma, Y. Chen, W. Wang, J. Zhang and F. Ouyang	2023	The association between maternal urinary Bisphenol A levels and neurodevelopment at age 2 years in Chinese boys and girls: A prospective cohort study	The impact of maternal exposure to Bisphenol A on child cognitive development as well as its sex dimorphism remains uncertain. This study used data of 335 mothers and their children from a birth cohort in Shanghai. Urinary BPA was measured in spot urine samples of mothers at late pregnancy and children at age 2 years. Cognitive development was evaluated by Ages & Stages Questionnaires, Third Edition (ASQ-3) at age 2 years. Logistic regression models were used to estimate the associations between maternal BPA and ASQ-3 delay. Maternal BPA was detected in 100% of the samples with a median level of 2.1 μg/g Cr. BPA concentrations were associated with 4.8 points lower (95% CI: -9.0, -1.2) gross motor and 3.2 points lower (95% CI: -5.6, -0.2) in problem-solving domain in girls, only with adjustment for maternal age, maternal education, pre-pregnancy BMI, passive smoking during pregnancy, parity, delivery mode, birth weight for gestational age, child age at ASQ-3 test). This negative association remained with additional adjustment for child urinary BPA concentrations at age 2 years. No association was observed in boys. These results suggested the sex dimorphism in the associations of maternal BPA exposure with gross motor and problem-solving domains in children at age 2 years. This study also indicated that optimal early child development should start with a healthy BPS-free "in utero" environment.	Ecotoxicol Environ Saf. 2023 Oct 1:264:115413.	10.1016/j.ecoenv.2023.115413	37651794	ヒト	-	-	-	-	-	-	コホート研究	1	1	-	-	-	-	1	1	-	-	-	-	-	-	-	-	-	-	-	-	-	-
統合_0099	X. Wang, Z. Hu, Y. Jin, M. Yang, Z. Zhang, X. Zhou, S. Qiu and X. Zou	2024	Exploring the relationships between exposure levels of bisphenols and phthalates and prostate cancer occurrence	We established an ultra-performance liquid chromatography-tandem mass spectrometry (UPLC-MS/MS) method to simultaneously analyze the metabolites of bisphenols and phthalates in urine to identify the correlation between exposure levels and prostate cancer (PCa). A hospital-based case-control study, 20 matched pairs were sampled, with 40 metabolites were separated on an ACQUITY HSS T3 column and MS detection was performed. The UPLC-MS/MS method has been proven effective at analyzing bisphenol and phthalate exposure. The limit of detection (LOD) and limit of quantification (LOQ) ranged from 0.009-0.131 μg/L and 0.028-0.436 μg/L, respectively. The detection rates of bisphenol A (BPA) and most phthalate metabolites were 100 %, ranging from 0.06 % to 100 % and 0.12-99.92 % in PCa patients and CG (BPAP) and 4-nonylphenol (4NP), respectively, while the detection rates of other bisphenols and most benzyl phthalate (BBzP) are low, ranging from 0 % to 10.12 %. Considering the variations of the metabolite levels, indicated that the exposure sources of BPS, di-ethyl phthalate (DEP), and di(2-ethylhexyl) phthalate (DEHP) were different, and that the exposure sources of di-n-octyl phthalate (DnOP) and di-isobutyl phthalate (DiBP) may differ between two groups. Logistic regression analysis revealed that BPA (OR=2.43 (95 % CI: 1.03-5.72)) and DEHP exposure (OR=21.75 (95 % CI: 1.45-325.18)) increased the risk of PCa. 統合_0100	P. W. Wang, Y. F. Huang, C. H. Wang, L. J. Fang and M. L. Chen	2024	Prenatal to preschool exposure of nonylphenol and bisphenol A exposure and neurodevelopment in young children	BACKGROUND: Nonylphenol (NP) and bisphenol A (BPA) are produced in large quantities worldwide as multipurpose agents. However, studies on relations between NP and BPA exposure and childhood neurodevelopment are few, and the results are inconsistent. This study aimed to investigate associations between prenatal and early childhood NP and BPA exposure and neurodevelopment in mother-child pairs. METHODS: Pregnant women at 21-36 weeks gestation were recruited, we were children 2-3 years of age (n = 96) and 4-5 years of age (n = 96) participated in this study. Urine was collected to assess NP and BPA exposure. Rates of Infant and Toddler Development Checklists Ruyky-III, Wechsler Preschool and Primary Scale of Intelligence (5th edition), and the Full-Scale Intelligence Quotient (WPPSI-IV-FSIQ) were used to assess the neurodevelopment of the children. RESULTS: Prenatal NP exposure was associated with lower cognitive development in 2-3 years old children. Compared to children in the lowest quartile of prenatal NP exposure, children in the third quartile had a reference group (1st and 2nd tertiles) based on natural log-transformed urine concentration of NP and BPA. Girls Ruyky-III motor scores in the high concentration group were higher than those of the BPA reference group (coef. of reference group (coef. = 4.46, 95% confidence interval [CI]: 1.68-12.23, Bayz FDR); in the higher concentration group were significantly lower than those in children 2-3 years old in the NP reference group (df. = -11.76, 95% CI: -18.61 to -5.90, adj. p = 0.01). CONCLUSIONS: Prenatal and childhood exposure to NP and BPA may have different effects on the neurodevelopment of young children, and there are no consistent effects between boys and girls.	Pediatr Neonatol. 2024 Jan;65(1):76-84.	10.1016/j.pedneo.2023.04.011	37679260	ヒト	-	-	-	-	-	-	コホート研究	1	1	-	-	-	-	1	1	-	-	-	-	-	-	-	-	-	-	-	-	-	-
統合_0101	N. Wang, Y. Wang, H. Zhang, Y. Gao, C. Chen, W. Zhang, H. Wan, J. Han and Y. Lu	2020	Association of bone mineral density with nine urinary personal care and consumer product chemicals and metabolites: A national-representative, population-based study	Personal care and consumer products are extensively used and contain various chemicals that are recognized as endocrine disrupting chemicals. Few epidemiological studies measured the associations of these chemicals and metabolites, especially phenols, with bone health. We measured the associations between nine urinary phenol biomarkers and BMD and the subsequent prevalence of osteopenia/osteoporosis. National representative data from 1/2 adults aged over 20 years who participated in the National Health and Nutrition Examination Survey from 2005 to 2010 were used. 2,567 men, 1,118 premenopausal women and 1,283 postmenopausal women were included in the analysis. Urinary concentrations of nine phenols were measured using automated solid-phase extraction coupled with high performance liquid chromatography-tandem mass spectrometry. Paraben concentrations, especially ethyl-, methyl- and propylparabens, were related to lower BMD in the femoral neck and trochanter,lumbar and lumbar spine in men and premenopausal women. 2,5-dichlorophenol concentrations was associated with lower BMD and a higher prevalence of osteopenia + osteoporosis in men. Bisphenol A was associated with a higher prevalence of osteopenia + osteoporosis in the lumbar spine in postmenopausal women. Benzophenone-3 tended to be associated with a higher BMD at femur in men and premenopausal women. In conclusion, certain urinary personal care and consumer product chemicals and metabolites were significantly associated with BMD or osteopenia + osteoporosis. These results further indicate that, in future research, determination of the causal relationships and elaboration of underlying mechanisms could be most important directions.	Environ Int. 2020 Sep:142:105865.	10.1016/j.envint.2020.105865	32585503	ヒト	-	-	-	-	-	-	横断研究	1	1	-	-	-	-	1	1	-	-	-	-	-	-	-	-	-	-	-	-	-	-
統合_0102	L. J. Wang, Y. H. Huang, W. J. Chiu, S. Y. Lee, H. Y. Chang, C. C. Chen and H. R. Chao	2023	Interrelationships among growth hormone, thyroid function, and endocrine-disrupting chemicals on the susceptibility to attention-deficit/hyperactivity disorder	Abnormal growth hormones and thyroid function may be linked to pathophysiology of attention-deficit/hyperactivity disorder (ADHD). Phthalates and bisphenol A (BPA), two endocrine-disrupting chemicals (EDCs), may affect the human endocrine system. In this study, we aimed to perform a comprehensive investigation of whether growth hormone, thyroid function, and EDCs exhibited potential mutual associations in ADHD patients and healthy controls. In total, 150 children with ADHD and 70 healthy control subjects were enrolled. Their endocrine systems were evaluated using the serum levels of insulin-like growth factor-1 (IGF-1), IGF- binding protein-3 (IGFBP-3), thyroid-stimulating hormone (TSH), triiodothyronine (T3), thyroxine (T4), and free T4. The urinary levels of EDCs, including monoethyl phthalate (MEP), monobutyl phthalate (MBP), monoethylhexyl phthalate (MEHP), mono-n-butyl phthalate (MnBP), monobenzyl phthalate (MBzP), and BPA, were also examined. Patients with ADHD had lower IGF-1 levels than healthy controls (p = 0.003), but we observed no significant differences in IGFBP-3, TSH, T3, T4, and free T4 between the two groups. Children with ADHD had higher urinary levels of MEP (p = 0.001), MBP (p = 0.001), MEHP (p = 0.001), MnBP (p = 0.001), MBzP (p = 0.001), and BPA (p = 0.001) than healthy controls. Urinary MEP, MBP, MEHP, MnBP, MBzP, and BPA levels (p < 0.001) were significantly correlated with ADHD symptoms. In a linear regression model, urinary MEP, MBP, MEHP, MnBP, MBzP, and BPA levels were negatively correlated with IGF-1 levels, but not with IGFBP-3, TSH, T3, T4, and free T4 levels. Urinary MEP, MBP, MEHP, MnBP, MBzP, and BPA levels (p < 0.001) were significantly correlated with ADHD symptoms and neuropsychological performance variables. We suggest that MEHP exposure may be associated with decreased serum levels of IGF-1 and increased risk of ADHD. The mechanism underlying this association may be important for protecting children from environmental chemicals that adversely affect neurodevelopment.	Eur Child Adolesc Psychiatry. 2023 Aug;32(8):1391-1401.	10.1007/s00787-021-01886-4	35119524	ヒト	-	-	-	-	-	-	症例対照研究	1	1	-	-	-	-	1	1	-	-	-	-	-	-	-	-	-	-	-	-	-	-
統合_0103	J. Wang, H. Mei, A. F. Zhou, L. L. Huang, Z. Q. Cao, A. B. Hong, M. Yang, Q. T. Xia, D. Chen, S. P. Yang, H. Xiao and P. Yang	2021	The associations of birth outcome differences in twins with prenatal exposure to bisphenol A and its alternatives	BACKGROUND: Bisphenol A (BPA) and its alternatives, including BPF and BPS, exhibit endocrine disruption activities. However, the effects of bisphenols on fetal growth in twins remain unclear. OBJECTIVE: To explore the associations of prenatal BPA, BPF, and BPS exposure with birth outcome differences in twins. METHODS: We recruited 288 twin pregnant women who visited the hospital for prenatal examination during the first trimester from 2017 to 2019. Maternal urine samples were collected during the first trimester. Birth outcomes were obtained from medical records. Multivariate linear regression models were applied to estimate the associations between prenatal bisphenol exposure and birth outcome differences in twins. We applied the multiple informant model to evaluate interactive associations between twins' bisphenol concentrations and birth outcome differences in twins. RESULTS: We found low reproducibility (ICC<0.40) for maternal urinary BPA and moderate reproducibility (0.40 < ICC <0.75) for BPF and BPS. Urinary BPA concentrations were positively associated with within-pair twin birth weight difference when comparing the third vs. the first tertile in each of the three trimesters (i.e., 130.0 g, 95% CI: 68.38, 191.6 g; 89.63 g, 95% CI: 38.38, 140.9 g; 84.21 g, 95% CI: 37.17, 131.2 g, in the 1st, 2nd, and 3rd trimester, respectively). The effect of urinary BPA concentration on increased birth length difference within pair twins were also observed across different trimesters (87.9 for trends < 0.05). Urinary BPS levels were positively associated with the within-pair birth weight and birth length differences across pregnancy trimesters (36 of Type I? for values < 0.05). CONCLUSIONS: Maternal BPA exposure appeared to influence birth weight and birth length differences in twins. Our results warrant further confirmation.	Environ Res. 2021 Sep:200:111459.	10.1016/j.envres.2021.111459	34126051	ヒト	-	-	-	-	-	-	コホート研究	1	1	-	-	-	-	1	1	-	-	-	1	-	-	-	-	-	-	-	-	-	-
統合_0104	H. Wang, S. Tang, X. Zhou, R. Gao, Z. Liu, X. Song and F. Zeng	2022	Urinary concentrations of bisphenol analogues in the south of China population and their contribution to the per capital mass loads in wastewater	Bisphenol analogues (BPs) are broadly used and negatively affect the health of human beings, however, there is little knowledge regarding human exposure to BPs other than BPA. This study aims to assess human exposure to BPs through investigating predictive and wastewater samples. Twenty-four pooled urine samples were prepared from 960 specimens (class-field by age and gender). Wastewater samples were collected from six major wastewater treatment plants (WWTPs) in Guangzhou, South of China. BPA, BPF, and BPSP were widely detected in urine samples, with a median concentration of 0.76, 0.02, and 0.15 μg/L, respectively. Median urinary levels of BPA and BPS were higher in males than females (p < 0.05). In addition, BPA and BPS of every male in young adults (16-35 years old) were greater than those in children (0-16 years old) (p < 0.05). Urinary BPA and BPS were positively correlated with age (p < 0.05). Daily intakes of BPA and BPS were estimated to be 0.03 and 0.01 μg/kg bw/day, respectively. Meanwhile, BPA, BPF, BPS, and BPSP were found in the influent samples of six WWTPs, and the summary of mass loads of detected BPs was 1.1 × 10^3 kg/day. BPA was the most frequently detected BP in wastewater, with a median concentration of 26.8 ng/L, and BPS (7.5 ng/L) was slightly lower than those of the residents. The indicators that important sources of BPs might include industrial wastewater and household cleaning products. Urinary BPA, BPS, and BPSP accounted for less than 5% per capital mass loads in wastewater, suggesting that most of the BPA, BPS, and BPSP in municipal wastewater originate non-human activities. Hence, the wastewater-based epidemiology (WBE) approach based on parent compounds is not available for assessing human exposure to BPs, neither for other industrial chemicals with diverse sources in municipal wastewater. These results contributes to the development of an efficient surveillance system which can provide insight in the trends of human exposure of BPs. 統合_0105	H. Wang, C. Tang, Y. Wang, M. Han, F. Jiang, L. Jiang, J. Wu, C. Fu, Y. Chen and Q. Jiang	2021	Urinary antibiotic level of school children in Shanghai, East China, 2017-2020	In recent years, an extensive exposure to antibiotics from various sources has been demonstrated in China by the biomonitoring method, but the temporal trend remains little known. The study aim was to explore the temporal trend of exposure to antibiotics and associated health risk in children. A dynamic child cohort was established in Shanghai, East China between 2017 and 2020. A total of 660 school children aged 7-12 years were included, and 280 in 2017, 219 in 2018, 188 in 2019, and 267 in 2020 participated in annual surveys. Twenty-three typical antibiotics and three metabolites from five categories (four tetracyclines, five sulfonamides, six quinolones, three macrolides, and two penicillins) were detected in urine samples by ultra-performance liquid chromatography-tandem mass spectrometry (UPLC-MS/MS). To investigate the associations between urinary antibiotics and the detection frequency of antibiotics in urine, Pearson correlation coefficients and three metabolites were found in 61.9% of urine samples. Compared to 2017, the detection frequency in urine reduced 12.8% in 2020 for all antibiotics. OBCPs in 38.7% and reduced 36.8%-55.8% for tetracyclines, 22.0% in 15%), spiroleno (16.0% in 21.3%), macrolides (6.8% in 3.9%), sulfonamides (3.4% in 0.7%), polybrominated (19.5% in 12.3%). After accounting for personal characteristics, food consumption, and urinary BPA and MBP, a decreasing temporal trend of detection frequencies was observed from 2017 to 2020 for most antibiotics. Urinary concentration, estimated daily intake, and acceptable daily intake based health risk of antibiotics showed a temporal trend similar to detection frequency. There was an extensive exposure to antibiotics in children. However, a decreasing temporal trend occurred for the exposure during the period from 2017 to 2020. The trend may likely to be caused by decreased antibiotic use and/or decreased residues in food and/or drinking water.	Environ Pollut Vol.291 Pages 118167	10.1016/j.envpol.2021.118167	34534827	ヒト	-	-	-	-	-	-	-	-	-	-	バイオモニタリング	1	1	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-
統合_0106	H. Wang, Z. H. Liu, J. Zhang, R. P. Huang, H. Yin and Z. Dang	2020	Human exposure of bisphenol A and its analogues: understandings from human urinary excretion data and wastewater-based epidemiology	This work evaluated human exposure to bisphenol A (BPA) and its analogues based on human urinary excretion data and wastewater-based epidemiology (WBE). The results showed that the worlds average human daily intake ranked from high to low is order of bisphenol A (BPA), bisphenol F (BPF), bisphenol S (BPS), bisphenol AP (BPAP), bisphenol B (BPB), bisphenol Z (BPZ), and bisphenol AF (BPAF), and their corresponding median values were 1.37, 0.0, 0.0, 0.0, 0.0, 0.0, and 0.0 ng/kg bw/day, respectively. Children and adolescents were found to be the most exposed population to human beings normally exposed to BPA analogues as well. Many BPA analogues showed comparable or even higher toxicities to those of BPA; therefore, the adverse effects of BPA analogues on humans should be comprehensively evaluated. The normal exposure levels obtained based on wastewater-based epidemiology method might to be two or to order of BPA (0.12-72 μg/kg bw/d), BPF (0.029 μg/kg bw/d), BPS (0.21 μg/kg bw/d), BPP (1.19 μg/kg bw/d), BPF (0.08 μg/kg bw/d), BPB (0.61 μg/kg bw/d), BPAF (0.08 μg/kg bw/d), and BPAP (0.36 μg/kg bw/d). The world's human average daily intakes of BPA and its analogues are only 0.5-0.9% of the intakes of their corresponding human normal exposures. This study suggests that other sources rather human excretions are important origins in municipal wastewater, which indicates that the WBE method based on parent compounds may underestimate the exposure levels of BPA and its analogues. Human excretions, landfill leachate, and industrial wastewater are important origins of BPA and its analogues in municipal wastewater. Municipal wastewater are likely influenced of industrial wastewater, discharges of hospital wastewater, and landfill leachate. To decrease discharges of BPA and its analogues to the natural environment, any mixing of industrial and hospital wastewater as well as landfill leachate in municipal wastewater is not favorable.	Environ Sci Pollut Res Int Vol.27 Issue 3 Pages 3247-3256	10.1007/s11356-019-07111-9	31838679	ヒト	-	-	-	-	-	-	-	-	-	-	バイオモニタリング	1	1	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-
統合_0107	H. Wang, R. Gao, W. Liang, S. Wei, Y. Zhou and Y. Zeng	2022	Assessment of BPA and BPS exposure in the general population in Guangzhou, China - Estimation of daily intakes based on urinary metabolites	Human exposure to bisphenol A (BPA) and bisphenol S (BPS) has garnered considerable global health concerns. In this paper, the daily intake (DI) of BPA and BPS in the general population of Guangzhou, China, were back-calculated using the biomarkers BPA glucuronides (BPA-G) and BPS glucuronides (BPS-G) measured in urine samples. The biomarkers are preferable to intact BPA and BPS measurements because they are not susceptible to external contamination. A total of 1410 urine samples were gathered from the general population in Guangzhou, China, which were classified by age and sex into 36 pooled urine samples. 100% and 98% of pooled urine samples had detectable BPA-G and BPS-G, respectively. The median DI of BPA was 0.0 ng/kg bw/d for all age and sex groups, and the highest value was 0.0 ng/kg bw/d for female adults (18-60 years old). The median DI of BPS was 0.0 ng/kg bw/d for all age and sex groups, and the highest value was 0.0 ng/kg bw/d for female adults (18-60 years old). Furthermore, our results revealed that for the entire dataset, BPA and BPS were statistically greater in males than in females ($p < 0.05$) and declined significantly with age ($p < 0.05$). For risk assessment, the estimated DIs of BPA and BPS were much lower than the European Food Safety Authority's (EFSA) first temporary acceptable reference dose of 4 μg/kg bw/d adopted for BPA, suggesting that the exposure risk of BPA and BPS for Guangzhou population is within a controllable safety range. This is the first study to investigate BPA and BPS exposure in the general population of Guangzhou, China, on the basis of urinary metabolites.	Environ Pollut Vol.315 Pages 120375	10.1016/j.envpol.2022.120375	36220574	ヒト	-	-	-	-	-	-	-	-	-	-	バイオモニタリング	1	1	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-
統合_0108	H. Wang, R. Gao, W. Liang, S. Wei, Y. Zhou, Z. Wang, L. Lan, J. Chen and F. Zeng	2023	Large-scale biomonitoring of bisphenol analogues and their metabolites in human urine from Guangzhou, China: Implications for health risk assessment	Bisphenol analogues (BPs) are ubiquitous in the environment and have gained significant attention regarding their associated health risks. However, there is a lack of comprehensive biomonitoring data on BPs and their metabolites in human urine. To address this, we conducted a study to assess the exposure to BPs in the general population of Guangzhou, China. A total of 1202 urine samples were collected from volunteers and analyzed for the presence of BPs and their metabolites after being pooled into 36 groups based on age and gender. The findings revealed the common detection of non-free-form BPs, as well as the urinary metabolites of BPS and BPZ, in the pooled urine samples. BPA was the predominant free-form compound, constituting 80% of the total BPs (∑BPs). The primary urinary metabolites of BPA and BPS were BPA-glucuronide (BPA-G) and BPS-G, respectively, indicating glucuronidation as their primary metabolic pathway. The composition of urinary metabolites of BPA and BPS varied by age and sex, with the concentration of total BPs in urine was not significantly associated with age or gender. The estimated daily intake (EDI) values of BPA and BPS were calculated based on the urinary concentrations of BPA-G and BPS-G. The median EDI values for BPA and BPS were found to be 0.0 ng/kg bw/day, with the highest values reaching 0.0 ng/kg bw/day and 0.0 ng/kg bw/day, respectively. These values were significantly lower than the reference dose (RfD) of 50 ng/kg bw/day established by the European Food Safety Authority (EFSA). Some of the BPs, including BPA, BPAF, BPAP, BPF, BPS, BPZ, BPE, and BPP, respectively, in the pooled urine samples. Preliminary risk assessments indicated that the estimated daily intake of BPA was much higher than the latest proposed tolerable daily intake. Due to the unavailability of health-based guideline values for alternative BPs, some of them exhibit daily intakes comparable to BPA, implying that greater attention should be paid to health risks associated with exposure to BPs.	Chemosphere Vol.338 Pages 139601	10.1016/j.chemosphere.2023.139601	37480947	ヒト	-	-	-	-	-	-	-	-	-	-	バイオモニタリング	1	1	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-
統合_0109	Y. Wang, Y. Zhang, S. Zhang, X. Han, Y. Wei, H. Guo, X. Zhang, H. Yang, T. Wu and M. He	2022	Combined effects of bisphenol A and diabetes genetic risk score on incident type 2 diabetes: A nested case-control study	Observational studies reported inconsistent results on the association between bisphenol A (BPA) and type 2 diabetes (T2D) risk. Whether genetic factors modified the association remains unclear. The present nested case-control study prospectively investigated the association of BPA with T2D risk, and the interaction and combined effects of diabetes genetic risk score (GRS) and serum BPA on T2D risk. Based on the Dongfeng-Tongji cohort study, 1,289 incident T2D cases and 1,289 matched controls were included. Serum BPA was measured using ultra-performance liquid chromatography-tandem mass spectrometry at baseline. Diabetes GRS was constructed by 88 diabetes-related SNPs. Adjusted hazard ratio (aHR) and 95% confidence interval (95% CI) were calculated by conditional logistic regression models. Participants with the highest vs. lowest serum BPA level had a higher risk of T2D (OR = 2.51, 95%CI: 1.89, 3.32, P < 0.001) and higher baseline FPG levels (β = 0.28, P < 0.001), compared with those with both lower serum BPA and lower BPA levels. Non-additive effects between BPA levels and GRS on T2D, fasting FPG levels, and 2-h changes of FPG were observed (P-interaction < 0.05). Our results suggested a synergistic association between BPA levels and T2D risk. Participants with higher serum BPA levels and diabetes genetic risk had higher FPG levels and higher risk of T2D. 統合_0110	C. Wang, H. Wang, J. Cai and X. Xu	2025	Individual and mixture analyses of the associations of phenols and phthalates with lung function among US adults	The effects of endocrine disruptors including phenols and phthalates on adult lung function remain unclear. In the present study, data from 2007-2012 National Health and Nutrition Examination Survey (NHANES) were extracted, and 3338 participants were included in the final analyses. The associations of three phenols and four phthalate metabolites, with six lung function parameters were investigated in generalized linear regression models. ELM3 and restricted cubic spline (RCS) analyses. bisphenol A (BPA) was associated with decreased forced expiratory volume in the first second (FEV1) and forced vital capacity (FVC), and 2,5-dichlorophenol (2,5-DCP) was associated with reduced FEV1, FVC, and peak respiratory flow rate (PEF), and increased prevalence of restrictive lung function (RLF) in adults. Furthermore, quantile-sum (WQS) regression and Bayesian kernel machine regression (BKMR) models demonstrated that mixed exposures to phenols and phthalates were linked to reduced FEV1, FVC and PEF and increased prevalence of RLF, and these associations were mainly driven by BPA and 2,5-DCP. Additionally, mediation analysis revealed that the association between BPA and FEV1 was linked to compromised peak expiratory flow. The mechanisms of the effects of phenol and phthalate exposures on lung function and respiratory diseases need to be further investigated.	Int J Environ Health Res Vol.35 Issue 2 Pages 330-344	10.1080/09603123.2024.2352609	38722165	ヒト	-	-	-	-	-	-	-	-	-	-	横断研究	1	1	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-
統合_0111	B. Wang, S. Wang, Z. Zhao, Y. Chen, Y. Xu, M. Li, M. Xu, W. Wang, G. Ning, Y. Bi and T. Wang	2020	Bisphenol A exposure in relation to altered lipid profile and dyslipidemia among Chinese adults: A repeated measures study	Animal experiments suggest that bisphenol A (BPA) could potentially induce lipid abnormalities. However, whether BPA exposure associates with altered lipid metabolism in humans has not been fully elucidated. We thus comprehensively investigated the relationship of BPA exposure and its change with lipid profile and development of incident dyslipidemia among Chinese adults. We initially included 1877 participants aged 18 years or older who were free of dyslipidemia at baseline in 2009, and followed them for 4 years. Urinary BPA and serum lipids including total cholesterol (TC), low-density lipoprotein cholesterol (LDL-C), high-density lipoprotein cholesterol (HDL-C), and triglycerides (TG) were measured at baseline and 4-year follow-up. Generalized estimating equation models were used to examine the associations of longitudinal changes in lipid profile and risk of incident dyslipidemia. In repeated measures analyses, per doubling of urinary BPA concentration was associated with higher serum levels of LDL-C (by 0.02 mmol/L, 95% CI: 0.00, 0.03), HDL-C ratio, and lower levels of HDL-C and TG. In longitudinal change analyses, participants with high BPA at both baseline and follow-up showed an additional 2.96% increase in LDL-C (95% CI: 0.01%, 5.90%) and 3.15% increase in TG (95% CI: 0.76%, 5.55%), as compared with those who maintained low BPA. Furthermore, participants with sustained high BPA at two time points had increased odds of developing hypo-LDL-cholesterolemia (odds ratio = 1.93, 95% CI: 1.02, 3.66). Our results suggested that high BPA exposure, especially maintained a long time period apart, was associated with deterioration of lipid profiles among middle-aged and elderly adults, supporting a detrimental role of BPA in lipid metabolism. 統合_0112	M. L. Y. Wan, V. A. Co and H. El-Nezami	2022	Endocrine disrupting chemicals and breast cancer: a systematic review of epidemiological studies	BACKGROUND: Endocrine disrupting compounds (EDCs) are ubiquitous substances that are found in our everyday lives, including pesticides, plasticizers, pharmaceutical agents, personal care products, and also in food and drinking water. Exposure to EDCs is associated with breast cancer risk. METHODS: The search was performed in accordance with the PRISMA guidelines. We retrieved articles from PubMed (MEDLINE) and ISI Web of Science. The key words used in this research were "Endocrine disruptor" OR "Endocrine disrupting chemicals" OR any of the individual EDCs' names or its aliases and breast cancer. Only articles published in English were included. We included only cohort studies and case-control studies. All relevant articles were accessed in full text and were evaluated and summarized in tables. RESULTS: We identified 131 studies. Among them, 23 studies were included in this review. Exposure to EDCs, especially some phenols (bisphenol A (BPA), 4-nonylphenol (4-NP), 4-tert-octylphenol (4-t-OP)), phthalates (di-(2-ethylhexyl) phthalate (DEHP), 2,3,5-trimethylbenzene or dioxin (TCDD) or dioxin-), synthetic chemicals (e.g. bisphenol A (BPA), phthalates, per- and polyfluoroalkyl substances (PFAS), parabens, polybrominated biphenyls (PBDEs), and pentachlorophenol (PCP)), pharmacogens (e.g. genistein, resveratrol), and certain mycotoxins (e.g. zearalenone). Most studies assessed environmental EDCs exposure via biomarker measurements, CONCLUSION: We identified certain EDC exposures could potentially elevate the risk of breast cancer. In majority of EDCs are highly persistent in the environment and the accumulation. It is essential to assess the long-term impacts of EDC exposures, especially multi-generational and transgenerational. Also, a low-level to chronic major route of exposure to EDCs, well-designed exposure assessments of potential EDCs in food and housekeeping are necessary and their potential risk to breast cancer development need to be carefully evaluated for subsequent EDC policy making and regulations. 統合_0113	A. Waits, C. H. Chang, Y. F. Huang, M. S. Tsai, J. W. Hsu, P. W. Wang, C. Y. Chen, C. J. Hsieh, M. T. Wu, S. L. Wang and M. L. Chen	2025	Socioeconomic status in the association between use of personal care products and exposure to endocrine-disrupting chemicals in pregnant Taiwanese women	BACKGROUND: Maternal exposure to endocrine-disrupting chemicals (EDCs), particularly those found in personal care products (PCPs), may affect child development. Socioeconomic inequalities in EDC exposure warrant further investigation. This study examined the role of income and education in the association between PCP use and exposure to bisphenol A (BPA) and parabens in pregnant women. METHODS: Associations between PCP use and urinary concentrations of BPA and four parabens in pregnant women from the Taiwan Maternal and Infant Cohort Study were estimated using linear regression, with results expressed as the percentage change in concentrations for each additional PCP used. The analysis was stratified by income and education and predicted concentrations, and a 95% confidence interval (CI) was graded according to the frequency of PCP use. RESULTS: Higher concentrations of methylparaben, ethylparaben, and propylparaben were associated with more frequent use of different PCPs, especially makeup. The above-listed increases in paraben concentrations were significantly greater among participants with low income (LI) (e.g., 95% CI: 0.19, 0.31) and low education (LE) (e.g., 95% CI: 0.19, 0.31) than among those with high income (HI) (e.g., 95% CI: 0.13, 0.19) and high education (HE) (e.g., 95% CI: 0.13, 0.19). For example, the 95% CI for methylparaben was 0.19, 0.31 for LI and 0.13, 0.19 for HI. Similarly, the 95% CI for methylparaben was 0.19, 0.31 for LE and 0.13, 0.19 for HE. Multivariate linear regression (MLR) models also revealed that PCP use was significantly associated with higher BPA concentrations in LI and LE groups. For example, the 95% CI for methylparaben was 0.19, 0.31 for LE and 0.13, 0.19 for HE. Similarly, the 95% CI for methylparaben was 0.19, 0.31 for LI and 0.13, 0.19 for HI

統合_0118	J. Vitku, T. Skodova, A. Vanucova, L. Gadus, L. Michnova, L. Horackova, L. Kolatorova, M. Simkova and J. Hosek	2023	Endocrine Disruptors and Estrogens in Human Prostatic Tissue	Endocrine disruptors (EDs) are ubiquitous substances both in the environment and everyday products that interfere with the hormonal systems. Growing evidence demonstrates their adverse effects on the organism, including the reproductive system and the prostate, owing to their (anti)estrogenic or (anti)androgenic effects. Since EDs can interact with steroid hormone actions on site, understanding the levels of intraprostatic EDs and their metabolites is crucial for assessing their impact on prostate health. This study aimed to determine the concentrations of 30 EDs, including their metabolites, parabens, and phytoestrogens in their unconjugated and conjugated forms, in prostate tissue by liquid chromatography–tandem mass spectrometry, and subsequently analyze 20 human prostate tissue samples. The method enabled 30 compounds to be analyzed: estrogens (estrone, estradiol, estriol), bisphenols (bisphenol A: BPA, BPS, BPF, BPAP, BPAF, BPZ, BPP), parabens (methyl-, ethyl-, propyl-, butyl-, benzyl- paraben), oxybenzone, nonylphenol, octylphenol, triclosan, triclocarban, and phytoestrogens (genistein, daidzein, equol). The limits of quantification (LOQs) ranged from 0.037 to 0.45 ng/g of tissue. The most frequently detected EDs in prostate tissues were unconjugated and conjugated forms of BPA (in 95% and 90% samples, respectively) with median concentrations of 0.76 and 0.12 ng/g, respectively. Unconjugated (4.76 %) and conjugated (4.76 %) forms of triclocarban and unconjugated (4.76 %) and conjugated (4.76 %) forms of triclosan were also detected. To the best of our knowledge, this is the first study detecting EDs, phytoestrogens and estrone conjugate (E1C) in the prostate. E2C was the most abundant estrogen in prostatic tissue. This highlights the need for further explorations into estrogen metabolism within the prostate. 統合_0119	J. Vian Matias de Oliveira, F. Martins de Albuquerque, A. de Jesus Fernandes, P. Baeli Zanella and M. Alves Silva	2025	Prenatal exposure to bisphenol-A and neurocognitive changes in children aged 2 to 5 years: a systematic review	Bisphenol A (BPA) is a synthetic organic compound considered an endocrine disruptor. Childhood exposure to BPA has been linked to impaired memory and learning, as well as Attention Deficit Hyperactivity Disorder. The objective of this study was to systematically review the literature on the association between prenatal exposure to BPA and neurocognitive changes in children aged 2 to 5 years. A systematic review (PROSPERO) was conducted between December 2023 and May 2024, following the recommendations of the Preferred Reporting Items for Systematic Reviews and Meta-Analyses (PRISMA) guidelines. The databases Science, Embase, and PubMed/database, were used for the search, with no publication date limit. The following terms, with the respective Boolean operators, were searched: (bisphenol A) OR (BPA) AND (symptoms) OR (pregnant women). Twenty non-longitudinal studies were collected for this review. Most studies have demonstrated negative effects of prenatal BPA exposure on the neurocognitive development of children aged 2-5 years. These results differed between the sexes, with females having lower emotional control, reduced language dominance and problem solving, and males having lower psychomotor development and higher prosocial behaviors. Additionally, BPA exposure has been linked to hyperactivity, inattention, impulsivity, anxiety, depression, aggressive behavior, inattention, and sleep problems. It is concluded that maternal exposure to BPA during pregnancy results in adverse health effects in children aged 2-5 years, with impairments in their neurocognitive development. Slama	2019	An Empirical Validation of the Within-subject Biospecimens Pooling Approach to Minimize Exposure Misclassification in Biomarker-based Studies	BACKGROUND: Within-subject biospecimens pooling can theoretically reduce bias in dose-response functions from biomarker-based studies when exposure assessment suffers from classical-type error. However, empirical validation of this approach is lacking. METHODS: Among pregnant women participating in the Study of Pregnancy and Thyroid Early Endocrine Disruptors (SPHERE), we collected a spot of each urine void over several nonconsecutive weeks, on complete concentrations of 13 phenols in daily, weekly, and pregnancy-wide within-subject pools. We studied other forms of daily samples. We simulated study using these data, we quantified bias in dose-response functions when using one to 20 urine samples per subject to assess methylparaben in compared with moderate within-subject variability) and bisphenol A (high variability) exposures. RESULTS: Correlations between exposure estimates from pools of all one of only three urine pools per day were almost 0.80 for all three compounds, except for benzophenone-3 and its losers in the daily time indices (correlations, 0.57-0.68). With one spot sample to assess pregnancy exposure, correlations were all below 0.74. Using only one biospecimen led to attenuation bias in the dose-response functions, of 39% (methylparaben) and 69% (bisphenol A); four samples for methylparaben and 19 for bisphenol A decreased bias to 10%. CONCLUSIONS: For neuroprotective chemicals, collecting and pooling three samples per day (instead of all daily samples efficiently estimates exposures over a week or more. Collecting around 20 biospecimens convincingly limit attenuation bias for nonpersistent chemicals such as bisphenol A. 統合_0121	M. Vellaquez-Gomez and S. Lacorte	2019	Nasal lavages as a tool for monitoring exposure to organic pollutants	Exposure to air and dust pollutants can cause external adverse effects on human health. This study proposes the use of nasal lavages as a non-invasive sampling technique to determine in a direct way pollutant intake through inhalation. We evaluate the occurrence of compounds widely used in domestic products and construction materials (organophosphorus flame retardants (OPFR), phthalates, alkylphenols and bisphenol A) applied in pest control in cities (pesticides) and emitted through use (tobacco smoke polycyclic aromatic hydrocarbons, PAHs) or cooking (nicotine). Contaminants were found in all nasal lavages and analyzed using gas chromatography coupled to tandem mass spectrometry (GC-MS/MS). All 29 individuals inhabiting in Barcelona city had phthalates and bisphenol A at concentrations up to 31,300 ng mL-1 in the dehydroxyl phthalate DEHP-OH. Other OPFR, pesticides and PAHs were also detected in nasal lavages at concentrations up to 1,000 ng mL-1. Concentrations in nasal lavages were 10 to 100 times higher than those detected in urine. Phthalates were detected at the highest concentrations in all active smokers (median 2,150 ng mL-1). Contrarily, pesticides were sporadically detected. Nasal lavages revealed to be an appropriate indicator likely to reflect exposure to dust and air contaminants. Eick	2024	Association of Phenols, Parabens, and Their Mixture with Maternal Blood Pressure Measurements in the PROTECT Cohort	BACKGROUND: Phenols and parabens are two classes of high-production volume chemicals that are used widely in consumer and personal care products and have been associated with reproductive harm and pregnancy complications. Pregnant women living in northern Puerto Rico may be at increased risk of exposure to these chemicals because of their frequent use of personal care products. OBJECTIVES: We investigated associations between individual phenols, parabens, and their mixture on maternal blood pressure measurements, including systolic and diastolic blood pressure (SBP and DBP) and hypertension during pregnancy. Gestational hypertension (GHTN) and preeclampsia (PE) with or without severe features (sPE) were also examined. METHODS: We examined these relationships cross-sectionally at two time points during pregnancy (16–26 and 24–36 wks gestation) and longitudinally using linear mixed models (LMMs). Finally, we used quantile g-computation to examine the mixture effects on continuous SBP, DBP, and blood pressure during pregnancy. Multivariate logistic regression models were used to examine associations between the mixture and GHTN, PE, and sPE. RESULTS: We observed a trend of higher odds of hypertension during pregnancy with exposure to multiple analytes and the overall mixture (including bisphenol A (BPA), bisopheol S (BPS), triclocarban (TCC), triclosan (TCS), methyl paraben (MeP), ethyl paraben (EtP), propyl paraben (PrP), and butyl paraben (BuP)). In the first trimester, a quartile increase in the mixture was associated with a 1.67 (95% CI: 1.00, 2.78) increase in the odds of GHTN. In the second trimester, a quartile increase in the mixture was associated with a 1.67 (95% CI: 1.02, 2.78) increase in the odds of GHTN. Lower SBP and higher DBP were also associated with individual analytes, with results from LMMs. Here was consistent for methyl paraben (MeP): a 1-unit increase in MeP in a propyl paraben (PrP)–free and increased SBP across pregnancy [adjusted fall (95% CI: 0.17, 1.38) and adjusted rise (95% CI: 0.08, 0.99) in SBP, respectively]. Conversely, a 1-unit increase in MeP in a propyl paraben (PrP)–exposed

Antignac	2022	European interlaboratory comparison investigations (ICI) and external quality assurance schemes (EQUAS) for the analysis of bisphenol A, S and F in human urine: Results from the HBM4EU project	The Human Biomonitoring for Europe initiative (HBM4EU) aims to study the exposure of citizens to chemicals and potentially associated health effects. One objective of this project has been to build a network of laboratories able to answer to the requirements of European human biomonitoring studies. Within the HBM4EU quality assurance and quality control scheme (QA/QC), a number of interlaboratory comparison investigations (ICIs) and external quality assurance schemes (EQUASs) were organized for selected priority biomarkers, including bisphenols (BPs). Seventeen laboratories (including fourteen HBM4EU laboratories) participated in the ICI for BPs. Participants received a set of human urine, in two rounds of 2 (2018) and three samples (2019), each target concentrations/levels were considered, related to around 95th and 99th of the typical exposure distribution observed in the European general population. Special attention was paid to the conjugated phase II metabolites known to be most dominant in samples of environmentally exposed individuals, through the application of enzymatic deconjugation procedures before sample preparation. The EQUAS for BPs was organized in 2019 and 2020 and included 17 participants. The first round's results were 80% for BPA, 75% for BPF and 81% for BPS. For the high level, the percentages of satisfactory results increased to 93% for BPA, 89% for BPF and 94% for BPS. Of a set of 29 participating laboratories, 24 (or 83%) were approved for the analysis of BPA in the HBM4EU project according to the defined criterion of 2 scores for both low and high concentration levels in at least two ICI/EQUAS rounds. For BPS and BPF, the number of qualified laboratories was 18 out of 27 (67%) and 13 out of 25 (52%), respectively. These results demonstrate a strong analytical capability for BPA and BPS in Europe, while improvements may be needed for BPF. Garofoli, P. Campiglia, H. Cena and R. Da Giuseppe	2024	Maternal Exposure to Endocrine-Disrupting Chemicals: Analysis of Their Impact on Infant Gut Microbiota Composition	Endocrine disruptors (EDCs) are chemicals that interfere with the endocrine system. EDC exposure may contribute to the development of obesity, type 2 diabetes, and cardiovascular diseases by impacting the composition of an infant's gut microbiota during the first 1000 days of life. To explore the relationship between maternal urinary levels of Bisphenol A and phthalates (UHPLC-MS/MS), and the composition of the infant gut microbiota (16S rDNA) at age 12 months (T12) and, retrospectively, at birth (T0), 1 month (T1), and 6 months (T2), stool samples from 20 infants between 6 and 12 months were analyzed. Metataxonomic barcoding relative abundances were correlated with EDC values. Based on median Bisphenol A levels, infants were assigned to the over-exposed group (E, n = 8) and the low-exposed group (N, n = 12). The B group (Bacteroides) was the most abundant at all time points in both groups. Over-exposed infants showed a significantly lower Firmicutes/Bacteroidetes (F/B) ratio at T0 (E: 0.64 ± 0.19 vs. N: 1.19 ± 0.46; two-tailed test, $t(18) = -3.2$, $p = 0.005$). At T1, the E group had a significantly higher abundance of Proteobacteria ($p = 0.04$). Exposure to phthalates, based on the presence of at least three phthalates in urine concentrations exceeding the infant median value, was differentially distributed in the two groups, according to the defined criterion of 2 scores for both low and high concentration levels in at least two ICI/EQUAS rounds. For BPS and BPF, the number of qualified laboratories was 18 out of 27 (67%) and 13 out of 25 (52%), respectively. These results demonstrate a strong analytical capability for BPA and BPS in Europe, while improvements may be needed for BPF. 統合_0133	Ö. Ürüey, O. Elbasan, P. Erel, N. S. Bulut and N. Yorgunar	2024	Endocrine-disrupting effects of bisphenol-A, thiamethoxam, and fipronil in hormone-naïve transmen compared to cis-women	BACKGROUND: Current evidence suggests that the etiology of gender dysphoria (GD) is multifactorial. Into, however, remains unclear. Endocrine-disrupting chemicals (EDCs) are one of the etiological hypotheses. Bisphenol-A (BPA), thiamethoxam (THM), and fipronil (FPN) are EDCs that are widely used in our daily lives. We aimed to investigate the effects of these EDCs on the hypothalamic-pituitary-gonadal axis hormones in transmen (TM) and cis-women (CW). METHODS: Drug-naïve transmen diagnosed with GD and cis-sex-matched controls from the psychiatry outpatient clinic in the outpatient clinic of the Department of Endocrinology, Marmara University Hospital, were included in the study. These individuals were evaluated for eligibility. 38 drug-naïve transmen and 23 cis-women were recruited as the control group. After anthropometric evaluation laboratory tests for TSH, LH, total testosterone, and estradiol were carried out, spot urine samples were collected to evaluate the urine metabolic excretion of BPA, thiamethoxam, and fipronil. RESULTS: We found that androgens, total testosterone, androstenedione, and DHEAS levels were significantly higher in transmen than in cis-women. Thiamethoxam was considerably higher in cis-women than in transmen, whereas fipronil and BPA levels were similar in both groups. A negative correlation was found between thiamethoxam and testosterone and androstenedione in transmen. CONCLUSION: The available data suggest that the EDCs that we are most exposed to in our lives are not the only factors in GD development. Even transmen who have not started hormone replacement have high testosterone levels; however, the mechanism has not as yet been elucidated. The challenge is to determine whether this is a factor leading to GD or a condition that develops in women with GD. 統合_0134	L. Urbanetz, J. M. Soares-Junior, R. Dos Santos Simões, G. A. R. Maciel, M. C. P. Baracat and E. C. Baracat	2024	Bisphenol A and polycystic ovary syndrome in human: A systematic review	BACKGROUND: Polycystic ovary syndrome (PCOS) is an endocrine disorder characterized by anovulation, hyperandrogenism, and polycystic ovarian morphology. Its etiology is uncertain and one of the hypotheses is that endocrine disruptors, such as bisphenol A (BPA), could contribute to the development of this syndrome. OBJECTIVE: To evaluate the relationship between BPA and PCOS. METHODS: Systematic review including studies published in English, Portuguese, and Spanish from January 2003 to March 2023 and available in Pubmed, Medline/PubMed, Bireme, Lilacs, Scielo, Google academic, and ICI databases. RESULTS: CRITERIA: Studies in humans that evaluated the association between exposure to BPA and a diagnosis of PCOS. DATA COLLECTION: AND ANALYSIS: Following PRISMA guidelines, study characteristics and relevant data were extracted. RISK OF BIAS: Selection of 10 cases and 7 cross-sectional studies with a total of 3 580 PCOS patients. The studies were carried out in China, Iran, Spain, Taiwan, South Korea, the USA, Iran, Iraq, Egypt, India, Czechia, and Slovakia. It was found a relationship between exposure to BPA and PCOS was described in 9 studies (269 [80.78%] of the PCOS patients). The fields used in the studies were serum, urine, and follicular fluid. The BPA concentrations in the PCOS group were higher in 6 studies (p < 0.05). Only 1 study found a lower BPA concentration in the PCOS group. The Newcastle-Ottawa Quality Scale (NOS) was used to rate the 16 selected studies and 11 studies were moderate (6-7) and 5 studies (8-9) were high quality. Only 1 study (6.25%) had a low risk of bias. CONCLUSION: The available data suggest that the EDCs that we are most exposed to in our lives are not the only factors in GD development. Even transmen who have not started hormone replacement have high testosterone levels; however, the mechanism has not as yet been elucidated. The challenge is to determine whether this is a factor leading to GD or a condition that develops in women with GD. 統合_0135	C. S. Ublibjerg, Y. H. Lim, M. Kiraus, H. Frederiksen, A. M. Andersson and E. V. Bräuner	2022	Sex-specific associations between maternal exposure to parabens, phenols and phthalates during pregnancy and birth size outcomes in offspring	Current evidence on the effects of prenatal exposure to endocrine-disrupting chemicals on birth size remains largely inconclusive. We aimed to investigate sex-specific associations between maternal exposure to parabens, phenols, and phthalates during pregnancy and birth weight, height and head/abdominal circumference. We performed a prospective study of 88 pregnant women who underwent ambulatory ultrasound in the period 2012 to 2014. Maternal urine samples were collected during pregnancy in weeks 12 to 36 (median 18 weeks). The concentrations of parabens, phenols and individual phthalate diester metabolites were analyzed by isotope-diluted liquid chromatography-tandem mass spectrometry and creatinine adjusted. Linear regression models were used to estimate the associations between maternal urinary concentrations (T1) (first trimester), (T2) (second trimester), (T3) (third trimester) and (T1+T2+T3) (average) and birth size, stratified by offspring sex. A total of three parabens, two phenols, four individual phthalate metabolites and four sums of diester metabolites were detectable above limits of detection in ≥ 70% of the urine samples. The sum of di-2-ethylhexyl phthalate metabolites (ΣDEHP) was detected in all samples. Maternal urinary concentrations of ΣDEHP (T1) were associated with across-sex outcomes (birth weight: -128 g (95% CI: -256 to -0.1), birth length: -1.3 cm (95% CI: -2.5 to -0.2)) in adjusted cross-sectional analyses. Maternal urinary concentrations (T1) of ΣDEHP were associated with lower birth weight (-361 g, 95% CI: -591 to -131) and length (-3.1 cm, 95% CI: -5.7 to -0.6) compared to low exposure. None of these associations were statistically significant in female offspring. Across all compounds, individual exposures were associated with more negative estimates of birth weight for male than for female offspring. Our study indicates that prenatal exposure to BPA and DEHP may negatively affect birth size outcomes, with a possible sex effect. Given the small sample size, these findings need to be replicated in future large studies. 統合_0136	C. S. Ublibjerg, J. Leader, L. Mínguez-Alarcón, O. Chagnon, R. Dadd, J. Ford, E. Fleury, P. Williams, A. Jual, D. C. Bellinger, A. M. Calafat, R. Hauser and J. M. Braun	2024	Associations of maternal and paternal preconception and maternal pregnancy urinary phthalate biomarker and bisphenol A concentrations with offspring autistic behaviors: The PEACE study	BACKGROUND: Environmental chemical exposures in utero may play a role in autism development. While preconception risk factors for autism are increasingly being investigated, little is known about the influence of chemical exposures during the preconception period, particularly for paternal exposures. METHODS: In 196 children from the Preconception Environmental exposures And Childhood Health Effects (PEACE) cohort born to parents recruited from a fertility clinic in Boston, Massachusetts between 2006 and 2017, we quantified concentrations of 11 phthalate metabolites and bisphenol A (BPA) in urine samples collected from mothers and fathers before conception and mothers throughout pregnancy. When children were 6-9.5 years old, parents completed the Social Responsiveness Scale (SRS) questionnaire assessing autistic behaviors. We used linear mixed-effect models to estimate covariate-adjusted associations of phthalate biomarker and BPA concentrations, separately for maternal preconception (n = 173), paternal preconception (n = 121), and maternal pregnancy (n = 196) exposures, with SRS total raw scores. We also estimated associations with SRS subscales for social cognition, communication, social motivation, autistic mannerisms, and restricted interests. RESULTS: Across-sex outcomes (177 ≤ n ≤ 196), a two-fold increase in the summed molar sum of DEHP metabolites (ΣDEHP) was associated with a 1.2 point (95% CI: 0.0, 2.4) higher SRS total score. The observed associations of higher mono-isobutyl phthalate (MiBP) concentrations, measured in maternal preconception and paternal preconception periods with lower SRS T scores (2 points; 95% CI: -3.8, -0.2; n = 121 and 1.9 points; 95% CI: -3.6, -0.1; n = 173, respectively), were inverse. In a subset of participants with maternal preconception urine information, we primarily observed stronger inverse associations with higher folate and iron intake, particularly for folate intake and ΣDEHP concentrations. CONCLUSIONS: Urinary phthalate diester and BPA concentrations during preconception (maternal and paternal) and pregnancy (maternal) were not associated with adverse autistic behaviors in these children. Larger studies are needed to elucidate the observed associations, while considering interactions between maternal nutrition and chemical exposures. 統合_0137	J. Y. Uhm and H. R. Kim	2022	Cross-Sectional Association of Urinary Bisphenol A and Vaccine-Induced Immunity against Hepatitis B Virus: Data from the 2003-2014 National Health and Nutrition Examination Survey	Hepatitis B virus (HBV) infection poses a serious health burden; bisphenol A (BPA), a commonly used plasticizer for consumer products, is a potential immune disruptor. However, epidemiologic studies revealing the association between BPA exposure and immunity are limited. This study investigates the association between environmental BPA exposure and immune response following HBV vaccination in a nationally representative population. Data from 1,103 participants aged 12-19 years who participated in the National Health and Nutrition Examination Survey (NHANES) 2003-2014 were analyzed. The outcome was vaccine-induced immunity (n = 1068). Associations between BPA level and HBV vaccinability were assessed using multivariable logistic regression and expressed as odds ratios (ORs) of the pooled data and data for each cycle, separately. There was a significant association in the pooled data after adjusting for potential confounders (adjusted OR (aOR) 1.16; 95% confidence interval (CI) 1.04-1.29). However, the associations between BPA concentration and HBV vaccinability were inconsistent across the survey cycles, and tended to decrease in more recent cycles. Although this study preliminarily suggests that BPA attenuates the immune response to hepatitis B vaccination, further prospective studies are warranted to elucidate the discrepancies observed. 統合_0138	P. Tyagi, T. James-Todd, L. Mínguez-Alarcón, J. B. Ford, M. Keller, J. Petrozza, A. M. Calafat, R. Hauser, P. L. Williams and A. Bellavia	2021	Identifying windows of susceptibility to endocrine disrupting chemicals in relation to gestational weight gain among pregnant women attending a fertility clinic	BACKGROUND: Exposure to endocrine disrupting chemicals (EDC), such as phthalates, and phenols, during pregnancy may be associated with excessive gestational weight gain (GWG), an important predictor of future obesity. OBJECTIVE: To identify windows of susceptibility to EDC exposure in relation to GWG among women undergoing fertility treatment. METHODS: We included 1,239 pregnancies conceived by 551 women in the LIFE Study (2005-2020). We examined the association between trimester-specific EDCs, mixtures and GWG in pregnant women attending a fertility clinic, to identify windows of susceptibility to EDC exposures, and assess the individual contribution of each chemical over pregnancy. METHODS: We included 252 pregnancy women from the Environment and Reproductive Health (ENVIRH) Study, who provided up to 3 urine samples (one per trimester), and with available data on GWG. Urinary concentrations of 7 phthalate metabolites, bisphenol A, and 2 parabens, corrected for specific gravity, were included in all models. The association between trimester-specific EDCs mixture and GWG was evaluated using multiple regression models - categorical g-computation. We used Bayesian Kernel Machine Regression (BKMR), while adjusting for potential confounders. RESULTS: During 1st trimester, higher EDC mixture was associated with lower GWG (-0.19 kg, 95% CI: -0.38, 0.00), with monobutyl phthalate (MBP) contributing the most to the negative association. During 2nd trimester, higher EDC mixture was associated with greater GWG (0.26 kg, 95% CI: 0.07, 0.45), with monoethyl phthalate (MEP) contributing the most to the positive association. RESULTS: During 3rd trimester, higher EDC was observed at higher sum of metabolites of di (2-ethylhexyl) phthalate (ΣDEHP) but not significantly associated with GWG (-0.12 kg, 95% CI: -0.32, 0.08). During 2nd and 3rd trimesters, positive associations with more or less significant phthalate and paraphenylene, and negative with 2 DEHP and methylparaben were observed. CONCLUSIONS: Exposure to EDC mixtures during 1st trimester was associated with lower GWG, while exposure during 2nd trimester was associated with greater GWG. In relation to GWG, within the 1st trimester, urinary 2-DEHP, mono-butoxyl phthalate and propylparaben had the highest contribution in the positive association between the mixture and GWG (0.03-0.05). All three ethylhexyl phthalate metabolites had similar contributions between urinary EDCs during pregnancy, especially DEHP metabolites, and GWG. Our results suggest the 1st trimester of pregnancy as the time window of highest susceptibility to the effects of EDCs on GWG, with potential indication for the design of public health interventions, informing preventive strategies for reducing sources of exposure at specific time points. Buszewski	2023	The Association between the Bisphenols Residues in Amniotic Fluid and Fetal Abnormalities in Polish Pregnant Women-Its Potential Clinical Application	The present study aimed to investigate the relationship between the concentrations of bisphenols residues in the amniotic fluid (AF) samples collected during aneuploidies and fetal chromosomal abnormalities in pregnant women. A total of 50 pregnant Polish women aged between 26 and 45 years, and scheduled to detect fetal risk for chromosomal defects in the first trimester, were included in this study. Samples were collected from three patients during routine diagnostics and treatment procedures at risk geneticist. The concentrations of various bisphenols residues in the samples were determined by liquid chromatography coupled with triple quadrupole tandem mass spectrometry (LC-ESI-QqQ-MS/MS). Recovery of eight analytes (BPS, BPF, BPA, BPAF, BADGE, BADGE·H2O, BADGE·2H2O and BADGE·H2O·HCl) was tested in amniotic fluid samples in the range 0.05 ng/mL to 5.38 ng/mL. Fetuses with chromosomal abnormalities showed a slightly higher frequency of occurrence of selected bisphenols residues in the AF samples collected between 15-36 weeks of pregnancy. Among the tested bisphenols, the highest concentrations in the AF samples were found for BPA and BPS. Statistically significant differences between the bisphenols concentrations in the healthy group (n = 30) and the group with fetal abnormalities (n = 20) were observed for BPA, BPS, BADGE·H2O and BADGE·2H2O. The AF samples taken from women after miscarriage in the second group. The number of detected compounds has been significant for the following analytes: BPS, BPAF, BADGE·H2O·HCl and BADGE. The proposed method may be an attractive alternative for application in large-scale human biomonitoring studies. 統合_0140	C. M. Tsen, J. H. Liu, D. P. Yang, H. R. Chau, J. L. Chen, W. C. Chou, Y. C. Ho and C. Y. Chiang	2021	Study on the correlation of bisphenol A exposure, pro-inflammatory gene expression, and C-reactive protein with potential cardiovascular disease symptoms in young adults	Bisphenol A (BPA) is a plasticizer used in the manufacture of polycarbonate and epoxy resins. It was found that higher urinary BPA levels are more likely to be associated with coronary artery disease (CAD). In recent years, the increasing incidence of CAD among young people is observed, which may be related with inflammation rather than the traditional triple-H risk factors. BPA is an endocrine disrupting chemical, and can induce inflammation. However, the correlation between BPA exposure and CAD development has not been established. Therefore, this study aimed to explore the association of BPA exposure with the gene expression of pro-inflammatory response (IL-6 and IL-8 mRNA), an inflammation biomarker of CAD (C-reactive protein, CRP), and symptoms of CAD development in young adults. The study divided BPA exposure levels into high and low groups based on the median plasma BPA level of 0.32 ng/mL, and found that the high BPA group obviously had higher BMI, blood pressure, CRP, IL-6 mRNA, and IL-8 mRNA levels than the low BPA group. Moreover, the BPA concentration was positively correlated with the above parameters. Furthermore, this study subjects who showed more CAD development symptoms had the highest levels of BPA (0.51 ng/mL), IL-6 mRNA (1.46), CRP (0.61 mg/L), IL-8 mRNA (1.46), BMI (21.68 kg/m2), and BP (SBP: 118.0 mm Hg; DBP: 74.0 mm Hg). These results indicated that exposure to BPA is potentially associated with expression of pro-inflammatory genes related to CRP secretion, which may promote the risk of CAD development symptoms in young adults. This study highlighted the possible connection between BPA exposure and CAD development but the mechanism between them needs to be further explored. 統合_0141	C. Tschersich, A. Murawski, G. Schwedler, E. Rucic, R. K. Moos, M. Kasper-Sonnenberg, H. M. Koch, T. Brüning and M. Kolossa-Gehring	2021	Bisphenol A and six other environmental phenols in urine of children and adolescents in Germany – human biomonitoring results of the German Environmental Survey 2014-2017 (GerES V)	Exposure to environmental phenols such as bisphenol A, benzophenone, 2-phenylphenol, triclosan, and triclocarbanis is of concern, because of their endocrine disrupting properties and broad application in consumer products. The current body burden of the 3-17-year-old population in Germany to these substances was assessed in first morning void urine samples (N = 510–512) collected within the population representative German Environmental Survey 2014–2017 (GerES V). Creatinine-corrected data were analysed for age and gender differences and compared to previous results from GerES IV (2003–2006). The limits of quantification (LOQ) for benzophenone-3 and bisphenol A (BPA) were 0.1 µg/L, 0.2 µg/L for triclosan, 0.4 µg/L for 2-phenylphenol, and 0.5 µg/L for triclocarbanis. Benzophenone-3, 2-phenylphenol and triclocarbanis were quantified in more than 50% of the samples. Benzophenone-3 and 2-phenylphenol concentrations were found to be associated with frequent application of personal care products. A comparison with the previous cycle of the survey, GerES IV (2003–2006), showed a decrease of urinary bisphenol A concentrations by 80% in children and by 70% in adolescents. Triclosan concentrations were found to be 50% lower in children and 70% lower in adolescents. BPA concentrations were still below the HBM-I value of 2 mg/L. To minimize environmental health risks, it is therefore necessary to maintain a further declining trend for bisphenol A and continue monitoring the exposure to environmental phenols, as well as to monitor substitutes such as bisphenol F and S. 統合_0142	C. S. Tsai, W. J. Chou, S. Y. Lee, M. J. Lee, M. C. Chia and L. J. Wang	2020	Phthalates, Para-Hydroxybenzoic Acids, Bisphenol-A, and Gonadal Hormones' Effects on Susceptibility to Attention-Deficit/Hyperactivity Disorder	This study aimed to examine whether endocrine-disrupting chemicals (EDCs), such as phthalates, para-hydroxybenzoic acids, and bisphenol-A (BPA), affect gonadal hormones and further link to the susceptibility to attention-deficit/hyperactivity disorder (ADHD). We recruited 98 boys with ADHD (7 girls with ADHD, 10 boys without ADHD) and any other psychiatric disorders, and 30 boys without ADHD and any other psychiatric disorders. Urine levels of EDCs, including mono-methyl phthalate (MMP), monoethyl phthalate (MEP), mono-n-butyl phthalate (MnBP), monobenzyl phthalate (MBzP), monohydroxy phthalate (MHP), methylparaben (MeP), ethylparaben (EtP), propylparaben (PrP), butylparaben (BuP), and BPA, were measured. Serum levels of testosterone, estradiol, progesterone, sex hormone binding globulin (SHBG), and prolactin were also measured. Boys with ADHD had higher urinary levels of MnBP, but not other urinary EDCs, than control boys. There were no significant differences regarding EDCs between the females with ADHD and control groups. No significant differences in testosterone, free testosterone, FTRI, LH, estradiol, progesterone, or SHBG were found between the ADHD group and controls among either boys or girls. Among boys with ADHD, urine MBzP and MEHP levels were positively correlated with serum testosterone levels. Among girls, urine MEP levels were positively correlated with serum LH, testosterone, and free testosterone levels. The findings suggest that the possibility of an adverse impact of EDCs on gonadal hormones and neurodevelopment may exist. However, the results could be subject to potential selection bias, and the findings in this study should be interpreted with caution. 統合_0143	Z. Tkalec, T. Kosjek, J. Sirot Tratnik, A. Stajnko, A. A. Runkel, M. Sykiotou, D. Mazej and M. Horvat	2021	Exposure of Slovenian children and adolescents to bisphenols, parabens and triclosan: Urinary levels, exposure patterns, determinants of exposure and susceptibility	Chemicals such as bisphenols, parabens and triclosan are endocrine disrupting chemicals. They are used in a wide variety of consumer products, making human exposure to these chemicals widespread. In the present study, levels of three bisphenols: Bisphenol A, F and S ("analytes: trienfs)", ethyl-, isopropyl-, propyl-, isobutyl-, butyl- (sum) paraben) and triclosan were measured in first morning void from 196 Slovenian children and adolescents, aged 9-14 and 15-19 years and living in a rural region of Slovenia. Median levels of specific gravity-corrected levels for bisphenol A, bisphenol F, methyl paraben and ethyl paraben were 0.4, 0.089, 1.6 and 23 µg/L for children and 0.6, 0.11, 1.7 and 8.0 µg/L for adolescents, respectively. Median levels for all other endocrine disrupting chemicals were < LOQ. The levels are comparable with the levels reported in studies across Europe. Urinary concentrations of bisphenol A, methyl paraben and ethyl paraben were significantly higher in adolescents than in children. Exposure was found to be associated with several factors. Furthermore, individuals living in one of the sampling locations, Zavrč ka, were exposed to higher levels of bisphenol F and ethyl paraben than those in the remaining two sampling locations. Information about participants' dietary habits, use of food packaging and personal care products was obtained through questionnaires, and used to investigate associations between urinary levels of the biomarkers and potential exposure sources. High fat foods were associated with bisphenol A exposure, and cosmetics items such as lipstick and perfume with methyl paraben exposure. Significant correlation between methyl- and propyl paraben was observed in children's samples, suggesting similar exposure sources, while other compounds were not largely correlated, indicating independent sources. Furthermore, association between a single nucleotide polymorphism (SNP) in the estrogen receptor 1 gene and urinary bisphenol A concentrations was observed. Considering the endocrine disrupting properties of bisphenol A, this finding could indicate a potential genetic susceptibility to adverse effects caused by the exposure. The present study reports exposure of children and adolescents in Slovenia to a wide range of different endocrine disrupting chemicals for the first time, connecting it to exposure patterns and exposure sources. The study is to the authors' knowledge the first that investigates direct connection between levels of urinary endocrine disrupting chemical biomarkers and genetic polymorphism in ESTRR1. Pan	2024	The relationship between semen quality in male infertility clinic patients and bisphenol A : A Chinese cross-sectional study	Bisphenol A (BPA) is a growing concern as xenobiotic-disrupting chemical due to its adverse health effects. However, the association between BPA and sperm quality in adult human males remains unclear. The aim of this study was to assess the daily life exposure level of BPA and analyze its correlation with sperm quality in males. Patients who sought treatment in Chinese infertility clinics between May and October 2020 were recruited for this study. Urine samples were collected for BPA detection, and the concentrations were adjusted for creatinine. Semen samples were collected, and sperm morphology was analyzed using an improved Papanicolaou stain. A total of 656 participants, averaging 33.01 ± 5.42 years old, were included. We observed no sex-specific skewing participants in infertility clinics. Principal component analysis was performed for each semen quality index, and three principal components, reflecting sperm motility, count, and morphology were extracted. The participants' mean urine BPA level was 0.99 ng/mL. Negative correlations were observed between serum BPA content and total sperm count, sperm density, forward motility rate, and non-forward motility rate. A positive correlation was found between the non-motile sperm rate and the head deformity rate. Morphological abnormalities were the predominant adverse effects observed. Despite low daily life BPA exposure, long-term low-dose exposure in the general population may damage semen quality. This study provides a scientific basis for managing health risks associated with BPA exposure. Erkekoğlu	2024	Plasma bisphenol a and phthalate levels in children with cerebral palsy: a case-control study	The case-control study aimed to evaluate potential sources of exposure and the plasma concentrations of bisphenol A (BPA) and phthalates in prepubertal children having cerebral palsy (CP) and healthy control. Blood samples of 68 CP and 70 controls were analyzed for BPA, di-(2-ethylhexyl) phthalate (DEHP), mono-(2-ethylhexyl) phthalate (MEHP), and alkyl phthalate (DBP, BPA and DEHP) levels were similar in groups. The median BPA level was 1.57 ng/mL. Significant correlations were observed between BPA and DEHP levels in the CP group. Gross motor function classification system, presence of spasticity, presence of dystonia, feeding difficulties, mixed/dual-type feeding, and oral-motor exercise were determined to increase odds of higher BPA and phthalate levels. In children with CP, in conclusion, potential exposure sources for BPA and phthalates differ in children with CP and healthy controls, and children with CP are not exposed to higher levels of BPA and phthalates. Liang	2022	Use of high-resolution metabolomics to assess the biological perturbations associated with maternal exposure to Bisphenol A and Bisphenol F among pregnant African American women	BACKGROUND: Human and animal exposure to bisphenol A (BPA) has been associated with adverse developmental and reproductive effects. The molecular mechanisms by which BPA exposure exerts its effects are not well understood. Bisphenol F (BPF) is a replacement chemical for BPA in consumer products. OBJECTIVES: To characterize the metabolic perturbations in pregnant African American women associated with BPA/BPF exposure. In a pregnant African American cohort (METABOX). From a subset of study participants enrolled in the Atlanta African American Maternal-Child cohort, we collected both urine samples, for targeted exposure assessment of BPA (N = 218) and BPF (N = 18), and serum samples, for high-resolution metabolomics (HRM) profiling (N = 230), during early pregnancy (8-14 weeks' gestation). Using a liquid chromatography-tandem mass spectrometry (LC-MS/MS) method, we measured urinary concentrations of BPA and BPF. We used a multivariable linear regression model to estimate associations between early pregnancy urinary BPA/BPF concentrations, SEULTO. The geometric mean creatinine-adjusted concentrations of urinary BPA and BPF were 2.66 ± 2.7 ng/mL and 0.28 ± 1.3 ng/mL, respectively. BPA values were found to decrease non-correction at 20 % level, 262 and 730 unique metabolic features were significantly associated with urinary BPA and BPF concentrations, representing 16 and 12 metabolic pathways, respectively. Three metabolic pathways, including steroid hormones biosynthesis, lysine and leucine metabolism, were significantly associated with both BPA and BPF exposure. Using chemical standards, we have confirmed the chemical identity of 14 metabolites significantly associated with BPA or BPF exposure. CONCLUSIONS: Our findings support that exposure to BPA and BPF in pregnant women is associated with the perturbation of aromatic amino acid metabolism, xenobiotics metabolism, steroid biosynthesis, and other amino acid metabolism closely linked to stress response, inflammation, neural development, reproduction, and weight regulation. 統合_0147	E. M. Tanner, M. U. Hallerbäck, S. Wikström, C. Lindh, H. Kiviranta, C. Gennings and C. G. Bornehag	2020	Early prenatal exposure to suspected endocrine disruptor mixtures is associated with lower IQ at age seven	BACKGROUND: Endocrine disrupting chemicals (EDCs) are xenobiotics with the ability to interfere with hormone action, even at low levels. Prior environmental epidemiology studies link numerous suspected EDCs, including phthalates, bisphenols, and perfluoroalkyl substances (PFAS), to neurodevelopmental deficits. However, most studies have focused on single chemicals. OBJECTIVE: To assess the overall impact of prenatal exposure to an EDC mixture on neurodevelopment in school-aged children, and identify chemicals of concern while accounting for co-exposures. METHODS: Among 718 mother-child pairs from the Swedish Environmental Longitudinal, Mother and child, Asthma and allergy study (SELMA) study, we used Weighted Quantile Sum (WQS) regression to assess the association between 29 EDCs, measured in late trimester urine or blood, with Wechsler Intelligence Scale for Children-IV) Intelligence Quotient (IQ) scores at age seven. Models were adjusted for child sex, gestational age, mother's education, maternal IQ, BMI/BMI, weight, and smoking status. To evaluate potential stability, we conducted repeated holdout validation, a machine learning technique. RESULTS: Using repeated holdout validation, IQ scores were 1.9 points (CI: -3.6, -0.2) lower per quartile increase in the EDC mixture. Maternal urinary concentrations of bisphenol A (BPA), bisphenol F (BPF), and PFAS had the strongest negative associations with IQ. BPA (-1.1 points; CI: -2.1, -0.1), BPF (-0.9 points; CI: -1.8, -0.1), MEHP (NA), MBuP (NA), MiBuP (NA), PFHxS (NA), PFHpA (NA), PFOA (-0.6 points; CI: -1.5, 0.3), PFNA (NA), PFDA (NA), PFUnDA (NA), and PFOS (-0.5; CI: -1.5, 0.5) were identified as chemicals of concern. Maternal urinary BPA and BPF concentrations were correlated (Spearman's rho = 0.7). Among all children whose testing and testing (at age 7), this identified bisphenol F as the primary chemical of concern, suggesting that the BPA replacement compound may not be any safer for children. Future studies are needed to confirm the potential neurotoxicity of replacement analogues. Mueller	2020	Urinary Concentrations of Bisphenols in the Australian Population and Their Association with the Per Capita Mass Loads in Wastewater	Health concerns and related regulation of bisphenol A (BPA) in some countries have led to an increase in the production and use of unregulated and poorly understood BPA analogues, including bisphenol S (BPS), bisphenol F (BPF), and bisphenol AF (BPAF). Biomonitoring data for these analogues in the general population are limited. This study investigated the occurrence of nine bisphenols in urine samples collected between 2012 and 2017 and analyzed for 5-hydroxytryptophol, a key untargeted human biomarker found in wastewater-based epidemiology studies. BPA and BPS were the most frequently detected bisphenols in both urine and wastewater samples, with median concentrations of 2.0 and 0.8 μg/L in urine and 0.92 and 1.1 μg/L in wastewater, respectively. BPA, BPF, and BPAF had low detection frequencies in both urine and wastewater samples. Concentrations of BPA in urine declined from 2012 to 2017, while BPS increased, with a significant (p < 0.05) increase in BPS and a significant decrease in BPA concentrations observed between 2015 and 2017 (Mann-Whitney U test). Urinary concentrations of BPA and BPS were significantly correlated with their per capita mass loads in wastewater (R^2 = 0.71 and 0.72, respectively). The quantile g-computation revealed a statistically significant and negative joint effect of the five bisphenols on the risk of GDM (OR: 0.67; 95% CI: 0.48, 0.72) with BPA (35.2%), TBBPA (21.3%), and BPB (9.9%) had positive contribution to the overall effect. These findings suggested that BPS had a positive effect on the risk of GDM, while BPA and TBBPA had negative effect on the risk of GDM. Moreover, exposure to the mixture of the five bisphenols was negatively associated with the risk of GDM.	Environ Sci Technol Vol.54 Issue 16 Pages 10141-10148	10.1021/acs.est.0c00921	32806918	ヒト	-	-	-	-	-	-	-	バイオモニタリング	1	1	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-

Qu	2023	Associations of bisphenol exposure with the risk of gestational diabetes mellitus: a nested case-control study in Guangxi, China	A growing number of epidemiologic studies have estimated the associations between endocrine disrupting chemicals and gestational diabetes mellitus (GDM). However, reports on the association between bisphenol A (BPA) substitutes and GDM are limited. This investigation aimed to explore the associations of maternal serum BPA, bisphenol B (BPB), bisphenol F (BPF), bisphenol S (BPS), and bisphenol AF (BPAF) with the risk of GDM. A nested case-control study was performed among 600 pregnant women. In unconditional logistic regression models, the OR for BPS was significantly increased in the medium exposure group: OR = 1.77, 95% CI: 1.02, 3.08 and the high exposure group: OR = 1.83, 95% CI: 1.05, 3.19 compared with the low exposure group. Restricted cubic spline (RCS) models revealed a linear dose-response relationship between BPS exposure and GDM risk ($P_{overall}$ = 0.027, $P_{nonlinear}$ = 0.102). In the stratified analysis, the joint effect of bisphenols was associated with the risk of GDM. BPS showed positively additive effects with BPA and TBBPA in multiple models, respectively. The quantile g-computation revealed a statistically significant and negative joint effect of the five bisphenols on the risk of GDM (OR: 0.67; 95% CI: 0.48, 0.72) with BPA (35.2%), TBBPA (21.3%), and BPB (9.9%) had positive contribution to the overall effect. These findings suggested that BPS had a positive effect on the risk of GDM, while BPA and TBBPA had negative effect on the risk of GDM. Moreover, exposure to the mixture of the five bisphenols was negatively associated with the risk of GDM. 統合_0150	N. Tang, D. Wang, K. Chen, M. Zhang, W. Lv and X. Wang	2022	Maternal bisphenol A and triclosan exposure and allergic diseases in childhood: a meta-analysis of cohort studies	Bisphenol A (BPA) and triclosan (TCS) are both endocrine-disrupting chemicals (EDCs), and pregnant women are usually exposed to them through daily consumption. This study aimed to explore the relationship between prenatal BPA and TCS exposure and allergic diseases in childhood by systematic review and meta-analysis. We searched the topic of prenatal BPA and TCS exposure and allergic diseases in childhood published before December 2021 in PubMed, Embase, Web of Science, Cochrane Library, and Google Scholar databases. Cohort studies with data on prenatal BPA and TCS exposure and allergic diseases in childhood were included in this meta-analysis. The cross-sectional between prenatal exposure to BPA and total allergic diseases in childhood showed a pooled effect estimate of 1.21 (95% CI: 1.03, 1.39; I^2 = 0%; P_h = 0.674). The effect estimates between BPA exposure and each allergic disease were 1.38 (95% CI: 1.02, 1.58) for wheezing, 1.23 (95% CI: 1.01, 1.50) for asthma, 1.08 (95% CI: 0.99, 1.18) for eczema/rashes or itches, and 1.19 (95% CI: 1.01, 1.39) for aeroallergens. Prenatal exposure to TCS had no association with the four types of allergic diseases in childhood. BPA exposure during the prenatal period was positively associated with allergic diseases in childhood. Strengthening prenatal EDC exposure control is necessary for child health. Life Persuaded Project	2021	Italian Children Exposure to Bisphenol A: Biomonitoring Data from the LIFE PERSUADED Project	A human biomonitoring (HBM) study on bisphenol A (BPA) in Italian children and adolescents was performed within the LIFE PERSUADED project, considering the resulting mass, sex and age. The median urinary BPA level was 1.32 μg/L, with children living in the South of Italy or in Sardinia having higher levels than those living in the North or in rural areas. Children aged 9–11 years had the highest BPA levels, more than those aged 7–8 and 12–14 years, but no differences were detected between sexes. The exposure in Italian children was higher compared to children from other countries, but lower than the HBM guidance value (130 μg/L). The estimated daily intake was 8.37 μg/kg body weight (bw) per day, about 20-fold below the temporary Tolerable Daily Intake of 4 μg/kg bw set by the established by the European Food Safety Authority. However, this threshold was exceeded in 1.46% of the enrolled children, raising concern about the normal exposure of Italian young population. 統合_0152	E. Taheri, R. Riahi, N. Rafiei, A. Fatehizadeh, H. M. N. Iqbal and S. M. Hosseini	2021	Bisphenol A exposure and abnormal glucose tolerance during pregnancy: systematic review and meta-analysis	In the present work, a systematic review and meta-analysis were performed to examine the probable relation between maternal exposure to bisphenol A (BPA), as estrogen-disrupting compounds, and gestational diabetes mellitus (GDM), and impaired glucose tolerance (IGT). We comprehensively searched three electronic databases to retrieve published studies on maternal exposure to BPA and GDM/IGT through February 2021. Cochran's Q test and I2 statistics were employed for testing heterogeneity across studies. DerSimonian and Laird random effects model was used to determine the pooled estimates. Ethanol, the fixed effects model with Mantel–Haenszel method was applied. Publication bias was assessed by Egger's regression asymmetry test and Begg's adjusted rank correlation test. Sensitivity analysis was performed to evaluate the effect of individual studies on the overall estimate by omitting one study in each turn. Weight and Egger's tests. The pooled odds ratio did not show BPA exposure to be a significant risk factor for GDM (OR = 0.98; 95% CI = 0.60–1.35; I2 = 0%; P_h = 0.96). Also, no significant association was observed between BPA exposure and risk of IGT (OR = 0.93; 95% CI = 0.60–1.38; I2 = 11.5%). Based on the findings of this study, no association was found between exposure to BPA during pregnancy and the risk of GDM/IGT. Albeit no heterogeneity was found between studies. Kolossa-Gehring, G. Schoeters, S. Dwyer, C. Filist and L. Rambaud	2024	Exposure to bisphenol A in European women from 2007 to 2014 using human biomonitoring data - The European Joint Programme HBM4EU	BACKGROUND: Bisphenol A (BPA) or 4,4′-isopropylidenediphenol) is an endocrine disrupting chemical. It was widely used in a variety of plastic-based manufactured products for several years. The European Food Safety Authority (EFSA) recently reduced the Tolerable Daily Intake (TDI) for BPA by 20,000 times due to concerns about immune toxicity. OBJECTIVE: We used human biomonitoring (HBM) data to investigate the general level of BPA exposure from 2007 to 2014 of European women aged 18–75 years (n = 1,236) and its determinants. METHODS: Fifteen studies from 12 countries (Austria, Belgium, Denmark, France, Germany, Greece, Israel, Luxembourg, Slovenia, Spain, Sweden, and the United Kingdom) were included in the BPA Study protocol developed within the European Joint Programme HBM4EU. Seventy variables related to the BPA exposure were harmonized and analyzed. Descriptive statistics, univariate and multivariate analyses were performed. RESULTS: The geometric mean (GM) of urinary BPA concentrations was 0.40 μg/L (95% CI: 0.38, 0.42) and the 95th percentile was 3.0 μg/L (95% CI: 2.7, 3.3). BPA was detected in 80–98% of women in 13 out of 15 contributing studies. Only the Austrian FRIDA study (Advanced Europe), which had a limit of quantification (LOQ) of 0.16 μg/L, and the Spanish INMA-Valencia study (Early Iberia) had a LOQ of 0.4 μg/L. The geometric mean (GM) of total urine BPA ranged from 0.77 to 2.37 μg/L among the contributing studies. The lowest GM of total BPA was observed in France (Western Europe) from the ELFE subset (GM = 0.77 μg/L, 0.68 μg/g creatinine), n = 1701), and the highest levels were found in Belgium (Western Europe) and Greece (Southern Europe), from ESTEBAN (GM = 2.37 μg/L, 2.12 μg/g creatinine), n = 139) and MOLI-SANI (GM = 2.27 μg/L, 2.13 μg/g creatinine), n = 190) subsets, respectively. One hundred percent of women in 13 out of 15 data collections in this study exceeded the health-based guidance value (HBGV) of 0.2 ng/kg bw/day established by EFSA in 2015. Only 1.5% of women in the Austrian FRIDA subset and 3.5% of women in the Spanish INMA-Valencia subset exceeded the HBGV. Several factors related to the socio-demographic characteristics (age, height, weight, education, smoking status) were collected in almost all studies, while several variables related to BPA exposure factors were not gathered in most of the original studies (consumption of beverages, contained in plastic bottles, consumption of canned food or beverages, consumption of food in contact with plastic packaging, use of plastic films or containers in the kitchen, frequency of use of plastic bottles). Univariate and multivariate analyses revealed that the socio-demographic characteristics among European women were found. A broader range of data planned for collection in the original questionnaires of the contributing studies would have enabled a more thorough investigation of the determinants of BPA exposure in European women. CONCLUSION: This study highlights the urgent need for action to further reduce exposure to BPA to protect the population, as is already the case in the European Union. The case study also underscores the importance of and harmonizing HBM design and data for producing comparable data and interpretable results at a European scale level, and to increase HBM uptake by regulatory agencies. Yurdakök	2023	Association of bisphenol A with 25(OH)D, 1,25(OH)2D and 25(OH)D ratio in cord blood	The aim was to investigate the association between bisphenol A (BPA), 25-hydroxy vitamin D (25(OH)D), and 1α,25-dihydroxy vitamin D (1,25(OH)2D) levels in the cord blood of newborn babies. BPA was measured by high-performance liquid chromatography-tandem mass spectrometry (HPLC-MS/MS) and 25(OH)D and 1,25(OH)2D by chemiluminescence immunoassay (CLIA) in 100 cord blood samples. The median BPA level was 1.0 ng/mL (IQR: 0.6–2.0) and median 1,25(OH)2D level was 51.5 pg/mL (IQR: 42.3–66.3). 25(OH)D levels were < 20 ng/mL in 74.0% of the babies. BPA was detectable in 72.4% of the cord blood samples; median BPA level was 1.57 ng/mL (IQR = [16.–0.05 ng/mL). Frequencies of vitamin D deficiency and frequencies of cases having the highest tertile active vitamin D levels were similar in groups of BPA tertiles in both univariate and multivariate analysis. In conclusion, both BPA exposure and insufficient vitamin D (mainly) or low cord blood are common in newborns. Bisphenol A levels were not correlated with vitamin D levels in cord blood of healthy mother–fetus pairs. Kinahan, B. Tonpa, P. Vuillermin, A. L. Ponsonby and M. C. Boon	2024	Male autism spectrum disorder is linked to brain aromatase disruption by prenatal BPA in multimodal investigations and 19HDA ameliorates the related mouse phenotype	Male sex, early life chemical exposure and the brain aromatase enzyme have been implicated in autism spectrum disorder (ASD). In the Barwon Infant Study birth cohort (n = 3270), higher prenatal maternal bisphenol A (BPA) levels are associated with higher ASD symptoms at age 2 and diagnosis at age 8 only in males with low aromatase genetic pathway activity scores. Higher prenatal BPA levels are predictive of higher cord blood methylation across the CYP19A1 brain promoter (1 region [P < 0.005] and aromatase gene methylation mediates (P = 0.02) the link between higher prenatal BPA and brain-derived neurotrophic factor methylation, with independent cohort replication. BPA suppressed aromatase expression in vitro and in vivo. Male mice exposed to mid-gestation BPA or with aromatase knockout have ASD-like behaviors with structural and functional brain changes. 3D-histology-7 discovers and 12HNEK, an estrogenic fatty acid alleviated these features and reversed detrimental neurodevelopmental gene expression. First we demonstrate that prenatal BPA exposure is associated with impaired brain aromatase function and ASD-related behaviors, and brain abnormalities. In males that may be reversible through postnatal 19HDA intervention. 統合_0156	C. Symeonides, E. Aromataris, Y. Mulders, J. Dizon, C. Stern, T. H. Barker, A. Whitehorn, D. Pollock, T. Marin and S. Dunlop	2024	An Umbrella Review of Meta-Analyses Evaluating Associations between Human Health and Exposure to Major Classes of Plastic-Associated Chemicals	Background: Epidemiological research investigating the impact of exposure to plastics, and plastic-associated chemicals, on human health is critical, especially given exponentially increasing plastic production. In parallel with increasing production, academic research has also increased exponentially both in terms of the primary literature and ensuing systematic reviews with meta-analysis. However, there are few overviews that capture a broad range of chemical classes to present a scale of play regarding impacts on human health. Methods: We undertook an umbrella review to review this systematic reviews with meta-analysis. Given the complex composition of plastic and the large number of identified plastic-associated chemicals, it was not possible to capture all chemicals that may be present in, and migrate from, plastic materials. We therefore focussed on a subset of chemicals that are commonly detected in humans and/or the environment, and/or are known to be used in the manufacture of plastics. These included bisphenols and their analogues, phthalates and flame retardants as the two classes of functional additive with the highest concentration ranges in plastics. In addition, we included bisphenols and per- and polyfluoroalkyl substances (PFAS) as two other major plastic-associated chemicals with significant known exposure through food contact materials. Epidemiology and PubMed were searched for systematic reviews with meta-analyses, meta-analyses, and pooled analyses evaluating the association of plastic polymers, particles (microplastics) or any of the selected groups of high volume plastic-associated chemicals above, measured directly in human biospecimens, with human health outcomes. Results: Fifty-two systematic reviews were included, with data contributing 178 meta-analyses. Most meta-analyses (78%) were from reviews of moderate methodological quality. Across all the publications, evidence was identified for 38 associations between exposure to plastics and plastic-associated chemicals and 20 unique health outcomes, including cancer, cardiometabolic, reproductive, and neurodevelopmental. Synthesized estimates of the effects of plastic-associated chemical exposure were identified for the following health outcome categories in humans: birth, childhood adult reproductive, endocrine, child neurodevelopment, nutritional, circulatory, respiratory, skin related and cancers. Bisphenol A (BPA) is associated with decreased positional distance in infants, type 2 diabetes (T2D) in adults, insulin resistance in children and adults, and increased body mass index (BMI) and overweight in children, attention deficit hyperactivity disorder (ADHD) in girls and allergic rhinitis. Potential protective associations were found, namely observed pubertal timing in boys being less common with higher phthalate exposure. Increased high-density lipoprotein (HDL) with exposure to mono(2-ethyl-5-oxohexyl) phthalate (MEHHP) and reduced incidence of chronic lymphocytic leukaemia in a subset of TAG 1 with PCB exposure. Conclusions: Exposure to plastic-associated chemicals is associated with adverse outcomes across a wide range of human health domains, and many plastic-associated chemical group is associated in at least one adverse health outcome. Large gaps remain for many plastic-associated chemicals. Given the complexity of plastic composition and the ubiquity of exposure, we recommend that regulation of plastic and plastic-associated chemicals should not be based solely on systematic reviews, could introduce minor- and investigative as well as emerging plastic-associated chemicals of concern such as bisphenol analogues and replacement phthalates and flame retardants. With respect to chemical regulation, we propose that safety for plastic-associated chemicals in humans cannot be assumed at market entry. We therefore recommend that improved independent, systematic based testing for all plastic-associated chemicals is undertaken before market release of products. In addition because of the limitations of laboratory-based testing for predicting harm from plastic in humans, independent and systematic post-market bio-monitoring and epidemiological studies are essential to detect potential unforeseen harms. 統合_0157	N. Suwannarin, Y. Nishihama, T. Isobe and S. F. Nakayama	2024	Urinary concentrations of environmental phenol among pregnant women in the Japan Environment and Children's Study	Humans are exposed to various bisphenols, alkylphenols and nitrophenols through dietary intake, food packaging and container materials, indoor and outdoor air/dust. This study aimed to evaluate exposure of Japanese pregnant women to environmental phenols, by measuring target compounds in urine samples. From a cohort of the Japan Environment and Children's Study, JECS program, we randomly selected and sent 40 questionnaires to pregnant women. Bisphenol A (BPA), bisphenol F (BPF), bisphenol AF (BPAF), para-nitrophenol (PNP), 3-methyl-4-nitrophenol (MNP), 2-sec-butyl-4,6-dinitrophenol (DNBP), and 2-cyclohexyl-4,6-dinitrophenol (DCHP) were analyzed in urine samples collected in the second trimester. Urinary BPA was detected in 99.8% of samples, and the geometric mean (GM) was 1.1 μg/L. Urinary BPF was detected in 97.6% of samples, and the GM was 0.4 μg/L. Urinary BPAF was detected in 1.2% of samples. Urinary PNP, MNP, DNBP, and DCHP were not detected in any samples. Urinary BPA concentrations were positively correlated with urinary BPF concentrations. Urinary BPA concentrations were higher in participants who were younger, had lower household income, and had lower educational attainment. Urinary BPA concentrations were lower in participants who had a history of allergic rhinitis. Potential protective associations were found, namely observed pubertal timing in boys being less common with higher phthalate exposure. Increased high-density lipoprotein (HDL) with exposure to mono(2-ethyl-5-oxohexyl) phthalate (MEHHP) and reduced incidence of chronic lymphocytic leukaemia in a subset of TAG 1 with PCB exposure. Conclusions: Exposure to plastic-associated chemicals is associated with adverse outcomes across a wide range of human health domains, and many plastic-associated chemical group is associated in at least one adverse health outcome. Large gaps remain for many plastic-associated chemicals. Given the complexity of plastic composition and the ubiquity of exposure, we recommend that regulation of plastic and plastic-associated chemicals should not be based solely on systematic reviews, could introduce minor- and investigative as well as emerging plastic-associated chemicals of concern such as bisphenol analogues and replacement phthalates and flame retardants. With respect to chemical regulation, we propose that safety for plastic-associated chemicals in humans cannot be assumed at market entry. 統合_0158	S. Suresh, S. A. Singh and C. Vellapandian	2022	Bisphenol A exposure links to exacerbation of memory and cognitive impairment: A systematic review of the literature	This systematic review probes the deleterious outcome of Bisphenol A (BPA) exposure on cognitive/memory by scrutinizing the extent pre-clinical studies on this focus, to promote apprehension about this environmental issue among the general population with a long-term goal to tackle plastic (BPA) free manufacturing practices. Methods: Bibliographic databases, including Scopus, ProQuest, PubMed Central, Science Direct, and ScienceDirect were searched for preclinical reports assessing the impact of BPA exposure on memory/cognition. The review protocol has been published in PROSPERO with the registration number CRD42021233966. The ETHICUS, PuBrowser, SYRCLE's RoB tool was employed to assess the quality of the studies. Results: Out of 1,256 records identified, 20 studies were included in the review. Most studies confirmed the likelihood of the latent neurodevelopmental dysfunction, which may manifest as memory/cognitive decline. BPA impairs memory and cognition by binding to estrogen receptors, inducing ROS/RNS/MDA signaling pathway, altering the expression of synaptic proteins, impacting the morphology of pyramidal neurons in the hippocampus, dysregulation of thyroid hormones, and altering the neurotransmitter levels. Kocer-Gumusel	2019	Oxidative stress markers, trace elements, and endocrine disrupting chemicals in children with Hashimoto's thyroiditis	In this study, we aimed to investigate whether bisphenol A (BPA) and di (2-ethylhexyl) phthalate (DEHP) exposure have any association with Hashimoto's thyroiditis (HT) and its biomarkers, and to determine whether oxidative stress biomarkers and trace element levels showed any alterations in children with HT. We found that superoxide dismutase and glutathione peroxidase activities are lower in HT group from control (39% and 48%, respectively, p < 0.05). Zinc levels were significantly lower in HT group vs. control. In addition, the levels of mono (2-ethylhexyl) phthalate (MEHP) which is the primary metabolite for DEHP, were markedly higher in HT group compared to control (p < 0.05). A negative correlation was observed between urinary BPA levels and FT3. In children with HT, redox/antioxidant balance is changed and these differences may be related to EDC exposure, the importance of which should be evaluated with further studies.	Toxicol Mech Methods Vol.29 Issue 9 Pages 633-643	10.1080/15376516.2019.1646367	31354016	ヒト	-	-	-	-	-	-	横断研究	1	1	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-

Piantaweetus	2025	Bisphenol A Biomonitoring after Sealant Placement: A Prospective Cohort Study in Schoolchildren	INTRODUCTION: Bisphenol A (BPA), known for its endocrine-disrupting properties, is a concern when leaching from dental sealants. This study investigates the systemic BPA exposure following the placement of Bis-GMA-based dental sealants in Thai primary school students. OBJECTIVES: The main objective was to evaluate the changes in urinary BPA concentrations after the application of Bis-GMA dental sealants in a cohort of Thai students. METHODS: In a prospective cohort of Thai primary school students participating in a voluntary sealant placement program, urinary BPA concentrations were measured. Urine samples (immediately before and on days 1, 7, and 14 after sealant application) BPA levels were measured using high-performance liquid chromatography. Repeated measures analysis using generalized estimating equations was performed to assess changes in BPA concentrations over time. Creatinine levels were also measured to account for urine dilution. Estimated daily intake (EDI) values were calculated using the formula: EDI = (BPA concentration × urine volume)/body weight, considering the mean urine volume for children aged 6–12 years. RESULTS: Data were collected from 50 Thai students (mean age of 8.9 ± 1.3 years; 60% female). The mean body mass index (BMI) was 17.7 ± 3.0 kg/m2, and the average volume was 0.4 ± 0.3 mL. Urinary BPA concentrations were 1.1–122 ng/mL with 0.66 creatinine. The median adjusted BPA levels before sealant placement and on days 1, 7, and 14 were 0.02, 0.03, 0.19, and 0.23 μg/g creatinine, respectively. The analysis revealed a significant association between the number of sealed teeth and increased BPA levels at all visits (GEE2) (0.0019). The application of Bis-GMA-based dental sealants, in children results in low-level BPA exposure due to chemical leaching. Despite such a low level of BPA exposure, approved by international health authorities, it could be considered a silent, chronic, and persistent systemic event, the long-term implications of which are yet to be fully understood. Our findings underscore the importance of monitoring BPA exposure from dental materials, aligning with international limits. However, the long-term effects are unknown. This information should inform dental care practices and guide policymakers in assessing the chronic impacts of BPA exposure from dental materials. Yurdakök	2019	Prenatal bisphenol a and phthalate exposure are risk factors for male reproductive system development and cord blood sex hormone levels	Bisphenol A (BPA) and phthalates can adversely affect the fetal development. However, observational studies on the effects of these chemicals on fetal male reproductive system are still limited. A hundred of umbilical cord blood samples were analyzed for the levels of BPA, di-2-ethylhexyl phthalate (DEHP), mono-(2-ethylhexyl) phthalate (MEHP), and sex hormones. After birth, male newborns underwent a physical examination that included measurements of anogenital distance, stretched penile length (SPL), and penile width. BPA, DEHP and MEHP levels were detectable in >99% of cord blood samples. In univariate adjusted models, cord blood BPA levels were inversely associated with SPL, of newborns and positively associated with cord blood estradiol levels. In addition, there was a significant inverse relationship between cord blood DEHP levels and anogenital distance index of newborn males. Our results suggest that in vitro BPA and DEHP exposure exerted adverse effects on fetal male reproductive development and cord blood estradiol levels. 統合_0162	M. Sung, H. M. Jee, J. H. Kim, E. K. Ha, Y. H. Shin, J. H. Kim, D. H. Lim and M. Y. Han	2022	Serum vitamin D level mitigates fractional exhaled nitric oxide linked to bisphenol-A in school-aged children	OBJECTIVE: Previous studies on the relationship of bisphenol A (BPA) with fractional exhaled nitric oxide (FeNO) had conflicting results, suggesting that other factors may modulate this relationship. Thus, we investigated the modifying effect of vitamin D on the relationship of BPA with FeNO in children. PATIENTS AND METHODS: This study recruited 1,130 children (6 to 12 years old) from 2 metropolitan areas of Korea between June and July 2017. We conducted measurements of urinary BPA, serum vitamin D, specific serum IgE, FeNO, and data from inactive oscillometry (resistance and [Xrs]), airway resistance at 5 Hz ([Rrs5]) and 20 Hz ([Rrs20]), and reactance area ([AX]). RESULTS: Urinary BPA was detected in 1,129 children (99.9%). Urinary BPA concentrations were significantly associated with FeNO in children with low vitamin D levels (1.25 ng/mL < d < 3.66 ng/mL, n = 282), but not in children with high vitamin D levels (≥ 3.75 ng/mL). The interaction of vitamin D and BPA had a significant effect on FeNO (p(int) = 0.005). There was no relationship with the airway lung function (Rrs5, Rrs20, and Rrs5–20) in serum vitamin D and urinary BPA level. Vitamin D ameliorated the BPA-mediated increase of FeNO in children. CONCLUSIONS: These results suggest that children with low vitamin D levels may be more susceptible to airway inflammation due to BPA. Ustuoglu	2022	Biomonitoring of bisphenol A, 4-nonylphenol, and 4-t-octylphenol in Turkish population: exposure and risk assessment	Biomonitoring studies are important tools to understand the effects of endocrine-disrupting compounds on human health. Up to now, there have been no biomonitoring and risk assessment studies conducted in Turkish population in which urinary bisphenol A (BPA), 4-nonylphenol (4-NP), and 4-t-octylphenol (4-t-OP) levels were measured simultaneously. The aim of this study is to measure urinary BPA, 4-NP, and 4-t-OP on Turkish population and to estimate exposure and risk assessment. Urine samples were collected from 100 adults (50 males and 50 females) in Izmir, Turkey. Urinary BPA, 4-NP, and 4-t-OP were analyzed by using mentioned methods, and human biomonitoring was used as a risk assessment tool in EDI estimations. Using a Monte Carlo, Turkey, Izmir BPA, 4-NP, and 4-t-OP medians were 0.0019, 0.0 μg/g creatinine, 0.027, 0.0 μg/g creatinine, and 0.016 μg/g creatinine, respectively. The obtained environmentally intakes (EDIs) were calculated as 0.098 μg/kg bw/day, 0.061 μg/kg bw/day, and 0.092 μg/kg bw/day for BPA, 4-NP, and 4-t-OP, respectively. In conclusion, although no potential health risk due to BPA and 4-NP exposure was observed, there might be health risks associated with 4-t-OP exposure in the Turkish population. 統合_0164	M. Sugiura-Ogasawara, N. Suwannarin, H. Tamada, T. Ebara, Y. Ito, S. F. Nakayama, M. Takagi, S. Saitoh and M. Kamijima	2025	Effect of maternal bisphenol exposure on adverse pregnancy and neonatal outcomes: The Japan Environment and Children's study	Maternal exposure to bisphenols, including bisphenol A (BPA), reportedly results in adverse pregnancy and offspring health outcomes. However, large birth cohort studies on the risk of BPA exposure during pregnancy remain limited. Here, we examined bisphenol effects on adverse pregnancy and neonatal outcomes using data from the Japan Environment and Children's Study, a nationwide birth cohort study. We selected 2013 women with pregnancies resulting in singleton live births. First trimester urine concentrations of bisphenols A, F, S, and AF were determined via high-performance liquid chromatography–tandem mass spectrometry. We analyzed the association between BPA exposure and preterm birth, hypertensive disorders of pregnancy, gestational hypertension, preeclampsia, small- and large-for-gestational-age infants, low birth weight, shortening physiological chromosome aberrations using Bayesian logistic regression analysis after applying the 50 limp imputation method for concentrations within the minimum reporting limit. Bisphenol detection rates were generally low (0.2–4.2%), except for BPA (96.2%). The median BPA concentration was 1.1 ng/mL, and the 95th percentile was 6.4 ng/mL. Only 0.2% of participants (4 individuals) exceeded the European Food Safety Authority's tolerable daily intake (0.0002 μg/kg/day). However, BPA intake was not significantly associated with any outcome. These findings suggest that BPA's current exposure levels do not affect measured pregnancy and neonate outcomes in Japan. Here, although BPA levels reflect only recent exposure, the potential health risks associated with BPA underscore the need for further research to investigate the long-term effects of low-level exposure on maternal and child health. 統合_0165	H. Su, J. Xi, M. Miao, H. Liang, Y. Chen, Z. Wang, Y. Zhou, Y. Jin, H. Ji and W. Yuan	2025	Bisphenol analogs exposure in 4-year-old children and their intelligence quotient at 6 years: A prospective cohort study	Prenatal exposure to bisphenol A (BPA) has been shown to impact offspring cognition, behavior, and intelligence. However, whether co-exposure to bisphenol analogs (BPs) during childhood affects children's intelligence remains unclear. We included 681 mother-child pairs from the Shanghai Minhang Birth Cohort Study to examine the impact of children's exposure to BPs at 4 years of age on the intelligence quotient (IQ) measured at 6 years. BPs concentrations were measured in single-void urine samples collected from 4-year-old children. We used the Wechsler Intelligence Scale for Children-revised edition to assess children's IQ. Multiple linear regression models were used to examine the associations between BPs and IQ. Bayesian kernel machine regression (BKMR) models were used to evaluate the joint and single-exposure effects of BPs. Within 14 girls, exposure to BPA was positively associated with full-scale IQ (FSIQ) (β = 3.92, 95% CI: 0.01, 7.83), verbal IQ (VIQ) (β = 4.08, 95% CI: 0.01, 8.15), and performance IQ (PIQ) (β = 4.08, 95% CI: 0.01, 8.15). BPA contributed the most to the joint effect of BPs in girls. The associations remained robust after adjusting for children IQ. In boys, exposure to bisphenol analogs (BPA + bisphenol S + bisphenol F) was positively associated with an increase in FSIQ and PIQ; however, the number of exposed boys was small. Our study suggests that BPs exposure at 4 years of age may be associated with a boost IQ at 6 years. In girls, BPF may not be a safe substitute for BPA. Further epidemiological studies are required to confirm these findings.	Environ Res. 2025 Jul 1:276:121528.	10.1016/j.envres.2025.121528	40185270	ヒト	発達神経	-	-	-	-	-	コホート研究	1	1	-	-	-	1	1	1	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-

Meeker	2024	Urinary phenol and paraben concentrations in association with markers of inflammation during pregnancy in Puerto Rico	Exposure to phenols and parabens may contribute to increased maternal inflammation and adverse birth outcomes, but these effects are not well-studied in humans. This study aimed to investigate relationships between concentrations of 8 phenols and 3 parabens with 4 inflammatory biomarkers (C-reactive protein (CRP), matrix metalloproteinase-9 (MMP-9, 2, and 9), intercellular adhesion molecule-1 (ICAM-1)) and vascular cell adhesion molecule-1 (VCAM-1)) measured at two time points in pregnancy in the PROTECT birth cohort in Puerto Rico. Linear mixed models were used, adjusting for covariates of interest. Results are expressed as the percent change (95% confidence interval (CI)) in inflammatory biomarkers per interquartile range increase in urinary chemical concentrations. Bisphenol A (BPA) was associated with increases in CRP (% change = 11.2; CI: −0.92, 24.0) and intercellular adhesion molecule-1 (ICAM-1; % change = 3.26; CI: 0.26, 6.35). However, significant positive associations were also detected for metabolites of BPA (MMP-9 (17.1%; 95 % CI: 5.67, 29.48) and methyl paraben and MMP-2 (10.76%; 95 % CI: 2.27, 20.11)). Significant interactions with female fetal sex and the later study visit (at 26–28 weeks gestation) showed more positive associations compared to male fetal sex and the earlier study visit (12–16 weeks gestation). Our results suggest that phenols and parabens may disrupt inflammatory processes pertaining to uterine remodeling and endothelial function, with important implications for pregnancy outcomes. More research is needed to further understand maternal inflammatory status in an effort to improve reproductive and developmental outcomes. Iversen	2022	Estimated daily intake of phthalates, parabens, and bisphenol A in hospitalised very low birth weight infants	Very low birth weight infants (VLBW, birth weight (BW) < 1500 g) are exposed to phthalates, parabens, and bisphenol A (BPA) early in life. We estimated daily intake (EDI) of these exposants in 60 VLBW infants the first and fifth week of life while hospitalised. Repeat urinary samples collected in 2015, EDI were calculated and compared to the tolerable daily intake (TDI) with hazard quotients (HQs) evaluated. A HQ > 1 indicates that EDI exceeded TDI with increased risk of adverse health effects. EDI was higher in VLBW infants compared to term infants and older children. VLBW infants born at mat gestational age (GA), or with lower BW, had higher EDI of DEHP, DBP, DiBP, BPA, and propylparaben (PrPa). EDI of DEHP, DBP, DiBP, BPA, and PrPa were higher in week 1 than week 5. HQ > 1 was found for DEHP and DiBP. DEHP + DiBP + DnBP, or a dual phthalate (DnBP, DiBP and di-iso-octyl phthalate (DiNP)) > 2.58xDiBP+DnBP+DEHP+DiNP, and in 50% of infants for propylparaben (PrPa), indicating increased risk of adverse effects. If this week EDI remained higher than TDI in all infants for BPA, in 75% for DEHP and 2.58xDiBP+DnBP+DEHP+DiNP, and 25% of infants for PrPa, indicating prolonged risk. Maximum EDI for di- iso-butyl phthalate was higher than TDI suggesting risk of adverse effects at maximum exposure. VLBW infants born earlier than 28 weeks GA had higher EDI, above TDI, for PrPa compared to infants born later than 28 weeks GA. Infants with low serum oxyphenisatrin (LOS) had higher EDI for DEHP, 2.58xDnBP+DiBP+DEHP+DiNP and BPA, above TDI, compared to infants achieving LOS. More 75% of the infants' EDI for DEHP and 2.58xDnBP+DiBP+DEHP+DiNP, 25% for PrPa, and 100% of infants' EDI for BPA, were above TDI resulting in HQs > 1, indicating increased risk of adverse health effects. 統合_0168	K. Stanmore, J. L. Lycha, S. J. Motta, M. H. B. M Ulhe, E. W. Blakstad, A. N. Alinaas, A. K. Satri, C. Thomsen, B. Nakstad, A. E. Rønnestad, C. A. Drevon and P. O. Iversen	2021	High urinary concentrations of parabens and bisphenol A in very low birth weight infants	Very low birth weight infants (VLBW; birth weight < 1500 g) are treated with pharmaceuticals and medical equipment containing parabens and bisphenol A (BPA). Parabens are used in pharmaceuticals, whereas BPA is medical equipment where concentrations are rarely reported in hospitalized VLBW infants. We measured urinary concentrations of parabens and BPA and hypothesized high and increasing concentrations in infants born extremely preterm (EPT; gestational age (GA) < 28 weeks) compared to infants born moderately preterm (MPT; GA 28–32 weeks) and near-term (NT; GA 33–36 weeks). Urine samples were collected during the first (n = 38) and 4th (n = 36) week of life. Methylparaben, ethylparaben, propylparaben, butylparaben, and BPA concentrations were measured using ultra high-performance liquid chromatography coupled to tandem mass spectrometry. VLBW infants had very high urinary concentrations of parabens and BPA compared to term infants and older children. The 3 paraben concentrations are higher than detected in previous studies on premature infants. Lower GA at birth was associated with higher concentrations of parabens and BPA. Infants born below 28 weeks GA had higher first week concentrations of propylparaben (38.6 % (95 % CI: 9.59 ng/mL, p = 0.007), butylparaben (52.8 % (95 % CI: 10.9 ng/mL, p = 0.06) and fifth week concentrations of BPA (19.1 % (95 % CI: 4.02 ng/mL, p = 0.02) than infants born after 28 weeks GA. Infants with LOS and BPD had higher fifth week concentrations of BPA than infants without LOS and BPD (0.05 (0.2 to -8.77 ng/mL, p = 0.07) BPD (8.6 to -7.02 ng/mL, p = 0.05). 統合_0169	T. P. Stein, M. D. Schluter, R. A. Steer and X. Ming	2023	Bisphenol-A and phthalate metabolism in children with neurodevelopmental disorders	BACKGROUND: The etiology of autism spectrum (ASD) and Attention Deficit Hyperactivity (ADHD) disorders are multifactorial. Epidemiological studies have shown associations with environmental pollutants, such as plasticizers. This study focused on two of these compounds, the Bisphenol A (BPA) and Diethylhexyl Phthalate (DEHP). The major pathway for BPA and DEHP excretion is via glucuronidation. Glucuronidation makes insoluble substances more water-soluble allowing for their subsequent elimination via urine. PTPRT/PTK7/SLITRK5 Glucuronidation of these two plasticizers is compromised in children with ASD and ADHD. Consequently, their tissues are more exposed to these two plasticizers. METHODS: We measured the efficiency of glucuronidation in three groups of children, ASD (n = 66), ADHD (n = 38) and healthy controls. (CTRL n = 37). The children were between the ages of 3 and 16 years old. Glucuronidation efficiencies for BPA and DEHP were calculated by measuring the ratio between the parent plasticizer and its glucuronide derivative. We used these ratio values for the efficiency of glucuronidation for 12 varied glucuronidation pathways including those for BPA and MEHP. RESULTS: (1) Both BPA and MEHP glucuronidation showed that the three groups of children were statistically different from each other. (2) Of the 12 pathways examined, only the BPA and MEHP pathways discriminated between the three groups. (3) Glucuronidation efficiencies for BPA were reduced by 13.1% in ASD (p < 0.025) and 17% for ADHD (p<0.001) compared to controls. DEHP-glucuronidation, but not significant levels. CONCLUSION: ASD and ADHD are clinically and metabolically different but share a reduction in the efficiency of detoxification for both BPA and DEHP with the reductions for BPA being statistically significant. 統合_0170	L. Stecca, I. Moscoso-Ruiz, Y. Gálvez-Ontiveros and A. Rivas	2022	Association between dietary exposure to bisphenols and body mass index in Spanish schoolchildren	The increase in children obesity worldwide has been of particular concern in recent decades. Environmental factors have been proposed as contributors to obesity, and there is a growing concern over obesogens, environmental chemicals with potential obesity-related endocrine disrupting properties. In this regard, bisphenol A (BPA) and its analogues are suspected to have obesogenic properties. Current document report on the activities of the latest, undertaken during the fourth, 2020-2021 cycle of the EU-COSI programme at the University of Granada, Institute of Nutrition and Food Science, in Spain. The work programme offered by the hosting site was related to the extrapolation of bisphenols exposure following the determination of these compounds in food frequently consumed by children and in the diet of children. The follow- ups were planned for the recruitment of the study population in the health centres. In addition, she has participated in the collection of the children biological samples, anthropometric measurements and dietary surveys and in the optimization of the laboratory methodology for the extraction of bisphenols, in biological samples. All these activities also provided the fellow an opportunity to develop her data science-related skills, which will benefit her professional development. In addition, the fellow gained an overview of various topics related to food safety risk assessment by attending the EU-FORA dedicated training modules. 統合_0171	A. Soundararajan, P. Prabu, V. Mohan, Y. Gibert and M. Balasubramanyam	2019	Novel insights of elevated systemic levels of bisphenol-A (BPA) linked to poor glycemic control, accelerated cellular senescence and insulin resistance in patients with type 2 diabetes	There is a striking interaction of genes and environment in the etiology of type 2 diabetes mellitus (T2DM). While endocrine disrupting chemicals (EDCs) like bisphenol-A (BPA) have received special attention for their mechanistic role in metabolic dysregulation, there is a lack of clinically relevant data on BPA levels in Asian Indians, a population which is more susceptible to type 2 diabetes mellitus (T2DM) and cardiovascular diseases. Therefore, we measured systemic levels of BPA in patients with T2DM compared to individuals with normal glucose tolerance (n = 50 each). Serum BPA levels were estimated using ELISA kit, and biochemical determinations were done by standard protocols. Peripheral blood mononuclear cells (PBMCs) were used to profile the gene expression alterations, with special reference to inflammation, estrogen receptors, and cellular senescence in these subjects. Serum levels of BPA were significantly higher in patients with T2DM compared to control individuals and positively correlated to poor glycemic control and insulin resistance. Patients with T2DM showed significantly higher expression of pro-inflammatory genes (TNF-α, IL-6, and MCP-1) in PBMCs, which positively correlated with BPA levels. Interestingly, the expression of estrogen receptor gamma (ERR-γ), a recently identified receptor for BPA, BPA levels were positively correlated to senescence indicators, inflammatory markers and ERR-γ and negatively correlated to telomere length. Our study is the first data in the clinical diabetic setting to demonstrate an association of increased BPA levels with cellular senescence, proinflammation, poor glycemic control, insulin resistance, and shortened telomeres in patients with T2DM. Dewey	2024	Maternal exposure to bisphenols, phthalates, perfluoroalkyl acids, and trace elements and their associations with gestational diabetes mellitus in the APrON cohort	The increasing global prevalence of gestational diabetes mellitus (GDM) has been hypothesized to be associated with maternal exposure to environmental chemicals. Here, among 526 women participating in the Alberta Pregnancy Outcomes and Nutrition (APrON) cohort study, we examined associations between GDM and urine concentrations of endocrine disrupting chemicals (EDCs): bisphenol A (BPA), bisphenol S (BPS), twelve phthalate metabolites, eight perfluoroalkyl acids (PFAAs), and eleven trace elements. Fifteen (3.0%) of the women were diagnosed with GDM, and associations between the environmental chemicals and GDM were investigated using multivariable logistic regression models. Urine samples were collected in the second trimester (median = 26.1 weeks gestation) and first morning voids were analyzed. Women with GDM had higher urinary concentrations of BPA (GDM: 1.3 ng/mL, IQR: 0.6, 2.1; CONTROL: 0.8 ng/mL, IQR: 0.4, 1.5; p = 0.009), BPS (GDM: 0.2 ng/mL, IQR: 0.1, 0.4; CONTROL: 0.1 ng/mL, IQR: 0.0, 0.2; p = 0.008), and perfluorooctanoic acid (PFOA) (GDM: 1.1 ng/mL, IQR: 0.7, 1.6; CONTROL: 0.8 ng/mL, IQR: 0.5, 1.2; p = 0.04). The combined risk for the Canadian cohort suggest that second trimester blood mercury was a robust predictor of GDM diagnosis, whereas blood zinc and PFOA risk were protective factors. Research into mechanisms that underlie the associations between mercury, zinc, PFOA, and the development of GDM is needed. Yuan	2020	Association between prenatal bisphenol a exposure and promoter hypermethylation of CAPS2, TNFRSF25, and HKR1 genes in cord blood	In utero exposure to bisphenol A (BPA) in early stages of development has been reported to exert adverse health effects as offspring later in life. Epigenetic alterations, particularly DNA methylation, may be one plausible biological mechanism involved. We examined the association between maternal BPA exposure and DNA methylation in cord blood. We randomly selected 96 paired samples of maternal urine and infant cord blood collected from the Shanghai Minhang Birth Cohort. BPA levels in maternal urine were measured using high-performance liquid chromatography (HPLC). Three cord blood samples with maternal BPA levels <2.0 μg/g Cr and three samples with undetected BPA were combined to generate wide methylation analysis using methylated DNA binding domain sequencing (MBD-Seq). Thirty genes with hypermethylated promoter regions were chosen for validation using quantitative methylation-specific polymerase chain reaction (Q-MSP). Based on MBD-seq results, we observed that maternal BPA exposure was primarily associated with hypermethylation of genes in cord blood. Validation of 30 genes revealed that CAPS2, TNFRSF25, and HKR1 were significantly hypermethylated in the high-BPA group. Hypermethylation of these genes was confirmed in an additional 90 paired samples. Multiple regression models using each increase in BPA was associated with 0.26% (95%CI: 7.1%, 17.1%), 19% (95%CI: 3.1%, 37.6%), and 14.5% (95% CI: 0.1%, 31.6%) increase in promoter of CAPS2, TNFRSF25, and HKR1 methylation, respectively. Our findings provide evidence that in utero exposure to BPA could alter the offspring's epigenome by altering DNA methylation pattern. 統合_0175	X. Song, Z. Wang, Z. Zhang, M. Miao, J. Liu, M. Luan, J. Du, H. Liang and W. Yuan	2021	Differential methylation of genes in the human placenta associated with bisphenol A exposure	Prenatal exposure to bisphenol A (BPA) is associated with numerous adverse health outcomes among offspring. Although DNA methylation is considered one of the underlying causes of these associations, few studies have focused on the association between prenatal BPA exposure and DNA methylation in the human placenta. In this study, we examined the association between prenatal BPA exposure and DNA methylation in the placenta of 116 mother–infant pairs from the Shanghai Minhang Birth Cohort Study. BPA concentrations in maternal urine samples were measured using high-performance liquid chromatography. The placenta samples were selected for whole-genome methylation analysis using Infinium HumanMethylation 850K BeadChip, followed by pyrosequencing-based methylation analysis of three selected genes in 116 placentas. Among 392 differentially methylated CpG sites (DMCs) identified between the high- and low-BPA groups, 382 DMCs were hypermethylated in the high-BPA group. Pyrosequencing validated the DMRs in individuals as determined using pyrosequencing, which was consistent with the whole-genome methylation analysis results. Compared with their subjects with low BPA exposure, the methylation level (re-transformed) of HLA-DRB6 in placentas from those with high BPA exposure increased by 0.29% (95% confidence interval [CI]: 0.07%, 0.50%) at the CpG site, and the average methylation level (re-transformed) of the three CpG sites increased by 0.26% (95%CI: -0.05%, 0.55%). Our findings provide evidence that prenatal BPA exposure might alter DNA methylation levels in the placenta. Santos	2021	Maternal bisphenol urine concentrations, fetal growth and adiverse birth outcomes: A population-based prospective cohort	BACKGROUND: Exposure to bisphenols may affect fetal growth and development. The trimester-specific effects of bisphenols on repeated measures of fetal growth remain unknown. Our objective was to examine the associations of maternal bisphenol urine concentrations with fetal growth measures and birth outcomes and identify potential critical exposure periods. METHODS: In a population-based prospective cohort study among 1279 pregnant women, we measured maternal bisphenol A, S and F urine concentrations in the first, second and third trimester. Fetal head circumference, length and weight were measured in the second and third trimester by ultrasound and at birth. RESULTS: An interquartile range increase in maternal pregnancy averaged bisphenol S concentrations was associated with larger fetal head circumference (difference 0.20 SD; 95% confidence interval (CI) 0.04, 0.36), length (0.19 SD; 95% CI 0.03, 0.35) and weight (0.19 SD; 95% CI 0.03, 0.35) at birth. Bisphenol S concentrations in the second trimester were associated with larger fetal head circumference (difference 0.14 SD; 95% CI 0.01, 0.27) and length (0.14 SD; 95% CI 0.01, 0.27) at birth. Bisphenol S concentrations in the third trimester were associated with larger second and third trimester fetal head circumference (difference 0.14 (95% CI 0.01 to 0.26 and 0.13 (95% CI 0.01 to 0.25) SDS, respectively) and fetal weight (difference 0.12 (95% CI 0.01 to 0.23) and 0.13 (95% CI 0.01 to 0.25) SDS, respectively). The other bisphenols were not consistently associated with fetal growth outcomes. Any detection of bisphenol S and bisphenol F in first trimester was also associated with a lower risk of being born small size for gestational age (Odds Ratio 0.58 (95% CI 0.38 to 0.72) and 0.53 (95% CI 0.34 to 0.80), respectively). Bisphenols were not associated with risk of preterm birth. CONCLUSIONS: Higher maternal bisphenol S urine concentrations, especially in the first trimester, seem to be related with larger fetal head circumference, higher weight and a lower risk of being small size for gestational age at birth.	33992119	ヒト	生殖発生	-	-	-	-	-	-	コホート研究	1	1	-	-	-	-	-	-	1	1	1	1	-	-	-	-	-	-	-	-	-	-	-	-
統合_0177	C. M. Sol, S. Santos, L. Duijts, A. G. Asimakopoulos, M. P. Martinez-Moral, K. Kannan, E. M. Philips, L. Trasande and V. W. V. Jaddoe	2020	Fetal exposure to phthalates and bisphenols and childhood general and organ fat. A population-based prospective cohort study	OBJECTIVES: Fetal exposure to phthalates and bisphenols might have long-lasting effects on growth and fat development. We could to know about the effects on general and organ fat development in childhood. We examined associations of maternal phthalate and bisphenol urine concentrations during pregnancy with childhood general and organ fat measures. METHODS: In a population-based prospective cohort study among 1,279 pregnant women, we measured maternal urinary phthalate metabolites and bisphenol concentrations in first, second, and third trimester. Offspring body mass index, fat mass, total body lean mass, total body bone mass, total body fat mass (dual-energy X-ray absorptiometry), and visceral and pericardial fat indices and liver fat fraction were measured by magnetic resonance imaging at 10 years. RESULTS: After adjustment for confounders and correction for multiple testing, an interquartile range increase in first trimester urinary concentrations of mono-(3-carboxypropyl) phthalate (MCPP) was associated with lower childhood visceral fat index (-0.12 SD; 95% confidence interval (CI) -0.21, -0.03). Associations of higher maternal low-molecular-weight phthalate urinary concentrations in second trimester with childhood pericardial fat index, but these were not significant after adjustment for multiple testing. High molecular-weight phthalate, di-2-ethylhexyl phthalate, and di-n-octyl phthalate concentrations were not associated with childhood outcomes. Maternal urinary bisphenol concentrations were not associated with childhood adiposity. CONCLUSIONS: Maternal first trimester phthalic acid concentrations are associated with increased childhood pericardial fat index at 10 years of age, whereas maternal bisphenol concentrations are not associated with childhood adiposity. We did not find significant sex-specific effects. These findings should be considered as hypothesis-generating and need further replication and identification of underlying mechanisms.	Int J Obes (Lond). 2020 Nov;44(11):2225-2235.	10.1038/s41366-020-00672-7	32920592	ヒト	代謝	-	-	-	-	-	-	コホート研究	1	1	-	-	-	-	-	-	1	1	1	-	-	-	-	-	-	-	-	-	-	-	-

Jaddoe	2020	Associations of maternal phthalate and bisphenol urine concentrations during pregnancy with childhood blood pressure in a population-based prospective cohort study	OBJECTIVES: Fetal exposure to phthalates and bisphenols may lead to vascular developmental adaptations, which program later cardiovascular disease. We examined the associations of fetal exposure to phthalates and bisphenols with childhood blood pressure. METHODS: In a population-based prospective cohort study among 1,063 mother-child pairs, we measured maternal urine phthalate and bisphenol concentrations in first, second, and third trimester. Systolic and diastolic blood pressure were measured at the age of 6 years. We used multivariable linear regression models. RESULTS: Maternal urinary concentrations of mono-(3-carboxypropyl) phthalate (MCPP) were associated with lower systolic blood pressure at 6 years (-0.22 SD; 95% confidence interval (CI) -0.39, -0.05) and diastolic blood pressure (-0.21 SD; 95% CI -0.38, -0.04). Higher maternal second trimester urinary concentrations of mono-(2-ethylhexyl) phthalate (MEHP) were associated with lower systolic and diastolic blood pressure among girls (p-values < 0.05). Also, higher second trimester maternal urine total bisphenol and bisphenol S concentrations were associated with higher systolic blood pressure among boys (p-values < 0.01), but tended to be associated with a lower diastolic blood pressure among girls. CONCLUSIONS: Our results suggest sex-dependent associations of maternal urine phthalate and bisphenol concentrations during pregnancy with childhood blood pressure. Further studies are needed to explore the underlying mechanisms and long-term consequences. 統合_0179	C. M. Sol, A. Gaylord, S. Santos, V. W. V. Jaddoe, J. F. Felix and L. Trasande	2022	Fetal exposure to phthalates and bisphenols and DNA methylation at birth: the Generation R Study	BACKGROUND: Phthalates and bisphenols are non-persistent endocrine disrupting chemicals that are ubiquitously present in our environment and may have long-lasting health effects following fetal exposure. A potential mechanism underlying these exposure-outcome relationships is differential DNA methylation. Our objective was to examine the associations of maternal phthalate and bisphenol concentrations during pregnancy with DNA methylation at birth. METHODS: In a population-based prospective cohort study among 1,279 pregnant women, we measured maternal urinary phthalate and bisphenol concentrations in first, second and third trimester. We measured DNA methylation in cord blood at birth using the Illumina Infinium HumanMethylation450 BeadChip and pre-engineered multi-associative approach. Using assembly computation, we examined the association of increasing all mixture components by one quartile with controlled DNA methylation. RESULTS: We did not find evidence for statistically significant associations of a maternal mixture of phthalates and bisphenols during any of the trimesters of pregnancy with DNA methylation in cord blood (all p-values > 0.01 * 10-4). However, we identified one suggestive association (p-value = 1.3 * 10-4) of the first trimester maternal mixture of phthalates and bisphenols and three suggestive associations of the second trimester maternal mixture of phthalates and bisphenols with DNA methylation in cord blood. CONCLUSIONS: Although we did not identify genome-wide significant results, we identified some suggestive associations of exposure to a maternal mixture of phthalates and bisphenols in the first and second trimester with DNA methylation in cord blood that need further exploration in larger study samples.	Clin Epigenetics. 2022 Oct 10;14(1):125.	10.1186/s13148-022-01345-0	36217170	ヒト	遺伝毒性	-	-	-	-	-	-	コホート研究	1	1	-	-	-	-	-	-	1	1	1	-	-	-	-	-	-	-	-	-	-	-	-
統合_0180	A. R. Smith, K. R. Kogut, K. Parra, A. Bradman, N. Holland and K. G. Harley	2022	Dietary intake and household exposures as predictors of urinary concentrations of high molecular weight phthalates and bisphenol A in a cohort of adolescents	BACKGROUND: Phthalates and bisphenol A (BPA) are endocrine disrupting chemicals used in consumer products, building materials, and food processing and packaging materials. They are associated with adverse health outcomes, especially when exposure occurs during heightened windows of vulnerability. OBJECTIVE: We evaluated the relationship between housing and dietary characteristics and the concentrations of several high molecular weight (HMW) phthalate metabolites and BPA in a cohort of Latina adolescents. METHODS: We collected information on recent food consumption and housing characteristics and quantified the concentration of HMW phthalate and BPA metabolites in urine collected at two different time points. We used generalized estimating equations (GEE) to assess predictors of each metabolite. RESULTS: In significant associations were observed between housing and dietary characteristics and metabolites of di(2-ethylhexyl) phthalate (DEHP) or BPA. In contrast, higher urinary monobenzyl phthalate (MBzP) concentration was associated with consuming fast food (β = 0.26; 95% CI: 0.03, 0.49) and canned soup (β = 0.23; 95% CI: 0.01, 0.45) in the previous 24 hours. Higher concentration of sulfur (ΔS.CR; change: p-value <0.01), and had lead (Δ0.1b; change: p-value <0.05). DISCUSSION/CONCLUSION: These findings may be useful in targeting interventions that reduce phthalate uptake in young adults. 統合_0181	M. Sladić, S. Smrkulj, G. Kavšek, S. Imamović-Kumalić, I. Vierdenk and I. Vivanti-Klun	2025	Bisphenol A in the Urine: Association with Urinary Creatinine, Impaired Kidney Function, Use of Plastic Food and Beverage Storage Products but Not with Serum Anti-Müllerian Hormone in Ovarian Malignancies	Bisphenol A (BPA) is a high-production-volume industrial chemical and component of commonly used plastic products. However, it is also an endocrine-disrupting chemical that can negatively affect human health. It is not yet known whether it is associated with the development of epithelial ovarian cancer (EOC), a severe and highly fatal human disease. Therefore, the purpose of this study was to determine the concentrations of BPA in the urine of patients with EOC and to investigate the relationship between BPA and the clinicopathological characteristics of EOC. Urine samples were collected from 100 patients with EOC and 100 healthy control subjects. Using a questionnaire, we collected sociodemographic, lifestyle, and clinical data, including information on BPA exposure sources. Urinary BPA concentrations were measured by high-performance liquid chromatography with fluorescence detection (HPLC-FLD). Creatinine (CRE) was measured using a colorimetric assay, and urinary BPA concentrations were normalized to CRE levels to account for variations in urine dilution. Serum anti-Müllerian hormone (AMH) levels were measured using an enzyme-linked immunosorbent assay (ELISA). Statistical analyses were performed to assess differences in BPA concentrations between EOC patients and healthy controls, as well as associations between BPA exposure and clinicopathological characteristics of EOC. Urinary BPA concentrations were significantly higher in EOC patients than in healthy controls ($p < 0.001$). Multivariate logistic regression analysis revealed that urinary BPA concentration was significantly associated with EOC risk (OR = 1.003, 95% CI: 1.001–1.005, $p = 0.001$). Additionally, urinary BPA concentrations were significantly correlated with serum AMH levels ($p = 0.001$), suggesting a potential relationship between BPA exposure and ovarian reserve. However, no significant associations were observed between urinary BPA concentrations and clinicopathological characteristics, including tumor stage, histological grade, or lymph node metastasis. These findings suggest that BPA exposure may be associated with EOC risk and ovarian reserve, but its role in disease progression remains unclear. Further prospective studies with larger cohorts are needed to validate these findings and explore potential mechanisms underlying the observed associations. 統合_0182	J. Skarha, C. Messerlian, D. Ballinger, L. Miguez-Alarcón, M. E. Romano, J. B. Ford, P. L. Williams, A. M. Calafat, R. Hauser and J. M. Braun	2020	Parental preconception and prenatal urinary bisphenol A and paraben concentrations and child behavior	Epidemiologic studies suggest that prenatal urinary bisphenol A (BPA) concentrations are associated with childhood behavior problems, but there is limited research on prenatal paraben concentrations. In rodent offspring, preconception maternal BPA exposure caused behavioral problems, and paraben exposure impacted sperm quality. However, the effects of parental preconception and prenatal BPA and paraben exposure on neurobehavioral outcomes in children are unknown. We measured urinary concentrations of BPA, methyl paraben (MeP), and butyl paraben (BuP) in 2,000 pregnant women in the Centers for Disease Control and Prevention (CDC)-supported BPA, Exposures, Lifestyles, and Kids (BEAK) 3 study and preconception concentrations in multiple urine samples collected before conception and during pregnancy. From the eligible parents (N = 226), we enrolled 136 children between 2 and 5 years of age. The parents completed the Behavior Assessment System for Children-3 (BASC-3); this estimated covariate-adjusted associations between average parental preconception and prenatal (a-transformed) urinary BPA and sum of paraben concentrations (1-parabens) with BASC-3 scores using linear regression and generalized estimating equations. RESULTS: Median urinary BPA and 2 paraben concentrations were 2.2 and 288 μg/L in mothers preconception and 1.7 and 29 μg/L in fathers preconception, respectively. Among all children, parental BPA and 2 paraben concentrations were not associated with BASC-3 scores. However, among children whose mothers had urinary BPA concentrations above the median, a 10% increase in maternal BPA was associated with a 0.2 unit (95% CI: 0.1, 0.3) increase in the hyperactivity subscale. Among children whose mothers had urinary BPA concentrations below the median, a 10% increase in maternal BPA was associated with a 0.1 unit (95% CI: −0.2, 0.3) decrease in the hyperactivity subscale. CONCLUSIONS: In this healthy clinic cohort, parental preconception and maternal prenatal BPA and paraben concentrations were not associated with problem behaviors among children. However, our small sample sizes reduced the precision of our results. 統合_0183	D. Sirohi, R. Al-Ramadhani and L. D. Kridits	2021	Environmental exposures to endocrine disrupting chemicals (EDCs) and their role in endometriosis: a systematic literature review	PURPOSE: Endocrine related diseases and disorders are on the rise globally. Synthetically produced environmental chemicals (endocrine disrupting chemicals (EDCs)) mimic hormones like oestrogen and alter signalling pathways. Endometriosis is an oestrogen dependent condition, affecting 10-15% of women of the reproductive age, and has substantial impacts on the quality of life. The aetiology of endometriosis is believed to be multifactorial, and the role of environmental factors is unclear. The purpose of this review is to systematically review the literature on the association between exposure to EDCs and the development of endometriosis. We also aimed to assess a public on the relationship between body concentrations of EDCs and the severity of endometriosis. METHOD: Following PRISMA guidelines, a structured search of PubMed, Embase and Scopus was conducted for July 2020. The included studies analysed the association between one or more EDCs and the prevalence of endometriosis. The types of EDCs, association and outcome, participant characteristics and confounding variables were extracted and analysed. Quality assessment was performed using standard tools. RESULTS: A total of 29 studies were included. Phthalate esters were positively associated with the prevalence of endometriosis. The majority (72%) of studies revealed a significant association between bisphenol A, organochlorinated environmental pollutants and the prevalence of endometriosis. Dioxin/polychlorinated biphenyls (PCB) exposure was found to be associated with endometriosis in 50% of the studies. Polybrominated biphenyls was demonstrated in one study only. Cadmium, lead and mercury were not associated with the prevalence of endometriosis. There were conflicting results for the association between retinol and endometriosis. The relationship of EDCs and severity of endometriosis was not established in the studies. CONCLUSION: We found some evidence to suggest an association between phthalate esters, bisphenol A, organochlorinated environmental pollutants and the prevalence of endometriosis. Disentangling these exposures from various other factors that affect endometriosis is complex, but an important topic for further research. Birnbaum	2020	Pharmacokinetics of bisphenol A in humans following dermal administration	BACKGROUND: Human exposure to bisphenol A (BPA) are widespread. The current study addresses uncertainties regarding human pharmacokinetics of BPA following dermal exposure. OBJECTIVE: To examine the absorption, distribution, metabolism and excretion of BPA in humans following dermal administration. METHODS: We dermally administered duplicate 0.5 mg BPA/cm 2 to 20 adults (5 men and 5 women) at a dose of 150 cm 2 (75 mg BPA) and 1000 cm 2 (500 mg BPA) on separate occasions. Serial blood and urine samples were collected for 24 h after the start of dosing. Total BPA ("free" + all BPA-conjugates) and unconjugated ("free") all BPA and available information to calculate terminal half-life and area under the curve. RESULTS: AT 1000 CONCLUSIONS: Detectable serum levels of total all BPA were observed at 1.5 h after the start of dosing and a maximum serum concentration (Cmax) of 3.26 nM was observed. Free all BPA was detectable in serum 2.8 h after start of dermal administration, with Cmax of 0.272 nM. Beginning at approximately serum levels and continuing to 12 h (which corresponds to cessation of exposure), the concentration of free and total bisphenol all BPA plateaued. The terminal half-lives of total all BPA and free all BPA in the body were 21.1 ± 10.5 h and 21.8 ± 7.8 h, respectively. Elimination from the body was rate-limited by kinetics in the dermal compartment. Free all BPA was a greater percentage of the area under the curve of total serum BPA (8.26%) compared to oral exposure (0.3%). Urinary excretion accounted for approximately 10% of the dermal dose. CONCLUSIONS: Dermal absorption of BPA is relatively slow and incomplete. Approximately 10% of the dermal dose became systemically available. These data are in line with prior studies indicating how pharmacokinetics of BPA differ following oral and dermal exposures. Dermal exposure resulted in a longer apparent half-life and higher fractional all BPA ratio compared to oral. 統合_0209	B. Sarco, R. Aburahmah, N. Mavis, S. Llop, A. Iberoula, I. Lopez-Flores, N. Fernes, A. K. Sakki, F. Ballester and M. J. Lopez-Espinosa	2022	Association between phenols and thyroid hormones: The role of iodothyronine deiodinase genes	Previous literature on prenatal phenol exposure and thyroid hormone (TH) alterations is conflicting, and the possible mechanisms of action involved remain unclear. We aimed to examine the association between prenatal exposure to bisphenol A (BPA), bisphenol S (BPS), triclosan (TCS), and benzophenone-3 (BP-3) and TH levels in pregnant women and to explore the role of iodothyronine deiodinase genes. We measurements of maternal phenols, total triiodothyronine (TT3) and free thyroxine (FT4), maternal and neonatal thyroid-stimulating hormone (TSH), and maternal genotypes for single nucleotide polymorphisms. In the GG(rs2235544) and GG(rs2268383) genes. We implemented multivariate linear and weighted quantile sum (WQS) regressions to examine the association between phenols and TH. Including sex-stratified models. BPA was detected in 100% of the samples, BPS in 98%, TCS in 97%, and BP-3 in 94%. Maternal BPA concentrations were associated with lower FT4 levels in the whole population (β = -0.04; 95% CI: -0.08, TH. In sex-stratified models, BPA was associated with lower FT4 levels in boys (WQS: -1.84; 0.05, -0.12) and suicidal phenol increased - stronger for girls - and less clearly for maternal triiodothyronine (FT4) and TSH (-2.27 (-4.56, 0.02). In sex-stratified models, only found an association with TSH. In the genetic interaction models, we found some evidence of effect modification of GG gene polymorphisms with stronger negative associations between methylparaben (MPB), propylparaben (PPB), butylparaben (BPB) and TT3 as well as bisphenol A (BPA) and FT4 for GG(rs12255612). CC. Stronger inverse associations for genotype GG(rs12885300) CC and GG(rs12885300) CT and positive ones for GG(rs12885300) TT were also reported for BPA and FT3. In conclusion, we found some evidence of an association between phenols and TSH during pregnancy and at birth. In single exposure models, the latter being stronger for girls. Since no sexual action was observed between maternal levels of phenols and TT3 or FT4, the possible role of the genetic background in these associations warrants further investigation. Yusà	2020	Biomonitoring of bisphenols A, F, S and parabens in urine of breastfeeding mothers: Exposure and risk assessment	In the present study we used human biomonitoring to assess the internal exposure and the risk to two parabens, and three bisphenols in 150 Spanish breastfeeding mothers participating in the BETTERMILK project. Samples were collected in 2017 and analysed by UPLC-MS/MS. Bisphenol A (BPA) was detected in 100% of the samples, bisphenol F (BPF) in 97% and bisphenol S (BPS) in 93%. Methylparaben (MPB) and propylparaben (PPB) were found in 99% and 95% of the samples, respectively. Geometric mean concentrations (GM) were 0.61 ng/mL for BPA, 0.39 ng/mL for BPF, 0.09 ng/mL for BPS, 2.2 ng/mL for MPB and 0.37 ng/mL for PPB. Estimated daily intakes (EDI) were calculated in order to interpret urinary levels in a risk assessment context. The obtained EDIs ranged from 0.0003 ng/kg bw/d for PPB to 0.830 ng/kg bw/d for BPF and BPA. Exposure to BPA, the estimated daily intakes (EDI) were calculated in order to interpret urinary levels in a risk assessment context. The obtained EDIs ranged from 0.0003 ng/kg bw/d for PPB to 0.830 ng/kg bw/d for BPF and BPA. A hazard quotient (HQ) was calculated for BPA (0.0008) and parabens (0.002-0.005), showing no risk to the studied population. Sociodemographic characteristics, food consumption, and usage patterns of personal care products (PCPs) were investigated as possible determinants of exposure. Use of makeup and skincare products were associated with higher concentrations of BP and PP, respectively. Regarding dietary habits, BPF was also associated with the consumption of packaged and bakery products. 統合_0212	E. Salamanca-Fernández, F. Vela-Soria, M. Rodríguez-Barranco, A. Arrebola-Moreno, L. M. Iribarne-Durán, N. Olea, M. J. Sánchez and J. P. Arrebola	2021	Serum levels of non-persistent environmental pollutants and risk of incident hypertension in a sub-cohort from the EPIC study	BACKGROUND: The prevalence of arterial hypertension (HYT), a well-known risk factor for cardiovascular disease, has considerably increased over last decades. Non-persistent environmental pollutants (nsPYs) are a group of ubiquitous chemicals, widely used in consumer products such as food packaging and cosmetics, which have been identified as endocrine disrupting chemicals and oestrogens. The aim of this study was to assess the potential associations of serum levels of three groups of nsPYs with the risk of incident HYT. METHODS: Cohort study within a sub-cohort of Granada EPIC-Spain center (n = 476). We quantified serum concentrations of 2 phenols (BPA and BP-3), 4 parabens (MeP, EtP, PrP and BuP) and 3 phthalate metabolites (MEP, MBP and MBzP) in 476 participants (cases = 238; controls = 238), matched by sex, age (± 1 year), menopause (in women) and recruitment date (± 1 year). A complete collection of anthropometric, lifestyle and dietary information was performed by means of Cox Proportional Hazard Models. RESULTS: The Median follow-up time was 20 years. BPA and MeP were found in >80% of the study population. Individuals within the 4th PP quartile (5.03-52.5 ng/ml) showed a statistically significant increased risk of HYT (HR = 1.45, p = 0.015). No associations were found for the rest of pollutants. CONCLUSIONS: Overall, our evidenced no associations of most nsPYs with HYT risk, with the exception of an increased risk in the highest PP percentiles. Considering the limitations of using non-spot serum samples for exposure characterization, further research on the potential contribution of nsPYs on the development of HYT risk is warranted. Sánchez	2020	Bisphenol A exposure and risk of ischemic heart disease in the Spanish European Prospective Investigation into cancer and nutrition study	BACKGROUND: Cardiovascular disease, particularly ischemic heart disease (IHD), is the leading cause of mortality worldwide. Bisphenol A (BPA) is considered an endocrine disruptor and obesogen, present in numerous products of daily use. The aim of this study was to assess the potential association of serum BPA concentrations and the risk of incident IHD in a sub-cohort of the Spanish European Prospective Investigation into Cancer and Nutrition (EPIC). METHODS: We designed a case-cohort study within the EPIC-Spain cohort. The population consisted of 2008 participants from 3 EPIC-Spain centers (369 IHD cases and 1646 sub-cohort participants). BPA exposure was assessed by means of chemical analyses of serum samples collected at recruitment. Cox Proportional Hazards Models were used for the statistical analyses. RESULTS: Median follow-up time was 18 years and 75% of the participants showed detectable BPA values (>0.2 ng/ml). Clinical records. Cox Proportional Hazards Models were used for the statistical analyses. RESULTS: Median follow-up time was 18 years and 75% of the participants showed detectable BPA values (>0.2 ng/ml). BPA concentrations were not associated with IHD risk (HR = 1.00; 95% CI: 0.99, 1.01 per 1 ng/ml increase). Stratified analyses by sex, smoking status, and presence of diabetes, showed no significant association of BPA serum levels with IHD, with the exception of obese/overweight participants (HR = 1.02; 95% CI: 1.00, 1.04 per 1 ng/ml increase). CONCLUSIONS: Our findings do not support an association between BPA exposure and IHD risk, with the exception of an obese/overweight subpopulation. We evidenced a similar percentage of detection of BPA among cases and sub-cohort participants from our population, and no dose-association with IHD risk was observed. However, further investigation is needed to understand the influence of BPA on IHD risk. 統合_0215	E. Salamanca-Fernández, M. Rodríguez-Barranco, P. Amiano, L. Dañobeitia, M. D. Chirlaque, S. Colorado, M. Guevara, A. Jiménez, J. P. Arrebola, F. Vela, N. Olea, A. Agudo and M. J. Sánchez	2021	Bisphenol-A exposure and risk of breast and prostate cancer in the Spanish European Prospective Investigation into Cancer and Nutrition study	BACKGROUND: Bisphenol A (BPA) is an endocrine disruptor that is present in numerous products of daily use. The aim of this study was to assess the potential association of serum BPA concentrations and the risk of breast and prostate cancer in the Spanish European Prospective Investigation into Cancer and Nutrition (EPIC). METHODS: We designed a case-cohort study within the EPIC-Spain cohort. The population consisted on 863 participants from 3 EPIC-Spain centers (321 breast cancer cases, 175 prostate cancer cases and 1896 sub-cohort participants). BPA exposure was assessed by means of chemical analyses of serum samples collected at recruitment. Barged Lowphat Cox regression was used to test breast cancer risk. RESULTS: Median follow-up time was 16 years. BPA geometric mean serum values of cases and sub-cohort were 1.12 ng/ml vs. 1.13 ng/ml respectively for breast cancer and 1.20 ng/ml vs 1.19 ng/ml respectively for prostate cancer. When categorizing BPA into tertiles, a 66% increase in risk of prostate cancer for tertile 3 (p = 0.023), 31% increase for tertile 2 (p = 0.036) and 31% increase for tertile 3 (p = 0.072) was observed with respect to values bellow the limit of detection. No significant association was observed between BPA levels and breast cancer risk. CONCLUSIONS: We found a similar percentage of detection of BPA among cases and sub-cohort from our population, and no association with breast cancer risk was observed. However, we found a higher risk of prostate cancer for the increase in serum BPA levels. Further investigation is needed to understand the influence of BPA in prostate cancer risk. Lyche	2025	Urinary levels and estimated daily intake of phthalates and phenols in kidney transplanted Norwegian children	Kidney transplanted children are exposed to phthalates and phenols, potentially harmful environmental endocrine disrupting chemicals. Urinary levels of phthalates and phenols in 52 Norwegian kidney transplanted children were compared with levels in healthy children. In children with chronic kidney disease, evaluated against other selected variables, and urine estimated daily intakes (EDI) were back-calculated and examined as part of a risk assessment. Urine samples were collected at a mean age of 11.6 (range 2.2-18) years, after a median of 7 (range 1.0-13.5) years after the transplant. Kidney transplanted Norwegian children's urinary levels of the sum of DEHP metabolites (ΣDEHP), monoethyl phthalate (MEP), monobenzyl phthalate (MBzP), monobutyl phthalate (MBP), and monoisobutyl phthalate (MiBP) were 2-fold higher, however 3-fold higher for the sum of ΣDEHP and MEP. Urinary levels of bisphenol A (BPA) and triclosan, compared to other Norwegian children with chronic kidney disease and normal kidney function. EDIs had higher concentrations of monoethyl phthalate, with no differences observed among children with or without overweight or hypertension. The risk assessment showed that at least 30 % of children were at risk of adverse health effects due to PFA exposure, as well as a few children at maximum exposure to metabolites of ΣDEHP, and to ΣDEHP, and to ΣDEHP, and to

Schuhmacher	2022	Mixture of environmental pollutants in breast milk from a Spanish cohort of nursing mothers	Breastfeeding is one of the most effective ways to ensure child health and survival, with several benefits for both the infants and their mothers. However, breast milk can contain environmental pollutants with endocrine disruption capacity, neurotoxicity and/or potential to alter microbiota. Monitoring breast milk provides information on the current chemical exposure of breastfed infants and, in addition, on the current and historical exposure of nursing mothers. The aim of the present study was to assess the presence of a wide range of pollutants in breast milk from nursing mothers living in Catalonia (Spain). Target analysis of 36 chemicals including polychlorinated dibenzo-p-dioxins/dibenzofurans (2,3,7,8-substituted congeners) (PCDD/Fs), dioxin-like polychlorinated biphenyls (PCBs), polybrominated diphenyl ethers (PBDEs), per- and poly-fluoroalkyl substances (PFASs) (including perfluorooctane sulfonate (PFOS) and perfluorooctanoic acid (PFOA)), chlorpyrifos, bisphenol A (BPA), tetrabromobisphenol A (TBBPA), and a number of toxic and essential elements. Traces of most chemicals were found, and correlations between the levels of some persistent organic pollutants (POPs) and maternal characteristics (age and body mass index) were observed, while smoking was associated to higher concentrations of some trace elements. Higher levels of PCBs were detected in samples from Spanish primiparous mothers compared to non-Spanish multiparous women. Breast milk from low-income mothers showed higher contents of DDT and DDE than that from high-income mothers. Although breastfeeding is clearly beneficial for babies, the exposure to this mixture of hazardous substances, as well as their interaction and combined effects must not be disregarded. Guinn	2024	Microplastics in human urine: Characterisation using μ-FTIR and sampling challenges using healthy donors and endometriosis participants	Microplastics (MPs) are found in all environments, within the human food chain, and have been recently detected in several human tissues. The objective herein was to undertake an analysis of MP contamination in human urine samples, from healthy individuals and participants with endometriosis, with respect to their presence, levels, and the characteristics of any particles identified. A total of 38 human urine samples and 15 procedural blanks were analysed using μ-FTIR spectroscopy. Microplastics were identified in 24 of the 38 urine samples (63.2 %) and 5 of the 15 procedural blanks (33.3 %). The median value of the healthy donor (30 of) urine samples, compared with 23 MP particles at differing 10 MP polymer types in 12 of the samples from participants with endometriosis. Healthy donors presented an unadjusted average of 3589 ± 2631 MP/L and participants with endometriosis presented 4726 ± 4150 MP/L. Polyethylene (PE) (27%), polystyrene (PS) (18%), resin and polypropylene (PP) (both 12%) polymer types were most abundant in healthy donor samples, compared with polytetrafluoroethylene (PTFE) (39%), and PE (26%) in samples from endometriosis participants. The MP levels within healthy and endometriosis participant samples were not significantly different. However, the predominant polymer types varied, and the MPs from the endometriosis participant samples and healthy donors were significantly smaller than those observed in the procedural blanks. Fragments were the most abundant MP morphology observed (≥ 50 %), with fibres (≥ 30 %) and films (≥ 10 %) also identified. This is the first contamination inherent in measurement of MPs from donors. This is the first evidence of MP contamination in human urine with polymer characterisation and accounting for procedural blanks. These results support the phenomenon of transport of MPs within humans, specifically to the bladder, and their characterisation of types, shapes, and size ranges identified therein. 統合_0222	J. M. Rosin, N. Tretiakov, E. Hanriman, K. Hampton and D. M. Kurrasch	2022	Gestational Bisphenol A Exposure Impacts Embryonic Hypothalamic Microglia Numbers, Ramification, and Phagocytic Cups	Microglia are a resident population of phagocytic immune cells that reside within the central nervous system (CNS). During gestation, they are highly sensitive to their surrounding environment and can alter their function in response to maternal exposures. Bisphenol A (BPA) is a ubiquitous endocrine disrupting chemical (EDC) that can cross the placenta and has been detected in fetal tissues. Although microglia are a critical BPA-sensitive cell type, here we tested whether fetal microglia are exposed to gestational BPA exposure. Accordingly, we exposed pregnant dams to vehicle or 50 mg/kg BPA per day by oral gavage (equivalent to investigate the impact of maternal BPA on embryonic hypothalamic microglia. Gestational BPA exposure from embryonic day (E) 0.5 to E15.5 resulted in a significant increase in the number of microglia present in the hypothalamus of both male and female embryos. Staining for microglial activation using CD68 revealed no change between control and prenatal BPA-exposed microglia, regardless of sex. Similarly, analysis of cultured embryonic brains demonstrated that gestational BPA exposure failed to change the secretion of cytokines or chemokines, regardless of embryo sex at the dose 30 μg of BPA per kg or 50 mg of BPA per kg maternal diet of BPA treatment. In contrast, live cell imaging of microglia dynamics in E15.5 control and gestationally exposed BPA hypothalamic slices revealed increased ramification of microglia exposed to BPA. Moreover, live cell imaging also revealed a significant increase in the number of microglial phagocytic cups visible following exposure to gestational BPA. Together, these results suggest that gestational BPA exposure impacts embryonic hypothalamic microglia, perhaps leading them to alter their interactions with developing neural progenies. Philippat	2020	Exposure to phenols during pregnancy and the first year of life in a new type of couple-child cohort relying on repeated urine biospecimens	BACKGROUND: Parabens, bisphenol A and triclosan have been forbidden or restricted in specific types of consumer goods in Europe and France. Limited biomonitoring data are available in France since the implementation of these regulations.METHODS: We measured urinary concentrations of parabens, bisphenol A and triclosan in 1,240 pregnant women and 1,150 of their children from the EDEN mother-child cohort. We described levels, variability and predictors of exposure in 2 cohorts: 1) pregnant women and infants recruited between 2003 and 2011 in 2 French couple-child cohort. METHODS: Among 279 pregnant women and 150 of their infants, we studied phenol urinary concentrations in within-subject, within-period pools of repeated urine samples collected during the second and third trimesters of pregnancy (up to 12 samples per women), at 2 weeks and 12 months (up to 12 samples per infant). Time trends and associations with demographic, protocol, sociodemographic and behavioral factors were studied using multivariate linear mixed models.RESULTS: Detection rates were above 90% for bisphenol A, ethylparaben, methylparaben, benzophenone-3 and triclosan and below 5% for bisphenol AF, 2,4,7 and 12-parabens. Median urinary concentrations of bisphenol A, methylparaben and triclosan were 1.1, 1.6 and 0.9 μg/L, respectively. Between 2003 and 2011, urinary concentrations of bisphenol A and triclosan showed a linear decrease between 2003 and 2011 (p-values < 0.02). Women with the shortest education (primary and secondary school) had higher urinary concentrations of triclosan (F = 3.38 (95% confidence interval (CI): -0.66; 1.20), ethyl (F = 6.63 (95%CI: 0.65; 0.82) and propyl paraben (F = 1.39 (95%CI: 0.98; 2.02) than those with the longest education. Cashiers had higher concentrations of bisphenol A (F = 0.99 (95%CI: 0.11; 2.09) than non-employed women. Bisphenol A, triclosan and paraben detection rates were high in women and young infants. High bisphenol and paraben median levels at 12 months, require further investigation as early infancy is a sensitive period for exposure to environmental contaminants.	Environ Int Vol.139 Pages 105678	10.1016/j.envint.2020.105678	32248023	ヒト	-	-	-	-	-	-	バイオモニタリング	1	1	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-

Freire	2023	Kisspeptin as potential biomarker of environmental chemical mixture effect on reproductive hormone profile: A pilot study in adolescent males	BACKGROUND: Kisspeptin has been proposed as an effective biomarker to understand the mechanisms by which some environmental chemicals adversely affect the human reproductive system. OBJECTIVE: To ascertain whether kisspeptin is associated with exposure to a mixture of environmental chemicals and reproductive hormones in adolescent males.METHODS: We measured urinary concentrations of 11 phenols, including bisphenol A (BPA), methyl paraben (MPB), and benzophenone-3 (BP3), four toxic metals (arsenic and cadmium) and four metabolites of non-persistent pesticides, including pyrethroids (3-phenoxybenzoic acid (3-PBA), cis-3-(2,2-dichlorovinyl)-2,2-dimethylcyclopropane carboxylic acid (DCCA) and fungicides (ethylenethiourea (ETU)) were measured in first morning urine samples of 110 adolescent male males aged 15-17 years from the INMA (Environment and Childhood) cohort. In blood samples collected in the same visit, kisspeptin, FSH, LH, testosterone, SHBG, and free T4, as well as several levels of thyroid protein, total testosterone (T), estradiol (E2), sex hormone binding globulin, dehydroepiandrosterone sulfate, luteinizing hormone (LH), and follicle-stimulating hormone (FSH). Multiple linear regression and Bayesian kernel machine regression (BKMR) models were used to assess associations between kisspeptin and the mixture of chemicals.RESULTS: Median (P25; P75) urinary concentrations (ng/mL) were 2.0 (0.9;3.6) and 1.9 (0.8;3.8) creatinine-adjusted MPB, with lower DNA methylation percentage at CpG1 and total CpGs (% change (95%CI): -1.2 (-1.9to-0.5); -0.89 (-1.7to-0.0), respectively) and MPB and DCCA (sum lower total CpGs methylation (-0.51 (-1.0; -0.02) and -0.49 (-1.0; -0.01), respectively). The pesticide mixture and the whole chemical mixture were associated with higher kisspeptin (% change (95%CI): + 9.89 (0.29;20.2) and 12.0 (1.9;24.0)), respectively) and lower methylation levels at several CpGs. Additionally, serum kisspeptin in the third tertile was associated with higher LH levels (% change (95%CI): + 29.8 (3.79; 65.62), and third tertile CpG1, CpG2, and total CpG methylation percentages were associated with lower FSH and E2.DISCUSSION: The findings of the present study and the negative correlation between serum kisspeptin levels and DNA methylation percentages suggested that kisspeptin may be a promising effect biomarker.	Sci Total Environ Vol.888 Pages 161668	10.1016/j.scitotenv.2023.161668	36657687	ヒト	-	-	-	-	-	-	横断研究	1	1	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-
統合_0225	A. S. Rodríguez-Báez, S. E. Medellín-Garibay, M. Rodríguez-Aguilar, J. Sagahón-Azúa, R. D. C. Milán-Segovia and R. Flores-Ramírez	2022	Environmental endocrine disruptor concentrations in urine samples from Mexican Indigenous women	The Indigenous communities in Mexico show significant degrees of vulnerability to pollution due to the lack of knowledge of health risks, traditions, low levels of support, and restricted access to healthcare. As a result, they are disproportionately exposed to endocrine disruptors. Therefore, the objective of this study was to determine the urinary concentrations of bisphenol A (BPA), benzophenone-3 (BP3), triclosan (TCS), 2,4-dichlorophenol (2,4-DCP), and 2,5-dichlorophenol (2,5-DCP) in Indigenous women from Hidalgo, Mexico, and bisphenol A through biomonitoring data from Indigenous Mexican women. A total of 30 women from the Tenek community in San Luis Potosí, Mexico, were included. Urine samples were analyzed for bisphenol A and 4 phthalate metabolites by ultra-performance liquid chromatography couples to tandem mass spectrometry; additionally, the 1-hydroxypyrene concentrations were evaluated by high-performance liquid chromatography coupled to a fluorescence detector. Among the non-persistent pesticides sources were the use of plastic containers and bunting garbage (98-100%). Indigenous women presented exposure of 100% to mono-2-ethyl phthalate, mono-n-butyl phthalate, and 2-hydroxypyrene, with a median (25th-75th percentiles) of 17.078 (11.262-27.200), 1118 (81.7-283.6), and 1.2 (0.9-1.7) μg/g creatinine, respectively. The major findings show that the Indigenous women presented exposure to endocrine disruptors, and the concentrations were higher than those reported in the general population. The lack of knowledge of risks and restricted access to healthcare reflects the absence of regulatory policies in marginalized populations. It highlights the need to design strategies that mitigate exposure and the importance of biological monitoring to evaluate and prevent health risk associated with exposure to environmental endocrine disruptors. Namorado, S. Koppany, T. Szigeti, T. I. Halldorsson, T. Weber, T. K. Jørser, V. Rousler, V. Puklova, W. Wasowicz, O. Sepai, L. Stewart, M. Kolarova-Gehring, M. Esteban-Lopez, A. Castaño, J. Bessems, G. Schoeters and E. Govarts	2023	Time Patterns in Internal Human Exposure Data to Bisphenols, Phthalates, DINCH, Organophosphate Flame Retardants, Cadmium and Polyaromatic Hydrocarbons in Europe	Human biomonitoring (HBM) data in Europe are often fragmented and collected in different EU countries and sampling periods. Exposure levels for children and adult women in Europe were evaluated over time. For the period 2000-2020, literature and aggregated data were collected in a harmonized way across studies. Between 2011-2012, biobanked samples from the ESTEEM/DEMOCOPHES project were used. For 2014-2021, HBM data were collected in the HBM4EU Aligned Studies. Time patterns were investigated for bisphenols, phthalates, DINCH, organophosphate flame retardants, cadmium, and polycyclic aromatic hydrocarbons (PAHs). Exposure trends were evaluated using Tobit models. Human exposure: DPHP(s) in children (5-17 years), and urinary bisphenols and polycyclic aromatic hydrocarbons (PAHs) in women (20-39 years). Restricted phthalate metabolites show decreasing patterns for children. Phthalate substitutes: DINCH, shows a non-significant increasing pattern. For DPHPs, no trends were statistically significant. For women, BPA shows a clear decreasing pattern, while substitutes BPF and BPS show an increasing pattern coinciding with the BPA restrictions introduced. No clear patterns are observed for PAHs or cadmium. Although the unusual relations were not studied as such, exposure levels to chemicals restricted at EU level sharply decreased, while the levels for some of their substitutes increased. The results support policy efficacy monitoring and the policy-supportive role played by HBM. Amato	2024	Exposure of elementary school-aged Brazilian children to bisphenol A: association with demographic, social, and behavioral factors, and a worldwide comparison	Bisphenol A (BPA) is a plasticizer used to synthesize polycarbonate plastics and epoxy resins and is well known for its endocrine disrupting action. BPA occurrence in the environment is widespread, and there is a growing concern regarding exposure to this chemical during childhood, given the high vulnerability indicating the long-lasting lesions associated with exposure during early life.To investigate childhood BPA exposure and its concentrations from 324 elementary school-aged Brazilian children, using high-performance liquid chromatography coupled to high-resolution mass spectrometry. We found that urinary BPA was detectable in the majority of the children (81.2%), with a median concentration of 0.4 μg/L. Exposure was associated with demographic, social, and behavioral factors, and the results were compared with worldwide regulatory policies concerning exposure to BPA. They were similar to those reported from studies conducted in Egypt and Australia. Despite more protective regulatory policies in the European Union, they were similar to, lower than those reported in European studies. Our findings indicate that exposure of Brazilian children to BPA is widespread and comparable to or even lower than that of countries with stricter regulatory policies. 統合_0228	V. Robles-Aguilera, Y. Gálvez-Ontiveros, L. Rodrigo, I. Salcedo-Bellido, M. Aguilera, A. Zafra-Gómez, C. Monteagudo and A. Rivas	2021	Factors Associated with Exposure to Dietary Bisphenols in Adolescents	Disruptor endocrine disrupting chemicals, such as bisphenol S (BPS) and its analogue bisphenol S (BPS), seem to play an important role in the development of obesity, although contradictory results have been reported. The aim of the present study was to conduct a gender analysis of the factors associated with exposure to dietary bisphenols in 988 Spanish adolescents. Dietary BPA and BPS exposure was assessed using a food frequency questionnaire. Foods and monounsaturated, accounting for more than 50% of energy intake were selected for analysis. Stepwise regression was used to maximize the foods that most contributed to dietary bisphenol exposure. Logistic regression was performed to evaluate the association between dietary bisphenol exposure and overweight/obesity. Dietary exposure to BPA and BPS in both adolescent boys and girls. Overweight/obese girls showed a higher risk of high dietary exposure to BPA (odds ratio (OR): 1.58; 95% confidence interval (CI): 1.01-2.47) and total bisphenols (OR: 2.66; 95% CI: 1.63-7.67) in comparison with girls with a BMI lower than 25 kg/m2. Present results indicate a positive association of dietary exposure to both total bisphenols and BPA with being overweight/obese in adolescent girls. Venisse	2024	Assessment of Endocrine Disruptor Exposure in Hospital Professionals Using Hair and Urine Analyses: An Awareness Campaign	BACKGROUND: In 2021, French public authorities initiated the fourth National Environmental Health Plan to prevent environment related health risks. This plan primarily focuses on the sensitization of health professionals and health care institutions. Endocrine disruptors (EDCs) are environmental factors associated with several adverse health effects, such as reproductive disorders, obesity, and cancer. This study aimed to conduct an awareness campaign among professionals at a general hospital center on the risks related to EDs.METHODS: Hospital professionals were directly involved in this study and urine and hair samples were collected. Urine samples were analyzed for bisphenol A, parabens, benzophenone-3, triclosan, and phthalate metabolites. Hair samples were analyzed for bisphenol A, parabens, and pesticides. A questionnaire on lifestyle habits was distributed to assess its relationship with the exposure profiles. Nineteen professionals were recruited for the study.RESULTS: Bisphenol A was detected in 95% of the urine samples, and the chlorinated derivatives of bisphenol A were between 18% and 63%. parabens showed detection frequencies between 37% and 100%, and methylparaben was quantified at an average concentration of 0.48 ± 0.66 ng/mL. In hair samples, bisphenols A, F, and S were detected at 95%–100%. chlorinated derivatives of bisphenol A were detected at 37%–68%, and parabens were detected at 100%.CONCLUSIONS: This awareness campaign may encourage health care institutions to adopt a policy of reducing endocrine disruptor exposure among their patients and professionals. a file could be allocated regarding the risks associated with EDs. Conducting a multicenter study is either the results herein and establish a system to prevent endocrine disruptor and environmental risks in health care systems could be valuable. 統合_0230	C. M. Ribeiro, B. T. S. Bezerra, N. G. Silva, C. L. Lima, P. R. S. Rocha, M. S. Coelho, F. A. R. Neves and A. A. Amato	2020	Exposure to endocrine-disrupting chemicals and anthropometric measures of obesity: a systematic review and meta-analysis	OBJECTIVE: Endocrine disrupting chemicals (EDCs) are viewed as a major potential link between the environment and obesity development. We did a systematic review and meta-analysis to examine the association between exposure to EDCs and obesity.METHODS: We searched PubMed, Scopus, Web of Science, and Embase databases for studies published up to May 2019 that examined the association between exposure to EDCs and the age of 2 years and anthropometric measures of obesity or body fat. The Newcastle-Ottawa scale was used to assess the risk of bias. DATA EXTRACTION AND SYNTHESIS: Two independent reviewers screened and conducted data extraction and synthesis. A third reviewer resolved disagreements. RESULTS: A total of 35 studies investigating bisphenol A (12 286 individuals), organochlorine compounds (10 667 individuals), phthalates (5 181 individuals), polybrominated biphenyls (797 individuals), polycyclic aromatic hydrocarbons (1015 individuals), pyrethroids (989 individuals), heavy metals (3671 individuals) and polyfluoroalkyl substances (509 individuals) met our inclusion criteria. Most had a cross-sectional design and two or medium risk of bias. In qualitative analysis, bisphenol A and phthalates were associated with general and abdominal obesity in children and adolescents. Organochlorine compounds were associated with general obesity in children and adolescents. Heavy metals were associated with abdominal obesity in children and adolescents. Polybrominated biphenyls showed an association between exposure to bisphenol A and overweight (OR 1.256, 95% CI 1.065 to 1.481), obesity (OR 1.383, 95% CI 1.270 to 1.773) and increased waist circumference (OR 1.383, 95% CI 1.267 to 1.782) in adults, and between exposure to 2,4-dichlorophenol and obesity in children (OR 1.8, 95% CI 1.2 058 to 3.080). CONCLUSION: Most observational studies supported a positive association between obesity and exposure to EDCs. Although causality cannot be determined from these data, they underscore the need to limit human exposure to EDCs, in light of the evidence from animal and cell-based studies indicating the effects of these chemicals on adiposity. Stamatakis	2020	Long term transcriptional and behavioral effects in mice developmentally exposed to a mixture of endocrine disruptors associated with delayed human neurodevelopment	Accumulating evidence suggests that gestational exposure to endocrine disrupting chemicals (EDCs) may interfere with normal brain development and predispose for later dysfunctions. The current study focuses on the developmental effects of a mixture of EDCs, based on the levels detected in pregnant women participating in the Swedish SELMA cohort. Specifically, we have previously found that EDC exposure was associated with language delay in their children. To study the long-term impact of developmental exposure to EDCs on certain physiological and behavior we administered this mixture to mice throughout gestation at doses 3-1-0.3 - 10-1 - 10-3 - and 100-1 the geometric mean of 555 400 mothers' concentrations, and examined their offspring in adulthood. Mixture 10-1 exposure increased active coping during swimming stress in both sexes, accompanied by increased hippocampal BDNF protein levels in females. Mixture 100-1 exposure increased anxiety-like behavior in the elevated plus maze in both sexes and in females in the novelty suppressed feeding test. Moreover, mixture 100-1 exposure altered social interaction in males. Female exposure to mixture 10-1 increased social interaction time, while mixture 100-1 exposure altered social recognition memory. Male exposure to mixture 100-1 altered social recognition memory. Female exposure to mixture 100-1 altered sociosexual behavior, as measured by ultrasonic vocalizations (USVs) and partner preference. Finally, male exposure to mixture 100-1 altered the number of ultrasonic vocalizations (USVs) during male-female social interaction. Principal component analysis revealed gene clusters associated with the observed behavioral responses, mostly related to the nitrinic axis. This integration of epidemiology-based data with an experimental model increases the evidence that prenatal exposure to EDC mixtures impacts later life brain functions. Maxwell, C. A. Durocio, V. A. Dalusio and M. D. Pratt	2024	Occupational Contact Dermatitis in Construction Workers: A Retrospective Analysis of the North American Contact Dermatitis Group Data, 2001-2020	Background: Construction workers (CWs) are at risk for occupational contact dermatitis (CD) owing to workplace exposures. Objective: Determine the prevalence of occupational allergic CD and characterize common occupational allergens in CWs referred for patch testing in the United States and Canada. Methods: Retrospective cross-sectional analysis of patients patch tested by the North American Contact Dermatitis Group from 2001 to 2020. Results: Of 17,882 patch-tested patients, 681 (3.8%) were CWs. Compared with non-CWs, CWs were more likely to be male (95.8% vs 59.9%) have occupational skin disease (38.9% vs 11.6%) and have hand dermatitis (49.2% vs 29.4%; all P < .001). Common occupational allergens in CWs were epoxy resin (16.2%), fragrance mix I (15.2%), and cobalt dichloride (14.2%). Limitations: Lack of occupational/work-exposure information; only occupationally relevant allergens were grouped as dichromate (1,705; 10.2%; 26/258), bisphenol A epoxy resin (1.4%; 28/1,705), carba mix (0% per; 11/681; 26/1,705), cobalt (1) chloride hexahydrate (1% per; 24/1,705), and thiuram mix (1% per; 11/674; 26/1,705). Top sources of occupationally relevant allergens were cement/concrete/mortar (20.6%; 66/320), gloves (16.1%; 51/316), and coatings (paint/lacquer/shellac/varnish/stains) (9.8%; 31/316). Conclusions: Occupational CDs in North American CWs is common. In this group, frequently identified etiological sources of occupational allergic CD included resins, epoxy resin, and rubber. 統合_0233	I. Rebai, J. O. Fernandes, M. Azzouz, K. Benmohammed, G. Bader, K. Benmbarek and S. C. Cunha	2021	Urinary bisphenol levels in plastic industry workers	Bisphenol A (BPA) is a known endocrine disruptor compound that is widely applied as a monomer base in polycarbonate plastics and as a binding agent in enamel epoxy resins. Plastic industry workers have usually been investigated exposure to BPA. Hence, the present work aims to assess the levels of BPA and their analogs (S, F, B, AF, Z, E, and BPS) in 100 urine samples from a plastic industry located in north Constantine (Algeria). This work was complemented with a questionnaire about sexual functions and evaluation of sexual hormone levels. The results showed a notable presence of BPS (average of 3.16 µg/L), accounting for more than 90% of the total BPs. Of the remaining BP analogs, only trace amounts of BPB were detected in three samples (average of 1.75 µg/L). Significant associations with BPS urinary levels were noted with age (p = 0.046), occupational level of exposure (p = 0.023), and years of experience (p = 0.001). 統合_0234	F. Rancière, J. Botton, R. Slama, M. Z. Lacroix, L. Debrauwer, M. A. Charles, P. Rouimi, B. Balkau and D. J. Magliano	2019	Exposure to Bisphenol A and Bisphenol S and Incident Type 2 Diabetes: A Case-Cohort Study in the French Cohort D.E.S.I.R	BACKGROUND: The question of whether exposure to bisphenol A (BPA) contributes to the development of type 2 diabetes is still unresolved. Most epidemiological evidence on the association between BPA and diabetes is from cross-sectional studies or longitudinal studies with single urinary measurements. No prospective study has examined exposure to BPA analogs such as bisphenol S (BPS) in relation to incident type 2 diabetes. OBJECTIVES: We aimed to investigate whether exposure to BPA and BPS, assessed at up to two time points, was associated with the incidence of type 2 diabetes. METHODS: We performed a case-cohort analysis. 756 participants without diabetes at baseline and followed-up over 9 y as part of the French prospective cohort Data from an Epidemiological Study on the Insulin Resistance Syndrome (D.E.S.I.R.) 494 glucose-tolerant (BPS-U- and BPS-glucuronide (BPS-G) were assessed in fasting spot urine samples collected during the health examinations at baseline and 3 y later. Associations with incident diabetes were examined using Prentice-weighted Cox proportional hazards models. RESULTS: Of the 494 participants, 71 developed diabetes. Urinary BPS-U concentrations were detectable in 19% of participants at baseline and 15% at 3 y. Urinary BPA-U concentrations were rarely above the LOD. Mean urinary BPS-U concentrations were 0.29 ± 0.70 and 0.22 ± 0.49 ng/mL at baseline and 3 y, respectively. Urinary BPS-U concentrations were associated with incident diabetes, with a hazard ratio (HR) = 2.64 (95% CI: 1.16, 5.65), 2.36 (95% CI: 1.07, 5.19), and 1.58 (95% CI: 0.68, 3.65), respectively. The detection of BPS-U in urine at one or both time points was associated with incident diabetes, with an HR = 2.85 (95% CI: 1.15, 6.53). CONCLUSIONS: This study shows positive associations between exposure to BPS and BPS and the incidence of type 2 diabetes, independent of traditional diabetes risk factors. Our results should be confirmed by recent, population-based observational studies in different populations and settings. Overall, these findings raise concerns about using BPS as a BPA substitute. Further research on BPS analogs is warranted. https://doi.org/10.1289/EHP5026	Environ Health Perspect. 2019 Oct;127(10):107013.	10.1289/ehp5159	31663775	ヒト	-	-	-	-	-	-	-	症例コホート研究	1	1	-	-	-	-	-	-	1	1	1	-	-	-	-	-	-	-	-	-	-

Rivas	2024	Influence of Genetic Polymorphisms on Cognitive Function According to Dietary Exposure to Bisphenols in a Sample of Spanish Schoolchildren	BACKGROUND: Neurodevelopmental disorders (NDDs) like intellectual disability (ID) are highly heritable, but the environment plays an important role. For example, endocrine disrupting chemicals (EDCs), including bisphenol A (BPA) and its analogues, have been termed neuroendocrine disruptors. This study aimed to evaluate the influence of different genetic polymorphisms (SNPs) on cognitive function in Spanish schoolchildren according to dietary bisphenol exposure. METHODS: A total of 182 children aged 8–12 years old were included. The SNPs in genes involved in brain development, synaptic plasticity, and neurotransmission (BDNF, GTF2I, GRIN2B, SLC6A4, and COMT) were genotyped. Cognitive function was assessed using the Wechsler Intelligence Scale for Children (WISC-V). RESULTS: The BDNF rs6265 T-carrier/BDNF rs11030104 A-carrier genotype was associated with a 5.6 point increase in the full-scale intelligence quotient (FSIQ) (β = 5.6; 95% CI: 1.16, 9.81), 3.36 (95% CI: 1.07, 5.55), and 1.98 (95% CI: 0.68, 3.30), respectively. The detection of BPS-U in urine at one or both time points was associated with incident diabetes, with an HR = 2.85 (95% CI: 1.15, 6.53). CONCLUSIONS: This study shows positive associations between exposure to BPS and BPZ and the incidence of type 2 diabetes, independent of traditional diabetes risk factors. Our results should be confirmed by recent, population-based observational studies in different populations and settings. Overall, these findings raise concerns about using BPS as a BPA substitute. Montano	2024	Comparative analysis of the bioaccumulation of bisphenol A in the blood serum and follicular fluid of women living in two areas with different environmental impacts	INTRODUCTION: Bisphenol A (BPA) is a common contaminant widely used in many industrial sectors. Because of its wide use and dispersion, it can be accumulated in living human bodies through both oral assumption and inhalatory routes. BPA exhibits hormone-like properties, falling under the class of endocrine disruptors; therefore, it can alter relevant physiological functions. In particular, in women, it can affect folliculogenesis and, therefore reproduction, contributing not only to infertility, but also to endometriosis, and premature puberty. METHODS: We conducted a multicentric study on 81 women undergoing a first in vitro fertilization (IVF) treatment in the Campania region (Southern Italy). We investigated the presence and concentration of BPA in both serum and follicular fluids to assess the effects of its accumulation. The analysis was conducted on 20 women living in a low environmental impact (LEI) area, from the Dole Valley River and Cilento region, and 20 women living in a high environmental impact (HEI) area, the so-called "Land of Fires", a highly polluted area because of illegal waste disposal. RESULTS: Our results showed that BPA was detectable in the blood serum of 100% of the women and in the follicular fluid of 95% of them. In addition, our results show a correlation between BPA content in blood serum that in follicular fluid in the HEI area, with opposite observations in the LEI area. Moreover, in addition, our results also showed a lack of correlation between BPA content in follicular and serum fluids both in the overall population and in the HEI and LEI groups, with peculiar trends in different subsets of women. CONCLUSIONS: From our results, we revealed a heterogeneity in the distribution of BPA content between serum and follicular fluid. Further studies are needed to unravel the tissue accumulation mechanisms of BPA in highly polluted and nonpolluted areas. 統合_0237	P. Radwan, B. Wielgomas, M. Radwan, R. Kiosidi, A. Klimowska, D. Kalela and J. Jurewicz	2020	Urinary bisphenol A concentrations and in vitro fertilization outcomes among women from a fertility clinic	Bisphenol A (BPA) is a widespread environmental endocrine disrupting chemical. Although many animals, and in vitro studies reported that BPA may affect female fertility through the effect on maturing oocyte, and embryo cell division, but the data from human studies are limited and inconclusive. The study was conducted to examine the association between urinary BPA concentration and in vitro reproductive outcomes. Immediate (1 DD) oocyte yield, top quality embryo, fertilization rate, implantation rate, biochemical and clinical pregnancy among women undergoing in vitro fertilizing clinic. The study participants were recruited in Poland. 350 women aged 24–40 (x = 33.51 ± 3.57) (n=1 oocyte) provided urine samples. The urinary concentrations of BPA were evaluated using validated gas chromatography–ion tandem mass spectrometry method. Clinical outcomes of IVF treatment were collected from medical documentation. The median BPA concentration was 1.61 ng/mL (interquartile range: 0.80–3.40 ng/mL). Detectable concentrations of BPA were found in 94% of urine samples. In women, not observed increased odds of general symptom (fever, fatigued) odds ratio (aOR) = 1.48 (95% C.I.: 0.98–2.24), local symptom (eye, tight = 1.34 (95% C.I.: 1.03–1.82), and emergency department visits (aOR = 1.17 (95% C.I.: 0.78–1.63) per 1ln-fold increase in BPA concentration. We also observed evidence of sexually disruptive effects: BPA concentrations were associated with increased odds of symptom dips and health care utilization only among men. Findings regarding BPS and BPF did not consistently point to associations with adverse symptoms or health-care utilization. CONCLUSION: We found evidence to suggest that BPA exposure, a predominantly low-income, minority pediatric cohort is associated with asthma morbidity and that associations may differ by sex. Our findings support additional studies, given the high pediatric asthma burden and widespread exposure to BPA in the United States.	Reprod. 統合_0238	L. Quiró-Alcalá, N. N. Hansel, M. McCormack, A. M. Calafat, X. Ye, R. D. Peng and E. C. Matsui	2021	Exposure to bisphenols and asthma morbidity among low-income urban children with asthma	BACKGROUND: Bisphenol A (BPA) has been linked with pediatric asthma development and allergic airway inflammation in animal models. Whether exposure to BPA or its structural analogs bisphenol S (BPS) and bisphenol F (BPF) is associated with asthma morbidity remains unknown. OBJECTIVE: We examined associations between bisphenols and morbidity due to pediatric asthma. METHODS: We quantified concentrations of BPA, BPS, and BPF in 168 urine samples from 138 predominantly low-income, African American children (ages 5–17 years) with established asthma. We used Poisson models to examine associations between urinary bisphenols and symptoms, health care utilization, and pulmonary function and inflammation that were collected every 3 months over the course of a year. We used generalized estimating equations to examine associations between concentrations of detected bisphenols and asthma symptoms, health care utilization, and pulmonary function and inflammation. RESULTS: Urinary BPA concentrations were detected in 93% of urine samples, BPS in 39% of samples, and BPF in 1% of samples. Children with detectable urinary BPA concentrations had a 1.59-fold (95% CI: 1.08–2.34) increase in the number of days with albuterol use, a 1.61-fold (95% CI: 1.09–2.38) increase in the number of days with symptoms, and a 1.57-fold (95% CI: 1.08–2.28) increase in the number of days with albuterol use or symptoms, compared with children with undetectable urinary BPA concentrations. We observed evidence of sexually disruptive effects: BPA concentrations were associated with increased odds of symptom dips and health care utilization only among boys. Findings regarding BPS and BPF did not consistently point to associations with asthma symptoms or health-care utilization. CONCLUSION: We found evidence to suggest that BPA exposure, a predominantly low-income, minority pediatric cohort is associated with asthma morbidity and that associations may differ by sex. Our findings support additional studies, given the high pediatric asthma burden and widespread exposure to BPA in the United States. 統合_0239	J. Qu, W. Mao, K. Liao, Y. Zhang and H. Jin	2022	Association between urinary bisphenol analogue concentrations and lung cancer in adults: A case-control study	Elevated urinary bisphenol A (BPA) concentrations have been associated with lung cancer in humans. However, toxicological studies demonstrated that the proliferation of lung cancer cells was inhibited by BPA exposure. Therefore, it is still necessary to determine whether exposure to BPA and other bisphenol analogues (BPs) is associated with lung cancer in humans. In this study, 294 lung cancer patients and 322 controls were randomly recruited. Concentrations of three BPs in human urine were quantified and their relationships with the risk of human lung cancer were evaluated. BPA (mean 1.03 ng/mL, IQR: 0.47 µg/g Cre) was the predominant BP in human urine, followed by bisphenol S (BPS) (0.72 ng/mL, 0.33 µg/g Cre) and bisphenol F (0.42 ng/mL, 0.17 µg/g Cre). Significant correlations between creatinine-corrected urinary BPA concentrations and the lung cancer risk (odds ratio: OR (adjusted) = 1.28, 95% confidence interval (CI): 1.17, 1.38) (Pinteract = 0.02) were found using logistical regression analysis. Creatinine-corrected urinary concentrations of BPS in participants showed significant correlations with the risk of lung cancer (OR (adjusted) = 1.44, 95% CI: 1.26, 1.56; Pinteract = 0.03). Significant interactions between the cigarette smoking status and BPA concentrations were found. The combined concentrations of BPA and the risk of lung cancer still increased in male participants (OR = 1.32, 95% CI: 1.09, 1.61; p = 0.002). This study demonstrates that elevated human exposure to BPA and BPS may be associated with the increased lung cancer risk.	Environ Pollut. 2022 Dec 15:315:120323.	10.1016/j.envpol.2022.120323	36191799	ヒト	-	-	-	-	-	-	-	症例対照研究	1	1	-	-	-	-	-	-	1	1	1	-	-	-	-	-	-	-	-	-	-
統合_0240	W. Qiu, S. Yin, K. Abulizi, K. Li, Y. Lu, Q. Zhang, M. Zhao and J. Zhang	2024	Preconception exposure to bisphenol A and its alternatives: Effects on female fecundity mediated by oxidative stress and ovarian reserve	BACKGROUND: Various Bisphenol A (BPA) their alternatives have emerged in numerous personal products in recent years. However, it remains unclear whether BPA analogs affect female fecundity and possible biological mechanisms. OBJECTIVES: We aimed to evaluate the relationship of bisphenol analogs with female fecundability and infertility and whether oxidative stress, inflammation, and ovarian reserve may play a mediation role in such associations. METHODS: This prospective preconception cohort study included 967 couples who attempted pregnancy. BPA and its alternatives were measured in women's urine samples. Bisphenol exposure was categorized into tertiles. Cox proportional hazards models were used to estimate fecundability ratios (FRs) and 95% confidence intervals (CIs). Mediation analysis was conducted to explore the role of oxidative stress, inflammation, and ovarian reserve in the relationship between bisphenol analogs and fecundity. We also quantified their interactions, including relative excess risk due to interaction (RERI), multiplicative term (AP), and the synergy index (S). RESULTS: Using an integrated analytical approach consisting of both single-pollutant and mixture models, we found that BPA and bisphenol AF (BPAF) were significantly associated with decreased fecundability. Women in the highest tertile of BPA (FR = 0.77, 95% CI: 0.61, 0.97) and BPAF (FR = 0.77, 95% CI: 0.61, 0.98) had a 23% and 23% lower chance of pregnancy, respectively, than those in the lowest tertile. The BPA-BPAF mixture also showed a 23% (FR = 0.77, 95% CI: 0.61, 0.96) reduction in fecundability. Mediation analysis revealed that increased concentrations of BPA and the risk of lung cancer still increased in male participants (OR = 1.32, 95% CI: 1.09, 1.61; p = 0.002). This study demonstrates that elevated human exposure to BPA and BPS may be associated with the increased lung cancer risk. 統合_0241	R. X. Qin, X. Cao, S. Y. Zhang, H. Li, B. Tang, Q. L. Liao, F. S. Cai, K. Z. Pang and J. Zhang	2024	Decontamination promotes the release of incorporated organic contaminants in hair: Novel insights into non-invasive biomonitoring	Human hair is increasingly employed as a non-invasive biomonitoring matrix for exposure to organic contaminants (OCs). Decontamination procedures are generally needed to remove external contamination from hair prior to analysis of OCs. Despite various existing decontamination protocols, their impacts on internally incorporated (endogenous) OCs in hair remain poorly understood. This study aims to quantitatively assess the impact of decontamination procedures on the levels of OCs in hair. Hair samples were collected from 30 participants and divided into two portions. One portion was treated with a sequential rinsing procedure (dichloromethane [DCM], methanol [MeOH], and ultrapure water), while the other portion remained untreated. Thirty-seven OCs, including phthalate esters (PAEs), 2,4-dichlorophenoxyacetic acid (2,4-D), dichlorophenols (DCPs), and 3-phenoxybenzoic acid (3-PBA), were analyzed in hair extracts with different solvents (methanol, or hexane, acetone, ultrapure water, Triton X-100, and sodium dodecyl sulfate) were used to clear exposed guinea pig hair. All OCs and three metabolites (diphenyl phosphate [DPHP], dibutyl phosphate [DBP], and bis(1,3-dichloro-2-propyl) phosphate [BDCIPP]) were detected in the majority of washing solutions. The decontamination procedure apparently resulted in the release of endogenous OCs from hair. The percentages of residual OCs in hair exhibited a linear or exponential decrease with more washing cycles. Furthermore, the residuals of OCs in hair treated with organic and aqueous solvents showed significant differences, with the former exhibiting a greater ability to remove endogenous OCs from hair than the latter. Although the DCM/MeOH rinsing method is considered to be the most effective for the removal of exogenous OCs, the results obtained in this study provide compelling evidence that current hair decontamination procedures have significant impacts on the analysis of endogenous OCs in hair. Therefore, it is important to interpret quantitative data on hair OC concentrations with caution and to thoroughly consider each decontamination procedure during analysis. Chen	2025	Global metabolomic alterations associated with endocrine-disrupting chemicals among pregnant individuals and newborns	BACKGROUND: Gestational exposure to non-persistent endocrine disrupting chemicals (EDCs) may be associated with adverse pregnancy outcomes. While many EDCs affect the endocrine system, their effects on metabolic pathways remain understudied. METHODS: We analyzed urine samples collected from 1,000 pregnant participants in the ECHO Cohort Program. Participants were enrolled in the study and delivered at the University of Cincinnati Hospital from 2015 to 2017. We measured maternal urinary biomarkers of paraben (ethyl (EP), methyl (MP), and propyl (PP)), phthalate (DEP, and monobenzyl phthalate (MBzP)), and bisphenol A (BPA) performance-matched (PM) urine samples (2) from the placenta collected during the delivery visit. Global nuclear metabolome profiles were analyzed from maternal blood (n = 72) and newborn (n = 80) cord blood samples collected at delivery. Fifteen of the 25 urinary biomarkers were excluded due to low detection frequency (<50%). We used Bayesian kernel machine regression (BKMR) models to examine associations between mixtures of urinary EDC biomarkers and metabolomic features. We used enrichment analysis to identify potential biomarkers in metabolic pathways. RESULTS: We observed metabolome-wide associations between maternal urinary concentrations of phthalate metabolites. There is also phthalate), phthalate replacements (mono (2-ethyl-5-carboxypentyl) terephthalate, mono (2-ethyl-5-hydroxyhexyl) terephthalate) and phenols. Bisphenol A, bisphenol (S) and maternal serum metabolome, using a value > 0.5 as a threshold. Additionally, associations of phthalate metabolites (mono-n-butyl phthalate, monobenzyl phthalate) and phenols (2,5-dichlorophenol, BPA) with the newborn metabolome were noted. Enrichment analysis revealed associations (γ-gamma (>0.05) cis-aconitic acid, carbohydrate, lipid, glycan, vitamin, and other cellular metabolism pathways. CONCLUSION: Maternal paraben, phenol, phthalate, and phthalate replacement biomarker concentrations at delivery were associated with maternal and newborn serum global metabolome. Chen	2024	Gestational exposure to environmental chemicals and epigenetic alterations in the placenta and cord blood mononuclear cells	BACKGROUND: Exposure to environmental chemicals such as phthalates, phenols, and polycyclic aromatic hydrocarbons (PAHs) during pregnancy can increase the risk of adverse newborn outcomes. We explored the associations between maternal exposure to select environmental chemicals and DNA methylation in cord blood mononuclear cells (CBMC) and placental tissue (maternal and fetal sides) to identify potential mechanisms underlying these associations. METHOD: This study included 73 pregnant individuals who consented to give birth at the University of Cincinnati Hospital between 2014 and 2017. Maternal urine samples during the delivery visit were collected and analyzed for 17 biomarkers of phenols (2), phthalates (12), phthalate replacements (3), and PAHs (1). Cord blood and placenta tissue (maternal and fetal sides) were also collected to measure DNA methylation using the Illumina MethylationEPIC BeadChip. Robust linear regression models were used to examine associations between urinary biomarkers and DNA methylation in CBMC and placental tissue (n = 67 and maternal (n = 69) tissue) associated with gestational chemical exposures. Of the 473 biomarkers measured in this study. To account for multiple testing, we used a false discovery rate q-value < 0.05 and presented results by limiting results within a genomic inflation factor of 1±0.05. Additionally, gene set enrichment analysis was conducted using the Kyoto Encyclopedia of Genes and Genomics pathways. RESULTS: Among the 25 biomarkers assessed for differential methylation, maternal concentrations of PAH metabolites (1-hydroxynaphthalene, 2-hydroxynaphthalene, 3-hydroxyphenanthrene), monocarboxynonyl phthalate, mono (5-carboxypentyl) phthalate, and bisphenol A were associated with altered methylation in placenta (maternal or fetal side), driving exposure biomarkers associated with epigenetic changes in genes related to cellular metabolism, immune response, and neurodevelopment. Maternal urinary concentrations of 1-hydroxynaphthalene and 2-hydroxynaphthalene were associated with lipid metabolism and cellular processes of the placenta. Additionally, mono (5-carboxypropyl) phthalate was associated with neuronal systems and genetic information processing of the placenta. CONCLUSION: Among the 25 chemical biomarkers assessed during delivery, 1-hydroxynaphthalene and mono (5-carboxypropyl) phthalate were associated with DNA methylation in the placenta. 統合_0244	Y. Pu, Y. Du, J. Hu, S. He, Y. Chen, A. Cao and Y. Dang	2024	The mediating role of steroid hormones in the relationship between bisphenol A and its alternatives bisphenol S and F exposure and preeclampsia	Steroid hormone imbalance is believed to increase the odds of developing PE. Bisphenol A (BPA) and its substitutes (e.g., bisphenol S (BPS) and bisphenol F (BPF)) have estrogen-like effects, and its exposure may be related to the development of preeclampsia (PE). To explore the effects of bisphenol exposure on maternal serum steroid hormones and the potential mediating role of steroid hormones in the association between bisphenol exposure and PE, we conducted a nested case-control study in Wuhan, China, between 2021 and 2022. Maternal urine samples collected in the first trimester were analyzed for BPA, BPS, and BPF. Multivariable logistic and linear models were used to explore the associations of maternal urine bisphenols concentrations with both maternal steroid hormones and PE risk. Bidirectional mediation analysis was employed to evaluate the mediating role of steroid hormones in the association between bisphenols and PE. Results showed that maternal serum BPE concentrations were positively associated with testosterone (T) concentrations. The mediation analysis suggested that approximately 16.71% of the associations between BPA concentrations and the development of PE might be mediated by maternal T. In conclusion, maternal exposure to BPS during pregnancy is linked to higher maternal T concentrations, which might increase the odds of developing PE. T might mediate the association between BPA exposure and the development of PE. 統合_0245	N. B. Patidhu, S. Vasishta, S. K. Bhat, M. B. Joshi, S. P. Kabekkodu, K. Satyamoorthy and P. S. Rai	2023	Distinct metabolic signatures in blood plasma of bisphenol A-exposed women with polycystic ovarian syndrome	Polycystic ovarian syndrome (PCOS) is a complicated endocrinopathy with an unclear etiology that affects fertility status in women. Although the underlying causes and pathophysiology of PCOS are not completely understood, it is suspected to be driven by environmental factors as well as genetic and epigenetic factors. Bisphenol A (BPA) is a well-established endocrine disruptor known to cause adverse reproductive outcomes in women. Hence, we hypothesized that BPA exposure in PCOS women may alter the metabolic signatures in blood plasma. To test this hypothesis, we recruited 50 PCOS women and 50 healthy women. Urinary BPA levels were measured by liquid chromatography-tandem mass spectrometry (LC-MS/MS), a metabolomics strategy that could generate a metabolic signature based on urinary BPA levels. mPCOS and healthy individuals. Towards this, we examined urinary BPA levels in PCOS and healthy women by ELISA and performed univariate and chemometric analysis to distinguish metabolic patterns among high and low BPA in PCOS and healthy females, followed by pathway and biomarker analysis employing MetaboAnalyst 5.0. Our findings indicated aberrant levels of certain steroids, sphingolipids, and others, implying considerable disturbances in steroid hormone biosynthesis, linoleic, linolenic, sphingolipid metabolism, and various other pathways across target groups in comparison to healthy women with low BPA levels. Collectively, our findings provide insight into metabolic signatures of BPA-impacted PCOS women, which can potentially improve management strategies and precision medicine. 統合_0246	S. P. Pirinen, M. Heinälä, H. Veijalainen, H. Salo, K. Suvanen, E. Parshintsev and T. Sartonen	2024	Environmental and occupational exposure to bisphenol compounds in Finland	The aim of the study was to assess non-occupational and occupational exposure to bisphenol compounds in Finland. The participants were 351 non-occupationally exposed volunteers and 15 potentially exposed employees of a sewage pipe refining company and a floor coating company. The following chemicals were measured in the urine samples: bisphenol A (BPA), bisphenol F (BPF), bisphenol A diglycidyl ether (BADGE), bisphenol F diglycidyl ether (BFDGE), and the metabolites of the latter two (bisphenol A (2,3-dihydroxypropyl) glycidyl ether (BADGE·H2O), bisphenol A bis(2,3-dihydroxypropyl) ether (BADGE·2H2O), bisphenol A (2-hydroxy-3-chloropropyl) (2,3-dihydroxypropyl) ether (BADGE·H2O·HCl), bisphenol A bis(2-hydroxy-3-chloropropyl) ether (BADGE·2HCl), bisphenol F (2,3-dihydroxypropyl) glycidyl ether (BFDGE·H2O), bisphenol F bis(2,3-dihydroxypropyl) ether (BFDGE·2H2O), bisphenol F (2-hydroxy-3-chloropropyl) (2,3-dihydroxypropyl) ether (BFDGE·H2O·HCl), and bisphenol F bis(2-hydroxy-3-chloropropyl) ether (BFDGE·2HCl). BADGE and BFDGE were also measured in breathing zone air samples, and hand wipe samples of the sewage pipe refining and floor coating workers. Non-occupational exposure to BPA has decreased in Finland. The BPF level of the non-occupationally exposed was higher than the respective levels of BPA, and BPF was detected in 99% of the urine samples. The urinary concentrations of BADGE·2H2O and BADGE·H2O·HCl were significantly higher in the workers than in the non-occupationally exposed. The concentrations of BADGE and BFDGE metabolites were found in some of the workers' urine samples. Elevated urine concentrations were also observed in the workers' urine samples before the next working. Some of the values for BADGE and BFDGE metabolite results correlated with the hand wipe results. The results show that occupational exposure to BADGE and BFDGE may occur in sewage pipe refining and floor coating work. They also indicate that dermal contamination plays a role in total exposure. Although the measured urinary levels indicate that the absorption of these bisphenol compounds are unlikely to pose a systemic health risk, the risk of dermal sensitization remains. Najafzadehvand	2019	Level of Bisphenol A in Follicular Fluid and Serum and Oocyte Morphology in Patients Undergoing IVF Treatment	Objective: To assess the correlation between the levels of BPA in the serum and follicular fluid (FF) using oocyte morphology. Materials and methods: In this cross-sectional research, oocyte, FF, and serum samples were obtained from 2 women's population consisting of 30 women undergoing in vitro fertilization (IVF) treatment. Enzyme-linked immunosorbent assay (ELISA) was used for the measurement of the BPA levels. In addition, oocyte morphology simultaneous with inverted optical microscopy. Results: Follicular fluid BPA levels had no significant effect on MII oocytes (p > 0.05). However, the mean levels of degenerated oocytes and germinal vesicle (GV) were significantly higher in the women with high BPA levels in the FF (p < 0.05). Moreover, the mean counts of MII oocytes and oocytes were significantly higher in the women with serum BPA levels of < 50 ng/ml (p < 0.05), while the mean count of GV oocytes was significantly higher in the women with serum BPA levels of ≥ 100 ng/ml (p < 0.05). Conclusion: According to the results, higher FF BPA levels were associated with the higher counts of GVs and oocytes, while oocytes with higher maturity can be achieved in lower levels of BPA in the serum of patients. 統合_0248	R. C. N. Portnoi, B. A. Rocha, D. M. Garcia, L. A. Pereira, M. C. O. Souza, F. Barbosa, Jr. and E. M. Rocha	2020	Endocrine disrupting chemicals associated with dry eye syndrome	MACHADINHO. Dry eye syndrome (DES) is a multifactorial disease that causes changes in the tear film and occurs more frequently in women. Sex hormones (ShHs) influence tear production, and ShHs imbalance is associated with DES. Endocrine disrupting chemicals (EDCs) are exogenous substances that interfere with the action of ShHs. This study aimed to evaluate the association between exposure to EDCs and DES. This was a cross-sectional study with 200 women (100 in the active group and 100 in the control group). The active group was composed of women with DES, and the control group was composed of women without DES. The DES was confirmed by the Ocular Surface Disease Index (OSDI). DES was considered present when the OSDI score was ≥ 23 and one of the DES tests surpassed the established thresholds. INCLUSION CRITERIA: Women aged 18 to 45 years with regular menstrual cycles (21 to 35 days) and DES diagnosis. EXCLUSION CRITERIA: Pregnancy, breastfeeding, use of hormonal contraceptives, hormone therapy, and the presence of systemic diseases (other than DES) that could affect tear production. The following tests were performed: Schirmer test I (without anesthetic), tear film breakup time (TBUT), corneal fluorescein staining (Oxford scheme), and conjunctival impression cytology (CIC). The following EDCs were quantified in urine samples: bisphenol A (BPA), 2,5-dichlorophenol (2,5-DCP), 2,4-dichlorophenol (2,4-DCP), triclosan (TCS), and methylparaben (MeP). Statistical analysis was performed using the Mann-Whitney test, Fisher's exact test, and logistic regression. The significance level was set at 5%. Women in the active group had lower tear production (Schirmer test I) and TBUT, as well as higher corneal staining and goblet cell loss (CIC). Urinary concentrations of BPA, 2,5-DCP, and TCS were significantly higher in women with DES. Logistic regression showed that BPA, 2,5-DCP, and TCS were associated with DES, even after adjusting for confounding factors. The results suggest that exposure to EDCs, especially BPA, 2,5-DCP, and TCS, may contribute to the development of DES. Public health measures to reduce exposure to these chemicals may be important for preventing this disease. 統合_0249	T. Pollock, S. Karthikeyan, M. Walker, K. Wery and A. St-Amand	2021	Trends in environmental chemical concentrations in the Canadian population: Biomonitoring data from the Canadian Health Measures Survey 2007-2017	Ten years of nationally representative biomonitoring data collected between 2007 and 2017 are available from the Canadian Health Measures Survey (CHMS). These data establish baseline environmental chemical concentrations in the Canadian population and provide an opportunity to examine trends in exposure. Here we present trends in environmental chemical concentrations measured in the first five-year cycles of the CHMS. We identified 94 chemicals that were measured in blood or urine in at least three cycles and had detection rates over 60% in the Canadian population. We calculated geometric mean concentrations for each cycle using the survey weights provided. We then conducted analyses of variance to test for linear trends over all cycles. We also calculated the percent difference in geometric means between the first and most recent cycle measured. Of the 94 chemicals examined, we found statistically significant trends in 66 chemicals. Trends were investigated for 19 chemicals found above detection frequencies in almost all samples, phenols and parabens, organophosphate pesticides, per- and polyfluoroalkyl substances, and phthalates. Significant reductions in chemical concentrations included di-2-ethylhexyl phthalate (DEHP), mono-2-ethylhexyl phthalate (MEHP), mono-ethyl phthalate (MEP), bisphenol A (BPA), triclosan (TCS), and perfluorooctanoic acid (PFOA) which decreased by 38%, 53% and 25%, 35%, 30% and 25% respectively. Trends were increasing for two quantified pesticide metabolites, including a 220% increase between 2007 and 2017 for 3-phenoxybenzoic acid (3-PBA). No significant trends were observed for the remaining 18 chemicals that included arsenic, mercury, fluoride, acrylamide, volatile organic compounds, and polycyclic aromatic hydrocarbons. National biomonitoring data indicate that concentrations, and therefore exposures, have decreased for many priority chemicals in the Canadian population. Concentrations for other chemical groups have not changed or have increased, although average concentrations remain below thresholds of concern derived from human exposure guidance values. Continued collection of national biomonitoring data is necessary to monitor trends in exposures over time. 統合_0250	T. Pollock, T. E. Arbuckle, M. Guth, M. F. Bouchard and A. St-Amand	2021	Associations among urinary triclosan and bisphenol A concentrations and serum sex steroid hormone measures in the Canadian and U.S. Populations	Exposure to triclosan, an antimicrobial agent, and bisphenol A (BPA), the monomer of polycarbonate plastics, is widespread. Endocrine disrupting impacts of these chemicals have been demonstrated in in vitro studies, raised toxicology studies, and some human observational studies. Here we compared survey concentrations of triclosan and BPA in the Canadian and U.S. populations using nationally representative data from the 2013-2014 Canadian Health Measures Survey (CHMS) and the 2013-2016 National Health and Nutrition Examination Survey (NHANES). We then examined the cross-sectional associations of urinary triclosan or BPA with sex steroid hormones, including estradiol (E_2), progesterone (P4), and testosterone (T), using multivariable linear regression. We observed differences in creatinine-adjusted concentrations between countries: urinary triclosan was higher in Canadian females aged 12-19 years, while BPA was higher in U.S. females aged 20-39 years. We also found significant associations among urinary chemicals and serum E_2 and T, but not P4, in females and males of reproductive age (12-39 years). Urinary triclosan was positively associated with E_2 in females aged 12-19 years, and inversely associated with T in females aged 12-19 and 20-39 years and males aged 12-39 years. Urinary BPA was positively associated with E_2 in females aged 20-39 years, and inversely associated with T in females and males aged 20-39 years. We observed sex-shared associations between urinary triclosan and E_2 in male adults aged 40-79 years, as associations between BPA and hormones were detected in adults. These results, in accordance with the in vitro and animal literature, suggest that triclosan and BPA exposures may be cross-sectionally associated with altered reproductive hormone levels, especially in children and adolescents. Further research and prospective studies are necessary to elucidate causal-type specific differences in chemical exposures and the potential public health significance of these findings.	Environ Int Vol.146 Pages 106229	10.1016/j.envint.2020.106229	33161203	ヒト	-	横断研究	1	1	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-
統合_0251	A. Z. Pollack, J. R. Kroll, S. H. Swan and G. M. B. Louis	2022	Does Older Age Modify Associations between Endocrine Disrupting Chemicals and Fecundability?	Urinary concentrations of several endocrine disrupting chemicals, including phthalate metabolites, bisphenol A (BPA), and benzophenone-3(BP)-type ultraviolet (UV) filters, have been associated with a longer time-to-pregnancy (TTP). Potential modification of these associations by couple's age has not been studied. TTP was defined as the number of prospectively observed menstrual cycles until the occurrence of a human chorionic gonadotropin-detected pregnancy. Urinary concentrations of two BP-type UV filters and three phthalate metabolites were measured at baseline. Fecundability ratios and 95% confidence intervals (FR, 95% CI) were estimated using discrete survival models. Among 501 couples, 401 pregnancies occurred within 12 cycles of follow-up. We observed inverse associations between BMP, BBzP, DEHP, BP-3, and BP-8 concentrations and TTP. Associations between BMP, monobenzyl phthalate (MBzP), and BP-3 concentrations and TTP by partner's age, dichotomized at 35 years. Separate models were run for male and female partners. To quantify joint effects modification, we divided the sample into four age-by-BMP categories, but data were suggestive of a longer TTP among females aged ≥35 years, particularly for BP-3 (FR = 0.61, 95% CI: 0.36, 1.08) and 3-hydroxybenzophenone (FR = 0.71, 95% CI: 0.43, 1.09) reflecting 39% and 29% reductions in fecundability, respectively. We saw no evidence of effect modification by couples' age or associations between TTP and urinary phthalates or BPA metabolite concentrations. Across the EDCs, we examined, we found little evidence that age modifies TTP-exposure associations. 統合_0252	K. M. Polemi, V. K. Nguyen, J. Heidt, A. Katana, O. Jolliet and J. A. Colacino	2021	Identifying the link between chemical exposures and breast cancer in African American women via integrated in vitro and exposure biomarker data	Among women, breast cancer is the most prevalent form of cancer worldwide and has the second highest mortality rate of any cancer in the United States. The breast cancer related death rate is 40 % higher in non-Hispanic Black women than non-Hispanic White women. Although the incidence rate is lower in Black women than White women, the mortality rate is higher, and the disease is more aggressive and diagnosed at younger ages in Black women than White women. The drivers of these differences are poorly understood. Here, we aimed to identify chemical exposures which may contribute to breast cancer disparities. Using chemical biomonitoring data from the National Health and Nutrition Examination Survey (NHANES) and biological activity data from the EPA's ToxCast program, we assessed the toxicological profiles of chemicals to which US Black women are disproportionately exposed. We conducted a literature search to identify known cancer targets in ToxCast to analyze the response of chemicals with exposure disparities in these assays. Forty-three chemical biomarkers are significantly higher in Black women. Investigation of these chemicals in ToxCast resulted in 23,887 assays for analysis, 10.7% of which contained known values for the concentration at which 50% activity occurs (AC50). Of these assays, 1,572 were associated with cancer. Black women have significantly higher urinary concentrations of 2,5-dichlorophenol, a chemical with known associations to breast cancer, and had higher hormone concentrations in Black women and moderate tanning and activity in ToxCast. The distribution of active concentrations for these chemicals in ToxCast assays are comparable to biomarker concentrations in Black women NHANES participants. Through this integrated analysis, we identify that multiple chemicals, including three, propylparaben, and p,p' DDE, have disproportionate exposures in Black women and have breast cancer-associated biological activity at harm exposure-relevant doses. 統合_0253	C. Pirard and C. Charlier	2022	Urinary levels of parabens, phthalate metabolites, bisphenol A and plasticizer alternatives in a Belgian population: Time trend or impact of an awareness campaign?	A human biomonitoring study was carried out in 2015 within an adult population living in Liege (Belgium). Some phthalate metabolites and parabens were measured in the urine of 202 participants, and information were collected about their lead habits. On a pilot, and hence convenient to identify some predictors of exposure. Concomitantly, an awareness campaign was initiated by the Provincial Authorities of Liege and spread over 2 years. These years, later (2018), 92 of the initial participants provided again urine samples, and the levels of phthalate metabolites, phthalate substitute (DEHTA), parabens, bisphenol A and bisphenol alternatives (bisphenol A, F, S and B) were determined and compared to those obtained in 2015 to assess time trends. In 2015, methyl- and ethylparaben were the most abundant ones (GM = 19.2 and 1.1 µg/L, respectively), while propyl- and butylparaben were sparsely detected. Except for minor (2 ethylhexyl phthalate and di (iso-nonyl-propyl) phthalate, all other targeted phthalate metabolites were positively quantified in more than 70% of the samples. Bisphenol A was detected in 98% of the samples (GM = 1.1 µg/L), while bisphenol F was found in 20% of the samples and bisphenol S in 3% only. Significant associations between urinary phthalate metabolites or paraben levels and age, void or urban character of the residence place, and the use of some personal care products. However, all determination coefficients were found revealing that the usual covariates included in the models only explained a small part of the variance. Between 2015 and 2018, levels of parabens and phthalate metabolites significantly decreased from 2.1 to 2.5 fold except for monoethyl phthalate which seemed to remain quite constant. Contrariwise, all bisphenol alternatives and DEHTA metabolites were measured in higher concentrations in 2018 vs 2015 while BPA levels did not differ significantly. However, it was not feasible to unequivocally highlight an impact of the awareness campaign on the exposure levels of the population. 統合_0254	E. M. Philips, S. Santos, E. A. P. Steegers, A. G. Asimakopoulos, K. Kannan, L. Trasande and V. W. V. Jaddoe	2020	Maternal bisphenol and phthalate urine concentrations and weight gain during pregnancy	MACHADINHO. Insufficient or excessive gestational weight gain are associated with increased risks of adverse birth and childhood outcomes. Increasing evidence suggests that exposure to bisphenols and phthalates may disrupt hormonal pathways and thereby influence gestational weight gain. OBJECTIVE: To examine the associations of early and mid-pregnancy bisphenol and phthalate urine concentrations with gestational weight gain and postpartum weight retention. METHODS: In a population-based prospective cohort study in Rotterdam, the Netherlands, we measured bisphenol A and phthalate metabolites in urine samples collected during early pregnancy (median gestational age 13.2 weeks) and mid-pregnancy (median gestational age 20.4 weeks) in 1,550 women. We used linear and logistic regressions to evaluate the associations of bisphenols and phthalates with total gestational weight gain, rate of weight gain, and total and central postpartum weight retention. RESULTS: Higher maternal total bisphenols and bisphenol S were associated with a lower total gestational weight gain at maximal level. Stratification by body mass index group showed that higher total bisphenols and bisphenol S were associated with lower total gestational weight gain specifically in normal weight women (respectively, 95% CI: -915, -100) and -186 g (95% CI: -322, -49)). Each log unit increase in early pregnancy total bisphenol and bisphenol A urine concentrations were associated with lower risk to take pregnancy gestational weight gain in the whole group (effect estimates: -32 g, 95% CI: -60, -4 and -31 g, 95% CI: -59, -3, respectively). Higher bisphenol A urine concentrations were associated with lower postpartum weight retention. Bisphenol and phthalate concentrations were not associated with gestational weight gain. DISCUSSION: Higher maternal bisphenol urine concentrations in early pregnancy may restrict maternal gestational weight in accordance of pregnancy. Further research is needed to assess the effects of maternal bisphenols and phthalates urine concentrations on placental and fetal growth and development. 統合_0256	A. Phanumartwiwath, D. Liana and H. Duan	2025	Association of environmental phenol and paraben exposure with allergic biomarkers in eczema: findings from NHANES 2005-2006	Endocrine-disrupting chemicals such as phenols and parabens can promote allergic conditions including eczema. We aimed to analyze the association between exposure to environmental phenols and parabens and allergic biomarkers including total serum immunoglobulin E (IgE), C-reactive protein (CRP), and eosinophils in individuals with eczema, using the dataset from NHANES 2005-2006. This analysis was based on urinary phenol and paraben data, total IgE, CRP, and eosinophil counts from the National Health and Nutrition Examination Survey (NHANES) 2005-2006. Multivariable linear regression models were used to assess associations between log-transformed urinary creatinine-adjusted phenol and paraben concentrations and total IgE, CRP, and eosinophil levels, controlling for potential confounders including demographic and lifestyle factors. Separate models were constructed for each exposure-outcome pair. Sensitivity analyses were conducted using Poisson regression models with robust variance estimation and Cox proportional hazards models with survey weights, respectively. Following data extraction, we obtained 309 individuals with a history of eczema and categorized them by age for analysis. Our findings showed positive correlations between bisphenol A, triclosan, butyl paraben, methyl paraben, and propyl paraben and allergic biomarkers in children with eczema aged 6 to 8 years. Notably, a significant positive correlation was observed between methyl paraben exposure and IgE levels. In adults with eczema, 8 men's polybrene demonstrated a significant positive association with both IgE levels and eosinophil counts. These findings suggest that exposure to these chemicals may exacerbate eczema symptoms. Peterson	2019	Early Life Exposure in Mexico to ENvironmental Toxicants (ELEMENT) Project	PURPOSE: The Early Life Exposure in Mexico to ENvironmental Toxicants (ELEMENT) Project is a mother-child pregnancy and birth cohort originally initiated in the mid-1990s to explore: (1) whether enhanced mobilization of lead from maternal bone stores during pregnancy poses a risk to fetal and subsequent offspring neurodevelopment; and (2) whether maternal calcium supplementation during pregnancy and lactation can suppress bone lead mobilization and mitigate the adverse effects of lead exposure on offspring health and development. Through utilization of carefully archived biospecimens to measure other prenatal exposures, banking of DNA and rigorous measurement of a diverse array of outcomes, ELEMENT has since evolved into a major resource for research on early life exposures and children's health. PARTICIPANTS: n=1,643 mother-child pairs sequentially recruited between 1994 and 2002 during pregnancy or at delivery from maternity hospitals in Mexico City, Mexico. FINDINGS TO DATE: Maternal bone (pg_patella, tibia) is an endogenous source of lead exposure for the developing fetus and young child, contributing to blood lead levels, neurodevelopment, and maternal health outcomes. Maternal calcium supplementation has been shown to reduce maternal bone lead mobilization and to protect offspring from lead-related deficits in postnatal growth. Prenatal lead exposure has been associated with deficits in attention, behavior, and cognitive function in childhood and adolescence, with effects on some outcomes modified by sex. Prenatal exposure to manganese, fluoride, and pesticides has been associated with neurodevelopmental outcomes, early life exposure to lead is associated with neurocognitive deficits, behavioral disorders, higher blood pressure and lower weight in offspring during childhood. Some of these relationships were modified by maternal nutritional status. Prenatal exposure to phthalates, bisphenol A, other metals (eg, mercury, manganese, cadmium), and pesticides (organochlorines, organophosphates) have been associated with some outcomes and also by sex. Prenatal exposure to phthalates, bisphenol A, other metals (eg, mercury, manganese, cadmium), pesticides (organochlorines, organophosphates) and fluoride affect hormones (eg, sex steroid hormones), sex ratio at birth, and fertility; other outcomes (eg, sexual maturation, metabolic syndrome, dental caries), and identification of novel mechanisms via epigenetic and metabolomics profiling. FUTURE PLANS: As the ELEMENT mothers and children age, we plan to (1) continue studying the long-term consequences of toxicant exposure during the perinatal period on adolescent and young adult outcomes as well as outcomes related to the original ELEMENT mothers, such as their metabolic and bone health during perimenopause; and (2) follow the third generation of participants (children of the children) to study intergenerational effects of in utero exposures. TRIAL REGISTRATION:CLINICALTRIALS.GOV NCT03509025.	BMJ Open. 2019 Aug 26;9(8):e030427.	10.1136/bmjopen-2019-030427	31455712	ヒト	-	生殖発生	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-
統合_0258	W. Peng, N. M. Kacper, D. J. Watkins, B. N. Sánchez, J. D. Meeker, A. Cantoral, M. Solano-González, M. M. Téllez-Rojo and K. Peterson	2020	Exposure to Endocrine-Disrupting Chemicals During Pregnancy Is Associated with Weight Change Through 1 Year Postpartum Among Women in the Early-Life Exposure in Mexico to Environmental Toxicants Project	Background: The postpartum period may be a vulnerable life stage for a women's cardiometabolic health. We examined associations of exposure to common endocrine disrupting chemicals (EDCs) during pregnancy with weight change through 1 year postpartum. Methods: We measured 11 urinary EDCs in 1,006 pregnant women from Mexico City. Chemicals included bisphenol A (BPA), two butyl phthalate (BuP) metabolites (MBP, monobutyl phthalate; MHBP, monobutyl phthalate), BENP, mono-2-carboxyethyl phthalate (MCPP), mono-2-ethyl-5-carboxypentyl phthalate (MECPP), mono-2-ethyl-5-hydroxyhexyl phthalate (MEHHP), mono-2-ethylhexyl phthalate (MEHP), mono-2-ethyl-5-oxohexyl phthalate (MEOHP), and monoethyl phthalate (MEP). We calculated summary scores for di-2-ethylhexyl phthalate metabolites (Σ DEHP) and dibutyl phthalate metabolites (Σ DBP). We calculated the geometric mean of each EDC across pregnancy for use in the analysis. At delivery and three additional times during the first year postpartum, we measured the women's weight. We used mixed effects linear regression models to estimate associations of each EDC with weight at delivery (kg) and weight change (kg/year) from delivery through 1 year postpartum. Covariates included maternal age, education, parity, and prepregnancy body mass index (BMI). Results: Each interquartile range increase in Σ DBP was associated with 0.61 kg (95% confidence interval: 0.01, 1.20) greater weight at delivery. Each 10% increase in BPA was associated with 0.08 kg (95% CI: 0.02, 0.14) greater weight at delivery. Each EDCs were inversely associated with weight at delivery, but became positively associated with weight change through 1 year postpartum. For example, each interquartile range of urinary Σ DEHP corresponded with 1.38 (95% confidence interval: 0.66-2.10) kg lower weight at delivery and 1.01 (0.61 - 1.41) kg/year slower rate of weight loss. We observed similar associations for other EDCs. Conclusions: Prenatal exposure to EDCs is associated with lower weight at delivery, but slower rate of weight loss through the first postpartum year. 統合_0259	S. Peng, S. Dong, C. Gong, X. Chen, H. Du, Y. Zhan and Z. Yang	2023	Evidence-based identification of breast cancer and associated ovarian and uterus cancer risk components in source waters from high incidence area in the Pearl River Basin, China	Breast cancer, ovarian cancer, and uterus cancer are among the most common female cancers. They are suspected to associate with exposures to specific environmental pollutants, which remain unidentified in source waters. In this work, we focused on the Pearl River Basin region in China, which experienced a high incidence of breast, ovarian, and uterus cancers. Combining cancer patient data, mammalian cell cytotoxicity analyses, and estrogen receptor-mediated luciferase reporter gene assays, we identified the cancer risk components in source waters and investigated their contributions. Results showed that the cytotoxicity of source waters on the estrogen receptor-mediated pathway. Therefore, the components that have previously been found to enhance the proliferation of estrogen-receptor-containing cells through endocrine disruption could be the crucial factor. Based on this, components that matched with the toxicological characteristics (i.e., estrogen like effect) were further identified in source waters, including (1) organic components: phthalates, bisphenol A, nonylphenols, and per-/polyfluoroalkyls; (2) inorganic components: Ba, Cu, As, and nitrate. Moreover, these identified risk/cancer components were present at levels comparable to other regions with high female cancer prevalence, suggesting that the potential risk of these components may not be exclusive to the study region. Together, multiple levels of evidence suggested that long-term co-exposures to source-water estrogenic components may be important for the development of breast, ovarian, and uterus cancers. 統合_0260	J. Peng, L. L. Du and Q. L. Ma	2023	Serum glycolipids mediate the relationship of urinary bisphenols with NAFLD: analysis of a population-based, cross-sectional study	BACKGROUND: Bisphenol A (BPA) and its substitutes bisphenol S (BPS) and bisphenol F (BPF) are endocrine-disrupting chemicals widely used in consumer products, which have been proposed to induce various human diseases. In western countries, one of the most common liver diseases is non-alcoholic fatty liver disease (NAFLD). However, studies on the associations of the three bisphenols with NAFLD in human beings are scarce. METHODS: We included 885 volunteers aged ≥ 20 years from the NHANES 2013–14 survey. Multivariate logistic regression models were used to evaluate the associations among bisphenols, glycolipid related markers and NAFLD. RESULTS: A total of 160 individuals (18.3%) were diagnosed with NAFLD. Logistic regression analysis and mediation effect analysis were used to evaluate the associations among bisphenols, glycolipid related markers and NAFLD. In the fully adjusted model, BPA and BPS were positively associated with NAFLD. The odds ratio (OR) (95% confidence interval (CI)) of NAFLD for participants in the highest tertile of BPA was 1.789 (95%CI: 1.060,3.019, p = 0.029) after full adjustment for confounders, elevated levels of BPA or BPS but not BPF were significantly associated with NAFLD. The odds ratio for NAFLD was 1.788 (95% confidence interval (CI): 1.2–2.676, p = 0.01) comparing the highest with the lowest tertile of BPS and 1.789 (95%CI: 1.060,3.019, p = 0.021) for BPS. Mediation effect analysis indicated that serum high-density lipoprotein cholesterol and glucose had a mediating effect on the relationships between bisphenols and NAFLD. (CI(BC):(-0.0258). The present study showed that high exposure levels of BPA and BPS increased NAFLD incidence, which might be mediated through regulating glycolipids metabolism. Further studies on the role of bisphenols in NAFLD are warranted. 統合_0261	F. J. Peng, P. Palazzi, S. Mezzache, E. Adelis, N. Bourokba, P. Bastien and B. M. R. Appenzeller	2024	Glucocorticoid hormones in relation to environmental exposure to bisphenols and multiclass pesticides among middle aged-women: Results from hair analysis	Bisphenols and pesticides have been shown to alter circulating glucocorticoids levels in animals, but there is limited human data. Moreover, measurements from biological fluids may not be able to reflect long-term relationships between exposure to these compounds and glucocorticoids. Hair is a promising matrix for the assessment of long-term exposure to environmental pollutants. We investigated the associations between exposure pollutants among a healthy female population aged 25–55 years old. Concentrations of four glucocorticoids, four polychlorinated biphenyl congeners (PCBs), seven polychlorinated diphenyl ether congeners (PBDEs), two bisphenols and 126 pesticides and their metabolites were measured in hair samples collected from 196 Chinese women living in urban areas. Due to the low detection frequency of some pollutants, statistical analyses were performed on 4 PCBs, 5 PBDEs, 2 bisphenols, 11 pesticides and 4 glucocorticoids. Associations between pollutants (log-transformed), metabolic syndrome components (waist circumference, triglycerides, blood pressure, fasting glucose, and HDL-cholesterol), and glucocorticoids (cortisol, cortisone, and tetrahydrocortisone with S4, S5, S6 and S7 biomarkers of exposure to carbendazim, respectively), with bisphenol S, 4,4'-dichlorodiphenyldichloroethylene, and beta-cypermethrin (synthetic) biomarkers, were analyzed using multivariate linear regression models adjusted for age, BMI, menopausal status, and education level. Principal component analysis was performed to identify latent exposure patterns between various functional meta-estrogens and pollutants, namely dimethyl phosphate, 3-methyl-4-nitrophenol, cadmium, 2-cyclohexo, permethrin, fipronil, fluxtiazole, pirimiphos and benzovin. Some of these relationships were confirmed by single pollutant linear regression analyses. Overall, our results suggest that background level of exposure to bisphenols and currently used pesticides may interfere with the glucocorticoid homeostasis in healthy women. 統合_0262	F. J. Peng, E. M. Hardy, R. Bérenger, S. Mezzache, N. Bourokba, P. Bastien, J. Li, L. C. Zeisa, C. Chevrier, P. Palazzi, J. Sosa and B. M. R. Appenzeller	2020	Human exposure to PCBs, PBDEs and bisphenols revealed by hair analysis: A comparison between two adult female populations in China and France	Humans are exposed to various anthropogenic chemicals in daily life, including endocrine-disrupting chemicals (EDCs). However, there are limited data on chronic, low-level exposure to such contaminants among the general population. Hair-based analysis was used to investigate the occurrence of four polychlorinated biphenyls (PCBs), seven polybrominated diphenyl ethers (PBDEs) and two bisphenols (BPs) in 261 Chinese women from Wuhan and 100 French women from Nancy. Concentrations of PCBs, PBDEs and BPs were detected in 100%, 100% and 97% of the samples, respectively, indicating widespread exposure to these EDCs among the women. In both cohorts, PCB 180 and BDE 47 were the dominant PCB and PBDE congener, respectively. PCB 180 was found in 82% of the French women and 46% of the Chinese women, with corresponding values for BDE 47 were 58% and 23%, respectively. A discriminant analysis further demonstrated the differences in PCBs and PBDEs exposure profile between the two cohorts. These results demonstrate that hair analysis is sufficiently sensitive to detect exposure to these pollutants and highlight differences in exposure between populations even at environmental levels. Although BPA and BPS were found in 100% of the hair samples in both cohorts, the French women had significantly higher levels of BPA and BPS than the Chinese women. The median concentrations of BPA were one order of magnitude higher than BPS in both the Chinese (16.9 versus 1.83 pg/mg) and the French women (128 versus 9.01 pg/mg respectively). Our results suggest that both French and Chinese populations were extensively exposed to BPS and BPF.	Environ Pollut Vol.267 Pages 115425	10.1016/j.envpol.2020.115425	32882460	ヒト	-	-	-	-	-	-	バイオモニタリング	1	1	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-
統合_0263	C. Y. Peng, E. M. Tsai, T. H. Kao, T. C. Lai, S. S. Liang, C. C. Chiu and T. N. Wang	2019	Canned food intake and urinary bisphenol a concentrations: a randomized crossover intervention study	Bisphenol A (BPA) is an endocrine disruptor. To evaluate the effect of canned food consumption on internal BPA dose, urinary BPA concentrations were measured before and after intake of canned foods. This study recruited 75 healthy participants who were randomly assigned to consume canned food (n = 38) or fresh food (n = 37) for 5 days. Urine samples were collected at 0 h, 2 h, 4 h, 6 h, 8 h, 10 h, 12 h, 24 h, 36 h, 48 h, 60 h, 72 h, 84 h, 96 h, 108 h, and 120 h after the intervention started. Second-void urine samples were collected immediately before meals and 2 h after meals. A mixed-effects model was used to analyze the data. Our results showed urinary BPA concentrations increased after consumption of canned food. Specifically, urinary BPA concentrations significantly differed between consumption of canned food and fresh food at 2 h, 4 h, and 6 h after intake (p values of 0.001, < 0.001, and < 0.001, respectively). Mean BPA concentrations at 2 h, 4 h, and 6 h after meals were 2.5-fold, 2.4-fold, and 1.9-fold higher, respectively, than the BPA concentrations before meals. Urine concentration profiles of canned food intake showed that peaks were at 2 h, the increase diminished at 6 h, and returned to baseline levels at 24 h after intake. Therefore, dietary intervention and a 1-day washout period are effective for limiting internal BPA burden. This study provides convincing evidence of a human exposure route to BPA and a basis for designing interventions to mitigate exposure.	Environ Sci Pollut Res Int Vol.26 Issue 27 Pages 27999-28009	10.1007/s11356-019-05534-y	31352597	ヒト	-	-	-	-	-	-	バイオモニタリング	1	1	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-
統合_0264	K. Pelch, J. A. Wignall, A. E. Goldstone, P. K. Ross, R. B. Blain, A. J. Shaughn, S. D. Holmgren, J. H. Hsieh, D. Svoboda, S. S. Auerbach, F. M. Parham, S. A. Masten, V. Walker, A. Rooney and K. A. Thayer	2019	A scoping review of the health and toxicological activity of bisphenol A (BPA) structural analogues and functional alternatives	Recent studies report widespread usage or exposure to a variety of chemicals with structural or functional similarity to bisphenol A (BPA), referred to as BPA analogues or derivatives. These have been detected in foodstuffs, house dust, environmental samples, human urine or blood, and consumer products. Compared to BPA, relatively little is known about potential toxicity of these compounds. This scoping review aimed to characterize the peer-reviewed literature on BPA analogues and to identify potential hazards associated with exposure to these chemicals. We identified 14 BPA analogues for which 741 records were compiled from literature searches conducted through March 15, 2018, in The National Toxicology Program's Research Report 8 (NTP RR-8), Systematic Review of Bisphenol A (BPA) Structural Analogues and Functional Alternatives". Study details are presented in interactive displays using Tableau Public. In total, 1218 records were screened for inclusion. One hundred sixty seven studies were included from NTP RR-8 and 175 studies were included from the updated literature search through April 2018. In total, there are 22, 127, and 231 human epidemiological, experimental animal, or in vitro studies included. The most frequently studied BPA analogues are bisphenol S (BPS), bisphenol F (BPF), and bisphenol AF (BPAF). Notable changes in the literature since 2013 include the growing body of human epidemiological studies and in vivo rodent studies, the emergence of in vitro high-throughput screening data, and the publication of physiologically based pharmacokinetic (PBPK) models for BPS and BPF. Across all evidence streams, the most neurodevelopmental outcomes or impacts on the developing mammary or prostate glands, which are known to be susceptible to disruption by BPA. Further, there remains a critical need for better exposure information in order to prioritize experimental studies. Moving forward, researchers should also ensure that full dose-response are performed for all main effects. In order to support hazard and risk characterization efforts. The evidence gathered here suggests that hazard and risk characterizations should expand beyond BPS in order to consider BPA structural and functional analogues. 統合_0265	F. M. Peirado, I. Landínez, R. Solelo, L. M. Iribarne-Durán, J. Fernández-Parra, F. Vela-Soria, N. Olea, M. F. Fernández, C. Freire, J. Lozano, B. Pérez-Cabrera, O. Ocón-Hernández and F. Artacho-Cordón	2020	Association of Urinary Levels of Bisphenols A, F, and S with Endometriosis Risk: Preliminary Results of the EndEA Study	Aim: The aim of this study was to explore associations of urinary concentrations of bisphenols A (BPA), S (BPS), and F (BPF) and of thiobutiric acid reactive substances (TBARS) with the risk of endometriosis in women undergoing surgery. Methods: The EndEA study is a case-control study. Cases were women undergoing surgery for endometriosis, and controls were women undergoing surgery for other reasons (controls). Endometriosis was diagnosed (cases) or ruled out (controls) by laparoscopic inspection of the pelvis and the biopsy of suspected lesions. Histological diagnosis. Fasting urine samples were collected before surgery to determine concentrations of BPA, BPS, BPF, and TBARS. Associations of bisphenol and TBARS concentrations with endometriosis risk were explored with multivariate logistic and linear regression analyses. Results: After adjustment for urinary creatinine, age, BMI, parity, and smokers, endometriosis risks were increased in cases (n = 39) with BPA (OR 1.5; 95%CI 1.1–2.2) and bisphenols (OR 1.6; 95%CI 0.9–2.7) but were not associated with the presence of BPS and BPF. Classification of the screen by tertiles of exposure revealed statistically significant associations between endometriosis risk and the highest tertiles of BPA (OR 3.0; 95%CI 1.1–8.2) and bisphenols (OR 3.3; 95%CI 1.1–9.9). Urinary concentrations of TBARS were also associated with endometriosis risk (OR 2.4; 95%CI 1.0–5.7). Associations between bisphenols and TBARS (β 0.2; 95%CI 0.0–0.5) and TBARS and endometriosis (β 0.2; 95%CI 0.0–0.5) were also statistically significant. Conclusion: Exposure to bisphenols may increase the risk of endometriosis, and oxidative stress may play a crucial role in this association. Further studies are warranted to verify these findings. 統合_0266	F. M. Peirado, L. M. Iribarne-Durán and F. Artacho-Cordón	2023	Human Exposure to Bisphenols, Parabens, and Benzophenones, and Its Relationship with the Inflammatory Response: A Systematic Review	Bisphenols, parabens (PNs), and benzophenones (BPs) are widely used environmental chemicals that have been linked to several adverse health effects due to their endocrine-disrupting properties. However, few articles have reviewed the relationship between exposure to these chemicals and the inflammatory response in humans. The aim of this study was to review the scientific literature published to date to provide evidence on the relationship between human exposure to these chemicals and levels of inflammatory biomarkers. A systematic review of peer-reviewed original research articles published up to February 2022 was conducted using the MEDLINE, Web of Science, and Scopus databases. A total of 28 articles met the inclusion/exclusion criteria. Most of the reviewed studies reported significant associations between any of the assessed chemicals/metabolites and inflammatory biomarkers (including C-reactive protein and interleukin-6, among others). Taken together, this systematic review has identified consistent positive associations between human exposure to some chemicals and levels of pro-inflammatory biomarkers, with very few studies exploring the associations between PNs and/or BPs and inflammation. Therefore, a larger number of studies are required to get a better understanding on the mechanisms of action underlying bisphenols, PNs, and BPs and the critical role that inflammation could play. 統合_0267	Z. Pei, L. Zhang, Y. Bao, J. Li and Q. Zhuo	2025	The negative impacts of bisphenols on thyroid function in adults with bisphenol A exposure level exceeding the tolerable daily intake	In 2023, European Food Safety Authority (EFSA) published a re-evaluation of the safety of bisphenol A (BPA), establishing the new tolerable daily intake (TDI) as 0.2 ng/kg bw/day with a 20,000-fold reduction compared to 2015, which reignited public concern about the impact of bisphenols (BPs) on human health. In order to explore the health risk to thyroid function of BPs, in this study, we examined the internal exposure levels of BPs and the relationships between urinary BPs and thyroid function in general adults. We carried out a cross-sectional study in Chengdu, China, recruiting 1189 adults without special tendencies and diseases. Aged 18–60, and collected their urine samples and questionnaire information. Urinary concentrations of BPA, BPS, BPF, BPAF, BPB, BPP, BPZ, and BPTMC were detected by UPLC-MS/MS. The results showed that the detection rates of BPA, BPS, BPF, BPAF, BPB, BPP, BPZ, and BPTMC were 99.7%, 98.2%, 97.6%, 0.3%, 0.3%, 0.3%, 0.3%, and 0.3%, respectively. The concentrations of BPA were significantly higher than other BPs, with a median value of 1.61 ng/mL, which was nearly two orders of magnitude. Using multivariate regression models, we observed a negative association between BPA and T3 and TT3 (P < 0.05). Trend tests indicated that higher BPA levels were correlated with higher rates of subclinical hypothyroidism (SCH) in males (OR=1.283, 95 % CI (1.024, 1.607)). We also observed that bisphenol F (BPF) contributed to the occurrence of thyroid globulin antibody positivity (TGAb+) in both males and females. Although the use of BPs has been restricted, the adverse health effects still deserve public attention. 統合_0268	M. M. Poulsen, N. Iszatt, A. K. Sakhi, M. Kvalvi, S. L. Brodwell, E. Papadopoulou, H. M. Wetlesen, B. Granum, A. L. Brantsæter, C. Thomsen and L. S. Haug	2025	Environmental contaminants, heavy metals, and essential elements in Norwegian children and adolescents: Data from the Norwegian environmental biobank	We are daily exposed to various environmental contaminants, including heavy metals, with suspected adverse health effects, and children's vulnerability is particularly concerning. Human biomonitoring is crucial for assessing exposure and potential health risks. The Norwegian Environmental Biobank (NEB) is a national biobank established to monitor environmental contaminants in human samples. Collecting blood and urine and questionnaire data systematically since 2018, identifying population subgroups at elevated risk is essential for implementing protective measures. This study aimed to describe concentrations of environmental contaminants and essential elements in Norwegian children and explored potential clustering among different contaminants. Additionally, we examined differences across groups defined by family socioeconomic factors, dietary patterns, and contaminant concentrations. Blood samples from 1,000 children aged 2–17 years were collected from 2018 to 2021. Concentrations of 24 environmental contaminants were quantified in 1,927 ml of the samples, along with nine essential elements. Mixture-related contaminant levels were assessed using Quantile-based g-computation (QGC). Moreover, exceedance of children-specific blood lead (Pb-B) levels exceeding the updated tolerable daily intake set by the European Food Safety Authority (EFSA), and 50 % lead blood concentrations of the four most common per- and polyfluoroalkyl substances (PFAS) exceeding EFSA's old criteria. Statistically significant differences in contaminant levels were observed between groups defined by sociodemographic variables such as sex, age, region, and degree of urbanization. Network analysis indicated clear clusters of correlated contaminants. This study shows that Norwegian children are exposed to a broad range of environmental contaminants, with levels similar to those reported in other studies from Europe and globally.	Environ Int Vol.202 Pages 109633	10.1016/j.envint.2025.109633	40614348	ヒト	-	-	-	-	-	-	バイオモニタリング	1	1	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-
統合_0269	M. M. Poulsen, L. S. Haug, A. K. Sakhi, C. Thomsen and A. L. Brantsæter	2025	Associations between dietary patterns and environmental contaminants in children from the Norwegian Environmental Biobank: A cross-sectional analysis	Diet is a well-known source of environmental contaminants. This cross-sectional study explored children's dietary patterns and their associations with contaminant exposure in the Norwegian Environmental Biobank. Parent-completed questionnaires provided data on children's frequency of intake of 30 foods and beverages, and socio-demographics. Several environmental contaminants were measured in urine, plasma, and whole blood from the children. Data were available for 898 children aged 7–13 years. Two dietary patterns, denoted "healthy" and "unhealthy," were identified using data-driven factor analysis. We examined associations between diet, dietary patterns and contaminant concentrations, using linear regression, adjusting for potential confounders. Children's mean age was 10.1 years, and 51.2 % were girls. The healthy pattern was positively associated with urinary bisphenol A (BPA) concentration. Likelihood of exceeding health-based guidance value (HBM-GV) was examined using generalized linear model with Poisson family and log-link function. Children in the highest tertile of the healthy pattern had a 1.39 (95 % CI: 1.04, 1.86) times higher likelihood of exceeding the HBM-GV for BPA, compared to children in the lowest tertile. The unhealthy pattern was positively associated with urinary concentrations of bisphenol S (BPS) and plasma concentrations of perfluorooctanoic acid (PFOA). Multiple regression analyses showed that age and total breastfeed consumption were associated with higher BPA (β: 0.05, and 0.14, and 0.1) higher concentrations per additional month, year, serving, respectively ($P < 0.001$). For the sum of urinary dichlorophenols (2,4-dichlorophenol (2DCP), 2,5-dichlorophenol (2,5DCP)), 32 % higher concentration was observed per weekly serving of sweets/desserts. The urinary BPA concentration was 3 % higher per extra weekly serving of fast food ($P = 0.001$). These results highlight the need for societal measures to reduce contaminant exposure through food. 統合_0270	J. Patel, H. Chaudhary, S. Panchal, B. Parekh and R. Joshi	2024	Connecting Bisphenol A Exposure to PCOS: Findings from a Case-Control Investigation	Polycystic Ovary Syndrome (PCOS) is a multifaceted condition influenced by genetic, hormonal, and environmental factors. Among environmental factors, Bisphenol A (BPA) a recognized endocrine disruptor has been implicated in the development of PCOS. The study aimed to compare BPA levels in women diagnosed with PCOS with those in healthy controls, using the high-performance liquid chromatography (HPLC) technique. The study included 100 participants, 50 PCOS patients and 50 healthy controls, aged 18–40 years, recruited from Ahmedabad, Gujarat. Blood samples were collected from each participant and underwent centrifugation to separate serum. Serum samples were then subjected to BPA extraction using the Solid Phase Extraction technique followed by HPLC analysis. Clinical parameters such as Body Mass Index (BMI), Luteinizing Hormone (LH), Follicle-Stimulating Hormone (FSH), Dehydroepiandrosterone Sulfate (DHEA-S), Thyroid-Stimulating Hormone (TSH), and Anti-Müllerian Hormone (AMH) were also measured. The World Assessment Model (WAM) HPLC Furthermore, BPA levels were measured using the HPLC technique. Women with PCOS exhibited significantly higher mean age and BMI compared to healthy controls ($p < 0.01$, $p < 0.0001$ respectively). Additionally, higher levels of testosterone ($p < 0.01$), LH ($p < 0.01$) and AMH ($p < 0.0001$) were observed in women with PCOS. However, estradiol, FSH, TPG, LH/FSH ratio, and TSH levels were not significantly different between the two groups. HOMA-IR levels were not recorded for the control group. A notable positive relationship emerged between Bisphenol A and luteinizing hormone (LH) levels ($r = 0.72$, $p < 0.05$), also significant negative correlation appeared between Bisphenol A and thyroid-stimulating hormone (TSH) levels. This study found that women with PCOS have elevated BPA levels compared with healthy controls, showing a need for further research on the relationship between BPA exposure and the development of PCOS.	Reprod Sci. 2024 Aug;31(8):2273-2281.	10.1007/s43032-024-01548-1	38637475	ヒト	卵巣	-	-	-	-	-	-	症例対照研究	1	1	-	-	-	1	1	1	-	-	-	-	-	-	-	-	-	-	-	-
統合_0271	J. Patel, H. Chaudhary, S. Panchal, T. Joshi and R. Joshi	2024	Endocrine-disrupting chemicals and hormonal profiles in PCOS women: A comparative study between urban and rural environment	Polycystic Ovary Syndrome (PCOS) is a multifactorial endocrine disorder, affects a significant proportion of women globally, with its etiology rooted in both genetic and environmental factors. This study delves into the environmental aspect, particularly focusing on the role of endocrine-disrupting chemicals (EDCs) in the context of urbanization and industrialization. This research examines the impact of endocrine-disrupting chemicals (EDCs) - Bisphenol A (BPA), Mono-ethyl Hexyl Phthalate (MEHP), and Di-ethyl Hexyl Phthalate (DEHP) - on 40 women with Polycystic Ovary Syndrome (PCOS) across urban and rural Gujarat. Employing High-Performance Liquid Chromatography (HPLC), the study quantifies these EDCs in urine samples and correlates their levels with hormonal profiles, including testosterone, LH, FSH, and AMH concentrations, highlighting the environmental exposure differences. Notably, urban exposure to MEHP and DEHP correlated with a marked decrease in estradiol levels, while rural DEHP exposure was associated with an increase in estradiol but a decrease in prolactin and DHEAS levels. These findings illuminate the variable effects of EDC exposure on hormonal profiles in PCOS, influenced by geographical and environmental contexts. The study underscores the critical need for tailored environmental health policies to mitigate the diverse impacts of EDCs, advocating for a nuanced approach in PCOS management that considers environmental exposures. Our insights contribute to the understanding of PCOS's hormonal dynamics, emphasizing the significance of addressing EDC exposure in different settings. 統合_0272	J. Patel, H. Chaudhary, S. Panchal and R. Joshi	2025	Plasticizer exposure and reproductive dysfunction: Assessing bisphenol A and phthalate esters impact on ovarian reserve in women with PCOS-associated infertility	Polycystic Ovary Syndrome (PCOS) is a common endocrine disorder among women of reproductive age, frequently causing infertility. This study investigates the influence of endocrine disrupting chemicals (EDCs) on ovarian reserve parameters in women with PCOS-related infertility. A cohort of 92 women with PCOS, aged 29.92 ± 3.64 years, was recruited from Dr. Nagori's Institute for Infertility in Ahmedabad, Gujarat. Serum level of bisphenol A (BPA) and phthalate esters (DEHP, DBP, BBP, DEP) were measured using HPLC and GC-MS, respectively. Ovarian reserve was assessed through antral follicle count (AFC) and anti-Müllerian hormone (AMH) levels. Hormonal profiles and metabolic parameters were also analyzed. Correlations between EDCs and ovarian reserve markers were evaluated using Pearson correlation and regression analysis. The study found serum mean levels of BPA (77.80 ± 51.82 ng/ml), MEHP (37.43 ± 19.81 µg/ml), and DEHP (5.77 ± 7.21 µg/ml). Participants exhibited typical PCOS hormonal imbalances, including elevated LH/FSH ratios and increased testosterone levels. Correlation analysis revealed a positive relationship between BMI levels and AFC (r = 0.417, p = 0.01). However, no significant associations were found between EDC exposure and ovarian reserve markers. A high prevalence of adenomyosis and bilateral polycystic ovaries was noted among the participants. While metabolic and hormonal disruptions are prominent in PCOS, the direct impact of EDCs on ovarian reserve parameters appears minimal. This study highlights the necessity of addressing metabolic health and environmental exposures in managing PCOS-related infertility to improve reproductive outcomes. 統合_0273	M. Pastor-Garcia, S. Gimeno-Martos, Ó. Zuniga, J. V. Sanfi and C. Cuenca-Carbunell	2020	[Congenital heart defects in the Valencian Community 2007-2014: The Population-Based Registry Of Congenital Anomalies]	INTRODUCTION: Congenital heart defects (CHDs) are the most prevalent and severe type of major congenital anomalies. (Cita). The objective of this study was to determine the frequency and distribution of CHDs in the Valencian Region from 2007 to 2014, describing common characteristics of the patients and their mothers. MATERIAL AND METHODS: We retrieved data on CHDs in live births, stillbirths and cases of termination of pregnancy for fetal anomaly between 2007 and 2014 (codes Q20-Q26 in the 10th Revision of the International Classification of Diseases-British Paediatric Association, ICD10-BPA) from the population-based Registry of congenital anomalies of the Valencian Region. We calculated the prevalence per every 10,000 births of CHDs overall and by subtype, analyzed temporal trends and the geographic distribution of cases, and documented the characteristics of the mothers and patients. RESULTS: We registered 1,534 cases of CHDs (1,512 live births, 19 stillbirths and 3 terminations of pregnancy). The overall prevalence was 127.9 (95% confidence interval [CI], 121.6-134.4) per 10,000 births, which remained stable throughout the study period. The most frequent CHDs were ventricular septal defects, atrial septal defect and patent ductus arteriosus (38.1 [CI, 35.2-41.1], 19.4 [CI, 17.4-21.5] and 13.9 [CI, 12.2-15.8] per 10,000 births, respectively). The most frequent associated extracardiac malformations were musculoskeletal, and 30.5% of patients had syndromes. The most frequent maternal diseases were diabetes mellitus, hypothyroidism and urinary tract infections. CONCLUSIONS: The prevalence of CHD and atrial septal defects was higher compared to European data, while the prevalence of ventricular septal defects was similar. Musculoskeletal malformations were the noncardiac CAs most frequently associated with CHDs. 統合_0274	S. Y. Park, J. H. Jeon, K. Jeong, H. W. Chung, H. Lee, Y. A. Sung, S. Ye and E. H. Ha	2021	The Association of Ovarian Reserve with Exposure to Bisphenol A and Phthalate in Reproductive-aged Women	BACKGROUND: Exposure to endocrine disrupting chemicals (EDCs) that influence the hormonal and homeostatic systems is known to be associated with gynecologic health risks in many countries. In this study, we evaluated exposure to EDCs, associated with diminished ovarian reserve (DOR) and gynecologic health risks. METHODS: This cross-sectional study was performed from September 2013 to November 2015 and included 307 Korean reproductive-aged women. Anthropometric measurements, laboratory tests with urine and blood sampling and pelvic ultrasound examinations were performed. RESULTS: Urinary bisphenol A (BA-B) level was significantly higher in the DOR group than in the non-DOR group (1.5 ± 0.1 vs. 1.2 ± 0.1 ng/mL, p = 0.042). Urinary phthalate metabolite concentrations were not significantly different between the two groups. In the DOR group, urinary BA-B was significantly correlated with age, body mass index, and urinary BPA levels. Logistic regression analysis suggested an increase in infertility in high BPA exposure group and the odds ratio (OR, 1.038) was statistically significant after adjustment for age, birth control pills, and the age of menarche, parity, and waist circumference. High phthalate exposure was associated with endometrial polyp after adjustment (OR, 2.782; CI[95%] 1.0555-7.3). CONCLUSIONS: BPA exposure might be associated with DOR and infertility. Meanwhile, endometrial polyp is increased in women with high phthalate exposure. Therefore, the risk of exposure to EDCs for reproduction should be a matter of concern in reproduction-aged women. 統合_0275	S. Park and C. Chung	2021	Effects of a dietary modification intervention on menstrual pain and urinary BPA levels: a single group clinical trial	BACKGROUND: Exposure to endocrine disrupting chemicals (EDCs) occurs mainly through dietary intake. Due to current lifestyle trends, young people tend to consume fast food, to eat disposable products, and to utilize plastic containers frequently. Exposure to EDCs is known to be associated with menstrual pain, which is a common symptom experienced by women during their reproductive years. Most women suffer from menstrual pain during their menstrual cycles. In female college students who experienced severe menstrual pain, We also analyzed participants' adherence to the intervention and examined whether their level of adherence was associated with differences in the effects of the intervention. METHODS: A single group pretest and repeated posttest experimental design was employed. Thirty female college students with a score of 5 or higher on a menstrual pain scale were recruited through convenience sampling. During three menstrual cycles, menstrual pain was scored on a 10-point scale for each cycle, and urinary BPA levels were measured from the first spot urine collected after each cycle. The intervention involved three components: small group education, follow-up monitoring, and peer support via social network communication. Statistical analyses were conducted using repeated measures analysis of variance (RM-ANOVA) and generalized estimating equations (GEE). RESULTS: The RM-ANOVA ($F = 3.16$, $p = 0.048$) and GEE ($\chi^2 = 6.16$, $p = 0.013$) results revealed statistically significant effects on menstrual pain scores at all three time points of menstrual cycles 2 ($t = -2.84$, $p = 0.008$) and cycle 3 ($t = -2.84$, $p = 0.008$) when compared with baseline. We had significant effects on menstrual pain scores at all three time points of menstrual cycles 2 ($t = -2.84$, $p = 0.008$) and cycle 3 ($t = -2.84$, $p = 0.008$) when compared with baseline. Urinary BPA levels also decreased significantly ($F = 7.96$, $p = 0.006$), but did not differ according to adherence level. CONCLUSIONS: The dietary modification intervention was effective and sustainable for reducing menstrual pain, and urinary BPA levels. Detailed information about EDCs, and dietary experiences centered to encourage the young women to become more concerned about EDCs and to perform self-protective actions. Further experimental research is suggested to examine the relationships of EDCs with various health indicators. (trial no. TRN: KCT0005778, KCT0006372 on 2019-11-5 retrospectively registered. 統合_0276	C. Park, M. Hwang, Y. Baek, S. Jung, Y. Lee, D. Paek and K. Choi	2019	Urinary phthalate metabolite and bisphenol A levels in the Korean adult population in association with sociodemographic and behavioral characteristics: Korean National Environmental Health Survey (KoNEHS) 2012-2014	BACKGROUND: Phthalates and bisphenol A (BPA) have been used in a variety of consumer products, and are detected widely in both humans and the environment. Demographic and socio-economic characteristics like gender, age, and household income have been associated with exposure to phthalates and BPA in previous studies. However, the results have been inconsistent. Also, there is relatively little is known about the socio-demographic characteristics that influence exposure to these chemicals among nationally representative populations of Asia. METHODS: Data are obtained from the Korean National Environmental Health Survey (2012-2014). In total, 6,078 adults (aged 19 and older) were recruited and sampled for urinary levels of major phthalate metabolites and bisphenol A. In addition, demographic and behavioral characteristics were collected through questionnaires. Multivariate linear regression models were used to examine the associations between the urinary levels of BPA, phthalate diester (DEHP) and phthalate (DBP) metabolites of Korean adults (aged 19 and older). RESULTS: Urinary bisphenol A (BPA) levels were higher than those reported from adults in the United States and Canada. Similar to other nationally representative populations, females and older adults showed higher creatinine-adjusted phthalate metabolite and BPA levels among the Korean population. Meanwhile, monthly household income and education were negatively associated with urinary phthalate metabolites. Among personal care products, nail polish use was positively associated with both phthalate metabolites and BPA concentrations. In urine. CONCLUSIONS: Our observations, based on a nationally representative population of Korea show that socio-demographic determinants for these urinary chemicals vary by country, and should be considered for developing appropriate mitigation measures, and policies. 統合_0277	H. Parada, Jr., M. D. Gammon, H. L. Ettore, J. Chen, A. M. Calafat, A. I. Neugut, R. M. Santella, M. S. Wolff and S. L. Teitelbaum	2019	Urinary concentrations of environmental phenols and their associations with breast cancer incidence and mortality following breast cancer	BACKGROUND: Environmental phenols, compounds used widely in personal care and consumer products, are known endocrine disruptors. Few epidemiologic studies have examined the association of phenol biomarkers with breast cancer incidence and survival. METHODS: We measured urinary concentrations of 11 phenols in spot samples collected on average within three months of diagnosis among 1,508 women with breast cancer and subsequent mortality, and examined their exposure modification by body mass index (BMI). METHODS: Participants included 711 women with breast cancer and 698 women without breast cancer who were interviewed for the population-based Long Island Breast Cancer Study Project. Among women with breast cancer, phenol biomarkers were quantified in spot urine samples collected on average within three months of a first diagnosis of primary in situ or invasive breast cancer. In 1996-1997, Women with breast cancer were followed for died cases using the National Death Index. After a median follow-up of 17.9 years, we identified 276 deaths, including 98 deaths from breast cancer. We examined creatinine-corrected phenol concentrations and the sum of parabens (7 parabens) in association with breast cancer incidence using logistic regression to estimate odds ratios (ORs) and 95% confidence intervals (CIs), and breast cancer mortality using Cox proportional hazards regression to estimate hazard ratios (HRs) and 95% CIs. We used restricted cubic spline models to evaluate nonlinear trends in nested models. RESULTS: The highest (vs lowest) quintiles of urinary methylparaben, propylparaben, and 3 parabens were associated with risk of cancer mortality HRs ranging from 0.58 to 0.77. Associations for breast cancer incidence were more pronounced among women with BMI < 25.0 kg/m2 than among women with BMI ≥ 25.0 kg/m2; however, associations for mortality were more pronounced among women with BMI ≥ 25 kg/m2 than among women with BMI < 25 kg/m2. CONCLUSIONS: Select parabens may have differential associations with risk of developing breast cancer and mortality following breast cancer. De Santis	2020	Phthalates and Bisphenol A: Presence in Blood Serum and Follicular Fluid of Italian Women Undergoing Assisted Reproduction Techniques	BACKGROUND: Infoliculogenesis is a strictly regulated process that may be affected by endocrine disrupting chemicals (EDCs) through sometimes not so clear molecular mechanisms. METHODS: we conducted a multicentric observational study involving six fertility centers across Italy, prospectively recruiting 132 women attending a fertility treatment. Recruited women had age ≤42 years, and normal ovarian reserve. Dissolved follicular fluid samples were taken for EDCs measurement using liquid chromatography tandem mass spectrometry and each woman completed an epidemiological questionnaire. RESULTS: The main EDCs found were monobutyl phthalate (MBP) (median blood: 8.90 ng/mL; follicular fluid:10.42 ng/mL), monoethylhexyl phthalate (MEHP) (median blood: 9.26 ng/mL; follicular fluid: 7.58 ng/mL) and bisphenol A (BPA) (median blood: 1.89 ng/mL; follicular fluid: 1.68 ng/mL). Women undergoing ICSI showed significantly higher blood MBP ($p = 0.0001$) and BPA ($p = 0.0001$) than women undergoing IVF. Women with a BMI ≥ 25 kg/m^2 had much higher blood MBP ($p = 0.0001$) and much lower for MEHP, indicating that the Two frequently detected biophenols have different placental transfer behaviors. The placental transfer of Mono-(2-ethyl-5-hydroxyhexyl) phthalate (MEHHP), Mono-(2-ethyl-5-oxohexyl) phthalate (MEOHP) and Mono-(2-ethyl-5-carboxypentyl) phthalate (MECPP) was also investigated. MEHHP, MEOHP and MECPP were detected in all follicular fluid samples, which were significantly higher than the PTE of BPAP. The PTE of BPAP was much higher than other BPs, indicating its strong maternal transfer and high fetal accumulation. The PTEs of bisphenols were inversely correlated, and passive diffusion was suggested as the potential mechanism of placental transfer. Significant concentration correlations of the five main bisphenols between maternal plasma and cord plasma were observed ($p < 0.05$). Meanwhile, significant associations of BPAP concentrations in maternal/cord plasma with some maternal characteristics and adverse birth outcomes were also identified ($p < 0.05$). 統合_0279	M. K. Pant, A. H. Ahmad, M. Nabhani and J. Pant	2022	Plastic bottle feeding produces changes in biochemical parameters in human infants - A pilot study	BACKGROUND: Plastic bottles are widely used by people to feed their infants when breastfeeding is not possible. Bisphenol A (BPA), an endocrine disruptor is widely used in the manufacturing of plastic scams and is leached out from these plastic scams on exposure to high temperature, changed pH, or cleaning the plastic scam by harsh detergents. PURPOSE: Feeding the infants from plastic bottles over prolong duration is suspected to expose the infants to leached BPA. Hence the present study was taken up to compare the effects of breastfeeding and plastic bottle feeding on biochemical parameters in infants and also detect for the presence of free BPA in the plasma and urine samples of the infants. METHODS: Twenty infants (10 male and 10 female) in the age group of 1-6 months were recruited for the present study. Ten infants were breastfed and plastic bottle fed. Further, plasma and urine samples of the infants were subjected to Liquid chromatography mass spectrometry analysis for detecting free BPA and BPA glucuronide. RESULTS: Biochemical changes in form of raised triglycerides, cholesterol, low-density lipoproteins, very low-density lipoproteins and increase in CK-MB, serum urea were observed in plastic bottle fed infants. BPA glucuronide was also detected in the urine of these infants. Free BPA was not detected in plasma or urine samples of the infants except in one plasma sample from bottle fed group. CONCLUSION: Plastic bottle feeding may lead to toxic changes in the functioning of organs which manifest as altered biochemical parameters.	Clin Exp Pediatr Vol.65 Issue 9 Pages 459-465	10.3345/cep.2022.00234	35588762	ヒト	-	-	-	-	-	-	バイオモニタリング	1	1	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-
統合_0280	Y. Pan, M. Deng, J. Li, B. Du, S. Lan, X. Liang and L. Zeng	2020	Occurrence and Maternal Transfer of Multiple Bisphenols, Including an Emerging Derivative with Unexpectedly High Concentrations, in the Human Maternal-Fetal-Placental Unit	In this study, a set of 13 bisphenols (BPs) and one emerging derivative (3-hydroxyphenyl-3-isopropylphenylindone, BPIDP) were analyzed in 60 pairs of maternal plasma, cord plasma, and placenta samples from pregnant women in South China. A total of 6 of the 13 target BPs, i.e., BPA, bisphenol F (BPF), bisphenol AF (BPAF), and bisphenol B (BPB), were frequently detected in the three human biological matrices. The derivative BPIDP was found to be the predominant BP analogue in placenta, with a median concentration of 1.08 ng/g, which was significantly higher than those of BPA (0.29 ng/g), BPF (0.12 ng/g), and BPAF (0.11 ng/g). The concentration of BPIDP was much higher in BPAF and much lower in BPAF, indicating that the Two frequently detected bisphenols have different placental transfer behaviors. The placental transfer efficiencies (TEs) of BPA, BPF, and BPAF were similar, which were significantly higher than the TFE of BPBP. The TFE of BPAF was much higher than other BPs, indicating its strong maternal transfer and high fetal accumulation. The TFEs of bisphenols were inversely correlated, and passive diffusion was suggested as the potential mechanism of placental transfer. Significant concentration correlations of the five main bisphenols between maternal plasma and cord plasma were observed ($p < 0.05$). Meanwhile, significant associations of BPAF concentrations in maternal/cord plasma with some maternal characteristics and adverse birth outcomes were also identified ($p < 0.05$). 統合_0281	R. Pan, C. Wang, R. Shi, Y. Zhang, Y. Wang, C. Cai, G. Ding, T. Yuan, Y. Tian and Y. Gao	2019	Prenatal Bisphenol A exposure and early childhood neurodevelopment in Shandong, China	BACKGROUND: Several epidemiological studies suggest that prenatal exposure to BPA may interfere with the neurodevelopment of pre-school and school age children. However, a limited number of studies are available for effects during children at a younger age, especially in China. METHODS: Based on Laizhou Wan Birth Cohort (LWBC), BPA concentrations were measured in urine areas 538 pregnant women during their hospital admission for delivery and neurodevelopment of their children were assessed using the Gesell Developmental Schedules at 12 months (n = 395) and 18 months (n = 388) of age. Generalized linear models were used to analyze the association between prenatal BPA exposure and the children's developmental quotient scores (DQs). RESULTS: The median of maternal BPA concentrations was 3.08 µg/L at 1.48 µ g/g creatinine. Prenatal BPA exposure was negatively associated with the gross motor DQ (GMDQ) at 12 months of age, especially among girls. Each 10-fold increase in BPA was associated with a 3.29 (95% CI: −5.83, −0.74) decrease in GMDQ. After stratified by gender, prenatal BPA concentrations were adversely associated with the adaptive domain DQ among boys (β = −3.62) and girls (β = −3.13) at 12 months of age. BPA was also negatively associated with the social domain DQs (β = −3.03) among girls. At 18 months of age, the significant adverse association was only found in the language domain among girls (β = −1.69, 95% CI: −3.23 to −0.15, p = 0.032). CONCLUSIONS: Based on a Chinese population, we found potential impacts of prenatal BPA exposure on childhood neurodevelopment at 12 and 18 months of age, especially among girls. 統合_0282	K. Pan, J. Xu, Y. Xu, C. Wang and J. Yu	2024	The association between endocrine disrupting chemicals and nonalcoholic fatty liver disease: A systematic review and meta-analysis	Nonalcoholic fatty liver disease (NAFLD) is one of the leading causes of chronic liver disease worldwide. Epidemiological studies have reported that exposure of the population to environmental endocrine disrupting chemicals (EDCs) is associated with NAFLD. However, EDCs are of different types, and there are inconsistencies in the relevant evidence and descriptions, which have not been systematically summarized so far. Therefore, the purpose of this study was to systematically summarize the relationship between EDCs and NAFLD and to provide a reference for the prevention of NAFLD. Studies included in this study: Methodological quality, heterogeneity, and publication bias of the included studies were assessed using the Newcastle-Ottawa scale, I2 statistics, Begg's test, and Egger's test. The estimated effect sizes of the included studies were pooled and evaluated using the random-effects model (I2 > 50%) and the fixed-effects model (I2 < 50%). The pooled estimated effect sizes showed that population exposure to Phthalates (PAEs) (OR = 1.18, 95 % CI:1.09-1.28), cadmium (Cd) (OR = 1.37, 95 % CI:1.08-1.73), and bisphenol A (OR = 1.23, 95 % CI:1.12-1.34) were significantly correlated with the risk of NAFLD. Exposure to mercury (Hg) (OR = 0.48, 95 % CI:0.27-1.00) tended to increase the risk of "elevated alanine aminotransferase". On the contrary, no significant association was identified between perfluoroalkyl substances (OR = 0.99, 95 % CI:0.90-1.10), polychlorinated biphenyls (OR = 1.00, 95 % CI:0.99-1.01), and polybrominated diphenyl ethers (OR = 1.00, 95 % CI:0.99-1.01) and the risk of NAFLD. Nevertheless, the current meta-analysis results of some of the meta-analyses were not stable and demonstrated high heterogeneity. The evidence for these associations is limited, and more large-scale population-based studies are required to confirm these findings. 統合_0283	Y. I. Palmieri, M. G. Gyngyetten, A. J. Arcari, V. Umido and A. Y. Feixe	2025	Endocrine disruptors as risk factors for idiopathic precocious thelarche in girls: A case-control study	Introduction: Idiopathic premature thelarche (IPT) is defined as breast growth in girls before age 8 without activation of the gonadotropic axis. Among the probable etiologies, endocrine disruptors (EDC) with estrogenic action have been suggested. Objective: To evaluate whether there is an association between exposure and degree of exposure to the main EDs with estrogenic action in our environment and the development of IPT. Methodology: Case-control study between 2021 and 2023 in girls aged 6 months to 8 years. Cases: girls with IPT. Controls: girls without breast development, matched for age and sex. Variables: considering the degree of exposure according to weekly frequency. Results: Categories of ED score (T1-2-3-4 years) and number of ED (1-2-3 years) were interested. An association was found between IPT and exposure to phytoestrogens in food (OR: 16.6 95%CI 1.8-158 p<0.011), the use of BPA containers exposed to temperature changes (OR 2.6; 95%CI 1.1-6.9; p<0.05), contact with phthalates (OR 2.6; 95%CI 1.2-7.4; p<0.03) and pesticides (OR 2.7; 95%CI 1.2-6.4; p<0.02). In all the detailed EDs, we also found an association of IPT according to their degree of exposure. Conclusions: Exposure and degree of exposure to different sources of phytoestrogens, BPA, pesticides, and phthalates were associated with the development of IPT. 統合_0284	E. Polak, W. Lebiedzińska, S. Arciszewski, M. Sołtysińska, P. Pierzyński, W. Wiczkowski, B. Z ołzowska-Rutkowska, G. N. Nikiforuk, D. Puntkowska-Tyczko and S. Walczyński	2021	The Association between Bisphenol A, Steroid Hormones, and Selected MicroRNAs Levels in Seminal Plasma of Men with Infertility	Bisphenol A (BPA), the most common endocrine disrupting chemical, has been associated with male reproductive dysfunctions. Recently, it has been shown that BPA may also affect miRNAs expression. Hereto, we aimed to evaluate the association of BPA levels with steroid hormone concentrations and circulating miRNAs levels to investigate the potential direct effect of BPA on hormonesis in the testis environment. The level of BPA in the seminal plasma of azoospermic men was significantly higher compared to the healthy control. The concentrations of estradiol (E2) and androstenedione (A) were significantly decreased in the seminal plasma of azoospermic men compared to the normospermic men. The levels of miR-34c-5p, miR-34c-3p, and miR-34b-3p were significantly up-regulated, and the level of miR-518-5p was significantly down-regulated in the seminal plasma of azoospermic men compared to the control group. Moreover, the level of miR-34c-5p was significantly positively correlated with the level of miR-34b-3p and miR-34c-3p, the level of miR-34b-3p was correlated with the level of miR-34c-3p, and miR-34c-5p and miR-34c-3p were correlated with miR-518-5p levels. Our results suggest that BPA may negatively affect sperm quality. Moreover, BPA correlated with the miR-34-5p, miR-34-3p, and miR-518 levels in seminal plasma, which suggests that BPA may act directly in seminal plasma, affecting the testicular environment. 統合_0285	M. Ciga and J. Jurewicz	2025	Environmental exposure to selected non-persistent endocrine disrupting chemicals and polycystic ovary syndrome: a systematic review	Polycystic ovary syndrome (PCOS) is an endocrine disorder manifesting with symptoms such as irregular menstrual cycles, hyperandrogenism, and/or polycystic ovaries. The exact cause of PCOS remains unknown, but it is considered multifactorial, involving genetic predisposition, lifestyle factors, and environmental influences. Non-persistent endocrine disrupting chemicals (EDCs) are a group of exogenous substances that can interfere with the endocrine system. EDCs, in addition to genetic and hormonal ones, also may influence PCOS. This is one of the first systematic reviews dealing with the exposure to non-persistent endocrine disrupting chemicals and PCOS. The review summarizes the existing knowledge about the association of EDCs with PCOS based on significant findings on the toxicity of various non-persistent environmental EDCs and polycystic ovaries syndrome risk. A systematic search of the literature was conducted in order to identify proper studies using PubMed, Scopus, Elsevier, and Springer databases. The results of the studies suggest that there is a positive association between bisphenol A (BPA), phthalates, octocrylene, and PCOS. The data concerning triclosan and PCOS were inconclusive. Additionally, no link between the exposure to parabens and PCOS was observed. Three results of the presented studies highlight the urgent need for continued research on EDCs and their role in PCOS, for Clin Exp Med Environ Health. 2025;26(2):99-121. 統合_0286	R. Gveli, N. N. Yenigl, S. Dilbaz, B. Dilbaz, O. Aldemi, I. Kaplanoğlu, F. Gl et, E. Bayer and M. Tekin Ö	2024	The Association of ICSI Outcomes with Semen and Blood Bisphenol A Concentrations of the Male Partner	This study investigated the association of blood and semen Bisphenol A (BPA) levels of the male partner on the reproductive outcome in intracytoplasmic sperm injection (ICSI) treatment cycles. For this prospective study, 100 couples undergoing ICSI treatment were included. Blood and semen samples were collected from male partners on the day of oocyte retrieval. Couples were divided into two groups according to their live-birth outcomes, while men with normal seminogram-free semen underwent ICSI due to tubal factor infertility were taken as the study group. Habitual consumption of drinking water from plastic surface bottles (PBW) at home was also questioned in both groups, as it was considered as chronic BPA exposure. The association of ICSI outcome with blood BPA (bBPA) and semen BPA (sBPA) levels was analyzed in both groups. No significant correlation was found between sperm parameters and bBPA levels in both groups. A negative correlation was found between sBPA levels and total sperm count and progressive sperm motility in men who consumed PBW. Embryo development arrest was found to be significantly higher in patients who have high sBPA levels. Although sBPA levels were not different in PBW consumers, sBPA levels were found to be significantly higher in patients who have high bBPA levels. Elevated bBPA were associated with a significant decrease in clinical pregnancy rate. Considering the widespread human exposure to BPA, the effects of BPA on female reproductive system needs to be further examined. 統合_0287	F. Ouyang, G. H. Zhang, K. Du, L. She, R. Ma, X. Wang, X. Wang and J. Zhang	2020	Maternal prenatal urinary bisphenol A level and child cardio-metabolic risk factors: A prospective cohort study	Exposure to endocrine disrupting chemicals during the first 1000 days of life may have long-lasting adverse effects on cardio-metabolic risk in later life. This study aimed to examine the associations between maternal prenatal urinary bisphenol A (BPA) concentrations and cardio-metabolic risk factors in children at 2 and 12 years of age. Mother-child pairs were recruited from Wuhan, China between 2010 and 2011. Maternal BPA concentration was measured in prenatal and child 2-year cast urine samples, and classified into high, medium and low tertiles. Child adiposity anthropometric measurements, resting glucose, glucose, serum insulin, and lipids (high density lipoprotein, low-density lipoprotein, cholesterol, triglyceride), systolic (SBP) and diastolic blood pressure (DBP) were measured. Linear regression was used to evaluate the associations between maternal BPA and child cardio-metabolic risk factors. Mediation analysis was conducted to explore the role of child BMI in the BPA-risk factor associations. A total of 1,346 and 1,109 mother-child pairs were successfully followed up at 2 and 12 years, respectively, and 95.6% of children at age 2 years. Compared to those with low prenatal BPA, mean SBP was 2.73 (95%CI: 0.99-4.47) mmHg higher, and BMP was 0.4 (95%CI: 0.11-0.70) mmHg higher in girls with high prenatal BPA levels, but these associations were not found in boys. In boys, medium maternal prenatal BPA level was associated with 0.38 (95% CI: 0.03-0.68) mmol/L higher plasma glucose. No associations were found between prenatal BPA and child BMI, skinfold thickness, serum lipids, or insulin in either girls or boys. There were no associations between concurrent child urinary BPA and cardio-metabolic risk factors in children. These results suggest that BPA exposure during prenatal period, susceptible time for fetal development, may be associated with increase in child BP and plasma glucose in a sex-specific manner. Further independent cohort studies are needed to confirm the findings. 統合_0288	M. Ouidir, A. H. Cissé, J. Botter, S. Lyon-Caen, C. Thirman, A. K. Sakhi, A. Sabaredzovic, S. Bayat, R. Slama, B. Heude and C. Philippat	2024	Fetal and Infancy Exposure to Phenols, Parabens, and Phthalates and Anthropometric Measurements up to 36 Months, in the Longitudinal SEPAGES Cohort	BACKGROUND: Endocrine disrupting chemicals may play a role in adiposity development during childhood. Until now literature in this scope suffers from methodologic limitations in exposure assessment using one or two urine samples collected during pregnancy and childhood. OBJECTIVES: We studied the associations of exposure to phenols, parabens, and phthalates, measured in repeated urine samples collected from mother-child pairs from the SEPAGES mother-child cohort recruitment (2014-2017) and follow-up visits, with anthropometric measurements from birth to 3 years. METHODS: We studied the associations of four phenols, four parabens, seven phthalates, and one hundredfold dilution factor newly quantified urine samples collected from the mother during second and third trimesters (median 28 and 30 gestational weeks, respectively) and infant at 2 and 12 months of age, and child growth until 36 months. We relied on repeated measures of weight, weight and head circumference from study visits and the child health booklet to predict growth outcomes at 2 and 36 months using the Jenss-Bayley nonlinear mixed model. We assessed associations with individual chemicals using adjusted linear regression and mixtures of chemicals using a Bayesian kernel machine regression model. RESULTS: The antipyrethroid pesticide metabolite 3-phenoxybenzoic acid (3-PBA) was frequently detected in pregnancy urine samples (detection frequency = 89%), whereas detection frequencies were lower than 50% for the other chemicals. Prenatal phthalate (DnBP) or 3-PBA urinary concentrations were not associated with body mass index (BMI), weight, and head circumference at 36 months. Mixture analysis revealed positive associations between exposure at 12 months and BMI and weight at 36 months, with DnBP showing the highest effect size within the mixture. CONCLUSIONS: This study suggests that exposure to early infancy may be associated with increased weight and BMI in early childhood, which are risk factors of obesity in later life. Furthermore, this study highlighted the impact of BPA, a compound replacing bisphenol A, which has never been studied in this context. https://doi.org/10.1289/EHP13644. 統合_0289	E. Ougier, F. Zeman, J. P. Antignac, C. Rouveelle, R. Lange, M. Kolossa-Gehring and P. Apel	2021	Human biomonitoring initiative (HBM4EU): Human biomonitoring guidance values (HBM-GVs) derived for bisphenol A	The "European Human Biomonitoring Initiative" (HBM4EU) derives human biomonitoring guidance values (HBM-GVs) for the general population (HBM-GVGenPop) and/or occupationally exposed adults (HBM-GVWorker) for several priority substances and substance groups as identified by policy makers, scientists and stakeholders at EU and national level, including Bisphenol A (BPA). Human exposure to BPA is widespread and the substance is known to cause reproductive toxicity in animal studies. Therefore, the derivation of HBM-GVs for BPA is of high relevance for public health protection. The derivation of HBM-GVs for BPA is considered to be most toxicologically and/or from the conjugated forms (e.g. BPA-glucuronide (BPA-G) and BPA-sulfate (BPA-S)). As measurement is blood provides the superior surrogate of the biologically effective dose. However, considering the difficulty of implementing blood sampling in large HBM cohorts, as well as the current analytical capacities complying with the quality assurance (QA)/quality control (QC) schemes, total BPA in urine (i.e. the sum of free and conjugated forms of BPA measured after an hydrolysis step) was identified as the most relevant matrix and biomarker for BPA. HBM-GVGenPop for total BPA in urine of 200 µg/L and 230 µg/L for adults and children, respectively, were developed on the basis of toxicological data. To derive these values, the concentrations of urinary total BPA consistent with a steady-state internal dose of 0.5 µg/kg bw/day, which is 5 times lower than the TDI of 4 µg/kg bw/day established by the European Food Safety Authority (EFSA) in 2015, were calculated by means of a PBPK model developed by Karrer et al. (2018) was used, assuming an oral exposure to BPA at the 1 TDI level and repeated over 24 h. Dermal uptake of BPA is suspected to contribute significantly to the total BPA body burden, which in comparison with the oral route, is generating a higher ratio of free BPA to total BPA in blood. Therefore, an alternative approach for calculating the HBM-GVGenPop according to the estimated relative contributions of free and conjugated BPA to the internal dose was developed. HBM-GVWorker for total BPA in urine of 1500 µg/L was derived by dividing the HBM-GVGenPop by a factor of 10 to take into account the lower tolerance of the BPA in adults. Considering the limited amount of data on the toxicokinetics in humans, the European Chemicals Agency (ECHA) and EFSA, as well as the BPA industry, have established an assessment factor of 4 for workers. The predicted concentration of urinary total BPA at steady-state is equivalent to, or exceeds the 95th percentile of total BPA in urine measured in different European HBM studies conducted in the general population. Thus, no HBM-GVWorker was proposed, as the high background level of BPA coming from environmental exposure – mostly through food intake – is making the discrimination with the occupational exposure to BPA difficult. 統合_0290	S. Onkar, M. S. Wolff, S. L. Teitelbaum and J. A. Stingone	2021	Identifying environmental exposure profiles associated with timing of menarche: A two-step machine learning approach to examine multiple environmental exposures	BACKGROUND: Variation in the timing of menarche has been linked with adverse health outcomes in later life. There is evidence that exposure to hormonally active agents (or endocrine disrupting chemicals; EDCs) during childhood may play a role in accelerating or delaying menarche. The goal of this study was to generate hypotheses on the relationship between exposure to multiple EDCs and timing of menarche by applying a two-stage machine learning approach. METHODS: We examined data from the National Health and Nutrition Examination Survey (NHANES) for years 2013-2018. Data were analyzed for participants 12-19 years of age who had blood and urine biomarker measures of 13 environmental exposures, all with <75% above limit of detection, in seven classes of chemicals. We modeled risk for earlier menarche (≤12 years of age vs. older) with weighted elastic net regression (Stage 1) and then applied Bayesian Kernel Machine Regression (Stage 2) to examine the joint effects of the exposures identified in Stage 1. RESULTS: Stage 1 regression results identified associations between exposure profiles ("combinations") and timing of menarche. NHSS 13,187 identified urinary concentrations of monoethyl-hexyl phthalate (MEHP) as the most important feature in partitioning girls into homogenous subgroups followed by bisphenol A (BPA) and 2,4-dichlorophenol (2,4-DCP). In this first stage, we identified 21 distinct exposure biomarker profiles, containing five different classes of EDCs, associated with menarche. Stage 2 BKMR analysis identified a positive association between MEHP and earlier menarche (OR = 1.28 ng/mL vs. 0.36 ng/mL; adjusted95% CI: 0.96, 1.61). Additionally, we found a negative association between BPA and earlier menarche (OR = 0.78 ng/mL vs. 2.39 ng/mL; adjusted95% CI: 0.58, 1.00). Combinations of lower MEHP with benzophenone-3 (2.32 ng/mL) or BPA had similar associations with earlier menarche, though slightly weaker in those smaller subgroups. For girls not having lower MEHP, exposure profiles included other biomarkers (BPA, antimicrobial, monobenzyl phthalate, cis-lauric, and 3-hydroxycotinine); these showed largely null associations in the second-stage analysis. Adjustment for covariates did not materially change the estimates or CIs of these models. Bio-statistical tools or null effect estimates for some exposure biomarker profiles and relevant profiles consisted of no more than two EDCs, possibly due to small sample sizes in subgroups. CONCLUSION: A two- stage approach incorporating machine learning was able to identify comparable constellations of biomarkers in relation to timing of menarche; these should be further explored in prospective studies. Machine learning methods can serve as a valuable tool to identify patterns within data and generate hypotheses that can be investigated within hybrid, targeted analyses. 統合_0291	S. Onkar, A. A. Balallan and J. A. Stingone	2024	Identifying critical windows of prenatal phenol, paraben, and pesticide exposure and child neurodevelopment: Findings from a prospective cohort study	BACKGROUND: This study aimed to investigate how exposure to a mixture of endocrine disrupting chemicals (EDCs) during two points in pregnancy affects early childhood neurodevelopment. METHODS: We analyzed publicly available data from a high-risk cohort of mothers and their children (2007-2012) that measured six EDCs, including methyl-, ethyl- and propyl paraben, (MEPB, EPB, PRPB), Bisphenol (BPA), 2,5,6-trichloro-3-pyridinol (TCPY), 3-phenoxybenzoic acid (3-PBA) in prenatal urine samples during the second and third trimesters. Neurodevelopmental scores were assessed using Mullen Scales of Early Learning (MSEL) at age 3. We used Bayesian kernel machine regression (BKMR) to examine associations between EDC mixtures and MSEL scores, and to identify critical windows of exposure. RESULTS: The analytic sample included 350 children. For females, the relationship between BPA and 3PBA with MSEL score varied between the two trimesters. In the second trimester, BPA had similar associations with earlier menarche, though slightly weaker in those smaller subgroups. For girls not having lower MEHP, exposure profiles included other biomarkers (BPA, antimicrobial, monobenzyl phthalate, cis-lauric, and 3-hydroxycotinine); these showed largely null associations in the second-stage analysis. Adjustment for covariates did not materially change the estimates or CIs of these models. Bio-statistical tools or null effect estimates for some exposure biomarker profiles and relevant profiles consisted of no more than two EDCs, possibly due to small sample sizes in subgroups. CONCLUSION: A two- stage approach incorporating machine learning was able to identify comparable constellations of biomarkers in relation to timing of menarche; these should be further explored in prospective studies. Machine learning methods can serve as a valuable tool to identify patterns within data and generate hypotheses that can be investigated within hybrid, targeted analyses. Miłyk	2022	Bisphenol A: Potential Factor of Miscarriage in Women in the Context of the Phenomenon of Neutrophil Extracellular Traps	Humans are exposed to a number of environmental pollutants every day. Among them, endocrine disruptors are particularly harmful to human health. Bisphenol A (BPA) is a xenoestrogen that has been shown to disrupt the functioning of the endocrine system in humans and animals. The aim of the study was to assess the concentration of BPA in the serum of women in the first trimester of pregnancy. The serum levels of cytoplasmic and PMN-perinuclear antinuclear antibodies were also determined. Samples were collected from healthy women and women who had miscarriage in the first trimester of pregnancy. The serum levels of cytoplasmic and PMN-perinuclear antinuclear antibodies were also determined using an immunoenzymatic method. The concentrations of key pro-inflammatory cytokines TNF-α and IL-17, as well as human neutrophil elastase subunits (hNE) and hCG, were also measured in the serum samples. The serum concentration of BPA was determined using gas chromatography. The results showed that the concentrations of BPA were significantly elevated in the serum of women in the first trimester of pregnancy compared to the control group, with the highest concentration found in the "hETs positive" group. The levels of hCG-1 and TNF-α were significantly higher in the "hETs positive" group compared to the "hETs negative" and control groups. The levels of hNE1 and hCG-1 were also higher in the "hETs positive" group compared to the "hETs negative" group. The study showed that BPA could play a role in the course of miscarriage through the formation of hETs. The results indicate the need to limit the exposure of women planning pregnancy to xenoestrogens, including BPA. 統合_0293	Y. Okubo, A. Handa and T. Ikeiri	2019	Serial cross-sectional study for the association between urinary bisphenol A and paediatric obesity: Recent updates using NHANES 2003-2014	BACKGROUND: Several studies have reported bisphenol A (BPA) as a potential risk factor for paediatric obesity, but the findings were inconsistent among these studies. METHODS: Using data from the National Health and Nutrition Examination Survey from 2003 to 2014, we conducted a serial cross-sectional study to examine the association between urinary BPA and paediatric obesity among children aged 6 and 19 years. The analytical sample included 6,826 children. Urinary BPA was measured using high-performance liquid chromatography-tandem mass spectrometry. Obesity was defined as BMI ≥ 95th percentile. RESULTS: We observed increasing trends in urinary BPA concentrations from 2003 to 2014. The associations between urinary BPA concentrations and obesity were inconsistent across the years of survey and even after different models for urinary creatinine adjustments were used. Children with obesity were positively associated with urinary creatinine concentrations, but was not with creatinine-adjusted models. Furthermore, children with higher urinary BPA concentrations had elevated odds of obesity during 2003 to 2008, whereas these associations were inconsistent during 2009 to 2014. CONCLUSIONS: The associations between paediatric obesity and urinary BPA concentrations differed across the years of survey and creatinine adjustments. Further studies are required to assess these discrepancies.	Pediatr Obes Vol.14 Issue 12 Pages e12566	10.1111/ijpo.12566	31364316	ヒト	-	-	-	-	-	-	-	連続横断研究	1	1	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-

Ha	2025	Sex-specific effects of prenatal exposure to phthalates and bisphenol A on adverse birth outcomes: Results from The Korean Children's Environmental Health Study (Ko-CHENS)	OBJECTIVES: Although previous epidemiological studies have reported the effects of fetal exposure to phthalates and phenols on birth outcomes, evidence is still limited. The objective of this study was to investigate whether prenatal exposure to endocrine-disrupting chemicals (EDCs), phthalates and bisphenol A (BPA), is associated with birth outcomes and whether there are sex-specific effects. METHODS: We used data from the Korean Children's Environmental Health Study (Ko-CHENS) cohort. Exposure to phthalates and BPA was measured by urine tests, and the information on outcomes and confounders was obtained from delivery records, questionnaires, and medical records. Multivariate linear and logistic regression models were used to examine associations between prenatal exposure and birth outcomes. Additionally, to evaluate the effects of EDC mixture exposure, we performed weighted quantile sum regression analysis. Subgroup analysis was further performed by sex and birth outcomes to examine potential differences in associations. RESULTS: This study included 2,176 mother-child pairs from the Ko-CHENS. We observed a significant association between the risk of PTB and exposure to BPA during early pregnancy and mono-carboxyoctyl phthalate (MCOP) during late pregnancy, with odds ratios of 1.23 (95% CI: 1.01, 1.49) and 1.29 (95% CI: 1.08, 1.55), respectively. Additionally, there was a significant association between exposure to MCOP during early pregnancy and the risk of LBW (OR: 1.30, 95% CI: 1.03, 1.64). For male infants, in particular, exposure to MCOP during early pregnancy was associated with the risk of LBW (OR: 1.61, 95% CI: 1.22, 2.13), and exposure to MCOP during late pregnancy was associated with the risk of PTB (OR: 1.46, 95% CI: 1.10, 1.92). CONCLUSIONS: This study suggests a potential association between exposure to BPA during early pregnancy and PTB, while exposure to MCOP during late pregnancy was associated with increased PTB risk in male infants. 統合_0295	N. Numcioksuket, T. Tawanathada, C. Bongsebandh u-Phubhakdi, S. Anuparkkongkol, K. Chi and V. Supornkchai	2023	Exposure to Bisphenol A and Its Analogs among Thai School-Age Children	Bisphenol F (BPF) and bisphenol S (BPS) have become popular substitutes for bisphenol A (BPA) in the plastic industry due to concerns over BPA's adverse effects. However, there is limited information on children's exposure to these chemicals. This study aims to assess the levels of BPA, BPF, and BPS in urine samples of Thai children. Spot urine samples and relevant factors that influence exposure to these chemicals were collected from 172 children, 6–7 years old, recruited between October 2019 and 2020. Two first-morning voids were collected one week apart. Demographic and exposure-related information was gathered. Urinary concentrations of bisphenols were analyzed by liquid chromatography–tandem mass spectrometry. Intraclass correlation coefficients (ICCs) were calculated to assess the reproducibility of the urinary bisphenol concentrations. Bisphenol exposure was estimated using a time-weighted average model. BPA, BPF, and BPS were detected at 79.6%, 11.0%, and 8.0%, with geometric mean (GM) concentrations of 1.41, 0.013, and 0.012 ng/mL, respectively. Dietary children aged ≤ 10 years exhibited 1.3–1.4 times higher GM levels of all bisphenols compared to older children. Exposure to food stored in plastic containers was associated with higher levels of BPF and BPS. In conclusion, BPA was the most frequently detected bisphenol in urine samples from Thai children, followed by BPF and BPS. 統合_0296	Y. Niu, B. Wang, R. Yang, Y. Wu, Y. Zhao, C. Li, J. Zhang, Y. Xing and B. Shao	2021	Bisphenol Analogues and Their Chlorinated Derivatives in Breast Milk in China: Occurrence and Exposure Assessment	Concentrations of bisphenol S (BPS) and its analogues (together with their chlorinated derivatives are referred to as BPs) were measured in 181 breastmilk samples collected from 9 provinces in China in 2016. Twelve BPs were more found. The BP concentrations ranged from not detected to 5.922 μg/L. BPA was the predominant BP, followed by bisphenol F (BPF) and bisphenol S (BPS). The mean BPA, BPF, and BPS levels were 0.041, 0.012, and 0.011 μg/L, respectively. Significant correlations were found between BPA and BPF (r = 0.5, p < 0.01) and between BPA and BPS (r = 0.4, p < 0.01). Higher BP levels were found in urban and southern regions. BPA accounted for approximately 70% of the BPs and BPF accounted for more than 50% of the BPs in these milk samples. The high correlations between BPA and BPF/BPS and regions, not only BPA should receive attention. The upper-bound daily intakes of BPs for infants 0-6 months old were 0.810-1.291 μg/kg bw/day. Despite the absence of tolerable daily intake data, attention should be paid not only on BPA but also BPF. 統合_0297	Y. Nishimura, K. Moriya, S. Kobayashi, A. Araki, F. Sata, T. Mitsui, S. Itoh, C. Miyashita, K. Chi, M. Kon, M. Nakamura, T. Kitta, S. Murai, R. Kishi and N. Shinohara	2020	Association of exposure to prenatal phthalate esters and bisphenol A and polymorphisms in the ESR1 gene with the second to fourth digit ratio in school-aged children: Data from the Hokkaido study	Phthalates and bisphenol A (BPA) are estrogenic endocrine disruptors. Polymorphisms in the gene encoding estrogen receptor 1 (ESR1) may contribute to the ratio of the lengths of the second and fourth digits (2D:4D), which is considered an index of prenatal exposure to sex hormones. Thus, we investigated whether ESR1 polymorphisms modify the effects of prenatal exposure to phthalates and BPA on 2D:4D in a birth cohort. Maternal urine samples were collected during pregnancy, and the concentrations of 11 phthalate metabolites and BPA were measured. Finger length was measured in 1,066 children (529 boys and 537 girls) at 6 years of age. We successfully performed genotyping for 10 nonsynonymous SNPs, particularly Pro87 (T → C, rs9340799), Ala594 (G → A, rs2077647), and Ala594Val (A → G). The associations among compound exposure, mean 2D:4D, and ESR1 polymorphisms were assessed by multiple linear regression adjusted for potential confounding factors. Boys with the AG/GG genotype at rs2077647 in the group exposed to high levels of mono(2-ethylhexyl) phthalate (MEHP) (≥ 2.52) and bisphenol A (BPA) (≥ 0.84) showed increased 2D:4D compared with boys with the AA genotype at rs2077647 who had low exposure to MEHP (< 2.52) and BPA (< 0.84). Increases in mean 2D:4D of 1.55%, 95% confidence interval (CI): 0.43–2.63, 2.06% increase in mean 2D:4D of 1.17%, 95% CI: 0.31–2.02). No significant differences were found among girls. There were no associations between mean 2D:4D and metabolites other than MEHP or BPA. These data suggest that ESR1 polymorphisms modify the effects of prenatal exposure to DEHP on mean 2D:4D among boys. 統合_0324	N. Moharoj, S. Prasanth, P. Rajapriya, G. Vinothkumar, V. M. Vinothini, R. Lenin, R. Jananthan and P. Venkatraman	2023	Bisphenol A accelerates the vascular complications in patients with Type 2 diabetes mellitus through vascular calcification-a molecular approach	PURPOSE: Environmental pollutant Bisphenol A (BPA) strongly interacts with insulin resistance, which leads to type 2 diabetes mellitus (T2DM). Uncontrolled glucose levels in both bloodand urine develops vascular complications in T2DM patients. However, glucose controlled diabetic patients are also affected by vascular complications due to vascular calcification, and there is a lack of clinically relevant data on BPA levels in T2DM patients with vascular calcification. Therefore, we investigated the association of BPA with T2DM and T2DM associated vascular complications and also BPA levels in T2DM with vascular calcification vitalsignsexpression. METHODS: This study involved 120 participants with T2DM and its associated vascular complications. Serum and urinary BPA were estimated using ELISA kit, and gene expression of the study participants in peripheral blood mononuclear cells (PBMCs) was studied with quantitative real-time PCR. RESULTS: Serum and urinary BPA levels were higher in T2DM and its associated vascular complications than in healthy controls. Moreover, T2DM patients with vascular calcification had significantly higher BPA levelshigher significance with both Scr (p < 0.001, r = 0.995), Rand2 (p < 0.01, p = 0.990) and IL-1beta (p < 0.001, p = 0.993) and TNF-alpha (p < 0.001, p = 0.993) in comparison to the study groups, but T2DM alone significant with Scr and BPA (p < 0.05). CONCLUSION: BPA levels were positively correlated with serum Scr and increased level in T2DM associated vascular complications patients. Also, higher expression of IL-1beta and TNF-alpha was observed in T2DM associated vascular complications patients. Our study is the first to associate BPA levels with vascular calcification in patients with T2DM and its associated vascular complications. Chavarro	2022	Pregnancy urinary concentrations of bisphenol A, parabens and other phenols in relation to serum levels of lipid biomarkers: Results from the EARTH study	The epidemiologic literature on associations between urinary phenol concentrations and lipid profiles during pregnancy is limited. We examined whether urinary concentrations of phenol and phenol replacement biomarkers were associated with serum lipid levels among pregnant women. This cross-sectional study included 176 women attending the Massachusetts General Hospital Fertility Center who enrolled in the Environment and Reproductive Health (EARTH) Study between 2007 and had matched urine and serum samples collected. Urinary phenol biomarkers and serum lipids during pregnancy. We used linear mixed models to assess the relationship between groups of urinary phenol and phenol replacement biomarkers and serum lipid levels (total cholesterol, high density lipoprotein (HDL), non-HDL, low-density lipoprotein (LDL), cholesterol, and triglycerides). Models were adjusted for age, race, body mass index, and gestational age at urine collection. We found positive associations between urinary bisphenol A (BPA) and serum lipids. Women in the highest urinary bisphenolate concentrations, in the highest tertile had 236 (95% CI: 11, 461 mg/dL), 22% (95% CI: 2, 38 mg/dL) and 28% (95% CI: 1, 55 mg/dL) higher mean total, non-HDL and LDL cholesterol, respectively, compared to women with concentrations in the lowest tertile. Similar relations were observed for urinary bisphenol S concentrations. Urinary bisphenol S, benzophenone-3, triclosan, methylparaben, ethylparaben, and butylparaben were unrelated to serum lipids. Among pregnant women, urinary concentrations of bisphenol A and propylparaben were associated with higher serum levels of total, non-HDL and LDL cholesterol. 統合_0326	L. Mínguez-Alarcón, A. Ballesta, A. J. Gaskins, J. E. Chavarro, J. B. Ford, I. Souter, A. M. Calafat, R. Hauser and P. L. Williams	2021	Paternal mixtures of urinary concentrations of phthalate metabolites, bisphenol A and parabens in relation to pregnancy outcomes among couples attending a fertility center	BACKGROUND: Few epidemiologic studies have evaluated the impact of paternal environmental exposures, particularly as mixtures, on couples' pregnancy outcomes. OBJECTIVE: We investigated whether mixtures of paternal urinary bisphenol A (BPA), parabens, and phthalates were associated with pregnancy outcomes among couples attending a fertility center. METHODS: We included 216 couples undergoing 384 in vitro fertilization (IVF) cycles between 2007 and 2017 in the Environment and Reproductive Health (EARTH) Study. Paternal urine samples were collected on the day of oocyte retrieval and analyzed for 15 phthalate metabolites, 2 parabens, and BPA. We used Bayesian kernel machine regression (BKMR) analysis (PCA) to identify correlations of biomarker concentrations and multivariable Cox proportional hazards models for discrete survival time to estimate the fecundability ratio (FR) and 95% CIs for the associations between PCA-derived factor scores and probability of failing to achieve a live birth. Interactions were also included in the models to examine strength of associations over three consecutive periods. Analyses transfer to IVF cycle outcomes were restricted to 1,004 IVF cycles among 384 couples. RESULTS: Paternal urinary concentrations of BPA, parabens, and phthalates were correlated. Men with higher intensity of fertility diagnosis, and when PCA factor scores, sensitivity analyses with further adjustment for maternal PCA factor scores, were performed. RESULTS: We identified three correlated components of phthalate, phthalate (DEHP) metabolites, BPA and non-DEHP metabolites, and parabens, accounting for 58%, 35%, and 28%, respectively, of the total variance explained. An interquartile range (25th-to-75th percentile) increase in the DEHP-related factor score was associated with elevated probability of failing prior to live birth (FR = 1.11; 95% CI: 1.00, 1.23) and the association was stronger between intermediate (time to pregnancy) or unsuccessful (no live birth) outcomes and between clinical pregnancy and live birth compared to before implantation. The overall 19% of failure for the BPA/non-DEHP-related and paraben-related factor scores were FR = 1.26 (95% CI: 0.97, 1.64) and FR = 0.96 (95% CI: 0.85, 1.10). We found similar FRs when additionally adjusting for maternal PCA factor scores. CONCLUSION: Paternal mixtures of urinary concentrations of DEHP metabolites were related to higher infertility treatment failure. 統合_0327	A. Mira, G. Bouzios, I. Papoutsis, G. Kaparas, P. Christopoulos, E. Kaseta, M. Mastrominas, S. Athanasiadis and G. Makrakakos	2022	Bisphenol A correlates with fewer retrieved oocytes in women with tubal factor infertility	PURPOSE: Serum and urinary bisphenol A (BPA) concentrations have been associated negatively with the number of retrieved oocytes after in vitro fertilization (IVF). The impact of BPA upon women with polycystic ovary syndrome (PCOS) and severe endometriosis (endometrioma) has not been investigated. To this purpose, associations among serum and urinary and follicular fluid (FF) BPA concentrations and the number of retrieved and fertilized oocytes and comparisons between pregnancy rates were evaluated. METHODS: This was a cross-sectional study conducted at a university-affiliated assisted conception unit between January and December 2019, including 93 women of reproductive age (PCOS: 30; TFI: 28; following IVF: 35 women). Unconjugated BPA in serum and urine samples was measured by gas chromatography-mass spectrometry method. The number of retrieved and fertilized oocytes and pregnancy rate were documented and evaluated. RESULTS: The number of oocytes retrieved from PCOS women was significantly higher than that of TFI women (p = 0.001) and women following IVF (p = 0.001). Serum BPA concentrations were significantly higher in PCOS than in TFI women (p = 0.001). Serum BPA concentrations in TFI women (p = 0.001) and women following IVF (p = 0.001) were significantly higher than in PCOS women. Serum and FF urine BPA concentrations did not significantly affect the number of retrieved oocytes, and pregnancy rate in both groups. CONCLUSION: FF BPA concentrations were lower in all PCOS women and in some eight/nine/ten PCOS than in TFI women. In TFI women, FF BPA concentrations correlated negatively with retrieved oocytes. Confirmation of these findings might lead to moderation of use of BPA-containing products by women undergoing IVF.	Hormones (Athens) Vol.21 Issue 2 Pages 305-315	10.1007/s42000-022-00370-1	35524040	ヒト	-	-	-	-	-	-	横断研究	1	1	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-

Trasande, S. T. Weiss and Y. Zhu	2025	Prenatal exposure to environmental bisphenols over time and their association with childhood asthma, allergic rhinitis and atopic dermatitis in the ECHO consortium	Concerns persist about the potential impact of prenatal exposure to bisphenols (BP) and their replacement analogues on childhood asthma and allergies. Previous studies on single and small cohorts had limited statistical power, few investigated analogues of BPA and BPS, and even those examined mixed outcomes. Our objective was to assess whether prenatal exposures to individual environmental bisphenols (BPA, BPF, BPS) influence risk of childhood asthma, allergic rhinitis, and atopic dermatitis. Data from the U.S. Environmental Influences on Child Health Outcomes (ECHO) consortium were harmonized on measures of prenatal urinary BPA, BPF, and BPS and asthma, allergic rhinitis, and atopic dermatitis (ever/never; up to age 5 years) from 1983 to 2019 in 1,460 children. Urine samples were collected between 1998 and 2019. In 1,460 pairs from nine cohorts with urine bisphenol analysis, median BPA levels decreased from 1.11 ng/ml (n 5,89 ng/ml, median BPF levels decreased from 0.01 ng/ml (n 2,89 ng/ml, and median BPS levels increased from 0.23 ng/ml (n 0.41 ng/ml (detection frequency 41%). Associations between prenatal bisphenol exposure and asthma, allergic rhinitis, and atopic dermatitis were examined using multivariable logistic regression models. Effects were tested for modification by child sex, race/ethnicity, household income, and maternal education. Prenatal BPA exposure was associated with a reduced odds of asthma (adjusted odds ratio [aOR] 0.87, 95% CI 0.77–0.98). Each doubling of asthma (odds ratio [OR] 0.87, 95% confidence interval [CI] 0.78, 0.98) or eczema (odds of prenatal BPA was associated with reduced odds of atopic dermatitis (OR 0.92, 95% CI 0.83, 0.99). The ongoing and changing patterns of exposure to bisphenols in the U.S. population require further study with additional attention to time-windows of exposure and co-occurring social determinants of health, to continue to inform current policies and evaluate the importance of limiting exposure to BPA and its analogues on childhood asthma, allergic rhinitis, and atopic dermatitis.	Environ Pollut. 2025 Feb 1;366:125415.	10.1016/j.envpol.2024.125415	39615574	ヒト	免疫	-	-	-	-	-	コホート研究	1	1	-	-	-	-	-	-	1	1	1	-	1	-	-	-	-	-	-	-	-	-	-	-
統合_0329	J. Milczarek-Banach, D. Rachoń, T. Bednarczuk, K. Wysocka-Czapla, A. Wasik and P. Miś Kiewicz	2020	Exposure to Bisphenol A Analogs and the Thyroid Function and Volume in Women of Reproductive Age-Cross-Sectional Study	Bisphenols (BPs) are commonly known abocitlons that are widely used in industry. The knowledge about the impact of BPs on thyroid function is scarce. Proper thyroid functioning is especially important for women of reproductive age, as hypothyroidism affects fertility, pregnancy outcomes and the offspring. There are no studies analyzing the influence of BPs on thyroid function and volume in non-pregnant young women. The aim of this cross-sectional study was to evaluate the relationship between bisphenol A and its 13 analogs (BPC, BPE, BPF, BPG, BPM, BPP, BPZ, BPS, 4-HPPH, 4-HPPOH, TMBPF, TMBPS) exposure and thyroid function and volume in women of reproductive age. Inclusion criteria were: females as per 18-50 years. Exclusion criteria were history of any thyroid disease, pharmacotherapy influencing thyroid function, pregnancy or puerperium, and diagnosis of autoimmune disease other than Hashimoto's thyroiditis. Thyroid function was assessed by measuring serum concentrations of TSH, fT4, fT3, TPOAb, TgAb, and TRAb. Thyroid volume was assessed by ultrasonography. Ultrasound examination of thyroid gland was performed. Five hundred eighty participants were included into the study. A negative correlation was found between urine BPZ and bisphenol A (BPA) (R = −0.266, p < 0.0001). Patients with detected urine BPC presented smaller thyroid glands than those with not detected urine BPC (p = 0.00002). A positive correlation was found between TSH and urine BPC (R = 0.216, p = 0.002). Patients with detected urine BPC presented higher concentrations of TSH versus those with not detected urine BPC (p = 0.003). There were no relationships between any of serum BPs as well as the urine ones BPs and thyroid function and its volume. The only BP that demonstrated the relationship between thyroid function and its volume was BPC, probably because of its chemical structure that most resembles thyroxine. Exposure to this BP may result in the development of hypothyroidism that could have a negative impact on pregnancy and the offspring. 統合_0330	M. Milanović, N. Milošević, I. Sučić, S. Stojanoski, M. Abenavoli, Krstonošić, A. Rjelica, N. Milić and M. Medić Stojanoska	2020	Can environmental pollutant bisphenol A increase metabolic risk in polycystic ovary syndrome?	BACKGROUND: Bisphenol A (BPA), a widespread industrial substance is recognized as endocrine-disrupting chemical and therefore could be associated with polycystic ovary syndrome (PCOS) related metabolic disturbances. METHODS: In this study 75 women of reproductive age with diagnosed PCOS were enrolled. METHODS: BPA in urine samples was analyzed by gas chromatography-mass spectrometry. RESULTS: BPA was detected in urines of 66.28% participants. The crude no-height ratio (WHtR) was statistically significant higher in PCOS BPA(+) in comparison to PCOS BPA(-) women (p = 0.026). PCOS BPA(+) women had 6.89 times (95% CI 1.160-33.068, p = 0.034, p = 0.026) higher risk for waist circumference above 88 cm and 5.49 odds (95%CI 1.009-29.896, p = 1.981, p = 0.038) to have WHtR over 0.5 when compared to PCOS BPA(-). Statistically significant positive association between BPA urine concentrations, and insulin serum levels (p = 0.038) was obtained. BPA urine values were associated with elevated HOMA-IR values, and reduced HOS, levels with statistical significance (p = 0.038, p = 0.026). Conclusion: There was 51% (95% CI 0.769-0.777) BPA(+) women in the PCOS group. There was a 3.896 (p = 0.004) higher risk for PCOS BPA(+) women to have testosterone levels above reference values. CONCLUSION: The obtained results suggested that the BPA exposition in PCOS women was followed by increased metabolic risk through promotion of obesity, especially the visceral type, hyperinsulinemia, insulin resistance, dyslipidemia and elevated androgen levels. 統合_0331	F. M. Metwally, H. Rashad, H. M. Zoidan and A. F. Hashish	2020	Impact of Bisphenol A on Gonadotropic Hormone Levels in Children with Autism Spectrum Disorders	Early developmental exposures to endocrine disruptors including bisphenol A (BPA) may affects the body's endocrine system producing adverse neurologic, reproductive, cardiovascular, metabolic, and immune effects in humans. Many studies show the effect of BPA on human reproductive or/ even concentrations than that of safety limit recommendations. However, limited studies have investigated the possible association between environmental exposure of BPA and gonadotropic hormone levels in children with autism spectrum disorders (ASDs). This study was done to evaluate association between the serum levels of hormones; follicle-stimulating (FSH), follicle (E2H2B), and estradiol (E2) and BPA in the ASD children compared with 30 healthy control children. Serum levels of FSH, E2H2B, and E2 were lower in ASD group than that of control. Correlations between BPA and FSH, E2H2, and E2 within autistic children were not significant. The observed results revealed that BPA may cause endocrine dysfunction in ASD children. 統合_0332	M. Medlin, C. Beausoleil, F. A. Zeman, J. P. Antignac, M. Kolossa-Gehring, C. Rousselle and P. Apel	2022	Human Biomonitoring Guidance Values (HBM-GVs) for Bisphenol S and Assessment of the Risk Due to the Exposure to Bisphenols A and S, in Europe	Within the European Joint Programme HBM4EU, Human Biomonitoring Guidance Values (HBM-GVs) were derived for several prioritised substances. In this paper, the derivation of HBM-GVs for the general population (HBM-GVGeneral) and workers (HBM-GVworker) referring to bisphenol S (BPS) is presented. For the general population, this resulted in an estimation of the total urinary concentration of BPS at 0.5 µg/L according to 23 h continuous exposure to BPS. For workers, the modelling was refined in order to reflect continuous exposure during the working day, leading to a total urinary concentration of BPS of 5.0 µg/L. The usefulness for risk assessment of the HBM-GVs derived for BPS is discussed by comparing them to the HBM-GVs derived for bisphenol A (BPA) in a previous publication. Due to the similarities between BPA and bisphenols, with a very low NOA regarding exposure to BPS, contrary to that observed for BPS. This may be due to the endocrine-mediated endpoints selected to derive the HBM-GVs for BPS, whereas the values calculated for BPS are based on the temporary Tolerable Daily Intake (t-TDI) from EFSA set in 2013, in comparison with the revised TDI recently opened for comments by EFSA is also discussed. Regarding the occupational field, results indicate that the risk from occupational exposure to both bisphenols cannot be disregarded. 統合_0334	A. Mehlsen, L. Hallund, H. Bips, H. Frederiksen, A. M. Andersson, S. Bruun, S. Huzby, T. K. Jensen and C. A. G. Timmermann	2022	Pregnancy exposure to bisphenol A and duration of breastfeeding	INTRODUCTION: Bisphenol A (BPA) is frequently used in the production of plastics. It is an endocrine disruptor, and BPA exposure in mice has been associated with reduced offspring growth due to insufficient milk production. However, human studies of associations between BPA exposure and duration of breastfeeding are sparse. METHODS: Pregnant women from the Odense Child Cohort (n = 730) donated a third-trimester morning urine sample, which was analyzed for BPA by LC-MS/MS. Information about duration of exclusive and any breastfeeding was obtained through questionnaires three and 18 months postpartum, and a subgroup of 400 participants was interviewed by telephone about breastfeeding duration. Associations between BPA exposure and duration of breastfeeding were analyzed using Cox regression models. RESULTS: The median urinary BPA concentration was 1.29 ng/mL. Compared to women within the lowest tertile of BPA exposure, women in the second and third tertiles had 8% and 14% shorter breastfeeding at any given time. HRs (95% CI) were 1.08 (0.87, 1.34) and 1.16 (0.93, 1.27), respectively, and in terminate exclusive breastfeeding at any time up to 26 weeks after birth. HRs (95% CI) were 1.07 (0.86, 1.28) and 1.06 (0.85, 1.27), respectively. However, confidence intervals were accountable with an effect or even a protective effect. DISCUSSION: This study indicated that high BPA exposure in pregnancy is associated with shorter duration of breastfeeding. Although our findings were not statistically significant, all estimates were above one suggesting increased risk of early breastfeeding termination with high exposure. Using a single spot morning urine sample to estimate BPA has likely caused imprecision as it might not adequately reflect long-term exposure. Future studies, should consider measuring BPA more than once, including other timepoints during pregnancy and after birth. Flores-Ramírez	2023	Urinary phthalate metabolite and BPA concentrations in women with cervical cancer	Environmental pollutants are involved in the development and progression of numerous cancers, including cervical cancer (CC). One possible explanation for this is the ability of several pollutants to mimic natural hormones, thus altering the endocrine system. Phthalates and bisphenol A (BPA) are ubiquitous pollutants that have been classified as endocrine disruptors (EDs). This study aimed to evaluate the association between CC risk and urinary concentrations of 10 phthalate metabolites and BPA. A case-control study (n = 70, 35 cases/subjects with CC and 35 controls/subjects without CC) was conducted in Mexico. Urine samples were analyzed for BPA, seven hydroxyl phthalate (OHMP), seven oxo-phthalate (oxoMP), and seven carboxyl phthalate (cxMP) using high-performance liquid chromatography coupled to a tandem mass detector. The detection rate of environmental pollutants was 100%, with a median concentration in the control group and cases and inter-range was 0.5-5.9, 5.3, 96.6, and 129 µg/g Cr (1.5-11, 13.1-193.1, 163, and 362 µg/g Cr) and 1.9, 10.8, 3.5, and 9.1 µg/g Cr for BPA, MEHP, MBP, and MEP, respectively. This study reveals high levels of phthalates, particularly MEHP, in urine samples of women in CC associated with human papillomavirus (HPV) infection. Further studies are needed to evaluate the possible role of phthalates in synergy with HPV in progression to CC. 統合_0336	C. M. McKinney, B. G. Lemus, A. L. Semirado, A. Kim, Z. Liu, S. Samy and S. Sathyanarayana	2020	A Prospective Cohort Study of Bisphenol A Exposure from Dental Treatment	Laboratory studies show that bisphenol A (BPA) leaches from bisphenol A glycidyl methacrylate (bisGMA)-based dental materials. We aimed to quantify the extent to which children are exposed to BPA from dental treatment with bisGMA materials, by amount of treatment and type of sealants. We hypothesized that posttreatment urinary BPA (uBPA) concentrations would be higher among patients with more surfaces treated with bisGMA sealants and composite restorations. We recruited children undergoing dental treatment at the University of Rochester Medical Center (URMC) Dental Clinics. Urine samples were collected before dental treatment. We measured uBPA concentrations in urine before treatment and at 3 and 6, 6 and 24 hr posttreatment. We elaborated treatment data (surfaces treated) from the chart. We generated descriptive statistics and compared pre- and posttreatment uBPA concentrations using generalized estimating equations. Participants were 53% female, 65% non-White, and 73% publicly insured. The median age was 8.1. The mean number of tooth surfaces exposed to BisGMA materials (composites/sealants) was 7.5 (SD 5.5). Overall, uBPA concentrations were 80% higher (95% confidence interval (CI) 20% to 165%, P = 0.002) at 3–6 posttreatment compared with pretreatment concentrations. The uBPA concentrations 3–6 posttreatment versus pretreatment tended to be higher (112%, 95% CI 0.5% to 296%) among those receiving treatment on >5 surfaces than those receiving treatment on ≤5 surfaces (48%, 95% CI −11% to 151%), but the difference was not statistically significant (P = 0.2). Urine collection was challenging for young children undergoing general anesthesia. Among all findings, uBPA concentrations returned to baseline by 6 hr. Children experience short-term increases in BPA from dental treatment. The impact of relatively high, short-term BPA exposure on child health is unknown. Given the widespread use of BisGMA-based dental materials, and that chronic low-dose BPA exposure may adversely affect child health, strategies that minimize BPA exposure could potentially improve child health. 統合_0337	G. McGee, M. Gérard-Walton, P. L. Williams, T. J. M. Koesser, J. E. Chavarro, J. D. Meeker, J. M. Braun, M. A. Brazier, J. B. Ford, A. M. Calafat, L. Souter, R. Hauser and L. Mínguez-Alarcón	2023	Associations of Maternal Urinary Concentrations of Phenols, Individually and as a Mixture, with Serum Biomarkers of Thyroid Function and Autoimmunity: Results from the EARTH Study	The associations between urinary phenol concentrations and markers of thyroid function and autoimmunity among potentially susceptible subgroups, such as euthyroid women, have been understudied, especially when considering chemical mixtures. We evaluated cross-sectional associations of urinary phenol concentrations, individually and as a mixture, with serum markers of thyroid function and autoimmunity. We included 138 women attending a fertility center who provided one spot urine and one blood sample at enrollment (2009-2015). We quantified four phenols in urine using isotope-dilution high-performance liquid chromatography tandem mass spectrometry: bisphenol A (BPA), bisphenol S (BPS), bisphenol F (BPF), and triclosan (TCS). We measured serum concentrations of thyroid-stimulating hormone (TSH), free thyroxine (FT4), free triiodothyronine (FT3), and thyroglobulin (Tg) antibodies (TgAb) to assess using electrochemiluminescence assays. We fit linear and logistic regression models to investigate the association between urinary phenols (each individually and as a mixture) and serum thyroid function and autoimmunity, adjusted for confounders. As a sensitivity analysis, we also applied Bayesian Kernel Machine Regression (BKMR) to investigate non-linear and non-additive interactions. Urinary bisphenol A was associated with thyroid function; in particular, FT3 (mean difference for a 1 ng/mL increase in concentration: -0.088; 95% CI: -0.151, -0.025) and FT3/FT4 (-0.004; 95% CI: -0.012, -0.003). Urinary methylparaben and triclosan were also associated with several thyroid hormones. The overall mixture was negatively associated with serum FT3 concentrations (mean difference comparing all four mixture components at the 75th vs. 25th percentiles: -0.19; 95% CI: -0.33, -0.05). We found no evidence of non-linearity or interactions. These results add to the current literature on phenol exposures and thyroid function in women, suggesting that some phenols may alter the thyroid system. 統合_0338	C. F. McCabe, V. Padmanabhan, D. C. Dolinoy, S. E. Domino, T. R. Jones, K. M. Bakulski and J. M. Goodrich	2020	Maternal environmental exposure to bisphenols and epigenome-wide DNA methylation in infant cord blood	Maternal prenatal exposures, including bisphenol A (BPA), are associated with offspring's risk of disease later in life. Alterations in DNA methylation may be a mechanism through which altered prenatal conditions (e.g. maternal exposure to environmental toxicants) elicit this disease risk. In the Michigan Mother-Infant Pairs Cohort, maternal first-trimester BPA, bisphenol S (BPS), and bisphenol F (BPF) concentrations were tested for association with DNA methylation patterns in infant umbilical cord blood leukocytes (N = 99). We used the Illumina Infinium MethylationEPIC BeadChip to quantitatively evaluate DNA methylation across the epigenome. We identified differentially methylated positions (DMPs) and regions (DMRs) associated with maternal bisphenol concentrations using robust linear regression models and the comb-p algorithm, and tested for an association between BPA-associated DMRs and placental DNA methylation. Finally, we used the Comparative Toxicogenomics Database to identify genes with curated associations between BPA exposure and disease, and tested for enrichment of BPA-associated DMRs in these genes. Maternal first-trimester urinary BPA was associated with DNA methylation at 875 of significant sites. BPA exposure-associated DNA methylation sites were enriched for 38 pathways significant at FDR <0.05. The pathway or gene set with the greatest odds of enrichment for differential methylation (FDR <0.05) was type I diarrhoea receptor binding. This study provides a novel understanding of fetal response to maternal bisphenol exposure through epigenetic change.	Environ Epigenet. 2020 Dec 23;6(1):dvaa021.	10.1093/eep/dvaa021	33391824	ヒト	遺伝毒性								コホート研究	1	1							1	1	1											
統合_0339	C. F. McCabe, J. M. Goodrich, K. M. Bakulski, S. E. Domino, T. R. Jones, J. Colacino, D. C. Dolinoy and V. Padmanabhan	2023	Probing prenatal bisphenol exposures and tissue-specific DNA methylation responses in cord blood, cord tissue, and placenta	The early gestational fetal epigenome establishes the landscape for fetal development and is susceptible to disruption via environmental stressors, including chemical exposures. Research has explored how cell- and tissue-specific DNA methylation (DNAm) responds to bisphenol exposures, but few studies have compared responses across tissues. We leveraged the Michigan Mother-Infant Pairs cohort to evaluate DNAm in four previously identified genes across matched cord blood (CB), cord tissue (CT), and placental (PL) samples from 35 mother-infant pairs. In the Michigan Mother-Infant Pairs study, evaluated associations between prenatal exposure to bisphenols (BPA, BPF, and BPS) and DNA methylation (DNAm) by tissue type; compared epigenome-wide DNAm of CB and PL; and explored associations between prenatal bisphenol exposure and epigenome-wide DNAm in PL. Bisphenol concentrations were quantified in first-trimester maternal urine. DNAm was assessed at four genes via pyrosequencing in three tissues: epigenome-wide DNAm analysis via Infinium MethylationEPIC array was completed in CB and PL. Candidate gene analysis revealed tissue-specific differences across all genes. In adjusted linear regression, BPA and BPF were associated with DNAm across candidate genes in PL, but not CB and CT. Epigenome-wide comparisons of matched (fetal) PL DNAm revealed tissue-specific differences at most CpG sites, and modest associations between maternal first-trimester bisphenol exposures and PL, but not CB DNAm. These data endorse inclusion of a variety of tissues in perinatal exposure studies. Overlapping and divergent responses in CB, CT, and PL demonstrate their utility in combination to capture a fuller picture of the epigenetic effect of developmental exposures. 統合_0340	A. Martínez-Ibarra, L. D. Martínez-Razo, E. R. Vázquez-Martínez, N. Martínez-Cruz, R. Flores-Ramírez, E. García-Gómez, M. López-López, C. Ortega-González, I. Camacho-Arroyo and M. Cerbón	2019	Unhealthy Levels of Phthalates and Bisphenol A in Mexican Pregnant Women with Gestational Diabetes and Its Association to Altered Expression of miRNAs Involved with Metabolic Disease	Several studies indicate that bisphenol A (BPA) and phthalates may have a role in the development of metabolic diseases using different molecular pathways, including epigenetic regulatory mechanisms. However, it is unclear whether exposure to these chemicals results in even levels of miRNAs associated with gestational diabetes mellitus (GDM) risk. In the present study, we evaluated the urinary levels of miRNAs associated with GDM (miR-9-5p, miR-16-5p, miR-29a-3p and miR-330-5p) and urinary levels of phthalate metabolites (mono-n-butyl phthalate (MBP), mono-isobutyl phthalate (MiBP), mono-benzyl phthalate (MBzP) and mono(2-ethyl-5-hydroxyhexyl) phthalate (MEHHP)) and BPA in pregnant women with GDM ($n = 30$) and healthy pregnant women ($n = 30$). Urinary BPA levels were higher ($p = 0.0001$) in pregnant women with GDM compared to non-diabetic subjects. Phthalates were detected in 87 (58%) of urine samples, while BPA was in 60%. Urinary MEHHP and BPA concentrations were higher in women exposed to previously reported data. Unadjusted MEHP levels and adjusted BPA levels were higher in non-diabetics than in GDM patients ($p = 0.03$, $p = 0.02$). We found positive correlations between adjusted urinary MEHP levels and miR-16-5p expression levels ($p = 0.04$), adjusted MEHP concentrations and miR-29a-3p expression levels ($p = 0.05$). We also found negative correlations between unadjusted and adjusted MEHP concentrations and miR-29a-3p expression levels ($p = 0.004$, $p = 0.04$), unadjusted MiBP concentrations and miR-29a-3p expression levels ($p = 0.01$). Urinary MEHP levels reflect a striking exposure in di(2-ethylhexyl) phthalate (DEHP) in Mexican women. This study highlights the need for a regulatory strategy in the manufacture of several items containing endocrine disruptors in order to avoid involuntary ingestion of these compounds in the Mexican population. 統合_0341	E. Martínez Steele, N. Khandpur, M. L. da Costa Louzada and C. A. Monteiro	2020	Association between dietary contribution of ultra-processed foods and urinary concentrations of phthalates and bisphenol in a nationally representative sample of the US population aged 6 years and older	Ultra-processed food consumption has been associated with several health outcomes such as obesity, hypertension, cardiovascular disease and cancer. The deleterious nutrient profile of these products, and the presence of food additives, reactive vapour compounds and contact materials such as phthalates and bisphenol may be some of the potential pathways through which ultra-processed food formulations decrease cancers. The aim of this study was to examine the association between dietary contribution of ultra-processed foods and urinary biomarker concentrations of parent compounds or their metabolites, including DiDP-ethylhexyl phthalate (1.3EHP), Di-2-ethylhexyl phthalate (1.5EHP), Monoisobutyl phthalate (mDiP), Mono (3-carboxypropyl) phthalate (mCPP), Monobenzyl phthalate (mBzP), Bisphenol A (BPA) and Bisphenol S (BPS). Participants from the cross-sectional 2009-2010 National Health and Nutrition Examination Survey, aged 6+ years, with urinary measures and with one 24 hour dietary recall were included in the study. Ultra-processed foods were identified according to the NOVA classification. Survey-weighted linear regression models were used to estimate the percentage difference in urinary creatinine-standardised concentrations across quintiles of energy contribution of ultra-processed foods. Models incorporated survey-sample weights and were evaluated for different sociodemographic and lifestyle variables. Adjusted geometric means of 1.3 EHP, mCNP, mCPP, mBzP and BPF increased monotonically from the lowest to the highest quintile of ultra-processed food consumption. As both phthalates, bisphenol and ultra-processed foods have been previously associated with insulin resistance, diabetes, general abdominal obesity and hypertension, our results suggest the possibility of contact materials in ultra-processed foods as one link between ultra-processed food and these health outcomes. Future studies could confirm findings and further explore these mechanisms of action. 統合_0342	M. Martínez, A. Salas-Huetos, M. Fernández de la Puente, C. Valle-Hita, M. Marqués, C. Del Egido-González, E. Davila-Cordova, C. Montes, M. S. Petersen, N. Balbis and J. Salas-Salvadó	2024	Exploring the association between urinary bisphenol A, S, and F levels and semen quality parameters: Findings from Led-Fertyl cross-sectional study	Infertility is recognized as a multifactorial condition affecting approximately 15% of couples globally, influenced by various factors, including genetic predisposition and environmental exposures. Among these environmental factors, endocrine disrupting chemicals (EDCs) have garnered attention for their potential impact on reproductive health. Bisphenols, a group of EDCs commonly found in plastics and other consumer products, are substances such as bisphenol A (BPA) and bisphenol F (BPF) have emerged. Animal studies have demonstrated a dose-dependent decline in testicular function and embryotoxicity following these exposures in BPA. However, literature data on human studies are limited and heterogeneous. Additionally, even less is known about the relationship between exposure to the BPA analogues (BPF) and BPS and sperm quality. Therefore, the present study aimed to examine the association between urinary concentrations of BPA, BPF, and BPS and semen quality parameters among 195 adult Spanish men from the Led-Fertyl study using multiple linear regression models adjusted by potential confounding variables. Our results revealed an inverse association between log-transformed creatinine-adjusted concentration (ng/mg) of BPA and BPF levels and the percentage of sperm with DNA damage (β: -0.06; 95%CI: -0.11, -0.01; p = 0.02 and β: -0.06; 95%CI: -0.11, -0.01; p = 0.02, respectively). Moreover, men in the highest tertile of BPA concentrations (≥ 1.5 ng/mL) showed lower values in the lowest quartile (Q1: 6.38 %; 95%CI: 5.60 to 7.15 and Q1: 9.60 %; 95%CI: 8.15 to 11.05; p = 0.04, respectively). These results supply epidemiological evidence establishing a relationship between bisphenols, urine exposure and sperm quality, suggesting that a re-evaluation of the current safety of BPA alternatives is warranted.	Environ Res Vol.263 Issue Pt 2 Pages 120086	10.1016/j.envres.2024.120086	39353529	ヒト									横断研究	1	1																		
統合_0343	M. Martínez, M. Marqués, A. Salas-Huetos, N. Babio, J. L. Domingo and J. Salas-Salvadó	2022	Lack of association between endocrine disrupting chemicals and male fertility: A systematic review and meta-analysis	The incidence of infertility currently affects about 15% of the world's population. Male factors are estimated to be responsible for up to 30-50% of these cases. While the cause of these reproductive disorders is still unknown, endocrine disrupting chemicals (EDCs) have emerged as a possible factor. The aim of this study was to systematically review the literature published to date (2000-2021) on the association between EDCs and male reproductive health. Cross-sectional studies reporting whether human male exposure to EDCs affects male fertility, Clinical and observational studies assessing the exposure to EDCs using urine quality, human semen reproductive disorders, sperm DNA damage, sperm oxidative stress, fertilization rate, implantation rate, clinical pregnancy rate, live birth rate, and miscarriage rate were included. The quality assessment tool from the NHLBI-NIH was used to assess their studies. Ten standardized quality criteria, Sensitivity analysis and heterogeneity among studies was assessed. Overall, the 32 selected articles, including 7835 individuals in the systematic review, explored 13 families of EDCs. The results revealed a high heterogeneity among studies. In relation to the association between exposure to EDCs and the endpoints analyzed. Meta-analyses were performed with data from 3 studies including 1240 men. The pooled estimates revealed a significant association between exposure to EDCs and sperm DNA damage (standardized mean difference (SMD) = 0.33; 95% CI: 0.04, 0.62). However, the conventional significant positive association between PCB153 exposure and sperm concentration. However, it would not be clinically relevant. No positive or inverse associations were found within for BPA, nor for PCB153 and the rest of sperm parameters analyzed. The high disparity between studies made difficult to draw conclusions on the potential harmful effects of EDCs on male fertility. Consequently, to delineate the potential relationship that EDCs can have on male fertility, an important conditions crossing the health system, further investigations are required. 統合_0344	M. Martínez, N. González, A. Marí, M. Marqués, J. Rovira, V. Kumar and M. Nadal	2021	Human biomonitoring of bisphenol A along pregnancy: An exposure reconstruction of the EXHES-Spain cohort	This study was aimed at reconstructing the exposure to bisphenol (BPA) of 60 pregnant women from the EXHES-Spain cohort. A biomonitoring study was conducted by determining BPA levels in urine samples over the three trimesters of pregnancy. Moreover, the correlations between BPA levels and the role of different potential exposure sources, with special emphasis on the dietary intake, were also studied. Urine samples were subjected to dispersive liquid-liquid microextraction and the analysis was performed by gas chromatography–mass spectrometry. BPA was detected in 76% of the collected samples. Significant decrease of urinary BPA levels was observed along pregnancy, as mean concentrations of creatinine-adjusted BPA were 3.82, 4.86 and 2.51 μg/g in the first, second and third trimester, respectively. This decrease was essentially associated with the lower BPA concentrations found in the third trimester samples. Estimated daily intakes (EDIs) were calculated for the three trimesters of pregnancy, and were found to be dissimilar. Very interestingly, significant differences in urine BPA levels were found according to the fish consumption pattern, as women who ate more citrus fruits showed lower BPA concentrations in urine. The reconstructed exposure to BPA was estimated to 0.072, 0.088 and 0.048 μg BPA/kg of body weight/day in the first, second and third trimesters, respectively. These values are far below the temporary tolerable daily intake (t-TDI) established by the EFSA.	Environ Res Vol.196 Pages 110941	10.1016/j.envres.2021.110941	33647302	ヒト									バイオモニタリング	1	1																		
統合_0345	D. Martín-Way, I. Puche-Sanz, J. M. Cozar, A. Zafra-Gomez, M. D. C. Gomez-Regalado, C. M. Morales-Alcaraz, A. F. Hernandez, L. J. Martinez-Gonzalez and M. J. Alvarez-Cubero	2022	Genetic variants of antioxidant enzymes and environmental exposures as molecular biomarkers associated with the risk and aggressiveness of bladder cancer	Bladder cancer (BC) is one of the top 10 most common cancers worldwide however, no molecular markers are currently available for tumor management and follow-up. BC could benefit from molecular biomarkers in environmental disease, which provide mechanistic understanding of individual susceptibility to exposure-related cancers and allow characterizing genetic alterations in the molecular pathway for malignancy. This case-control study performed a molecular analysis in 99 BC and 125 controls. Buccal swabs were collected to assess SNPs in eleven genes coding for xenobiotic detoxification enzymes, cellular antioxidant defenses, and hormone synthesis and signaling (NAT2 rs1801280, SPINK1 rs17438068 and rs7849382, TAYSB1 rs1125900, PRSS1 rs17438062, PRSS2 rs6465651, GSTT1 rs17856199, GSTT2 rs17856272 and GSTT2 rs17856273). A structured questionnaire was administered to study participants to assess environmental and dietary chemical exposures. Several mRNAs associated to BC and aggressiveness were also analyzed in tumor tissues and matched controls (TERT, CLDN3, EGFR, ERBB2, PTEN, and GPX3). Urine samples were collected from BC patients to assess environmental pollutants (polycyclic aromatic hydrocarbons and endocrine-disrupting chemicals) were determined in urine from a subsample of BC cases and controls. We found that CYP1A1, GSTT2, ERBB2, PTEN, and GPX3 (rs17856199T) were associated with BC risk. Furthermore, exposure to smoke and/or diet, and alcohol intake were identified as risk factors for BC. Increased urinary levels of benzo[a]pyrene and bisphenol A were observed in BC patients relative to controls, along with an increased expression of miR-100b, miR-27b, and miR-97-5p in BC. Nevertheless, further studies with a larger sample size are warranted to confirm these exploratory results. This study also shows that the combination of genetic markers (PON1 and CYP27A1) and miRNA (miR-21) 3p and miR-92-1p) opens new scenarios in the use of non-invasive biomarkers in the classification of BC to guide personalized medicine, which is extremely urged in the current clinical setting. 統合_0346	J. Martín, J. L. Santos, I. Aparicio and E. Alonso	2019	Exposure assessment to parabens, bisphenol A and perfluoroalkyl compounds in children, women and men by hair analysis	Population is continuously exposed to endocrine disrupting compounds present in everyday products such as parabens, bisphenol A (BPA), and perfluoroalkyl compounds (PFCs). The aims of this study were: first, to evaluate human exposure to three parabens (methylparaben (MeP), ethylparaben (EtP) and propylparaben (PrP)), BPA and six PFCs (perfluorobutanoic acid, perfluoropentanoic acid, perfluorohexanoic acid (PFHxA), perfluoroctanoic acid (PFOA) and perfluorooctanesulfonic acid (PFOS)) through the analysis of hair samples from children, women and men and, then, to evaluate possible relationships between the concentrations found in hair and several factors potentially influencing exposure. Hair samples were collected from 100 children (50 girls and 50 boys) and 100 women and 100 men from Madrid (Spain). Analytical methods based on ultrasound-assisted extraction (UAE) followed by ultra-high performance liquid chromatography–tandem mass spectrometry (UHPLC-MS/MS) were developed and validated for the analysis of hair samples. The highest concentrations and frequency of detection (DF) of the analytes were found in the case of MeP and PrP (up to 11,100 and 9888 ng/g, respectively). BPA was found in 85% of the samples at concentrations in the range from 26 to 1227 ng/g whereas PFCs were detected at concentrations in the range from 0.6 to 13.3 ng/g, being PFHxA and PFOS the ones most frequently detected (85% and 76%, respectively). Concentrations of BPA and parabens in adults were statistically higher than those in children. The results of this study reveal the suitability of hair for biomonitoring endocrine disrupting compounds of high concern: PFCs, parabens and BPA) to which population is internally or/and externally but continuously exposed.	Sci Total Environ Vol.695 Pages 133864	10.1016/j.scitotenv.2019.133864	31421338	ヒト									バイオモニタリング	1	1																		
統合_0347	V. Marotta, L. Grumetto, I. Nori, G. Russo, A. Tortora, G. Izzo, I. Parravicini, D. Rocco, L. Pezzullo and M. Vitale	2023	Exposure to Bisphenol A increases malignancy risk of thyroid nodules in overweight/obese patients	Bisphenol A (BPA) is a widespread thyroid disruptor, but evidence about an association with thyroid cancer is weak. Excess body weight is a risk factor for thyroid cancer and affects activity of endocrine disruptors. Aim of the study was to investigate the association between BPA exposure and thyroid cancer, verifying the effect modification related to body weight. We performed a multicentric, cross-sectional study including consecutive patients undergoing thyroid surgery for nodules. Urinary BPA was measured by high-performance liquid chromatography-tandem mass spectrometry. Logistic regression models were used to detect risk factors for malignancy detection. Ninety-six patients were included: 50 benign nodules, 46 thyroid cancers, 28 normal weight, and 68 overweight/obese. BPA was detected in 79 subjects. The overall median BPA value was 0.6 ng/mL and in the group with BMI<25 kg/m2 BPA exposure was not significantly correlated to thyroid cancer (p = 0.08 and 0.759, respectively). In the group with BMI≥25 kg/m2, BPA-exposed subjects showed significantly higher risk of malignancy (OR 5.2, p = 0.026). In multivariate analysis, such association was independent of smoking, alcohol consumption, occupational exposure, and phthalates exposure (p = 0.025 and 0.026, respectively), but was lost after adjustment for the presence of metabolic syndrome (p = 0.089). In overweight/obese subjects, BPA exposure was significantly associated with higher thyroid-stimulating hormone levels. Our study suggests that BPA exposure is a risk factor for thyroid cancer in overweight/obese subjects. 統合_0348	V. S. Malik, K. Ravindra, P. Rattan, D. Dayal and S. V. Attri	2021	Environmental exposure to urinary Bisphenol-A in North Indian children aged between 6 and 16 years and its association with body mass index	This study investigates the effect of environmental risk factors among North Indian children aged between 6 and 16 years associated with body mass index by comparing fasting and non-fasting urine Bisphenol-A, urine creatinine, and anthropometric measurements. Urine samples were collected from 200 children (100 fasting and 100 non-fasting) and analyzed for Bisphenol-A and creatinine using HPLC and UV-Vis spectrophotometer, respectively. Children were grouped into obese, non-obese, and underweight categories based on age- and gender-specific Centre for Disease Control (CDC) 2000 growth chart and compared according to their body mass index. The overall mean ± SD (standard deviation) of age (years) was 10.65 ± 2.38 (boys, age 10.58 ± 2.38 and girls age 10.65 ± 2.45). Urinary Bisphenol-A concentration (ng/mL ± SD) was higher among obese (2.48 ± 0.42) than non-obese (1.98 ± 0.32) and underweight (1.52 ± 0.29) children. Urinary Bisphenol-A concentration (ng/mL ± SD) was higher among females (2.08 ± 0.42) than males (1.89 ± 0.32). Urinary Bisphenol-A concentration (ng/mL ± SD) was higher among fasting (2.04 ± 0.42) than non-fasting (1.93 ± 0.32) children. Urinary Bisphenol-A concentration (ng/mL) was significantly ($p < 0.05$) higher among obese subjects than non-obese and underweight subjects. Urinary Bisphenol-A concentration (ng/mL) was significantly ($p < 0.05$) higher among females than males and fasting than non-fasting

統合_0350	J. Majewska, A. Berg, J. Jurewicz, K. Daroszek, R. Zajdel, A. Kilanowicz, A. Wasik and D. Rachoń	2024	Bisphenol A analogues and metabolic syndrome in women with polycystic ovary syndrome	Bisphenols (BPs) have become a chemical group of special interest due to their ability to interfere with the endocrine system and their ubiquitous presence in the environment. As some of them possess mild estrogenic and anti-androgenic effects, they might be associated with the diagnosis of polycystic ovary syndrome (PCOS). Acting on multiple tissues, BPs exposure may lead to metabolic derangements, characteristic for metabolic syndrome (MetS). The aim of the study was to assess the relationship between exposure to bisphenol A (BPA), bisphenol S (BPS), bisphenol F (BPF), bisphenol AF (BPAF), and bisphenol AP (BPAP) and MetS in women with PCOS. In 1 year, women who were diagnosed with PCOS (study group; n = 100) and who were not (control group; n = 100) were enrolled in the study. BP concentrations were measured in the fasted state in serum samples using a validated method based on liquid chromatography coupled with tandem mass spectrometry (LC-MS/MS). Women who were overweight or obese (BMI ≥ 25 kg/m2) were more likely to be diagnosed with PCOS (adjusted OR (95%CI) 0.45 (0.25–0.80), P = 0.007) and MetS (0.37 (0.19–0.74), P = 0.005, correspondingly). Serum concentrations of BPs were not associated with the MetS diagnosis in the PCOS group. There was a negative correlation between the concentrations of serum BPAP and total serum cholesterol (r = − 0.19, P = 0.050), BPA and serum cholesterol (r = − 0.18, P = 0.032) as well as BPS and HDL cholesterol (r = − 0.208, P = 0.036). There was a positive correlation between the concentrations of BPAP and serum triglycerides (r = 0.20, P = 0.036). Our results point to the potential association between exposure to BPA, BPS, and the diagnosis of PCOS, along with the impact of BPAP, BPS, BPC, and BPF on the metabolic features of the MetS. 統合_0351	V. Magalhães, M. Severo, S. A. Costa, D. Correia, C. Carvalho, D. Torres, S. Casal, S. Cunha and C. Lopes	2024	Bisphenol A and cardiometabolic risk in adolescents: Data from the Generation XXI cohort	BACKGROUND AND AIMS: Bisphenol A (BPA), an endocrine-disruptor widely used in food contact materials, has been linked to a worse health profile. This study intends to estimate the association between BPA exposure and cardiometabolic patterns at adolescence. METHODS AND RESULTS: Data from the Portuguese population-based birth cohort Generation XXI at the age of 13 were used (n = 288 providing 3-day food diaries and fasting blood samples). BPA exposure was measured in 24 h urine samples (n = 288) and then predicted at participants' age using a validated mixed model. Multivariate regression models were applied to associate BPA. Three cardiometabolic patterns were identified (normal, modified lipid profile and higher cardiometabolic risk), using a probabilistic Gaussian mixture model. Multinomial regression models were applied to associate BPA exposure with the cardiometabolic patterns. Adolescents with higher BPA exposure were more likely to present a modified lipid profile (OR (95%CI) 1.03 (1.00–1.06), P = 0.030) and higher cardiometabolic risk (1.04 (1.01–1.08), P = 0.009), when compared to normal cardiometabolic pattern. Boys with higher BPA exposure had higher medium and lower levels of total, LDL and HDL cholesterol (β = -0.04, P = 0.030; β = -0.04, P = 0.040; β = 0.04, P = 0.040, respectively). Adolescents with higher BPA exposure had higher medium and lower levels of total, LDL and HDL cholesterol (β = -0.04, P = 0.030; β = -0.04, P = 0.040; β = 0.04, P = 0.040, respectively). Boys with higher BPA exposure had higher levels of body fat (kg) (β = 0.04, P = 0.040) and trunk fat (kg) (β = 0.04, P = 0.040). Girls

統合_0363	J. López-Vázquez, R. Rodil, M. J. Trujillo-Rodríguez, J. B. Quintana, R. Cela and M. Miró	2022	Mimicking human ingestion of microplastics: Oral bioaccessibility tests of bisphenol A and phthalate esters under fed and fasted states	Notwithstanding the fact that microplastic fragments were encountered in the human stool, little effort has been geared towards elucidating the impact of chemical additives upon the human health. In this work, standardised bioaccessibility tests under both fasting and fed conditions are herein applied to the investigation of human oral bioaccessibility of plastic additives and monomers (i.e. eight phthalate esters, PAEs, and bisphenol A (BPA)) in low-density polyethylene (LDPE) and polyvinyl chloride (PVC) microplastics. The generation of phthalate monoesters is evaluated in the time course of the three enzymatic tests. Gluconeo-gastric conditions are found to be responsible for the hydrolysis of PAEs, with half-lives ranging from 20 to 40 min. Bile salts and pancreatin are responsible for the intestinal hydrolysis of phthalate and diethyl phthalate, respectively, whereas their hydrolytic products are considered. Bioaccessible fractions of solid PAEs are moderate and the physicochemical characteristics of the microplastics, i.e., the glass transition temperature, seem to have a significant role in the bioaccessibility of PAEs. Bioaccessibility values ranged from 0.1% to 32.1%, with upper-significantly larger monoester percentages for LDPE. Our results suggested that the highest gastro-pancreatic bioaccessibility of the eight PAEs and BPA is reached under fed-state gastrointestinal extraction conditions because of the larger amounts of surface-active biomolecules. Even including the bioaccessibility factor within human risk assessment/exposure studies to microplastics, concentrations of dimethyl phthalate, di-n-butyl phthalate and BPA exceeding 0.3% (w/w) may pose severe risks after oral uptake in contrast to the more hydrophobic congeners for which concentrations above 3% (w/w), except for diethylhexyl phthalate, would be tolerated. Aguilera	2022	Culturing and Molecular Approaches for Identifying Microbiota Taxa Impacting Children's Obesogenic Phenotypes Related to Xenobiotic Dietary Exposure	Integrated data from molecular and improved culturomics studies might offer holistic insights on gut microbiome dysbiosis triggered by xenobiotics, such as obesity and metabolic disorders. Bisphenol A (BPA), a dietary xenobiotic obesogen, was chosen for a directed culturing approach using the microbiota from 50 children with obesity and normal weight profiles. Culture-dependent molecular analyses were carried out to estimate the BPA metabolizing capacities. Finally, catalogues of 257 BPA-directed cultured microorganisms were isolated using five selected media and varied BPA treatments and conditions. Taxa from Firmicutes, Proteobacteria, Actinobacteria, and Bacteroidetes phyla were identified. Bacteroides, Clostridium, Escherichia, Bifidobacterium, and Lactobacillus were genera with the highest BPA-degrading capacities. Unexpectedly, the representative isolates' taxa from normal-weight vs. overweight/obese were grouped as BPA-biodegradable, tolerant, or resistant bacteria according to their BPA-degradation and BPA-enzymes richer whole genome sequences. Remarkably, the presence of xyanolytic and commonly Bacillus spp. showed the higher BPA biodegradation potential in overweight/obese group compared to normal weight, which could drive a relevant role in obesity and metabolic dysbiosis triggered by these xenobiotics. 統合_0365	A. López-Moreno, P. Largeña, R. Martín and M. Aguilera	2023	Microbiota analysis for risk assessment of xenobiotic exposure and the impact on dysbiosis: identifying potential next-generation probiotics	On-going projects of the team are currently dealing with microbiota, xenobiotics, endocrine-disrupting chemicals (EDCs), obesity, inflammation and probiotics. The combination of diet, lifestyle and the exposure to dietary xenobiotics, including EDCs, can contribute to the development of obesity and metabolic disorders. Gut microbiota dysbiosis has been associated with obesity and its related phenotypes. Specific, complementary, and combined preventive and treatments are needed to face these altered microbial patterns and the specific misbalances they induce. In this sense, searching for next-generation probiotics (NGP) by microbiota culturing, and focusing on their demonstrated, extensive scope and well-defined functions, could contribute to counteracting and repairing the effects of obesogens. Therefore, EU FORI project contributes to present a perspective through compiling information and key strategies for directed culturing and culture of NGP that could be performed by using conventional selective and related dysbiosis by (1) observing the differential abundance of specific microbiota taxa in obesity-related patients and analyzing their functional roles, (2) developing microbiota-directed strategies for culturing these taxa in vitro, (3) design and applying the most suitable and completed criteria from novel NGP clinical studies. New isolated or cultivable microorganisms from healthy gut microbiota specifically related to metabolic obesogenic bacterial pattern shifts might be used as an NGP single strain or in consortia, both presenting functions and the ability to palliate metabolic-related disorders. Identification of holistic approaches for searching and using potential NGP, key aspects, the how, gaps and proposals of solutions were also considered in this workplan.	Efsa j Vol.21 Issue Suppl 1 Pages e211010	10.2903/j.efsa.2023.e211010	38047127	ヒト	-	-	-	-	-	-	腸内細菌叢解析	1	1	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-
統合_0366	A. López-Moreno, K. Cerk, L. Rodrigo, A. Suarez, M. Aguilera and A. Ruiz-Rodriguez	2024	Bisphenol A exposure affects specific gut taxa and drives microbiota dynamics in childhood obesity	Cumulative xenobiotic exposure has an environmental and human health impact which is currently assessed under the One Health approach. Bisphenol A (BPA) exposure and its potential link with childhood obesity that has parallelly increased during the last decades deserves special attention. It stands during prenatal or early life and could trigger comorbidities and non-communicable diseases along life. Accumulation in the nature of synthetic chemicals supports the "environmental obesogen" hypothesis, such as BPA. This estrogen-mimicking xenobiotic has shown endocrine-disruptive and obesogenic effects, also potentially gut microbiota misbalance that is not yet well elucidated. This study aimed to investigate specific microbiota taxa isolated and cultured by direct BPA exposure and reveal its role on the overall children microbiota community and dynamics. Fecal samples from 50 children (25 with obesity and 25 normal weight) were cultured in selective media supplemented with BPA (0 and 400 µg/mL) to isolate BPA-resistant microbial community. The selected BPA-induced taxa themselves showed a significant impact on viable BPA-degradation rates. Specifically, Clostridium and Pantoea taxa were positively correlated with BPA-enzymes richer communities, while Enterobacter, Escherichia-Shigella, Bifidobacterium, and Lactobacillus were negatively associated. Microbial community dynamics and networks analyses showed differences according to the study groups. The normal weight children group exhibited a more enriched, structured, and connected taxa network compared to overweight and obese groups, which could mean a more vulnerability to xenobiotic substances. In this sense, subnetwork analysis generated with the BPA-cultured genera showed a correlation between taxa connectivity and more diverse potential enzymatic BPA-degradation capacities/functionalities. Our findings suggested that BPA-induced microbiota dysbiosis could be associated with childhood obesity development, and how these taxa influenced the overall dynamics/ecological patterns of diversity generally recognized in dysbiosis. Commonly network and subnetwork analyses corroborated the better connectedness and stability profiles for normal weight group compared to the overweight and obese groups.	mSystems Vol.9 Issue 3 Pages e0095723	10.1128/msystems.00957-23	38426791	ヒト	-	-	-	-	-	-	腸内細菌叢解析	1	1	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-
統合_0367	L. López-Carrillo, A. Morán-Ortega, N. Gómez-Ruiz, L. Hernández-Garciadiego and B. Gamboa-Loira	2021	Exposure to bisphenol A and breast cancer risk in northern Mexican women	OBJECTIVE: To evaluate the association between BC and urinary concentrations of free bisphenol A (BPA-F), the biological form of BPA, among women residing in Northern Mexico. METHODS: The population under study comprised 1,503 histologically confirmed BC cases and 1,503 age-matched controls. Women were interviewed face to face about their sociodemographic and reproductive characteristics. BPA-F was determined by high-pressure liquid chromatography equipped with a fluorescence detector (HPLC-FLD). Logistic regression models were used to estimate the adjusted BC risk in relation to BPA-F. RESULTS: BPA-F geometric mean were significantly higher among cases compared to controls (5.16 µg/L in cases and 2.27 µg/L in controls). A significant adjusted BC odds ratio of 2.32 (95% CI: 1.87-2.76) was estimated for the highest category of BPA-F compared to the lowest category. CONCLUSION: BPA-F may be an environmental cofactor of BC. Since this is the first report on BPA-F association with BC, our results need to be replicated. 統合_0368	X. Liu, L. Wang, X. Liu, P. Yu, Y. Diao, T. Chen, Y. Sheng, D. Zhang, D. Peng, Y. Gu, S. Li and R. Xu	2025	Microplastics, plastics, and their products exposures and cancer: a pooled analysis	OBJECTIVE: This meta-analysis aims to evaluate the impact of microplastic pollutant exposure on cancer risk by analyzing data from existing cohort and case-control studies. METHODS: The researchers systematically searched PubMed, Embase, and the Cochrane Library on 30 June 2024 to identify relevant studies. The analysis focused on cancer incidence and mortality, with subgroup assessments for different types of cancers and microplastic pollutants, and dose-response analysis for further investigation.Publication bias was assessed by funnel plots, Egger's test, and Begg's test. All data processing and analysis were performed using Stata 17.0 software. RESULTS: The meta-analysis included 11 studies, comprising 5,363 children with cancer and 1,072,000 participants. The pooled results indicated that exposure to microplastic pollutants was associated with an increased risk of cancer (OR = 1.16, 95% CI = 1.03 to 1.30), but not for cohort studies (OR = 1.03, 95% CI = 0.96 to 1.12). Subgroup and dose-response analysis revealed that phthalates (OR = 1.28, 95% CI = 1.08 to 1.52) and bisphenol A (OR = 1.08, 95% CI = 1.03 to 1.14) might be associated with cancer risk in case-control studies. CONCLUSION: Existing evidence from case-control studies suggests a weak correlation between microplastic pollutant exposure and cancer risk. However, this causal relationship needs to be interpreted with caution due to the methodological limitations of existing evidence. 統合_0369	J. Liu, M. Tian, H. Qin, D. Chen, S. M. Mzava, X. Wang and F. M. Bigambo	2024	Maternal bisphenols exposure and thyroid function in children: a systematic review and meta-analysis	BACKGROUND: Evidence from animal experiments and epidemiological studies has reported controversial results about the effects of prenatal bisphenols (BPs) exposure on childhood thyroid function. This study aims to explore the associations of prenatal exposure to BPs with thyroid-related hormones (THs) in newborns and early childhood, with a particular focus on the sex-dependent and exposure level effects. METHODS: Correlated studies were systematically searched from PubMed, Web of Science, Medline, Cochrane, and Embase until February 21, 2024. The exposure assessed include bisphenol A (BPA), bisphenol F (BPF), bisphenol S (BPS), and other BPs. The outcomes were specified as any hormones from maternal/cord blood, newborn blood spots, and children's blood. RESULTS: A total of 2,390 records were identified, and 19 studies with a total of 7,390 maternal-child pairs and their response rate were included in meta-analyses. Statistical analyses were conducted using Stata 16.0. The methodological quality of the included studies was evaluated using the Newcastle-Ottawa Scale (NOS). RESULTS: Eleven cohort studies comprising 5,363 children were included in our meta-analysis. Prenatal bisphenol concentrations were statistically significant related to alterations in thyroid hormones in children, exclusively in female infants during mid-late pregnancy. Specifically, BPA was positively associated with TSH levels (β = 0.02, 95% CI: 0.00, 0.03), and inversely with high concentrations of bisphenols (>1.5 µg/g creatinine) significantly reduced FT3 levels in children (β = -0.01, 95% CI: -0.02, -0.00). CONCLUSION: Prenatal bisphenol exposure is linked to alterations in thyroid hormone levels in girls, necessitating enhanced measures to control bisphenol exposure levels during pregnancy for child health protection. 統合_0370	J. Liu, L. J. Martin, I. Dinu, C. J. Field, D. Dewey and J. W. Martin	2021	Interaction of prenatal bisphenols, maternal nutrients, and toxic metal exposures on neurodevelopment of 2-year-olds in the APrON cohort	BACKGROUND: Epidemiological studies suggest that Bisphenol A (BPA) is a developmental neurotoxicant, but the modifying effects of maternal nutrient status or neurotoxicant metal co-exposures have not been reported. Bisphenol F (BPF) is being used as a BPA alternative, but few epidemiological studies have evaluated its effects. OBJECTIVES: To examine if prenatal maternal BPA/BPF exposures are associated with children's neurodevelopment at two years of age while adjusting for effect measure modification by sex, maternal nutrients, and co-exposure to neurotoxic metals. METHODS: Total BPA and BPF concentrations were measured in urine samples collected from pregnant women (n = 1,503) enrolled in the Alberta Pregnancy Outcomes and Nutrition (APrON) cohort. Neurodevelopment was assessed in their children at age 2 (n = 1,258) using the Bayley-III scales. Higher maternal C3 was significantly correlated with poorer motor performance (p < 0.01), and higher levels of maternal Se were significantly associated with poorer performance on the cognitive scale (p < 0.05). Maternal Se was also found to significantly modify the effects of BPA on cognitive scores (p < 0.05). Stratified analyses revealed that in boys, under adequate maternal Se conditions, Associations between BPA exposure and social-emotional scores were negative for boys (p = 0.056) but positive for girls (p = 0.065). Higher exposures to BPA were associated with fewer motor scores among children with lower levels of maternal Se. CONCLUSIONS: Higher maternal C3 was associated with poorer motor development, but it was not an effect measure modifier of bisphenols' effects on motor development. Maternal Se may be protective against adverse effects of bisphenols, and additional nutrient-bisphenol interaction studies examining sex-specific effects of BPA and BPF on child development are warranted. 統合_0371	J. Liu and J. W. Martin	2019	Comparison of Bisphenol A and Bisphenol S Percutaneous Absorption and Biotransformation	BACKGROUND: Bisphenol S (BPS) has been widely substituted for bisphenol A (BPA) on thermal papers, but little is known about its skin absorption. OBJECTIVES: We compared the percutaneous absorption and biotransformation of BPS and BPA in vitro and in a controlled human trial. METHODS: Absorption and biotransformation of BPS and BPA were monitored across reconstructed human epidermis at two environmentally relevant doses (0.1 and 1 μg/cm2). Urinary biomarkers of exposure were measured in 6 adult volunteers (3 females and 3 males) who applied 1 mg/cm2 of BPS or BPA to their forearms and hands. Each participant repeated the experiment with exceeded monitoring. BPS data were compared with published data for isotope-labeled BPA ([^{13}C$_{12}$]-BPA; use test) from the same participants. RESULTS: In doses at 1.0 and 0.1 μg/cm2, BPS was 19- and 8-fold more permeable than BPA (Permeability coefficient of BPS: 0.699 and [Formula: see text], respectively; [Formula: see text] was significantly lower than for BPA: 0.036 and [Formula: see text], respectively), and metabolism of both bisphenols was negligible in participants handling thermal receipts, the quantities of BPS and [Formula: see text] in hands was significantly (>6 times) higher than BPA ([Formula: see text], but the slope was lower for BPS than BPA ([Formula: see text] and 1, respectively). As a proportion of total urinary bisphenol, free BPS ([Formula: see text]) was higher than for free BPA ([Formula: see text]), and the concentrations of free BPS were 19 times greater than free BPA. Conjugation (GlcA) of BPS was more variable than BPA. Based on the BPS dose-response range of BPA in background studies, 57 ([Formula: see text]; [Formula: see text]), CONCLUSIONS: Both the in vitro and human studies suggested lower percutaneous absorption of BPS compared with BPA, but a lower biotransformation efficiency of BPS should also be considered in its evaluation as a BPA substitute. https://doi.org/10.1289/EHP5863. 統合_0372	M. Liu, Y. Zhou, Y. Li and Z. Gong	2023	Important roles of Hif1a in maternal or adult BPA exposure induced pancreatic injuries	Bisphenol A (BPA) is a monomer to produce polycarbonate plastics, and can be released into the environment through human activities, leading to its accumulation in animals, plants and humans through direct contact or environmental exposure. Epidemiological studies have reported that BPA exposure is associated with metabolic disorders. The pancreas is an important endocrine organ and plays an important role in metabolic disorders. To explore the possible long-term effects of BPA exposure on maternal health, bioinformatic methods were used to identify differentially expressed genes (DEGs) by comparing the neonatal pancreas after maternal exposure to BPA with those of controls. Gene Ontology (GO) and Kyoto Encyclopedia of Genes and Genomes (KEGG) analyses were performed using the Database for Annotation, Visualization and Integrated Discovery (DAVID) Bioinformatics Resources 6.8 and the Search Tool for the Retrieval of Interacting Genes/Proteins (STRING) database. Cytoscape was used to visualize the protein-protein interaction (PPI) network and to identify hub genes. Results: The pancreatic tissues of mice exposed to BPA during pregnancy were collected. Control (or BPA-exposed) offspring (maternal exposure) and Control (or BPA-exposed) adults (direct exposure) were defined as Control (or BPA) groups. The results showed that BPA disturbed the normal function of the pancreas in both offspring and adults, with offspring showing higher susceptibility to BPA than adults. Downstream insulin secretion related DEGs (Slc6a5, Fam3d, Nts3, Jph3, Hrh3, Ngp, Ntrk1, Fam3, Slc6a5, Cpa1, Pde1c, Rab3c, Ank1, Cnr2, Rab3, Ins1, and Kcnj9) in the BPA group were identified, and Hif1a was identified as the hub gene. Conclusion: Hif1a may be a potential target for BPA-induced pancreatic injuries in offspring. 統合_0374	C. Liu, Y. Liu, J. Ning, C. Wu, X. Lu, Y. Guo, P. He, C. Qiu and J. Wu	2024	Association between bisphenol A exposure and adiposity measures in children	Bisphenol A (BPA) is a chemical that has adverse effects on human health and may cause childhood obesity. Nevertheless, the association between BPA exposure and adiposity measures in children remains controversial, especially in young children. A cross-sectional study was conducted on 208 randomly selected children (3 to 6 years old) attending preschools in Guangzhou, China. BPA exposure was assessed through urine high-performance liquid chromatography-tandem mass spectrometry. Adiposity measures, including body mass index z-score (z-BMI), waist circumference z-score (z-WC), and waist-to-height ratio z-score (z-WHtR), were calculated. Linear regression models were used to assess the associations between BPA exposure and adiposity measures. Children with a higher body mass index z-score (β = 0.672; 95% confidence interval (CI): 0.053, 0.682), and they were at a greater risk of overweight or obesity (odds ratio (OR) = 1.306; 95% CI: 1.211, 1.699). Higher urinary BPA concentrations were associated with an elevated z-score for height-for-age (β = 0.807; 95% CI: 0.802, 0.812), and they were at a higher risk of abdominal obesity (OR = 1.711; 95% CI: 1.211, 2.699). Higher urinary BPA concentrations were also associated with increased upper arm circumference and skinfold thickness in the adjusted models. (β = -0.546; 95% CI: 0.278, 0.813). (β = 0.702; 95% CI: 0.139, 1.266, respectively). Higher urinary BPA concentrations in children 3 to 6 years old were associated with a greater risk of overweight/obesity and abdominal obesity. BPA exposure might increase the risk of obesity in children. Further investigations are needed to confirm this association and explore the underlying mechanisms. 統合_0375	B. Liu, Y. Yan, J. Xia, J. Sun, H. J. Lehmler, L. Trasande, R. B. Wallace and W. Bao	2024	Bisphenol S, bisphenol F, bisphenol A exposure and body composition in US adults	Bisphenol S (BPS) and bisphenol F (BPF) are increasingly used to replace bisphenol A (BPA), an endocrine-disrupting chemical with putative obesogenic properties, whether and how BPS and BPF affect adiposity in humans remains unclear. We examined associations of urinary BPS, BPF, and BPA with dual-energy X-ray absorptiometry (DXA)-measured body composition in 2,747 adults aged 20 to 59 years from the National Health and Nutrition Examination Survey 2013-2014 who had information on urinary BPS, BPF, and BPF concentrations, and body composition measured using dual-energy x-ray absorptiometry. After full adjustment for potential confounders in linear regression models, BPS was significantly associated with the % body fat of the whole body, arm, and leg, with the β (95% CI) for the highest quartile vs. the lowest quartile of 1.18 (95%CI [0.11, 2.26]; P = 0.03), 1.40 (95%CI [0.35, 2.45]; P = 0.01), and 1.43 (95%CI [0.31, 2.55]; P = 0.01), respectively. No association between BPS and lean mass was found. For BPF, significant associations were found for % body fat of the whole body (β [95% CI] = -1.20 [-2.38, -2.36]; P = 0.05), trunk (-2.96% [-5.1, -0.72]; P = 0.01), and arm (-2.76% [-5.1, -1.38] [0.05, 2.73]; P = 0.01), as well as lean mass of the whole body (β [95% CI] = -0.61 [-1.19, -0.03]; P = 0.04). No significant associations were found for BPA. Urinary BPS, BPF, and BPA were detected in 75.1%, 20.1%, and 96.4% of participants, respectively. The lowest quartile vs. the highest quartile for significant associations was observed between BPF and % body fat and lean mass. Results suggest that higher BPS levels were significantly associated with greater % body fat of the whole body and limbs, and there was suggestive evidence that BPS levels were associated with both % body fat and lean mass of the whole body and body parts in a nonmonotonic relationship. 統合_0376	B. Liu, X. Lu, A. Jiang, Y. Lu, H. Zhang and B. Xu	2024	Influence of maternal endocrine disrupting chemicals exposure on adverse pregnancy outcomes: A systematic review and meta-analysis	Maternal endocrine disrupting chemicals (EDCs) exposure, the common environmental pollutants, was capable of inducing inadverse pregnancy outcomes. However, the evidence of their connection is not consistent. Our study aimed to systematically review the effects of maternal exposure to EDCs on adverse pregnancy outcomes. We searched PubMed, Embase, Web of Science, and Cochrane Library for studies published before January 2023 that investigated the association between maternal EDCs exposure and adverse pregnancy outcomes including miscarriage, small for gestational age (SGA), low birth weight (LBW) and preterm birth (PTB). We found that maternal PFOA exposure was positively correlated with LBW (OR 1.21, 95% CI 1.18–1.23), SGA (OR 1.12, 95% CI 1.08–1.16) and miscarriage (OR 1.09, 95% CI 1.03–1.15). The pooled estimates also showed maternal PFOS exposure was linked with PTB (OR 1.06, 95% CI 1.01–1.11), SGA (OR 1.04, 95% CI 1.01–1.07), and miscarriage (OR 1.04, 95% CI 1.00–1.08). In addition, maternal exposure to some specific class of EDCs including PFOS, MBP, MEHP, DEHP, and BPA was associated with PTB. Maternal exposure to PFOS, PFOA, PFNA/I was associated with SGA. Maternal exposure to BPA was associated with LBW. Maternal exposure to MBP, MEHP, MCMHP, MECPP, BPA was associated with miscarriage. Maternal PFHxS, PFAS and BPA exposure may increase adverse pregnancy outcomes risk according to our study. However, the limited number of studies on dose-response hampered further explanation for causal associations. Fiorucci	2021	Endocrine disruption in Crohn's disease: Bisphenol A enhances systemic inflammatory response in patients with gut barrier translocation of dysbiotic microbiota products	The relevance of environmental triggers in Crohn's disease remains poorly explored, despite the well-known association between industrialization and disease onset/progression. We have aimed at evaluating the influence of endocrine disrupting chemicals in CD patients. We performed a prospective observational study on consecutive patients diagnosed of CD. Serum levels of endocrine disruptors, short-chain fatty acids, proinflammatory cytokines were measured. Bacterial DNA and some metabolic levels were determined in portal blood. Intestinal expression of TJ proteins was assessed in colon biopsies. Patients were genotyped for SLC22 and ATG16L1 polymorphisms. A series of 200 CD patients (100 in remission, 65 with active disease) was included in the study. Bisphenol A was significantly higher in patients with active disease versus remission and in controls (p = 0.0001 and p = 0.0001, respectively). Bisphenol A was significantly higher in patients with gut barrier translocation of dysbiotic microbiota products (p = 0.0001 and p = 0.0001, respectively). Bisphenol A was significantly higher in patients with gut barrier translocation of dysbiotic microbiota products (p = 0.017; P = .002). Serum lipopolysaccharide levels were significantly lower in patients with bacterial DNA and an inverse relationship was present between them and BPA levels (r = -0.455; P < .001; r = -0.441; P = .002). Serum BPA levels correlated with IL-23 (r = 0.607; P = .001) and IL-17A (r = 0.703; P = .001). The multivariate analysis revealed an independent significant contribution of BPA and bacterial DNA to serum levels of IL-23 and IL-17A. In conclusion, bisphenol A significantly affects systemic inflammatory response in CD patients with gut barrier disruption and dysbiotic microbiota secretory products in blood. These results provide evidence of an endocrine disruptor playing an unusual pathogenic role on CD. Hu ang	2024	Exposure characteristics and cumulative risk assessment of bisphenol A and its substitutes: the Taiwan environmental survey for toxicants 2013	INTRODUCTION: Ever since the use of bisphenol A (BPA) has been restricted, concerns have been raised regarding the use of its substitutes, such as bisphenol S (BPS) and bisphenol F (BPF). Meanwhile, the EU-mandated biomonitoring of BPA and its substitutes in urine samples has been implemented since 2019. However, the exposure characteristics of BPA and its substitutes in Taiwan remain unclear. This study conducted to identify BPA and its substitute's exposure characteristics of the general Taiwanese population and estimate the cumulative risk of bisphenol exposure. METHODS: Urine samples (N = 360 [adult, 271; school, 89]) were collected from individuals who participated in the Taiwan Environmental Survey for Toxicants 2013. The samples were analyzed for BPA, BPS, and BPF through ultraperformance liquid chromatography tandem mass spectrometry. Creatinine was measured to correct the urinary concentrations. Hazard quotients (HQs) were calculated to assess the risk of exposure to BPA and its substitutes. HQs for each bisphenol values were calculated. RESULTS: Our study found that the median level of BPA (0.5 μg/g creatinine) was significantly higher in adults. HQs (1 μg/g creatinine) were also significantly higher in adults. HQs (1 μg/g creatinine) were also significantly higher in adults. HQs (1 μg/g creatinine) were also

統合_0389	J. Liang, C. Yang, T. Liu, H. J. J. Tan, Y. Sheng, L. Wei, P. Tang, H. Huang, X. Zeng, S. Liu, D. Huang and X. Qiu	2021	Prenatal exposure to bisphenols and risk of preterm birth: Findings from Guangxi Zhuang birth cohort in China	Preterm birth (PTB), a serious adverse birth outcome, is the leading cause of perinatal mortality and morbidity. Bisphenols induce endocrine disruption that spreads across the placenta, which may affect fetal growth and development. However, the effects of bisphenols on PTB, particularly their combined effects, remain unknown. This study investigated the association between prenatal bisphenol exposure and PTB. Study participants were from the Guangxi Zhuang Birth Cohort. Concentrations of bisphenol A (BPA), bisphenol S (BPS), and bisphenol F (BPF) in maternal urine samples collected during early pregnancy and pregnancy outcomes were obtained from medical records. Multivariate logistic regression, restricted cubic spline, principal component analysis (PCA), quantile g-computation (Qgcomp), and Bayesian kernel machine regression (BKMR) were used to examine the association between serum bisphenol levels and PTB. Li-ion beam/cerebral BPS concentrations were associated with an increased risk of PTB only in female infants. OR= 1.38 (95% CI: 1.01, 1.89) and 1.39 (95% CI: 1.01, 1.92), respectively. Maternal BPA, BPS, and BPF levels were not associated with PTB. Stratified analysis revealed that maternal BPA, bisphenol S (BPS), and tetrabromobisphenol A (TBBPA) levels and the risk of PTB (P-overall = 0.06, P-nor-linear = 0.05). After sex stratification, the association with female BPS overlaps and PTB was only observed in males. In Qgcomp analysis, bisphenol mixtures were related to an increased risk of PTB (OR = 1.52, 95% CI: 1.00, 2.31), with BPF (33.7%), BPS (29.6%) and BPA (26.8%) having the greatest positive contribution. Results indicate that prenatal exposure to bisphenol mixtures might increase the risk of PTB, which might be primarily driven by BPS, BPF, and BPA. There may also be sex-specific and nonmonotonic dose-dependent effects. Qiu	2023	Effects of prenatal single and mixed bisphenol exposure on bone mineral density in preschool children: A population-based prospective cohort study	Exposure to bisphenols can affect bone mineral density (BMD) in animals and humans. However, the effects of maternal exposure to bisphenols during pregnancy on bone health in preschool children remain unknown. We aimed to examine the associations between prenatal exposure to BPA, bisphenol S (BPS), bisphenol F (BPF), and tetrabromobisphenol A (TBBPA) and bone mass in preschool children. Participants were from the Guangxi Zhuang Birth Cohort. Each natural log (Ln)-unit increase in tetrabromobisphenol A was related to a 0.007 m/s (95 % CI: -0.013, 0.028) decrease in Ln-transformed speed of sound (SOS) among girls. Decreased BMD Z scores in preschool children were associated with increased maternal BPA (β = -0.165, 95 % CI: -0.330, -0.001), BPS (β = -0.166, 95 % CI: -0.331, -0.001), and TBBPA (β = -0.165, 95 % CI: -0.330, -0.001) levels. Ln (1.50) increase in BPA, BPS, and TBBPA and Ln (2.00) increase in BPF were associated with 1.162 (1.042, 1.161) and high exposure group of BPF (OR = 3.345, 95 % CI: 1.035, 10.186) compared with the low exposure group in girls, the risk of BMD decreased in mixed exposure (OR = 0.433, 95 % CI: 0.218, 0.721). BCI analysis revealed a U-shaped nonlinear correlation between BPA concentration and BMD. In girls (P-overall = 0.011, P-nonlinear = 0.009), in PCA, a U-shaped dose-response relationship was found between PC2 and the risk of BMD. (P-overall = 0.008, P-nonlinear = 0.002), and a significant association was only noted in girls. Inverted U-shaped correlations were also observed between a decrease in birth weight (P for trend = 0.007), birth length (P for trend = 0.026), and birth weight Z scores (P for trend = 0.046) in males. Our data suggested an inverse association of prenatal exposure to BPA, BPF, and TBBPA and birth size, which may be more pronounced in male infants.	Ecotoxicol Environ Saf. 2023 Nov 15:267:115665.	10.1016/j.ecoenv.2023.115665	37951091	ヒト	骨	-	-	-	-	-	-	コホート研究	1	1	-	-	-	1	1	1	-	-	-	-	-	-	-	-	-	-	-	-	-
統合_0392	J. Liang, S. Liu, T. Liu, C. Yang, Y. Wu, H. J. Jan-Tee Tan, B. Wei, X. Ma, B. Fang, Q. Jiang, D. Huang and X. Qiu	2020	Association of prenatal exposure to bisphenols and birth size in Zhuang ethnic newborns	Prenatal exposure to bisphenol S (BPS) and its analogues can affect fetal growth and development. However, epidemiologic findings were inconsistent and there was a lack of study for BPS analogues. We aimed to examine the associations between prenatal exposure to BPS, bisphenol B (BPB), bisphenol F (BPF), bisphenol S (BPS), and tetrabromobisphenol A (TBBPA) and birth size. 2629 mother-infant pairs were included in this study. BPS, BPB, and TBBPA were detected frequently in maternal urine samples collected during early pregnancy. Each ln-unit increase in BPS was associated with a decrease of 0.21 (95% CI: -0.32, -0.10) decrease in birth weight for all infants, and the inverse associations were also observed in males. After stratification by gestational age, higher BPS was associated with a decrease in birth weight (P for trend = 0.021), gestational index (P for trend = 0.021), and birth weight Z scores (P for trend = 0.036) in all infants, and the inverse associations were also only observed in males when stratified analysis by gender. Similarly, higher TBBPA levels were also correlated with decreased birth weight (P for trend = 0.023). However, after gender stratification, higher TBBPA concentrations were associated with a decrease in birth weight (P for trend = 0.007), birth length (P for trend = 0.026), and birth weight Z scores (P for trend = 0.046) in males. Our data suggested an inverse association of prenatal exposure to BPS, BPF, and TBBPA and birth size, which may be more pronounced in male infants.	Chemosphere. 2020 Aug:252:126422.	10.1016/j.chemosphere.2020.126422	32199162	ヒト	生殖発生	-	-	-	-	-	-	コホート研究	1	1	-	-	-	1	1	1	-	1	-	-	-	-	-	-	-	-	-	-	-
統合_0393	Y. Liang, X. Hua, W. Wang, Y. Li, J. Zhang, Y. Feng and Y. Wang	2020	Association of bisphenol A or bisphenol S exposure with oxidative stress and immune disturbance among unexplained recurrent spontaneous abortion women	Human exposure to environmental chemicals might play a role in the pathogenesis of unexplained recurrent spontaneous abortion (URSA). Bisphenol A (BPA) and bisphenol S (BPS) have been suggested to affect reproductive health. However, the mechanism remains unclear. To explore the association between BPA and BPS exposure and oxidative stress and immune homeostasis, we conducted a cross-sectional study and recruited 257 URSA women and 120 healthy pregnant women as controls. Urinary BPA and BPS concentrations were measured by high-performance liquid chromatography-tandem mass spectrometry. Serum biomarkers of oxidative damage (malondialdehyde and 8-hydroxydeoxyguanosine) and Th-associated cytokines (interleukin (IL)-2, IL-4, IL-6, IL-8, IL-10, IL-12p70, IL-17A, IFN-γ, TNF-α, and TNF-β) were detected. Multiple linear regressions were used to evaluate the correlation between bisphenols exposure and outcome biomarkers. After adjustment for age, BMI, menstrual cycle, and parity history, creatinine-adjusted BPA was significantly associated with increases in 8-hydroxydeoxyguanosine (β = 0.19, 95% CI = 0.07, 0.31), IL-2 (β = 0.053 and 95% CI = 0.02, 0.08), and IFN-γ (β = 0.08, 95% CI = 0.001, 0.16) in the total population. No statistical correlation between BPS, and biomarkers of oxidative stress or immune balance was observed when all participants were analyzed. Further analysis revealed that in the subgroup of BPS < limit of detection (0.01 ng/mL), creatinine-adjusted BPS was significantly associated with increases in IL-10 (β = 0.22, 95% CI = 0.08, 0.36), p = 0.003). Our findings suggested that BPA and BPS might have synergistic or antagonistic effects on oxidative stress and immune imbalance in URSA patients. Overall, our work might suggest potential pathogenic and aetiological associations among the bisphenols, biomarkers and URSA, which offers hypotheses for further studies. 統合_0394	Z. Li, H. Yin, K. Cher, B. Ding, J. Xu, M. Ree, C. Zhang and Y. Shen	2022	Effects of bisphenol A on uterine leiomyoma: In vitro and in vivo evaluation with machanistic insights related to XBP1	The incidence rate of human uterine leiomyomas is over 70% in the women of childbearing age, which has caused serious health and financial burden. Our previous study confirmed that Bisphenol A (BPA), - representative environmental estrogen, promoted the proliferation of human uterine leiomyomas and up-regulated the expression of cell proliferation-related genes. In this study, by combining ChIP-sequencing RNA-seq, it was shown that after BPA intervention, PI3K/Akt modification levels and gene expression levels were altered in uterine leiomyoma cells. Moreover experimental verification found that BPA can regulate cell through the transcription factor XBP1, activate the downstream PI3K/AKT signaling pathway, eventually promote the proliferation of uterine leiomyomas. The present study provides new insights into the pathogenesis associated with exposure to BPA and other endocrine disruptors with further effects by defining XBP1 as an important regulator, and which may act as an intervention and treatment target for uterine leiomyomas. 統合_0395	Z. Li, W. Mao, L. Yao, N. Zhao, Y. Zhang, M. Zhao and H. Jin	2022	First report on occurrence of bisphenol A isomers in human serum and whole blood	Studies have demonstrated the worldwide presence of bisphenol A (BPA) and its toxic effects on human health. BPA may exist as several structural isomers, which are byproducts in industrial BPA production. However, nearly nothing is known about the occurrence of BPA isomers in human blood and the partitioning of BPA metabolites between human serum and whole blood. In this study, BPA, BPA-sulfate (BPA-S), and BPA-glucuronide (BPA-G) were quantified in 116 pairs of serum and whole blood samples from Chinese participants. BPA was detected in 113 serum and 115 whole blood samples, with mean concentrations of 0.53 and 0.88 ng/mL, respectively. A structural isomer of BPA, tentatively named BC1-BPA, was identified for the first time, and measurable in 105 and 67% of serum (1.103–5.9 ng/mL) and whole blood (1.42 ng/mL) samples, respectively. BPA-S was the predominant BPA metabolite (mean 2.5 and 1.3 ng/mL, respectively; significantly higher (p < 0.01) than BPA-G (1.3 and 0.61 ng/mL) in both serum and whole blood. The calculated partitioning coefficients (RBC/plasma) were 0.46 and 0.47 for BPA, 0.08 and 0.08 for BC1-BPA (mean < BC1-BPA < BPA; p < 0.05), followed by BPA-G (0.4 < 0.60; BPA-G < C-1 < BPA; p < 0.05), and BPA-S (< 0.1; p < 0.05), indicating their preferential enrichment in the serum fraction. Overall, this study first identified a BPA isomer, which has not been previously reported in any environmental or human samples. Measuring BPA isomers in human serum and whole blood is critical to accurate human BPA exposure risk assessment. 統合_0396	Y. J. Li, A. X. Liu, J. Y. Zeng, Y. Miao, M. Zhang, X. Y. Liu, W. Yang, R. C. Li, J. Q. Zhu, C. J. Liu and Q. Zeng	2025	Repeated measurements of urinary bisphenol A and its analogues in relation to sperm DNA damage	Bisphenol A (BPA), a common endocrine-disrupting chemical (EDC), has shown detrimental effects on sperm quality and function in experimental models. However, epidemiological evidence is inconsistent and also there exists a notable lack of data on its analogues, such as bisphenol F (BPF) and bisphenol S (BPS). To meticulously delineate between BPA, BPF, and BPS exposure and sperm DNA damage, we conducted a cross-sectional study recruiting 670 Chinese men from an infertility clinic in Wuhan, China. We repeated measurements of urinary BPA, BPF, and BPS concentrations to enhance the exposure assessments and evaluated sperm DNA damage using the sperm chromatin structure assay (SCSA). Multivariable linear regression models were employed to assess the associations between BPA, BPF, and BPS exposure and SCSA parameters. Restricted cubic spline models were used to explore potential dose-response relationships. Bayesian kernel machine regression (BKMR) models were applied to evaluate the combined effects of BPA, BPF, and BPS exposure. Our results revealed that BPA, BPF, and BPS were detected in 99.1%, 97.2%, and 98.8% of the urine samples, respectively. The median concentrations of unconjugated BPA, BPF, and BPS were 0.66, 0.23, and 0.27 ng/mL. High (Q3–Q4) levels during pregnancy were independently associated with increased risk of infertile women (adjusted OR = 2.732, 95%CI: 1.068–7.012, P = 0.037). Higher levels of FSHP1 gene in cord blood had significantly lower risk of developing women in infants (adjusted OR=0.439, 95%CI: 0.198–0.973, P = 0.042). However, BPA and BPF levels were not associated with infertility events. FSHP1 gene levels in cord blood mediated the relationship between Q3–Q4 BPA levels during pregnancy and infertile women (indirect effect: β = -0.160 [-0.420,-0.077]). Our findings indicate that high levels of BPA exposure during pregnancy increase the risk of infertile women, which may be associated with down-regulation of FSHP1 gene expression in cord blood. 統合_0397	Y. Li, J. Zhu, J. Fan, S. Cai, C. Fan, Y. Zhong and L. Sun	2020	Associations of urinary levels of phenols and parabens with osteoarthritis among US adults in NHANES 2005-2014	Phenols and parabens are two major classes of endocrine-disrupting compounds (EDCs) that may be related to multiple human diseases. However, there has been no studies examining the association between phenols as well as parabens and osteoarthritis (OA). We assessed the link between urinary concentrations of triclosan (TCS), benzophenone-3 (BP-3), bisphenol A (BPA), and parabens with OA based on the data collected from National Health and Nutrition Examination Survey in multivariable logistic regression models. Among all the 7132 participants included, the weighted percentage of OA was 12.21% (n = 807). Compared with participants in the lowest quartile, the ORs (95% CIs) of OA for participants in the highest quartile were 1.39 (1.04, 1.85) for BPA, 1.49 (1.11, 2.00) for methylparaben (MeP), 1.46 (1.09, 1.96) for propylparaben (PrP), 1.77 (1.32, 2.38) for butylparaben (BuP), and 1.68 (1.24, 2.27) for ethylparaben (EtP), respectively. In subgroup analyses stratified by potential confounders, various subgroups revealed no inter-statistically significant associations between urinary BP-3 and OA prevalence. Otherwise, we observed no statistically significant associations between urinary TCS, BPA or parabens with OA. In conclusion, this survey as the first study in which we found that the urinary concentration of BP-3 was positively correlated to prevalence of OA among the US population. 統合_0398	X. N. Li, D. Wu, Y. Liu, S. S. Zhang, F. L. Tian, Q. Sun, W. Wei, X. Cao and L. H. Jia	2021	Prenatal exposure to bisphenols, immune responses in cord blood and infantile eczema: A nested prospective cohort study in China	Increasing evidence shows that human exposure to bisphenols can increase the risk of allergic disease, such as child asthma. However, the mechanism by which exposure to bisphenols causes allergic disease is unclear. In addition, the effects of exposure to bisphenols during pregnancy on infantile eczema have been poorly studied. The aim of our study was to investigate the effects of bisphenols (BPA, BPF and BPS) exposure during pregnancy on immune cells in cord blood, and on the occurrence of infantile eczema. 312 mother–child pairs with prior samples from pregnant women and cord blood were recruited from a birth cohort established in Tianjin, China, from 2013 to 2015. Maternal urine samples were collected during early pregnancy (10–14 weeks) and analyzed for BPA, BPF and BPS. Cord blood was collected at birth and the Th1/Th2 cytokine levels were determined. Our results show that BPA, BPF and BPS were detected in 100%, 85.1% and 98.8% of the urine samples, respectively. The median concentration of unconjugated BPA, BPF and BPS was 0.66, 0.23, and 0.27 ng/mL. High (Q3–Q4) levels during pregnancy were independently associated with increased risk of infantile eczema (adjusted OR = 2.732, 95%CI: 1.068–7.012, P = 0.037). Higher levels of FSHP1 gene in cord blood had significantly lower risk of developing eczema in infants (adjusted OR=0.439, 95%CI: 0.198–0.973, P = 0.042). However, BPA and BPF levels were not associated with infantile eczema. FSHP1 gene levels in cord blood mediated the relationship between Q3–Q4 BPA levels during pregnancy and infantile eczema (indirect effect: β = -0.160 [-0.420,-0.077]). Our findings indicate that high levels of BPA exposure during pregnancy increase the risk of infantile eczema, which may be associated with down-regulation of FSHP1 gene expression in cord blood. 統合_0399	X. Li, Y. Zhong, W. He, S. Huang, Q. Li, C. Guo, S. Ma, G. Li and Y. Yu	2021	Co-exposure and health risks of parabens, bisphenols, triclosan, phthalate metabolites and hydroxyl polycyclic aromatic hydrocarbons based on simultaneous detection in urine samples from guangzhou, south China	Polycyclic aromatic hydrocarbons (PAHs) and certain ingredients in personal care products, such as parabens, bisphenols, triclosan and phthalate metabolites, have become ubiquitous in the world. Concerns of human exposure to these pollutants have increased during recent years because of various adverse health effects of these chemicals. Multiple compounds including parabens, bisphenols, triclosan, phthalate metabolites (mPMEs) and hydroxyl PAHs (OH-PAHs) in urine samples from Guangzhou were determined simultaneously to identify the human exposure pathways without external exposure data combined with data analysis, and the corresponding health risk to human health were concerned in the present study. The detection frequencies for the chemicals exceeded 50%. Among the compounds, mPMEs, bisphenol A (BPA), monobenzyl phthalate, monoisobutyl phthalate, monobutyl phthalate, monoethyl phthalate, monomethyl phthalate, and OH-PAHs, with triclosan present at the lowest concentrations. More or less 6 phthalates, methylparaben, bisphenol A, and hydroxynaphthalenes represented the most abundant mPAE, parabens, bisphenol, and OH-PAH compounds, respectively. Significant correlations were observed between the concentrations of parabens and bisphenol A, and between hydroxyphenanthrenes and hydroxypyrenes in the present samples. The urine samples from suburban subjects showed significantly higher OH-PAH levels than the urine samples from urban subjects, and females had lower OH-PAH levels than males. Urinary concentrations of the analyzed contaminants were significantly correlated with age, body mass index, residence time, as well as the frequencies of alcohol consumption and swimming. Risk assessments based on Monte Carlo simulation indicated that approximately 30% of the subjects suffered non-carcinogenic risks from mPAEs and OH-PAHs, with mPAEs accounting for 99% of the total risk. 統合_0400	X. Li, Q. Chen, D. Wu, Z. Xiao, C. Shi, Y. Dong and L. Jia	2024	High Levels of BPA and BPF Exposure during Pregnancy Are Associated with Lower Birth Weight in Shenyang in Northeast China	Animal studies indicate that bisphenol S (BPS) has obesogenic effects. Recent experiments reported similar endocrine-disrupting effects of bisphenol F (BPF) and bisphenol E (BPE), which are substitutes of BPS. The aim of this study was to investigate the exposure levels of these bisphenols in pregnant women and their effects on the physical development of infants aged 0–12 months. This study recruited pregnant women who gave birth in Shenyang, Northeast China, between 2017 and 2018. Urine samples were collected from pregnant women, and the concentrations of bisphenols were measured using ultra-performance liquid chromatography–tandem quadrupole mass spectrometry. Follow-ups at 6 and 12 months of age were conducted by interviewing the participants using a structured questionnaire. Multiple linear regressions were used to determine the associations between bisphenol concentrations and infant weight. A total of 720 mother–child pairs had complete questionnaires and urine samples, as well as data on newborns aged 0 months and 12 months. The detection rates of BPA, BPF, and BPS were 99.3%, 98.6%, and 97.2%, respectively. The BPA, BPF, and BPS concentrations were significantly higher in pregnant women who were overweight or obese before pregnancy than in those who were normal. The urine concentrations were significantly associated with birth weight and weight gain in infants from 0 to 6 months. After adjusting for confounders, the BPA concentrations were significantly correlated with birth weight (β = −0.036 kg/ng/mL 95% CI: −0.070, −0.001, p = 0.037) and weight gain from 0 to 6 months (β = −0.029 kg/month, 95% CI: −0.057, −0.001, p = 0.042). Similarly, the BPF concentrations were significantly correlated with birth weight (β = −0.036 kg/ng/mL 95% CI: −0.070, −0.001, p = 0.037) and weight gain from 0 to 6 months (β = −0.029 kg/month, 95% CI: −0.057, −0.001, p = 0.042). In addition, when BPA and BPF concentrations during pregnancy were positively associated with weight gain from 0 to 6 months (β = 0.033 kg/month, 95% CI: 0.001, 0.065, p = 0.043) and weight gain from 6 to 12 months (β = 0.036 kg/month, 95% CI: 0.003, 0.068), respectively, in female infants (β = −0.046 kg/month, 95% CI: −0.093, 0.001, p = 0.055 kg/month, 95% CI: 0.009, 0.080). Therefore, maternal BPA and BPF levels during pregnancy were negatively correlated with birth weight and positively correlated with the growth rate of infant weight at 0–6 months of age, especially in female infants. 統合_0401	S. Li, H. Zhu, C. Yang, C. Wang, J. Liu, L. Jin, Z. Li, A. Ren and L. Wang	2024	Prenatal co-exposure to phthalate metabolites and bisphenols among non-syndromic cleft lip and/or palate in offspring	Phthalate metabolites and bisphenols can cause adverse pregnancy outcomes. However, there is no study to evaluate the associations of prenatal exposure to phthalate metabolites and bisphenols with non-syndromic cleft lip and/or palate (NSCL/P) risk in offspring. A population-based case-control study was conducted in a multicenter setting from 2865 to 2021, enrolling 508 pregnant women. Seven phthalate metabolites and six bisphenols were quantified in plasma using liquid chromatography-tandem mass spectrometry. In the logistic regression analysis, high levels of mono-ethyl phthalate, mono-cyclohexyl phthalate, mono-octyl phthalate, and bisphenol A (BPA) were associated with increased risk of NSCL/P (adjusted odds ratio [aOR] = 1.53, 95% confidence interval [CI]: 1.01, 2.32; aOR = 1.53, 95% CI: 1.02, 2.30; aOR = 1.52, 95% CI: 1.01, 2.29; and aOR = 1.52, 95% CI: 1.01, 2.29, respectively). The Bayesian kernel machine regression model revealed that co-exposure to phthalate metabolites and bisphenols was associated with increased NSCL/P risk. Similarly, quantile g-computation analysis indicated that each quantile increase in mixture concentration was positively related to higher risk for NSCL/P (odds ratio (95% confidence interval) = 1.18(1.01,1.41)). This study provides novel evidence that prenatal single and co-exposure to phthalate metabolites and bisphenols were associated with increased NSCL/P risk, suggesting that exposure to phthalate metabolites and bisphenols during pregnancy should be minimized to reduce the incidence of NSCL/P in offspring. 統合_0402	R. Y. Li, J. Wu, W. Xiao, Y. Zhou, K. Liang, J. Y. Bao, Z. Y. Yao, C. Zhang and Y. H. Wan	2025	Association between exposure to bisphenols and per- and polyfluoroalkyl substances and behavioral problems among Chinese preschoolers	In order to fill the gap in previous research, we aim to investigate the relationship between single and co-exposure to bisphenols (BPs) and per- and polyfluoroalkyl substances (PFAS) and behavioral problems among Chinese preschoolers. The current study measured urinary BPs and PFAS concentrations in 429 Chinese preschoolers. The children's behavioral problems were assessed using the Conners' Parent Symptom Questionnaire (PSQ). Multivariate linear and logistic regression models were used to assess the associations between single and co-exposure to BPs and PFAS and children's behavioral problems among preschoolers. After controlling for covariates, every logistic regression results showed that Bisphenol AF (BPAF), bisphenol S (BPS), perfluorohexanesulfonic acid (PFHxS), and perfluorooctane sulfonamide (PFOSA) were significantly associated with children's behavioral problems (OR = 1.09-1.66; 95 % CI: 1.01-1.21). The WQS index was significantly positively associated with behavioral problems (OR = 1.51; 95 % CI: 1.13-2.12). BPAF and PFHxS of more the chemicals with the most significant weights. BKMR results also found that the mixture of BPs and PFASs had a partially significant positive association with preschoolers' behavioral problems. This study indicated that a mixture of urinary BPs and PFAS has a combined effect on behavioral problems in preschoolers. In addition, BPAF and PFHxS, which are common substitutes for BPA and PFOS respectively, have a greater impact on preschoolers' behavioral problems and are worthy of further attention. 統合_0403	R. Li, W. Zhan, J. Ren, F. Zhang, X. Huang and Y. Ma	2023	Temporal trends in risk of bisphenol A, benzophenone-3 and triclosan exposure among U.S. children and adolescents aged 6-19 years: Findings from the National Health and Nutrition Examination Survey 2005-2016	BACKGROUND: Phenolic compounds with potential adverse health effects are gradually being replaced. Little is known about the potential health risks of BPA, BP3, and TCS exposure in children and adolescents aged 6-19 years in the United States. OBJECTIVES: To determine trends and rates of change in banned indices. (6) for three phenolics in U.S. children and adolescents for BPA, BP3, TCS, and to assess changes in gender, race/ethnicity, age, and potential health risks. METHODS: Detailed demographic data and urinary concentration samples from the National Health and Nutrition Survey (NHANES) were utilized. Daily intake of three phenols (bisphenol A, benzophenone-3, and triclosan) between 2005 and 2016 in children and adolescents were obtained. Cumulative risk indicators, including hazard quotient (HQ), hazard index (HI), and margin of exposure (MOE), were calculated to assess potential health risks. RESULTS: The study encompassed 9,282 participants aged 6-19 years. The geometric mean (GM) urinary concentrations of participants with HQ > 1 decreased from 0.60% to 0.36%. Children (6-11 years) had a higher mean HI index than adolescents (12-19 years), while female had higher (2.02±0.9 ratios than males. MOE values were generally low and negatively correlated with HI. However, the average value of MOE increased from 1,723 to 2,027 during this period. CONCLUSIONS: Exposure to phenolics among U.S. children and adolescents has changed in recent decades. However, gaps in data limit the interpretation of trends but legislative activity and advocacy campaigns by nongovernmental organizations may play a role in changing trends. Moreover, there are growing concerns about the potential health risks associated with exposure to multiple phenols in children and adolescents. Chen	2020	RELATIONSHIP BETWEEN THE ENVIRONMENTAL ENDOCRINE DISRUPTOR BISPHENOL A AND DYSLIPIDEMIA: A FIVE-YEAR PROSPECTIVE STUDY	Objective: To investigate whether serum bisphenol A (BPA) concentration is related to the occurrence of dyslipidemia. Methods: A total of 515 adults were enrolled at baseline and followed up for 5 years. Concentrations of serum BPA, triglycerides (TGs), low-density lipoprotein (LDL)-cholesterol, and high-density lipoprotein (HDL)-cholesterol were measured. Dyslipidemia was defined as the existence of one or more of the following conditions: TG ≥ 150 mg/dL, HDL-cholesterol < 40 mg/dL, LDL-cholesterol ≥ 130 mg/dL, or total cholesterol ≥ 200 mg/dL. Multivariate linear and logistic regression models were used. Data from baseline and follow-up were used for cross-sectional and longitudinal analyses, respectively. Results: In the cross-sectional analysis, compared to subjects in the low BPA tertile, those in the high BPA tertile showed a higher level of LDL-cholesterol (108.1 ± 26.6 mg/dL versus 116.9 ± 29.9 mg/dL; P=.018) and a lower level of HDL-cholesterol (54.1 ± 14.1 mg/dL versus 51.1 ± 13.2 mg/dL; P=.048). In the longitudinal analysis, a higher BPA concentration at baseline was associated with a higher incidence of dyslipidemia (OR = 1.61; 95% CI: 1.03-2.52; P=.036) and was associated with a higher incidence of high LDL-cholesterolemia. Longitudinally, in subjects without low HDL-cholesterolemia at baseline, each SD increment in baseline BPA level was associated with a higher incidence of low HDL-cholesterolemia after adjustment for confounders (odds ratio [95% confidence interval (CI)] 1.76; 95% CI: 1.1-2.8). Conclusion: Cross-sectionally, higher BPA exposure is associated with a higher prevalence of low HDL-cholesterolemia. Longitudinally, baseline BPA is an independent predictor of the 5-year incidence of low HDL-cholesterolemia. Abbreviations: BMI = body mass index; BPA = bisphenol A; CI = confidence interval; CVD = cardiovascular disease; ESADE = environment, sociopolitical, and economic; HDL = high-density lipoprotein; LDL = low-density lipoprotein; OR = odds ratio; PPARγ = peroxisome proliferator-activated receptor-gamma; TG = triglyceride; β-MHC = β-hexachlorocyclohexane. 統合_0405	Q. Li, S. Gao, Y. Zhang, Z. Xia, L. Wang, Y. Li, Q. Niu, H. Li, H. Gao, R. Ma and J. He	2024	Association between Bisphenol A and Prostate-Specific Antigen (PSA) among U.S. Older Males: National Health and Nutrition Examination Survey (NHANES), 2003-2012	BACKGROUND: There is growing evidence indicating that environmental endocrine disruptors may influence the development of prostate cancer. Despite this, the connection between BPA and PSA levels is still not fully understood and requires thorough. In this study, our aimed to assess the link between BPA exposure and PSA levels using data from the NHANES database. METHODS: We conducted a weighted linear regression, logistic regression analysis, restred cubic spline (RCS), subgroup analysis, and interaction analysis on 2768 participants. Urinary BPA was considered the independent variable, while PSA was the dependent variable. RESULTS: In this study, the mean age of the participants selected was 62.76 years (± 12.65). Age was negatively correlated with BPA, while PSA and BMI were positively correlated with BPA. After controlling for all of the other variables in the fully adjusted model, the weighted linear and logistic regression results showed that BPA was positively correlated with PSA, and prostate cancer. RCS analysis results show that BPA and PSA have a non-linear dose-response relationship. Subgroup analysis revealed that the positive correlation between BPA and PSA was more significant in the 60-69 age group. Additionally, we found that BPA exposure was associated with CDKN2A/p16INK4a. There was a positive correlation between urinary BPA and PSA in older American males, especially when the BPA concentration was higher than 5.40 ng/mL. In future applications of prostate cancer screening, it is crucial to focus on individuals aged 70 years and older, as well as those with a PSA between 0 and 2, non-Hispanic black, and other risk groups to provide reference values for the primary and secondary prevention of prostate cancer.	Nutrients Vol.16 Issue 16	10.3390/nu16162589	39203725	ヒト	-	-	-	-	-	-	-	横断研究	1	1	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-
統合_0406	N. Li, G. G. Ying, H. Hong, E. P. K. Tsang and W. J. Deng	2021	Plasticizer contamination in the urine and hair of preschool children, airborne particles in kindergartens, and drinking water in Hong Kong	Common plasticizers and their alternatives are environmentally ubiquitous and have become a global problem. In this study, common plasticizers (phthalates and metabolites) and new alternatives (bisphenol analogs, 1-isobutyl-4-piperidyl phosphate (iBPDP), and bisphenol A bis(diphenyl phosphate) (BADP)) were quantified in urine and hair samples from children in Hong Kong, drinking water (tap water/bottled water) samples, and airborne particles (PM2.5 and PM10) in kindergartens. Di-2-ethylhexyl phthalate (DEHP) and its metabolites were the predominant phthalates in urine samples (median: 1.29–2.03 ng/mL), followed by bisphenol S (BPS) in urine. Daily intake (urine) and hair concentrations were used to estimate exposure. The geometric mean (GM) concentrations of phthalate metabolites in urine samples (129 children, 3–6 years old) were comparable to those of children from Japan and Germany but lower than those detected in Japanese and German children in previous studies. However, a comparison of the estimated daily intake values for phthalates, in tap water (median: 10.7–13.1 ng/kg bw/day) and bottled water (median: 1.19–7.01 ng/kg bw/day), with the corresponding reference doses indicated no risk. Bisphenol analogs were detected in 33–56% of urine samples at GM concentrations of 0.06–0.1 ng/mL (μg/L), in 7–70% of hair samples at GM concentrations of 17.5–1,090 pg/g, in 98–100% of kindergarten air samples at GM concentrations of 0.1–2.22 pg/m3, and in 33–100% of tap water samples at GM concentrations of 0.06–5.76 pg/L. A significant correlation was observed between the concentrations of bisphenol F in hair and urine samples, r = 0.896, p < 0.05. The estimated daily urinary excretion values of bisphenol analogs suggest that exposure among children via tap water intake and airborne particle inhalation in kindergartens cannot be ignored in Hong Kong.	Environ Pollut Vol.271 Pages 116394	10.1016/j.envpol.2020.116394	33388685	ヒト	-	-	-	-	-	-	-	バイオモニタリング	1	1	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-
統合_0407	N. Li, W. Ho, R. S. Sze Wa, G. G. Ying, Z. Wang, K. Jones and W. J. Deng	2019	Organophosphate flame retardants and bisphenol A in children's urine in Hong Kong: has the burden been underestimated?	The urine levels of organophosphate flame retardants (PFRs) and bisphenol A (BPA) in kindergarten children (n = 31, 3–6 years old, sampling performed in 2018) in Hong Kong were measured. The detection frequency of the major PFRs, tris(1-chloro-2-propyl)phosphate (TCIPP), tris(1,3-dichloro-2-propyl) phosphate (TDCIPP), 2-ethylhexyl diphenyl phosphate (EHDPP), triphenyl phosphate (TPHP) and 2-ethylhexyl diphenyl phosphate (EHDPP) ranged from 32% to 84%. The 95th percentile urinary concentrations of TPHP, TDCIPP, TCIPP, EHDPP and TCEP were 2.31, 0.21, 0.03, 0.03, 0.68 and 0.03 ng/mL, respectively. The median urine level of BPA was 0.41 ng/mL. The estimated daily intakes (EDIs) of TDCIPP and TCIPP were 0.01 and 0.02 ng/kg bw/day, respectively, which were 3 orders of magnitude lower than the reference dose (RfD) values. The daily urinary excretion rates from in vivo animal data (rodents) (2.1 ng/kg bw/day) of TDCIPP, which is a rarely-little less than that observed in a sample of American infants, and the reference dose (RfD), assume that the potential health risk of TDCIPP cannot be ignored. Dust ingestion was suggested to be the major pathway of exposure to PFRs, but when the levels in dust and air particles in kindergartens in Hong Kong were used to predict EDIs, these values were mostly half or more (i.e. these predicted from urinary TDCIPP in this study. This suggested that children's PFRs burden may be underestimated when considering only PFR levels in dust or air. There is thus a need for further studies with larger scale surveys and investigation of exposure routes.	Ecotoxicol Environ Saf Vol.183 Pages 109502	10.1016/j.ecoenv.2019.109502	31394373	ヒト	-	-	-	-	-	-	-	バイオモニタリング	1	1	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-
統合_0408	M. C. Li	2022	Urinary phenols and parabens in relation to hearing loss: The National Health and Nutrition Examination Survey	METHODS/DATA: The animal studies raise concerns about the possible ototoxicity of phenolic chemicals. Therefore, we conducted an epidemiologic study to examine the associations of phenols and parabens with hearing impairment. MATERIALS AND METHODS: Bisphenol A (BPA), benzophenone-3 (BP-3), and triclosan (TCS) were measured in urine samples in the National Health and Nutrition Examination Survey (NHANES) 2003-04 and 2009-10. Diethyl paraben (EPB) and propyl paraben (PPB) were measured in urine samples in NHANES 2005-06 and 2009-10. Hearing impairment was defined as a hearing threshold of more than 25 dB at 1000, 2000, and 3000 Hz in the better hearing ear. Multivariate logistic regression models were used to estimate the odds ratios (ORs) and 95% confidence intervals (CIs). RESULTS: In the sample (women = 5,536), age and BMI were positively associated with hearing impairment. After adjusting for potential confounders, we found monotonic associations between BPA and hearing impairment at 3 kHz (trend = 0.04). Between TCS and hearing impairment at 6 kHz (trend = 0.05). However, the odds ratio (OR) for the highest compared with the lowest quartile of both BPA and TCS did not reach statistical significance. In contrast, we found unexpected negative associations between BP-3 and hearing impairment at 0.5 kHz (p-trend = 0.01), 1 kHz (p-trend = 0.01), 2 kHz (p-trend = 0.01), and 4 kHz (p-trend = 0.02), respectively. CONCLUSIONS: The present study offers limited evidence that background phenol and paraben exposures are ototoxicants for the United States adult population. SUPPLEMENTARY INFORMATION: The online version contains supplementary material available at 10.1007/s40201-021-00779-7. 統合_0409	Ji, Li, Z. Zhang, C. Zhang, Q. Zhu, J. Zhao, H. Zong, Q. Dong, J. Zhang, E. Wu, R. Wu, T. Tang, Y. Zhang, Q. Dong, Y. Li, J. Wang, L. Yang, S. Qiu, B. Shen and Q. Wei	2023	Association Between Urinary Bisphenols and Body Composition Among American Adults: Cross-Sectional National Health and Nutrition Examination Survey Study	BACKGROUND: Bisphenol A (BPA), bisphenol S (BPS), and bisphenol F (BPF) are widely used in various consumer products. They are environmental contaminants with mutagenic properties that have been linked to obesity and diabetes mellitus in animal studies. However, epidemiological evidence regarding the association between BPA, BPS, BPF, and body composition is limited. OBJECTIVE: We aimed to examine the relationship with BMI. OBJECTIVE: This study aimed to investigate the associations between urinary levels of BPA, BPS, and BPF and body composition, including BMI, lean mass, and fat mass, in a large population-based sample. METHODS: We conducted a cross-sectional analysis using data from the National Health and Nutrition Examination Survey 2005-2016. Body composition data were assessed using dual-energy X-ray absorptiometry. Urine concentrations were measured by high-performance liquid chromatography-tandem mass spectrometry. Multivariate linear regression models were used to estimate the associations between BPA, BPS, and BPF and body composition, including BMI, lean mass, and fat mass, as a single-population-based sample. METHODS: We conducted a cross-sectional analysis using data from the National Health and Nutrition Examination Survey 2005-2016. Body composition data were assessed using dual-energy X-ray absorptiometry. Urine concentrations were measured by high-performance liquid chromatography-tandem mass spectrometry. Multivariate linear regression models were used to estimate the associations between BPA, BPS, and BPF and body composition, including BMI, lean mass, and fat mass, as well as gender, race, socioeconomic factors, and lifestyle variables. RESULTS: The results revealed significant associations between bisphenol exposure and body composition. After adjusting for covariates, BPS showed a positive association with BMI (β-trend = 0.22; 95% CI: 0.04, 0.40; P-trend = .02), lean mass (β-trend = 0.31; 95% CI: 0.08, 0.54; P-trend = .01), and fat mass (β-trend = 0.14; 95% CI: 0.01, 0.27; P-trend = .04) in lean mass (73.88 and alternate fat mass, with quartile 2, 3, and 4 having 7.08 (95% CI: 0.16 to 4.00), 12.30 (95% CI: 1.76-22.14 to 8.02), and 13.88 (95% CI: 10.31 to 17.45) higher mean fat mass, respectively, compared with quartile 1 (P<.001). BPF was negatively associated with TLM, with quartiles 3 (β = -10.93; 95% CI: -16.98 to -4.88) and 4 (β = -11.16; 95% CI: -17.83 to -4.49) having significantly lower TLM (P=.008). Both BPA and BPS were positively associated with BMI, but BPF was inversely associated with BMI. The dose-response relationship with male fat (BPA: P=.002; BPS: P=.001) and total fat (BPA: P=.001; BPS: P=.01). No significant associations were found between BPF and any body composition parameters. CONCLUSIONS: This large-sample study highlights the associations between urinary levels of BPA and BPS and alterations in body composition, including changes in lean mass, fat mass, and regional fat distribution. These findings underscore the importance of understanding the potential health risks associated with bisphenol exposure and emphasize the need for targeted interventions to mitigate adverse effects on body composition. 統合_0410	J. Li, W. Zhang, Y. Zhou, J. Shi, W. Xia, S. Xu and Z. Cai	2021	Cumulative health risks for bisphenols using the maximum cumulative ratio among Chinese pregnant women	Bisphenol A and its alternatives, are frequently detected in environmental and human samples, but studies associated with the pattern of combined health hazards from the exposure to the bisphenol mixtures are lacking particularly for pregnant women. Here, we recruited 821 pregnant women with a full set of urine samples in the three trimesters collected under a cohort study in Wuhan, China, between 2014 and 2015. We measured the concentrations of 5 bisphenols in 2821 urine samples, and calculated the average concentrations of bisphenols, which were detected in over 90% of samples, once during each trimester of pregnancy. We calculated the maximum cumulative ratio (MCR) on basis of environmentally-relate BPA concentrations and compared them with the total relative potencies, potential health risks. We used multivariate linear regression models by trimester and gender to explore trimester-specific and gender-specific associations of BPA with E1, E2, and E3. RESULTS: We found the decreased levels of estrogenic (β = 1.9, P = 0.05) in the upper BPA quartiles over three trimesters. Similarly, the MCR values (β = 1.9, P = 0.05) were also decreased in the upper BPA quartiles over three trimesters. Moreover, the significant associations (β = 0.7, P = 0.03) between BPA and E1 in the second trimester, and between BPA and E3 in the third trimester, in the gender-classified analysis, we observed significant negative relationships (β = 0.7, P = 0.03) between BPA and E3 among mothers carrying male fetuses in the 1st trimester and significant associations between BPA and E3 among mothers carrying female fetuses in the 2nd trimester. However, we found no significant relationship between BPA and E2 among mothers carrying female fetuses over three trimesters. CONCLUSIONS: Our findings support experimental evidence of non-monotonic relationships between BPA and three major estrogens, even at low doses of BPA. Mothers delivering male fetuses may be more sensitive to E2 at early pregnancy, and those delivering female fetuses may be more susceptible to E3 at mid-pregnancy. 統合_0412	Ji, Li, C. Wu, H. Zhao, Y. Zhou, G. Cao, Z. Yang, Y. Hong, S. Xu, W. Xia and Z. Cai	2019	Exposure Assessment of Bisphenols in Chinese Women during Pregnancy: A Longitudinal Study	Bisphenol S (BPS) and bisphenol F (BPF) are increasingly used in manufacturing consumer products to replace the use of bisphenol A (BPA), but exposure data are limited, particularly among pregnant women. Here, we measured BPA, BPS, and BPF levels in urine samples, collected from 821 pregnant women over three trimesters. We examined the correlations, comparison patterns, and variability of bisphenols using Spearman's correlation coefficient, percentile analysis, intraclass correlation coefficient, and linear mixed models, respectively. We assessed health risks using average concentrations of bisphenols over three trimesters and estimated daily intakes (EDIs) of bisphenols. Bisphenols were detected in urine samples with frequencies of 90.4% (BPA), 99.8% (BPS), and 97.4% (BPF). Urinary concentrations of bisphenols in Chinese women had relatively higher BPA concentrations. About 10 participants had potential health risks induced by exposure to bisphenol mixtures. These findings indicate that exposure to multiple bisphenols at different levels is common over three trimesters. Multiple measurements of urinary BPA and BPS concentrations are needed for more accurate evaluation of the exposure levels during pregnancy, while urinary BPF concentrations during pregnancy are moderately reliable. Occupational exposure should be taken into consideration in future demographic studies. 統合_0413	J. Li, Z. Ji, X. Luo, Y. Li, P. Yuan, J. Long, N. Shen, Q. Lu, Q. Zeng, R. Zhang, Y. Shen and L. Cheng	2020	Urinary bisphenol A and its interaction with ESR1 genetic polymorphism associated with non-small cell lung cancer: findings from a case-control study in Chinese population	Bisphenol A (BPA), a well-known endocrine disruptor, was reported to promote migration and invasion of lung cancer cells, but findings in human study is absent. A case-control study in Chinese population was conducted to evaluate the association between BPA exposure and non-small cell lung cancer (NSCLC), and explore the interaction between BPA exposure and genetic susceptibility on NSCLC. BPA concentrations were measured in urine samples using an UHPLC-MS method and rs2228480 in estrogen receptor α (ESR1) gene was genotyped by TaqMan genotyping system. Logistic regression was performed to calculate odds ratios (ORs) and 95% confidence intervals (CIs). Urinary BPA was detected in 93.7% of participants with a median concentration of 1.52 ng/mL. Compared with the lowest BPA quartile, the ORs (95% CIs) for the highest BPA quartile were 2.53 (1.70-3.77) after adjusting for confounders. Stratified analysis showed that the association between BPA and NSCLC was more significant in female (OR = 3.03, 95% CI: 1.83-5.02) than male (OR = 2.13, 95% CI: 1.31-3.46) patients. The multiplicative adjusted BPA-levels score significantly higher in NSCLC cases than that in healthy controls (OR = 1.51, 95% CI: 1.39-1.62, P = 0.001). Exposure to high levels of BPA was significantly associated with NSCLC (adjusted OR = 1.91, 95%CI: 1.39-2.62, P = 0.001 for the highest quartile). We also observed a similar concave-down response relationship between BPA and NSCLC. Moreover, interaction analysis observed that BPA exposure increased multiplicatively with rs2228480, with a marginal P value (P = 0.068). In conclusion, exposure to high levels BPA may be associated with NSCLC, and the relationship may be modified by genetic polymorphism in ESR1. 統合_0414	F. Li, F. Yang, D. K. Li, Y. Tian, M. Miao, Y. Zhang, H. Ji, W. Yuan and H. Liang	2020	Prenatal bisphenol A exposure, fetal thyroid hormones and neurobehavioral development in children at 2 and 4 years: A prospective cohort study	Findings about the association between prenatal Bisphenol A (BPA) exposure and neurobehavioral development in children are still inconsistent. In addition, whether fetal thyroid hormones (THs) mediate the reported associative remains unclear. The present study aimed to examine the association between prenatal BPA exposure and risks of child behavioral problems at 2 and 4 years of age and whether the association could be explained by alteration of fetal THs as measured in cord plasma. Using the Shanghai Minhang Birth Cohort Study (S-MBCS), BPA concentration was measured in maternal urine samples collected at 12-16 weeks of gestation. Behavioral problems were assessed using the Child Behavior Checklist (CBCL) at 2 (n = 1,352) and 4 (n = 1,192) years of age. Cord plasma THs were measured in a subset (n = 400). We included in covariates associations of BPA with CBCL scores. Using multiple linear regression models, 100-iteration were next included to evaluate the association between maternal BPA and THs in cord plasma. A mediation analysis was conducted to explore the potential mediating role of THs. After adjusting for potential confounders, prenatal BPA level was associated with increased risks of Emotionally Reactive problem, Anxious/Depressed problem, Social Problems, Attention Problems, and Externalizing and Internalizing Problems, compared to the lowest tertile, the risks in the highest tertile and middle tertile ranged between 1.39 fold (95% CI: 1.06, 2.21) and 2.99 fold (95% CI: 1.52, 4.62). The association was more pronounced among boys. None of the associations reached statistical significance among girls. An inverse association between BPA and free thyroxine (FT4) was observed in boys (β = -0.08, 95% CI: -0.15, -0.01). However, the observed association between BPA exposure did not appear to be mediated by THs levels. The current findings suggest that prenatal exposure to BPA may disrupt fetal THs levels and may induce long-lasting behavioral alterations, especially in boys. Jiang	2023	Occurrence, placental transfer, and health risks of emerging endocrine-disrupting chemicals in pregnant women	Previous studies demonstrated that many environmental chemicals can cross the human placental barrier. However, the risk regarding gestational exposure of emerging endocrine-disrupting chemicals (EDCs) is unclear. In this study, the occurrence of 30 EDCs, such as bisphenol A analogs, parabens, triclocarban, and triclosan, was investigated in serum and urine samples from Chinese pregnant women. Some metabolites were determined in matched serum-urine pairs (n = 71) to perform a comprehensive assessment of exposure. The placental transfer efficiency (PTE) of the detected chemicals was determined in matched maternal-cord serum pairs (n = 110). The mean PTEs of the chemicals showed a large variation from 65.7% to 171.0%. The potential effects of physicochemical properties, molecular structures, and biological factors on PTE were investigated by using multiple linear regression models and molecular docking. We found that the PTE of methyl paraben, ethyl paraben, and propyl paraben was associated with their increasing alkyl chain lengths. Furthermore, a comprehensive exposure assessment of EDCs revealed that 15.7% of pregnant women had a health index > 1, which indicated potential health risks during pregnancy. However, toxicity and the underlying mechanisms of these EDCs remains to be further studied. 統合_0418	J. L. Lewerenz, S. C. Hammel, K. Hoffman, A. L. Phillips, S. Zhang, X. Ye, A. M. Calafat, T. F. Webster and H. M. Stapleton	2021	Young children's exposure to phenols in the home: Associations between house dust, hand wipes, silicone wristbands, and urinary biomarkers	BACKGROUND: Environmental phenols, such as parabens, bisphenol A, and triclosan, are ubiquitous in labor environments because of their use in packaging, plastics, personal care products, and as anti-microbials. The primary pathways of exposure, as well as habits and behaviors that may lead to greater exposure, are still unclear. OBJECTIVES: Herein, we investigate the relationships between phenols found in residential environments, by comparing levels in paired samples of house dust and hand wipes with children's urine. In addition, phenols were analyzed in a novel exposure tool, the silicone wristband, to investigate which external matrix best correlates with individual exposure based on urinary phenol biomarkers. METHODS: Children aged 3-6 years in central North Carolina, United States, provided paired hand wipe (n = 202), wristband (n = 76), and spot urine (n = 202) samples. Dust samples (n = 202) were collected from the participants' homes. Phenols were analyzed using online solid phase extraction-high performance liquid chromatography-isotope dilution tandem mass spectrometry (SPE-HPLC-IDMS/MS). RESULTS: Environmental phenols detected frequently in all matrices investigated. Ethyl, methyl, and propylparaben levels, observed in hand wipes, dust, and urine, were significantly correlated to the associated urinary biomarkers. In addition, inter-paraben correlations were noted, with biomarkers of ethyl, methyl, and propylparabens generally positively and significantly correlated, which suggests co-application of parabens in products. Triclosan levels in dust were positive and significantly correlated with levels in hand wipes and wristbands and with urinary concentrations, suggesting her personal care product sources may be important to children's overall triclosan exposure. Generally, chemicals on wristbands were more highly correlated with urinary biomarkers than with chemicals in hand wipes or house dust. In addition, more frequent lotion use was associated with higher urinary concentrations of parabens (e.g., ~2.5 times higher for methylparaben). CONCLUSIONS: Wristbands may be a useful tool for assessing exposure to phenols for some environmental phenols (e.g., triclosan in house dust). Associations between wristbands and biomarkers of exposure, which were stronger than for hand wipes and house dust, suggest that silicone wristbands may provide a suitable exposure assessment tool for some phenols. Ha	2021	Joint association of prenatal bisphenol-A and phthalates exposure with risk of atopic dermatitis in 6-month-old infants	BACKGROUND: Prenatal exposure to bisphenol A (BPA) and phthalates could trigger immune response. Few studies have investigated the association between prenatal BPA and phthalate exposure and atopic dermatitis (AD) in infants. OBJECTIVE: We aimed to clarify the joint association of prenatal exposure to BPA and phthalate metabolites with AD incidence in 6-month-old infants. METHODS: We included 613 mother-infant pairs from the Mothers and Children's Environmental Health (MOCEH) in a prospective birth cohort study. Maternal urinary BPA, mono-2-ethyl-5-hydroxyhexyl phthalate (MEHHP), mono-2-ethyl-5-oxohexyl phthalate (MEOHP), and mono-n-butyl phthalate (MnBP) concentrations were measured during early and late pregnancy. We applied Bayesian kernel machine regression (BKMR) models to examine the association of BPA and phthalate metabolites with AD incidence after adjusting for potential confounders. Individual association was estimated by differences in predicted probabilities comparing each individual chemical concentration at 75th percentile to 25th percentile, while fixing other chemicals at 25th percentile. RESULTS: Prenatal BPA, MEHHP, MEOHP, and MnBP concentrations were detected in 99.8%, 99.8%, 99.8%, and 98.5% of pregnant women, respectively. Bayesian kernel machine regression (BKMR) was used to evaluate the joint effect of urinary phenols and parabens as mixtures. Participants included within IQ (IQ), black (BLK), and other (OR) ICU women. Urinary 2,4-dichlorophenol was associated with 6.0% (95% CI: 1.26%, 10.8%) higher HbSAV adiponectin and urinary bisphenol F was associated with 3.60% (0.18%, 6.71%) higher sOR. R. Urinary methyl paraben

統合_0428	A. Lee, J. E. Lim, S. Mok, S. Kim, I. Lee, H. B. Moon, K. Choi, S. Kim and J. Park	2025	Exploring overlooked bisphenol exposure sources through a comprehensive 7-day investigation using time-activity diaries and urinary biomonitoring	Bisphenols (BPs), widely used in polycarbonate plastics and epoxy resins, are associated with potential health risks, yet many exposure sources remain inadequately characterized. This study employed a novel approach by integrating 7-day time-activity diaries with individualized urinary biomonitoring to capture overlooked BP exposure sources. Twelve adult participants meticulously documented their daily activities, including food intake, product use, and lifestyle factors, while collecting first-morning urine samples. Urinary concentrations of nine BPs (BPA, BPF, BPS, BPB, BPAF, BPAP, BPP, BPZ, and BPTMC) were quantified and BP2 outcomes, log-oxyate-used, ambiguously, and pregnancy rates) were evaluated using regression models. ECs from 336 patients were collected and measured for BPS for 28 hours to maintain progesterone and estradiol secretion based on clinical parameters. RESULTS: TPE and BPS were the most prevalent BPs in follicular fluid. BP exposure was associated with reduced fertilization rates (P = .01). Obesity tended to have four-birth rates (P = .08) but did not affect embryo development or implantation. Age significantly impacted embryo quantity (P = .04) and quality (P = .05). BC progesterone secretion was correlated to fertilization age after exposure to 1 µM and 10 µM BPB (P = .07 for both). SCs from younger women appeared more sensitive to BPB. CONCLUSION: Although obesity did not affect embryo development, it may reduce the likelihood of successful fertilization. Age-related differences in BP sensitivity were observed in fetal development. Age was linked to lower antral follicle count, pregnancy rates, and live-birth rates. Younger women's SCs may exhibit heightened sensitivity to BPB exposure, warranting further investigation. Braun	2024	Associations of parental preconception and maternal pregnancy urinary phthalate biomarker and bisphenol-a concentrations with child eating behaviors	BACKGROUND: Eating behaviors are controlled by the neuroendocrine system. Whether endocrine disrupting chemicals have the potential to affect eating behaviors has not been widely studied in humans. We investigated whether maternal and paternal preconception and maternal pregnancy urinary phthalate biomarker and bisphenol A (BPA) concentrations were associated with children's eating behaviors. METHODS: We analyzed data from the Preconception Environmental exposures And Childhood health Effects (PEACE) Study, an ongoing prospective cohort study of children aged 6-12 years. Participants were previously enrolled in a fertility clinic- based preconception study. We quantified urinary concentrations of 12 phthalate metabolites and BPA in parents' pre-conception samples, collected pre-conceptionally and during pregnancy. Parents rated children's eating behavior using the Child Eating Behavior Questionnaire (CEBQ). Using multivariable linear regression, accounting for correlation among twins, we estimated covariate-adjusted associations between parental and maternal pregnancy urinary biomarker concentrations and CEBQ scores. RESULTS: The 257 children (mean age = 8.9 years; 51% female; 51% White) were predominantly non-Hispanic white (mothers and fathers)(80). Parental and maternal preconception monoethyl phthalate (MEP) and monobenzyl phthalate (MBzP) concentrations were related to higher mean externalizing problems. Maternal pregnancy MEP, mono-isobutyl phthalate (MiBP) and bisPhenol A (BPA) concentrations were associated with increased emotional undereating scores. Maternal pregnancy monocarboxy- isononyl phthalate concentrations were related to decreased food seeking subscale scores. CONCLUSIONS: In this cohort, parental and maternal preconception phthalate urinary concentrations of some phthalate biomarkers were associated with increased food approaching behavior scores and decreased food avoiding behavior scores, which could lead to increased adiposity in children. 統合_0432	Z. Lazúrová, J. Figurski, B. Hubková, J. Mati ľaníková and I. Lazúrová	2021	Urinary bisphenol A in women with polycystic ovary syndrome - a possible suppressive effect on steroidogenesis?	OBJECTIVES: There is a growing evidence indicating an impact of endocrine-disrupting chemicals, such as bisphenol A (BPA) on human reproduction. Its higher levels in serum or urine have been documented in women with polycystic ovary syndrome (PCOS), however the relationship to ovarian steroidogenesis remains unclear. Aim of the study was to compare urinary BPA (U-BPA) concentrations among PCOS women and control group. METHODS: The study was performed in 2 groups of women: PCOS (n = 50) and control (n = 50). Inclusion criteria for PCOS group were: hyperandrogenism, oligo- or anovulation, age 18-40 years. Women in control group (n = 50) were included in the study. Fasting blood samples were analyzed for hormonal parameters and lipid profile. U-BPA was measured in the morning urine by high pressure liquid chromatography. RESULTS: PCOS women had significantly higher U-BPA as compared with control group (p=0.0001). Those with high levels of U-BPA (> UPP = 2.1 µg/g creatinine) demonstrated higher serum insulin (p=0.039) and FSH (P=0.0017), lower serum estrone (p=0.05), estradiol (p=0.0218), FSH- (p=0.0006), and FSH- (p=0.0001) as compared with low BPA group (LP - UPP = 2.1 µg/g creatinine). In PCOS women, U-BPA positively correlated with age (p=0.0329; R2(S=0.07), negatively with estradiol (p=0.0001; R2=0.1856), and testosterone (p=0.0019; R2=0.1128), free testosterone (p=0.0006; R2=0.123 and FAI (p=0.0008; R2=0.1137), respectively. CONCLUSIONS: PCOS women have significantly higher U-BPA concentrations than healthy controls. U-BPA positively correlates with age and negatively with serum steroid hormones, suggesting a possible suppressive effect of bisphenol A on ovarian steroidogenesis.	Horm Mol Biol Clin Investig. Andersson	2023	Urinary concentration of phthalates and bisphenol A during minipuberty is associated with reproductive hormone concentrations in infant boys	BACKGROUND: The transient postnatal activation of the hypothalamic-pituitary-gonadal hormone axis is termed minipuberty and considered an important developmental period, which is highly sensitive to endocrine disruption. Here, we explore exposure-outcome associations during minipuberty between concentrations of potentially endocrine disrupting chemicals (EDCs) in urine of infant boys and their serum reproductive hormone concentrations. METHODS: We included 70 boys from the Copenhagen Minipuberty Study, a longitudinal study of healthy infant boys. Urine samples were collected at 1, 3, and 6 months of age (M1-M3) and serum samples from samples collected on the same day. Serum concentrations of reproductive hormones were measured by immunoassays or by LC-MS/MS. Urinary concentrations of metabolites of 30 non-persisting chemicals, including phthalates and phenols - compounds, were measured by LC-MS/MS. Nineteen chemicals had concentrations above the limit of detection in >80% of children and were included in data analysis. Associations of urinary phthalate metabolite and phenol concentrations (in females), with hormone outcomes (age- and sex-specific SD-scores) were analyzed by linear regression. Primarily, we focused on 672 regulated phthalate, bisphenol phthalate (BBzP), di-n-butyl phthalate (DnBP), di-n-butyl phthalate (DnBP), and di (2-ethylhexyl) phthalate (DEHP) as well as bisphenol A (BPA). Urinary metabolites of DBP, DnBP and DEHP were summed to molar sum of DBP (ΣDBP). RESULTS: Urinary ΣDBP was positively associated with serum inhibin B (M1: β = 0.24 SD-score/ln(ΣDBP) (95% CI: 0.03; 0.45), p = 0.03) and testosterone (M3: β = 0.23 SD-score/ln(ΣDBP) (95% CI: 0.01; 0.45), p = 0.04) and MEHP was positively associated with testosterone (M3: β = 0.23 SD-score/ln(MEHP) (95% CI: 0.01; 0.45), p = 0.04). Urinary concentrations of metabolites of DEHP were inversely associated with testosterone (M3: β = -0.23 SD-score/ln(ΣDEHP) (95% CI: -0.45; -0.01), p = 0.04). Further, higher levels (the peptide 5 (M3) SD-score and bone (M3) SD-score in boys in the highest ΣDnBP-tertile (SD: 0.13, 1.75) and -0.89 (-1.51; -0.28), respectively) were observed. In addition, boys in the middle and highest ΣDEHP-tertile had higher (+1.37 (0.35; 2.39), and 0.71 (-0.03; 1.45), respectively) and in the highest ΣDEHP-tertile also higher (MH: 0.85 (0.10; 1.61)) concentration SD-scores, respectively. Boys in the highest BPA tertile had significantly higher (MH and bone (M3)SD) concentration compared to boys in the lowest BPA tertile (1.26 (0.50; 2.02) and -0.72 (-1.45; -0.02), respectively. CONCLUSIONS: Our findings suggest that exposure to phthalates and bisphenol A during minipuberty is associated with reproductive hormone concentrations, especially the FSI-regulated DnBP, DEHP and BPA, may modify male reproductive hormone concentrations in infant boys, suggesting that minipuberty is a critical window sensitive to endocrine disruption. 統合_0434	J. A. Kwon, B. Shin and B. Kim	2020	Urinary bisphenol A and thyroid function by BMI in the Korean National Environmental Health Survey (KoNEHS) 2012-2014	Bisphenol A (BPA) is one of the largest amounts of chemicals in daily life and source of polycarbonate plastics, epoxy resins, medical equipment, plastic consumer products. Recent studies reported that the effects of BPA on human health is the thyroid hormone. Therefore, this study aimed to indicate the association between urinary BPA concentration and thyroid function in total (disability)ratio (TS), thyroxine (T4), thyroidal hormone (TH) and thyroid stimulating hormone (TSH) by body mass index (BMI) in the Korean National Environmental Health Survey (KoNEHS) 2012-2014 and 2015-2017. METHODS: KoNEHS, 2012-2017. We measured BPA in urine and total T3, T4 and TSH in serum in the third KoNEHS cycle. The multiple regression analysis was performed to study the association of urinary BPA concentrations with thyroid hormone after BMI stratification. Urinary BPA associated with thyroid hormone. Especially, BPA is related to T3 (-0.423) in all group, and T4 (-0.685 -0.686) in all group and the group of BMI (N.Reg) not or more negatively. When stratified by BPA, T3 and T4 were significantly decreased with the high BPA exposure compared with the low BPA exposure for BMI more than 25.0kg/m2 (adjusted β = -1.102, 95% CI: -1.562, -1.642, adjusted β = -0.298, 95% CI: 0.538, -0.058). However, no obvious associations were found between BPA concentration and TSH. The results of urinary BPA decrease with T3 and T4 levels. Increase in the highest BMI group is area finding which does not exist in recent studies of Korea. 統合_0435	R. Kumar, S. Adhikari, E. Driver, J. Zeultz and R. U. Halden	2022	Application of wastewater-based epidemiology for estimating population-wide human exposure to phthalate esters, bisphenols, and terephthalic acid	Phthalates, bisphenols (BPs), and terephthalic acid (TPA) are widely used plasticizers and monomers in plastic manufacturing. Most of them are known to have an adverse effect on the human body, functioning as endocrine disrupting chemicals (EDCs). Biomonitoring studies have documented widespread human exposure to these chemicals, but population-wide exposure estimates are lacking for many countries. The objective of the present study was to evaluate population-level exposure to phthalates, BPs, and TPA by measuring urinary metabolites in community wastewater. Composited community wastewater (24 h samples) from five sewer sub-catchments of a southwestern city within the United States were analyzed for urinary biomarkers of phthalates, BPs, and TPA using solid-phase extraction liquid chromatography tandem mass spectrometry in conjunction with the isotope dilution method for absolute quantification. For all analytes, were detected at least once in community wastewater above the method detection limit (MDL), with MDLs ranging from 27 to 310 ng/L. The population-normalized mass load of TPA was the highest, followed by the human metabolite of di (2-ethylhexyl) phthalate (DEHP), Bisphenol S and monoethyl phthalate were detected frequently but at relatively low concentrations and loads. Mass loads of phthalates and BPs were comparable to previous reports in plastic-consumers, to handle, practicable, and informative, as large, conservative steps are taken to determine, quantify and account for background levels of plastic analytes in the laboratory environment. Buckley	2023	Associations of maternal gestational urinary environmental phenols concentrations with bone mineral density among 12-year-old children in the HOME Study	BACKGROUND: Early life environmental exposures may affect bone mass accrual in childhood, but only one study has assessed the role of environmental phenols on child bone health. METHODS: We used data from 233 mother-child pairs enrolled in the HOME Study, a prospective pre-birth cohort study recruited in Cincinnati, OH, USA (2003-2006). We measured urinary concentrations of 11 phenols in maternal urine collected at 16- and 26-weeks gestation and calculated the average of creatinine-adjusted concentrations. We performed dual x-ray absorptiometry at age 12 years and calculated Z-scores for whole body (less head), total hip, femoral neck, and L2-four bone mineral content (BMC) and areal bone mineral density (aBMD) as well as other distal radius aBMD and spine BMC and bone mineral apparent density (BMAD). We estimated covariate-adjusted associations (in standing of maternal urinary environmental concentrations in linear regression models. We also estimated associations by child's sex and assessed associations of the environmental phenol mixture with BMC and aBMD using quantile g-computation. RESULTS: By the cincinnati-specific cut-points for all analytes and lower measures. Yet, in adjusted models, maternal urinary concentrations of benzophenone-3 (BP3) were associated with lower total body less head BMC (-0.06 SD; 95% CI: -0.11, -0.01) and spine BMC (-0.06 SD; 95% CI: -0.11, -0.01) at age 12 years. In sex-stratified analyses, the magnitude of the BMC association was similar for females (-0.16; 95% CI: 0.26, 0.06) and for males (-0.02; 95% CI: 0.08, 0.13). The environmental phenol mixture was associated with greater 1.0-unit distal radius BMC and aBMD 2-scores in both sexes, which was mostly driven by benzophenone-3 in males and 2,5-dichlorophenol in females. CONCLUSIONS: In this prospective cohort study, we observed generally null associations for environmental phenols with BMC and aBMD at age 12 years. While there was a positive association of 2,5-dichlorophenol concentrations during fetal development with distal radius BMC and aBMD at age 12 years, future studies utilizing methods capable of differentiating cortical and trabecular bone are needed to elucidate potential mechanisms and implications for bone strength and skeletal fracture. 統合_0438	D. Koutaki, G. Paltoglou, A. Vounotrypa and E. Charmandari	2021	The Impact of Bisphenol A on Thyroid Function in Neonates and Children: A Systematic Review of the Literature	BACKGROUND: Bisphenol A (BPA) is an endocrine disrupting chemical widely used in plastic products that may have an adverse effect on several physiologic functions in children. The aim of this systematic review is to summarize the current knowledge of the impact of BPA concentrations on thyroid function in neonates, children, and adolescents. METHODS: A systematic search of Medline, Scopus, Clinical Trials.gov, Cochrane Library, and Google Scholar for the terms "bisphenol A" and "thyroid" was performed. RESULTS: Twenty-two studies were identified that met the inclusion criteria. Eleven studies investigated the association between Bisphenol A and thyroid function in neonates and children aged <18 years, one included only children who were accessed, while nine restricted to adolescents. A total of 13 articles were assessed by two independent researchers based on the title/abstract and the predetermined inclusion and exclusion criteria. According to the eligibility criteria, 10 full-text articles were selected for further assessment. Finally, 12 full-text articles were included in the present systematic review. RESULTS: The presented studies offer data that suggest a negative correlation of BPA concentrations with TSH in children, a gender-specific manner of action, and a potential effect on proper neurodevelopment. However, the results are inconclusive with respect to specific thyroid hormone concentrations and the effect on thyroid autoimmunity. CONCLUSIONS: The presence and significance of BPA in the developing thyroid gland of children that may affect proper neurodevelopment, suggesting the need to focus future research on designing studies that elucidate the underlying mechanisms and the effects of BPA on thyroid function in early life. 統合_0439	M. Kouchki, A. H. Duzzinotaghi, N. Amiri-Dashtaan, M. Farahani, H. Chidi, R. Vanda and S. Aramesh	2024	Impact of bisphenol A exposure on the risk of gestational diabetes: a meta-analysis of observational studies	PURPOSE: A growing number of evidence have assessed the association between bisphenol A (BPA) as an endocrine disrupting agent and the risk of gestational diabetes (GDM). This meta-analysis aimed to measure the data on the exclusive of BPA levels in women with GDM compared to the control. METHODS: A comprehensive literature search was conducted in Medline, Embase, Scopus, and Web of Science to screen relevant published studies up to May 2021. 12 articles were included in the meta-analysis. DerSimonian and Laird random effects model was used to estimate the pooled odds ratio (OR). Sensitivity analysis was conducted to assess the stability of the results. Publication bias was evaluated by Begg's funnel plot and Egger's test. Subgroup analysis was performed to explore the source of heterogeneity based on study design and geographical area. RESULTS: The results showed that there was no significant association between circulating and urinary BPA concentrations with the risk of GDM (OR: 0.76; 95% CI: 0.60-1.14; I2= 0.0%). No significant heterogeneity was found among the studies. Using Begg's correlation (P = 0.99) and Egger's linear regression (P = 0.86) tests, no publication bias was observed. The sensitivity analysis shows that our findings were completely robust and stable. Meta-regression indicated a significant association between BPA levels and study design and geometric mean as an index of the risk of GDM. CONCLUSION: The present meta-analysis demonstrates exposure to BPA was associated with a reduced risk of GDM. Further studies are needed for about the reliable results. 統合_0440	A. Kortenkamp, M. Scholze, S. Ermler, L. Priskorn, N. Jørgensen, A. M. Andersson and H. Frederiksen	2022	Combined exposures to bisphenols, polychlorinated dioxins, paracetamol, and phthalates as drivers of deteriorating semen quality	BACKGROUND: Semen quality in men continues to decline in Western countries, but the contours of the issue remain obscure. In relation to contributing chemicals. OBJECTIVES: To obtain more clarity about the role of environmental chemicals in male reproductive health, we investigated associations between 11 chemicals and 4 semen quality parameters. METHODS: We used data from 1,106 young men from three European countries, among them androgen receptor antagonists, substances that disrupt prostaglandin signalling, aromatase inhibitors (aromatase synthesis), inhibin biosynthesis enzymes or activate the aryl hydrocarbon receptor. We employed the Hazard Index approach (HI), based on risk quotients of exposures in Europe and reference doses for reductions in semen quality. By summing up the risk quotients of the 39 chemicals included in the assessment we examined risk-exceedances of "acceptable" mixture exposures relative to an index value of 1.7 in Vuolanto A, P. A. phthalates (DEHP, DnBP, BBzP, DINP, n-hex) powders and polyurethane) we relied on biomarkers of exposure. RESULTS: Bisphenols A made the largest contribution to the HI, followed by polychlorinated dioxins, bisphenols, S and F and DEHP. Eliminating Bisphenol A alone would still have unacceptably high mixture risks. Paracetamol is also a driver of mixture risks among subjects using the drug. CONCLUSIONS: Tolerable exposures to substances associated with deteriorations of semen quality are exceedingly large. Bisphenols, polychlorinated dioxins, phthalates, and analgesics drive these risks. Dedicated efforts towards lowering exposures to these substances are necessary to mitigate risks. 統合_0454	K. Kim, H. M. Shin, S. A. Bungerg, D. B. Barr, P. Panuwet, R. J. Schmidt, I. Hertz-Picciotto and D. H. Bennett	2021	Temporal Trends of Phenol, Paraben, and Triclocarban Exposure in California Pregnant Women during 2007-2014	Little is known about temporal trends of pregnant women's exposures to environmental phenols and parabens. We quantified four phenols (bisphenol A (BPA), bisphenol F, bisphenol S, and triclosan), four parabens (butyl paraben, ethyl paraben, methyl paraben, and propyl paraben), and triclocarban in spot urine samples collected from 1,239 pregnant women in California during 2007-2014. We used multivariable linear regression with log-transformed biomarker concentrations as the outcome and survey-weighted, multivariable regression to compare trends over gestation to mean of urinary concentrations, and computed average annual percent changes. We compared our urinary concentrations with those of other study populations to examine geographic variations in pregnant women's exposure to these target compounds. Urinary concentrations of BPA, MEPB, ETPB, and PRPB in this study population decreased over the study period (percent changes per year (95% confidence interval): -6.1% (-8.0%, -3.9%), -13.6% (-18.0%, -7.7%), -5.8% (-12.0%, 0.9%), and -13.0% (-18.9%, -6.5%), respectively) and were consistently lower than those in pregnant women in other U.S. regions during the same study period. In recent years, certain phenols and parabens with known adverse health effects are being regulated or replaced with alternatives, which explains decreased body burdens observed in this study population. Either the national regulations or the advocacy campaigns in California may have influenced exposures in consumer product choices. 統合_0455	J. I. Kim, Y. A. Lee, C. H. Shin, Y. C. Hong, B. N. Kim and Y. H. Lim	2022	Association of bisphenol A, bisphenol F, and bisphenol S with ADHD symptoms in children	BACKGROUND: Bisphenol A (BPA) has been linked to attention-deficit/hyperactivity disorder (ADHD) symptoms, but the neurotoxic effects of bisphenol substitutes such as bisphenol F (BPF) and S (BPS) have not been well investigated. We investigated the associations between BPA, BPF, and BPS with ADHD symptoms at multiple time points in children. METHODS: The levels of BPA (at ages 3, 4, and 8), BPF (at ages 4 and 8), and BPS (at ages 4 and 8) were measured in 570 children. Because of the low detection frequency of BPF and BPS levels, participants were divided into categories (i.e., a low/undetectable [LOD] vs. BPF: > LOD, ≤ median; or > median) for BPSS. ADHD symptoms were assessed using the ADHD Rating Scale-IV (ARS). The relationship between bisphenols and ARS scores was analyzed using Poisson regression models, and sex-stratified analyses were performed because of significant interactions between sex and bisphenols. RESULTS: The detection frequencies of BPA, BPF, and BPS were 99.8%, 15.4%, and 11.2% at age 3; 99.8%, 15.4%, and 11.2% for BPF and 43.2% for BPS at age 4; 54.1% for BPF and 31.5% for BPS). Doubling in BPA levels was associated with increased ARS scores by 6.7% (95% confidence interval [CI]: 0.5, 12.7) at age 8. The association was greater with BPA levels higher than 0.8 μg/g creatinine (24.2% [95% CI: 3.5, 51.6]) increase). The BPF > LOD group had 10.8% (95% CI: 1.2, 21.2) higher ARS scores than the BPF ≤ LOD group. The BPS > median group had 11.0% (95% CI: 2.4, 20.1) higher ARS scores than the BPS ≤ LOD group. CONCLUSION: Of bisphenols, in particular those at or above the LOD or median levels, were associated with ADHD symptoms at age 8. Further prospective studies are warranted to determine causal inference. 統合_0456	J. H. Kim, H. S. Shin and W. H. Lee	2021	Impact of Endocrine-Disrupting Chemicals in Breast Milk on Postpartum Depression in Korean Mothers	Previous human and animal studies have reported an association between endocrine-disrupting chemicals (EDCs) and anxiety/depression. This study aimed to determine how the concentrations of phthalate metabolites, bisphenol A, triclosan, and parabens in breast milk are associated with the risk of developing postpartum depression (PPD) in Korean mothers. We recruited 322 mothers who were receiving lactation coaching at postpartum care centers. Their sociodemographic characteristics and PPD symptoms were collected using questionnaires, including the Edinburgh Postnatal Depression Scale. Breast milk samples were collected from the participants 1 month postpartum to measure the concentrations of 15 EDCs, including phthalate, bisphenol A, parabens, and triclosan. Results: Exposure to the mixture of EDCs was not significantly associated with the risk of PPD. This study was the first attempt to analyze the association between the levels of EDCs in breast milk and the risk of PPD. Considering that PPD is a condition that affects not only the women diagnosed with it, but also their children and families, the results of this study may have great relevance to population. It is incrementally sensitive periods.	Int J Environ Res Public Health. 2021 Apr 22;18(9):4444.	10.3390/ijerph18094444	33922135	ヒト	神経(産後うつ)	-	-	-	-	-	-	横断研究	1	1	-	-	-	1	1	1	-	-	-	-	-	-	-	-	-	-	-	-	-	-
統合_0457	J. H. Kim, N. Moon, E. Ji and H. B. Moon	2023	Effects of postnatal exposure to phthalate, bisphenol a, triclosan, parabens, and per- and poly-fluoroalkyl substances on maternal postpartum depression and infant neurodevelopment: a korean mother-infant pair cohort study	Exposure to endocrine-disrupting chemicals (EDCs) can promote infant neurodevelopmental impairment and maternal postpartum depression (PPD). However, the associations between lactation exposure to EDCs, maternal PPD, and infant neurodevelopment are unclear. Hence, we investigated these relationships in infants aged 36–37 months. We recruited 322 Korean mothers and evaluated EDCs, The Edinburgh Postnatal Depression Scale (EPDS) was used to assess maternal PPD. Bayley scales of infant development: the Korean, Ages, and Pethem rating scale (BSAP), and the Child Behavior Checklist (CBCL) were used to assess neurodevelopment in infants exposed to the top 50% of EDC concentrations. Multiple regression analyses were adjusted for maternal age, pre-pregnancy body mass index, education, employment, residence, and infant age and sex. The rates of infants with clinically abnormal diagnoses on neurologic developmental tests (Bailey, BSAP, and CBCL scales) ranged from 7.7 to 38.5% in this study, with the motor and behavioral/emotional domains showing the highest rates. Maternal PPD was significantly associated with exposure to mixtures of EDCs, particularly phthalates, parabens, and triclosan, and hyperactivity. Perfluorooctanoic acid (PFOA) and perfluorooctane sulfonate (PFOS) levels correlated significantly with motor development at BSID-III and total CBCL score which mother might have been developmental status. EDC concentrations in breast milk were not associated with maternal PPD. Overall, lactational exposure to EDCs during the postpartum period can exert a negative effect on maternal PPD and infant neurodevelopment.	Environ Sci Pollut Res Int. 2023 Sep;30(42):96384-96399.	10.1007/s11356-023-29292-0	37572253	ヒト	神経(産後うつ)	-	-	-	-	-	-	コホート研究	1	1	-	-	-	1	1	1	-	-	-	-	-	-	-	-	-	-	-	-	-	-
統合_0458	J. H. Kim, N. Moon, S. J. Heo, Y. W. Jeong and D. R. Kang	2024	Repeated measurements and mixture effects of urinary bisphenols, parabens, polycyclic aromatic hydrocarbons, and other chemicals on biomarkers of oxidative stress in pre- and postpartum women	The association between oxidative stress and exposure to bisphenols, parabens, phenols, polycyclic aromatic hydrocarbons (PAH), and volatile organic compounds (VOCs) has been investigated by many in vitro and in vivo studies. However, most of these findings are based on cross-sectional studies, as a result of which the combined effects of these compounds have been rarely analyzed. In this study, we objective was to assess urinary bisphenols, parabens, PAHs, and VOCs, in relation to oxidative stress during pre-and postpartum periods, analyze the association between these chemicals and oxidative stress via repeated measurements using a linear mixed model (LMM), and evaluate the combined effects these chemicals on oxidative stress using Bayesian kernel Machine Regression (BKMR). A total 500 urine samples from 50 pregnant women during the 1st and 2nd trimesters, as well as postpartum follow-ups. Three biophenols, four parabens, benzophenone-3 (BP-3), triclosan (TCS), four PAHs, two VOCs, and 3- phenoxy benzoic acid (3-PBA) were measured in urine samples. Urinary 8-hydroxy-2'-deoxyguanosine (8-OHdG) was measured as a biomarker of oxidative stress. The LMM and BKMR were used to assess the effects of chemicals via mixt. For both the intervention and control groups, questionnaire results and maternal urine samples were accessed at baseline, during the intervention, and after one month. After the intervention, the urinary concentrations of mono (2-ethylhexyl) phthalate (MEHP), mono (2-ethyl-5-oxohexyl) phthalate (MEOHP), bisphenol A (BPA), methylparaben (MP), ethylparaben (EP), and propylparaben (PP) were found to be significantly decreased in the intervention group. Compared to the control group, the intervention group showed significantly decreased urinary geometric mean values of MEHP, MEOHP, BPA, MP, and PP after one month compared with those during the intervention (1.86, 1.63.16, 28.30, 9.74, and 29.35, respectively). Hence, the web-based behavioral intervention was effective at reducing the exposure to endocrine disruptors in mothers with young children. 統合_0459	J. H. Kim, J. M. Kwak and H. Kang	2021	Web-based behavioral intervention to reduce exposure to phthalate metabolites, bisphenol A, triclosan, and parabens in mothers with young children: A randomized controlled trial	In this study, a web-based behavioral intervention was designed, which aimed to reduce exposure to phthalate metabolites, bisphenol A, triclosan, and parabens in mothers with young children. A randomized controlled design with two groups was used to verify the effects of the intervention pre- and post-test. In total, 51 mothers participated in the study, categorizing 26 and 25 in the intervention and control groups, respectively. The web-based behavioral intervention focused on changes in diet, personal care products, and habits related to indoor and outdoor behavior through encouragement. This program included an educational video, a game for handling endocrine disruptors at home, a method for locating facilities potentially emitting endocrine disruptors, resources, and a questions and answers mode. Data were collected from May 18 to June 30, 2020. Participants in the intervention group were provided with a link to the web-based behavioral intervention program for 1 month. Urine samples were collected from participants to measure the concentrations of endocrine disruptors via mol. For both the intervention and control groups, questionnaire results and maternal urine samples were accessed at baseline, during the intervention, and after one month. After the intervention, the urinary concentrations of mono (2-ethylhexyl) phthalate (MEHP), mono (2-ethyl-5-oxohexyl) phthalate (MEOHP), bisphenol A (BPA), methylparaben (MP), ethylparaben (EP), and propylparaben (PP) were found to be significantly decreased in the intervention group. Compared to the control group, the intervention group showed significantly decreased urinary geometric mean values of MEHP, MEOHP, BPA, MP, and PP after one month compared with those during the intervention (1.86, 1.63.16, 28.30, 9.74, and 29.35, respectively). Hence, the web-based behavioral intervention was effective at reducing the exposure to endocrine disruptors in mothers with young children. 統合_0460	J. H. Kim, D. Kim, S. M. Moon and E. J. Yang	2020	Associations of lifestyle factors with phthalate metabolites, bisphenol A, parabens, and triclosan concentrations in breast milk of Korean mothers	The toxicity of endocrine disruptors depends on the synergistic interactions of biological, environmental, and behavioral factors. The specific effects of diet, consumer product use, and behaviors, however, are debated in the literature, particularly with regard to endocrine disruptors found in breast milk. This study aimed to measure the levels of phthalate metabolites, bisphenol A, parabens, and triclosan in breast milk, and to investigate their associations with various lifestyle factors. The breast milk samples as well as surveys were collected from 233 first-time mothers throughout South Korea and each sample was analyzed for the presence of 15 endocrine disruptors. Phthalate metabolites were detected in 0.4-85.3% of the samples, with median concentrations of 0.05-1.72 μg/L, while bisphenol A, parabens, and triclosan were detected in 24.9-88.3% of the samples, with median concentrations of 0.27-1.67 μg/L. High levels of endocrine disruptors were associated with frequent consumption of fish and cup noodles; the use of plastic and disposable food containers; the use of cosmetics, sunscreen, and hair products; and exposure to indoor dust. Our results suggest that exposure to endocrine disruptors is widespread among lactating women in South Korea, and that the detected levels are associated with the lifestyle factors of the mothers. Our data provide evidence of the potential effects of diet, consumer products, and behavior on the presence of phthalate metabolites, bisphenol A, parabens, and triclosan in breast milk. Future studies should include community or regional impact on a mothers' exposure to endocrine disruptors, to assess the joint contribution of both individual and neighborhood factors.	Chemosphere Vol.249 Pages 126149	10.1016/j.chemosphere.2020.126149	32062213	ヒト	バイオモニタリング	1	1	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-
統合_0461	J. H. Kim, Y. H. Cho and Y. C. Hong	2020	MicroRNA expression in response to bisphenol A is associated with high blood pressure	Bisphenol A (BPA) is a ubiquitous environmental contaminant that is known to be associated with the risk of arterial hypertension. However, the underlying mechanism, describing how BPA exposure leads to high blood pressure (BP) remains unclear. We investigated the association between BPA exposure and microRNA (miRNA) expression in relation to BP in a panel study of elderly residents in Seoul, Korea. We measured urinary BPA and BP levels of 60 participants aged 60 years or more. The participants visited the study site 3 times and were clean dependently exposed to BPA. Two hours after exposure to BPA, urine and whole blood were collected for BPA measurement and miRNA profiling, and BP was measured. Relationships among urinary BPA level, miRNA expression, and BP were estimated using the mixed-effect model. Decreases in miR-18a-5p, miR-582-3p, miR-107-5p, and miR-572-5p and increases in miR-548-3p and miR-1228-3p in the baseline-to-BPA exposure were associated with high BP. The over-functional network from BPA exposure to increased BP via miR-18a-5p, miR-582-3p, miR-107-5p, and miR-572-5p through three miRNAs and their predicted BP-related target genes. Our results suggest that epigenetic biomarkers for BPA exposure and hypertension provide mechanistic data to explain hypertension exacerbation as well as key information for predicting the health effects of BPA exposure. 統合_0462	D. Kim, E. R. Yoo, A. A. Li, G. Chalasani, S. P. Tighe, W. Kim, S. A. Harrison and A. Ahmad	2019	Elevated urinary bisphenol A levels are associated with non-alcoholic fatty liver disease among adults in the United States	BACKGROUND AND AIMS: The relationship between bisphenol A (BPA) and non-alcoholic fatty liver disease (NAFLD) is unclarified. We studied the impact of BPA on NAFLD. METHODS: We performed a cross-sectional analysis of 2,838 participants from the National Health and Nutrition Examination Survey (NHANES) 2003-2004. Urinary BPA was measured by high-performance liquid chromatography. NAFLD was defined by the hepatic steatosis index (HSI) ≥ 36 in the absence of other causes of chronic liver disease. The final sample using HSI consisted of 1,765 adults. The race-and-gender-using (AFI) corrected BPA participants with availability of health data. RESULTS: Of the first 1765 participants (mean age 37 years, 48.6% male), the prevalence of NAFLD and abnormally elevated alanine aminotransferase (ALT) levels was correlated with urinary BPA levels. (P < 0.05). Compared to the reference group with lowest quartile of urinary BPA levels, those with the third and fourth quartile levels had 2.5- and 3.5- more likely to develop NAFLD and 50% more likely to develop NAFLD in a multivariate model. An 10% for NAFLD in the third and fourth quartiles were 1.29 (95% CI: 1.09-1.50) and 1.22 (95% CI: 1.06-1.76) respectively (P for trend: <0.001). In the second sample using LDFT, a high BPA levels (fourth quartile) remained an independent predictor of NAFLD (OR 1.45, 95% CI: 1.05-1.98, P for trend = 0.012). CONCLUSIONS: High levels of urinary BPA were associated with NAFLD in a nationally representative sample of adults in the US. The pathophysiology remains unclear and warrants further investigation. 統合_0463	B. Kim, B. Park, C. H. Kim, S. Kim and B. Park	2022	Association between endocrine-disrupting chemical mixture and metabolic indices among children, adolescents, and adults: A population-based study in Korea	Exposure to endocrine-disrupting chemicals (EDCs) play a role in the etiology of obesity and dyslipidemia. However, few studies have analyzed the combined effects of EDC mixtures. This study explored the association between urinary EDC mixtures and metabolic indices among children, adolescents, and adults. We used data from the 2015–2017 Korean National Environmental Health Survey (KoNEHS) cycle 3. The National Environmental Health Survey (2015 to 2017 cycle included in this. assay. sectional study. Urinary concentrations of eight phthalate metabolites, three phenols, three parabens, and one quantized pesticides metabolite were quantified. Body mass index (BMI) was measured for all participants, and triglyceride (TG) and high-density lipoprotein cholesterol (HDL-c) levels were measured for adolescents and adults. Associations between EDC mixtures and metabolic indices were analyzed using weighted quantile sum (WQS) regression. The WQS index was constructed based on the quartiles of each EDC. The WQS index for BMI, TG, and HDL-c were derived in more than 95% of participants. There was a significant association between a high cumulative phthalate metabolites index (the high cumulative index quartiles). The WQS index for the EDC mixture was associated with higher BMI in both adolescents and adults, with greater significance in adults compared with adolescents, and a higher TG WQL in male adolescents. In adolescents, WBP and MCPP drove the main effects on BMI and TG WQL, respectively. In adults, DMA and BPA drove the main effects on BMI. The findings of this study suggest that exposure to EDC mixtures is associated with higher BMI and TG/HDL, and adults.cence may be a critical period for EDC mixture in terms of both outcomes. Further studies are needed, but strategies to reduce EDC exposure from early life stages may be necessary to lower the risk of metabolic disease. 統合_0464	K. R. Kilcoyne and R. T. Mitchell	2019	Effect of environmental and pharmaceutical exposures on fetal testis development and function: a systematic review of human experimental data	BACKGROUND: Overall, the incidence of male reproductive disorders has increased in recent decades. Testicular development during fetal life is crucial for subsequent male reproductive function. Non-genetic factors such as environmental chemicals, pharmaceuticals and lifestyle have been proposed to impact on human fetal testicular development resulting in subsequent effects on male reproductive health. Whilst experimental studies using animal models have provided support for this hypothesis, more recently a number of experimental studies using human tissues and cells have begun to translate these findings to determine direct human relevance. OBJECTIVE AND RATIONALE: To systematically review the literature describing the effects of environmental and pharmaceutical exposures on human fetal testis development and function. We present the effects of environmental, pharmaceutical and lifestyle factors in experimental systems involving exposure of human fetal testis tissues and cells to chemicals, with a focus on epidemiological data currently derived from a recent meta-analysis. SEARCH METHODS: For identification of experimental studies, PubMed and EMBASE were searched for articles published in English between 01/01/1966 and 15/07/2018 using search terms including 'testosterone biosynthesis', 'human', 'fetal', 'testis', 'gonad' and 'endocrine disruptor'. Bibliographies of relevant articles were searched for further retrospective Epidemiological studies, involving exposure to the same agents were extracted from a recent systematic review and meta-analysis. Additional studies were identified through screening of bibliographies of relevant articles. OUTCOMES AND REVIEW: Of 1,616 articles identified, 130 were included in the review. Effects of environmental chemicals, pharmaceuticals and lifestyle factors on human fetal gonad development are demonstrated in experimental models, correlating with evidence from epidemiological studies and animal models. Furthermore, analysis of human fetal testis tissue and cells has revealed reduction in fetal testosterone production, which predisposes to the development of male reproductive disorders, has been reported in studies involving human tissues, which also supports data from animal and epidemiological studies. However, while reduced testosterone production has been demonstrated in animal studies following exposure(s) to a variety of environmental chemicals, including phthalates and bisphenol A, these effects are not reproduced in experimental approaches using human fetal testis tissues. WIDER IMPLICATIONS: Direct experimental evidence for effects of prenatal exposure(s) on human fetal testis development and function exists, however, for many exposures little data is available. The increasing use of human relevant models systems is starting to determine the effects of environmental exposures. Combining mixed exposures on development and function of human tissues should form an important part of the process for assessment of such exposures by regulatory bodies to take account of animal–human differences in susceptibility. 統合_0465	D. Khodasevich, N. Holland, K. G. Harley, B. Eskenazi, L. F. Barcellos and A. Cardenas	2024	Prenatal exposure to environmental phenols and phthalates and altered patterns of DNA methylation in childhood	INTRODUCTION: Epigenetic marks are key biomarkers linking the prenatal environment to health and development. However, DNA methylation associations and persistence of marks for prenatal exposure to multiple Endocrine-Disrupting Chemicals (EDCs) in human populations have not been examined in great detail. METHODS: We measured Bisphenol A (BPA), triclosan, benzophenone-3 (BP3), methyl paraben, propyl paraben, and 11 phthalate metabolites in urine collected during pregnancy from participants in the CHAMACOS cohort (Salinas Valley, CA; 1999–2000). We measured DNA methylation in cord blood (n = 333) and at 5 years (n = 309) using Illumina HumanMethylationEPIC BeadChip. We used an Elastic Net penalized regression approach to identify differentially methylated probes (DMPs) and comb-p was used to identify differentially methylated regions (DMRs) in association with pregnancy averaged EDC concentrations. Quantile g-computation was used to assess associations of the whole phenol/phthalate mixture with DMPs and DMRs. RESULTS: Prenatal BP3 exposure was associated with 1 CpG among males and Parabens were associated with 10 CpGs among females at Bonferroni-level significance in cord blood. Other suggestive DMPs (unadjusted p-value < 1 × 10–5) and several DMRs associated with the individual phenols and whole mixture were also identified. A total of 3 DMPs were associated with prenatal BP3 exposure at age 5 years among males, and 1 DMP was associated with prenatal BPA exposure among females. We identified 1 DMR and 2 DMPs at age 5 specific associations between prenatal phenol exposure and DNA methylation, particularly with BP3 in males and Parabens in females. Additionally, cord blood-derived DMPs that maintained significant associations with prenatal EDC exposures at age 5 well-age 10 years. Kavachiyadi	2024	Endocrine-Disrupting Chemicals and the Development of Diabetes Mellitus Type 1: A 5-Year Systematic Review	INTRODUCTION: According to the Institute of Environmental Sciences, endocrine-disrupting chemicals (EDCs) are "natural or human-made chemicals that may mimic, block, or interfere with the body's hormones, potentially causing adverse health effects". Diabetes mellitus type 1 (DMT1) is a chronic disease that is caused by the destruction of pancreatic β-cells, leading to insulin deficiency. Both genetic and environmental factors contribute to the development of DMT1, with endocrine-disrupting chemicals (EDCs) being one of the environmental factors under investigation. AIM/PURPOSE: The purpose of this study was to investigate the correlation between the EDCs and the development of T1DM. METHODOLOGY: Then, a 5-year systematic review was conducted to bring light to this research question. Using the meta-analysis and systematic review guidelines protocol, a PRISMA flow diagram was constructed and, using the keywords 'diabetes mellitus type 1' AND 'endocrine-disrupting chemicals' in the databases PubMed, Scopus and ScienceDirect, the relevant data was collected and extracted into tables. Quality assessment tools were employed to evaluate the quality of the content of each article retrieved. RESULTS: Based on the data collected and extracted from both human and animal studies, an association was found between TCDD and certain EDCs, such as bisphenol A (BPA), bisphenol S (BPS), perchlorinated organic pollutants (POPs), phthalates, and dioxins. Moreover, the focal on the quality assessment performed, using the Newcastle–Ottawa Scale and AMSTAR quality assessment tool, the articles were considered of high quality and thus eligible to justify the correlation of the EDCs and the development of T1DM. CONCLUSIONS: Based on the above study, the correlation can be justified. However, additional studies can be made focusing mainly on humans to understand further the pathophysiologic mechanisms involved in this association. Sabzevari	2021	Bisphenol-A in biological samples of breast cancer mastectomy and mammoplasty patients and correlation with levels measured in urine and tissue	Endocrine-disrupting chemicals (EDCs) are organic compounds that have estrogenic activity and can interfere with the endocrine system. Bisphenol-A (BPA) is one of these compounds which arouses a potential risk to human health. The aim of this study was to investigate the association between BPA levels in breast tissue and urine samples of breast cancer patients. BPA levels in breast tissue of the cancerous and non-cancerous tissues were measured by HPLC-FLD. BPA levels in urine samples of 61 mastectomy patients were compared with those of 61 healthy controls. Urine and breast adjacent tissue samples from 61 breast cancer mastectomy and 61 mammoplasty patients were taken. BPA concentrations were detected using an ELISA assay. Urinary BPA concentrations were significantly higher in cancerous patients (2.22 ± 1.48 ng/ml, P = 0.01) compared to non-cancerous (0.91 ± 0.42 ng/ml). Likewise, tissue BPA concentrations in cancerous patients (3.24 ± 2.66 ng/g tissue, P = 0.01) were significantly higher than non -cancerous (1.88 ± 1.39 ng/g tissue). Urinary BPA concentrations were positively correlated with tissue-adjacent tissue BPA in the case group (P = 0.001, R = 0.998). We showed that BPA was present in urine and breast adjacent tissue samples of the studied populations. With regard to higher BPA mean concentration in cancerous patients than non-cancerous individuals in this study, BPA might increase the risk of breast cancer incidence. 統合_0468	H. Kaya Ozden and A. S. Karadag	2021	Could endocrine disruptors be a new player for acne pathogenesis? The effect of bisphenol A on the formation and severity of acne vulgaris: A prospective, case-controlled study	BACKGROUND: Acne is one of the most common skin diseases in the adolescent period. Bisphenol A (BPA) is the most frequently observed endocrine-disrupting chemicals that us are exposed to in daily life. BPA can affect the hormonal balance and cause acne formation. OBJECTIVE: The aim of this study was to investigate the relationship between BPA and acne. METHODS: Patients with acne and 50 healthy controls, whose ages varied between 18 and 30 years and applied to our dermatology outpatient clinic, were evaluated. A questionnaire containing dietary and lifestyle habits, for BPA exposure was filled. BPA and BPA glucuronides were analyzed in the LC-MS/MS system in the first morning urine samples of the patients. Statistical significance was set at p < 0.05. RESULTS: The median levels of total BPA were significantly higher in the acne group compared with the control group (7.61 [3.69-20.52] vs. 1.42 [1.32-21.00] µg/g creatinine, respectively; p = 0.001). The acne severity was positively correlated with the BPA values (p = 0.04 vs. r: 0.302). Higher BPA level was noticed in younger acne onset age (r = 0.023 r: - 0.349). When the many questions were evaluated, no difference was found between the study groups regarding BPA exposure (P > 0.05). CONCLUSION: Although BPA exposure was not found to be different in the acne group, it may be beneficial to prevent BPA exposure and acne occurrence, in the adolescence and post-adolescence period, to which industrial products such as junk food and plastic-bottled water are used more frequently. 統合_0469	I. Katsikantami, M. N. Tzatzarakis, V. Karzi, A. Stavroulaki, P. Xezonaki, E. Yakoumaki, A. K. Alegakis, S. Sifakis, A. K. Rizos and A. M. Tsatsakis	2020	Biomonitoring of bisphenols A and S and phthalate metabolites in hair from pregnant women in Crete	Phthalates, bisphenols A and S (BPA, BPS) are used as plasticizers and many of them are documented or suspected of being endocrine disruptors. Several studies indicate that exposure during pregnancy may affect the fetal development and the pregnancy outcome. The aim of this study was to investigate the exposure of pregnant women in Crete, Greece, to BPA, BPS and phthalates. Hair samples were collected from 74 pregnant women and analyzed for 11 compounds: seven monoesterified phthalate (mEPP, MBEL), mono-carboxyl phthalates (mMP, MBX, BPH, OPH), BPS, DEHA and mono-n-butyl phthalate (mnBP) (MBA). Phthalate metabolites were detected at medians from 19.6 to 161.4 pg/mg, BPA at 69.9 pg/mg and BPS at 5.0 pg/mg. Significant positive correlations between phthalate metabolites were found which indicated their common sources of exposure. The frequent use of plastics for food storage was strongly associated to mEPP (p = .012) and a weaker association was found for mMP (p = .065). The frequent use of cosmetics during pregnancy was associated with levels of phthalate metabolites. In fact, 95 cm specifically, the use of hair spray before pregnancy was significantly correlated with monoesterp phthalate (mBeP) (p = .021) and a trend was found for mBP (p = .066). The use of makeup products during pregnancy was strongly associated with mBP (p = .020) and the use of deodorant during pregnancy was inversely associated with mEHP (p = .051). Dietary associations, namely an inverse mEHP and fresh fruits weight (Spearman correlation coefficient, r = -0.262, p = .022) and exposure to BPS was associated with increased body mass index of the participants (p = .058). Although data in literature on biomonitoring of the compounds in hair are limited, the findings of this study are promising and in agreement with existing data in hair or urine. 統合_0470	S. Karthikeyan, T. Pollock, M. Walker, C. Khoury and A. St-Amand	2024	Analysis of chemical exposures in racial populations in Canada: An investigation based on the Canadian health measures survey	Despite demonstrated disparities in environmental chemical exposures by racial identity, no Canadian study has systematically assessed the feasibility of using a nationally representative dataset to examine differences in exposure between racial groups. This study aimed to address this gap by leveraging the Canadian Health Measures Survey (CHMS) to investigate racial disparities in exposure to chemicals measured in biomonitoring data collected through the Canadian Health Measures Survey (CHMS). Our primary objectives were to assess the ability to: 1) generate geometric means and percentiles of chemical concentrations for racial populations by age or sex, 2) statistically compare concentrations among racial populations, and 3) calculate time trends of concentrations by race. We conducted these analyses for several priority chemicals: lead, cadmium, benzene, bisphenol A (BPA), and di(2-ethylhexyl) phthalate (DEHP). Survey participants self-identified as one of the following: White, Black, East and Southeast Asian, South Asian, Middle Eastern, Latin American, First Nations, Métis, and Inuk. Analyses were conducted for individual and combined cycles of the CHMS. Using data from the latest CHMS cycle in which each chemical was measured, we observed that geometric means and percentiles could be generated for most racial populations, but not for all chemicals and racial groups. Statistically significant differences in exposure between racial groups were commonly reported for all racial populations in the analysis. While we were able to statistically compare concentrations among racial populations, the analysis was constrained by limited statistical degrees of freedom available in a single CHMS cycle. Both of these constraints were alleviated by combining multiple cycles of data. The analysis of time trends was less subject to privacy and statistical limitations; we were able to calculate time trends of chemical concentrations for all racial populations. Our findings provide an important baseline for follow-up investigations of descriptive and etiological analyses of environmental chemical exposures and race in the CHMS. 統合_0471	C. Karrer, M. Andreasen, N. von Goetz, F. Sonnet, A. A. Sakhi, K. Hungerbühler, H. Dirven and T. Husøy	2020	The EuroMix human biomonitoring study: Source-to-dose modeling of cumulative and aggregate exposure for the bisphenols BPA, BPS, and BPF and comparison with measured urinary levels	BACKGROUND: Bisphenol A (BPA) and, with increasing occurrence, its analogs bisphenol S (BPS) and bisphenol F (BPF) are applied in many consumer products, leading to humans being exposed from a vast number of sources and via several routes. Exogenic and anti-androgenic effects are exerted by the chemical BPA, and also by its analogs. Therefore, realistic exposure assessments are needed for assessing risks. OBJECTIVES: Biomonitoring for BPA, BPS, and BPF was conducted in a human study embedded in the EU project EuroMix and the measured urinary concentrations were compared to source-to-dose model predictions. METHODS: Spot urine samples (n = 2,551) from 1,258 adults (20-39 years) from 10 countries in Europe were collected and analyzed using ultra-high performance liquid chromatography coupled to tandem mass spectrometry (UPLC-MS/MS). In line with the information obtained from the first study day, bisphenol exposure from food, PCPs, TP, and dust was modeled primarily individual based with probabilistic models. RESULTS: BPA, BPS, and BPF were frequently detected in urine samples (98%, 95%, and 77%, respectively). Median concentrations were 1.1 ng/mL for BPA, 0.16 ng/mL for BPS, and 0.19 ng/mL for BPF. Urinary levels, in general, individual based medians of modeled BPA exposure were in good agreement with the measurements, but individual specific correlations were rather poor. Medians of modeled BPS and BPF levels in participants with positive measurements (55% and 8%), except for the PBK values of modeled BPA exposure that were higher than measured amounts (~TP was handled. Most likely, diet and TP were the sources contributing the most to BP exposure in this study. Urinary measurements did not reveal a significant correlation between the amounts of consumed food containing TP, the number of PCPs used, or the number of TP handling events and levels of BPA, BPS, or BPF. CONCLUSIONS: The good agreement between the ranges of modeled BPA exposure and measured BPA amounts indicates that available concentrations, especially from food, are sufficient to explain exposure to BPA in the majority of the participants. Considering the poor correlation between modeled and measured BPA exposure on an individual level, individual measurements and modeled exposures did not vary in parallel, e.g. due to intended n-HBP concentrations in food, TP, and other sources, or delayed internal exposure. The underestimation of modeled BPS and BPF exposure suggests that not all relevant sources were included in the respective exposure models. This could be due to a lack of input data, e.g. for food items, or due to an increased replacement of BPA with structural analogs compared to the used concentration and occurrence data.	Environ Int Vol.136 Pages 105397	10.1016/j.envint.2019.105397	31884417	ヒト	-	-	-	-	-	-	バイオモニタリング	1	1	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-
統合_0472	T. Kavramani, C. Sol, K. Kannan, L. Tiesarska, V. Jaddoe and L. Duijts	2023	Bisphenol and phthalate exposure during pregnancy and the development of childhood lung function and asthma. The Generation R Study	BACKGROUND: Fetal exposure to bisphenols and phthalates may lead to alterations in the respiratory and immune system development in children, and to adverse respiratory health. AIM: To study the associations of maternal urine bisphenol and phthalate concentrations with childhood lung function and asthma. METHODS: We measured bisphenol A, F and S and phthalate metabolites in urine samples collected in mid-pregnancy from 2,547 participants in a population-based birth cohort in the Netherlands. We measured maternal urine bisphenol and phthalate concentrations in the first, second and third trimester of pregnancy, and lung function by spirometry and asthma by questionnaire at age 10 years. Multivariable linear and logistic regression models were applied. RESULTS: Maternal urine bisphenol and phthalate concentrations averaged during pregnancy were not associated with childhood lung function or asthma. Associations of maternal urine bisphenol and phthalate concentrations in specific trimesters with respiratory outcomes showed that one bisphenol A (BPA) or bisphenol F (BPF) and DEHP metabolite was mostly associated with childhood lung function or asthma. Associations of maternal urine bisphenol and phthalate concentrations in the second trimester was associated with a higher FEV1/FVC, but not with asthma, accounting for confounders and multiple testing correction. Although there were associations of higher second trimester BPA, BPF, MEHP, MEOHP, MECPP, MEHHP, and MEP concentrations with higher FEV1/FVC, and higher third trimester BPA, BPF, MEHP, MEOHP, MECPP, MEHHP, and MEP with lower FEV1, these did not remain significant after correction for multiple testing. Results were not modified by maternal history of asthma or atopy. CONCLUSIONS: Maternal urine bisphenol and phthalate concentrations averaged or in specific trimesters during pregnancy were not strongly associated with childhood lung function and asthma at age 10 years. BPA, as a BPA substitute, tended to be associated with impaired lung function and altered risk of asthma, partly non-dependent, but its strength was limited by a relatively low detection rate and should be queried in contemporary cohorts. 統合_0473	S. Kang, B. H. Shin, J. A. Kwon, C. W. Lee, E. K. Park, E. Y. Park and B. Kim	2020	Urinary bisphenol A and its analogues and haemato-biochemical alterations of pregnant women in Korea	INTRODUCTION: Bisphenol F (BPF) and bisphenol S (BPS) are chemical substitutes for, and may have similar physiological effects to, bisphenol A (BPA). Bisphenols provoke endocrine disorders and are cytotoxic, cardiac hemoglobin, and induce morphological changes in human red blood cells (RBC). It is more sensitive to changes in the RBC number and hemoglobin (Hb) level during pregnancy. Therefore, we investigated the effects of bisphenols on the haemato-biochemical parameters of pregnant women. METHODS: Urine samples were collected from 1,000 pregnant women in the Ewha Birth and Growth Cohort Study, recruitment for which occurred from 2017 to 2018. We measured the levels of BPA, BPF and BPS in urine samples and collected data on socioeconomic, lifestyle, and environmental factors via questionnaires. The associations between the levels of the three BPs and biochemical parameters were analyzed by multiple linear regression (RESULTS). The geometric mean urinary concentrations of specific gravity adjusted BPA, BPF, and BPS were 1.19, 0.19, and 0.29 ng/mL, respectively. There was a significant negative association between the urinary concentrations of BPA and the Hb level (β = -0.11, p = 0.02). After stratification by the median concentrations of the three BPs, the concentrations of BPA had a significantly negative effect on the RBC count, Hb level, and hematocrit in the high-BPA-concentration group (RBC: β = -0.5, p = 0.001; Hb: β = -0.3, p = 0.002; Hct: β = -0.2, p = 0.02). CONCLUSIONS: BPA has a harmful effect on human biochemical changes that occur during pregnancy. Further studies should investigate the relation between unbalanced exposure to bisphenols and effects on human health.	Environ Res Vol.182 Pages 109104	10.1016/j.envres.2019.109104	31927299	ヒト	-	-	-	-	-	-	横断研究	1	1	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-
統合_0474	J. Kang, H. Kang and Y. H. Choi	2025	Changes of urinary bisphenol A and alternatives in Korea 2015-2020 and environmental disparities by socioeconomic status	BACKGROUND: Bisphenol A (BPA), mainly used as an ingredient for epoxy resins, is widely utilized in numerous daily necessities. However, due to its endocrine-disrupting property, many countries have regulated BPA usage in consumer products, which might motivate industries to prefer alternative chemicals such as bisphenol S (BPS) and bisphenol F (BPF). This study aimed to evaluate temporal changes in consumption patterns of bisphenols and to investigate socioeconomic disparities in exposure to bisphenols among Korean adults. METHODS: We analyzed urinary bisphenol concentrations in 5,000 participants aged ≥ 19 years from the Korean National Environmental Health Survey (KoNEHS) 2015-2020 (n = 6000). Weighted measures were measured by urinary concentrations of BPA, BPS, and BPF. A ratio of alternatives to bisphenols (BP ratio) (0 = only BPA, 1 = only BPS/BPF). Associations between BP ratio and ESTI indices (each variable and a composite score of household income, residence area, occupation, and education) were examined using survey-weighted multiple linear regression models. RESULTS: During the study period of 2015-2020, BP ratio (0.01 → 0.25) (P < 0.05) demonstrated increases with a steep linear trend (SE = 0.04, β = 0.03). BP ratio (0.08 to 0.27) (P < 0.05) corresponded to a series of BPA regulations since 2018, which had banned BPA-containing products (i.e., food containers, utensils, and baby products) and set the Distinct reference dose. Trends of BP ratio differed by ESTI, but not by age or sex (P for interaction = 0.04). The lowest ESTI group showed the highest BP ratio (0.17 [0.15, 0.19]) and the highest ESTI group showed the lowest BP ratio (0.11 [0.10, 0.12]) (P < 0.05) after adjusting for age and sex. CONCLUSIONS: Bisphenol exposure of the general Korean adults shifted from BPA to its alternatives (coupled with consecutive BPA regulations. Such an exposure shift was more pronounced in adults with higher SES. Further bisphenol regulations should consider environmental disparities of the public.	Environ Res Vol.285 Issue Pt 1 Pages 122307	10.1016/j.envres.2025.122307	40623515	ヒト	-	-	-	-	-	-	バイオモニタリング	1	1	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-
統合_0475	H. Kang, J. P. Lee and K. Choi	2021	Exposure to phthalates and environmental phenols in association with chronic kidney disease (CKD) among the general US population participating in multi-cycle NHANES (2005-2016)	Exposure to consumer chemicals has been associated with chronic kidney disease (CKD) among humans, but their associations with estimated glomerular filtration rate (eGFR) are inconsistent. Such observations may be attributable to the use of spot urine samples and the cross-sectional study design. We investigated the associations of urinary phthalate and phenol biomarkers with eGFR decline associated with CKD by applying an alternative adjustment method of urine dilution: bound covariate-adjusted creatinine adjustment in traditional creatinine adjustment and the exposure concept in the association model. For this purpose, the adult participants of US National Health and Nutrition Examination Survey (NHANES) 2005-2016 (n = 9008) were used, and the associations of urinary exposure biomarkers of 11 phthalates and 5 phenols with eGFR were investigated by multiple linear regression models. RESULTS: During the study period, the geometric mean (GM) concentrations of urinary biomarkers of adjusted creatinine concentrations resulted in significant inverse associations with eGFR for most measured chemicals, unlike the results with the use of the conventional creatinine adjustment. Metabolic metabolites such as monobutyl phthalate (MBP) and mono-benzyl phthalate (MBzP), were positively associated with eGFR. Even in mixture exposure models, using weighted quantile sum (WQS) regression, MBzP, metabolites of di-(2-ethylhexyl) phthalate (DEHP), and mono-ethyl phthalate (MEP) were revealed as major drivers of the association with eGFR in CKD. Results of sensitivity analyses with the subpopulation with normal eGFR ranges (> = 75(2) were generally similar. Our observation suggests that exposure to benzyl butyl phthalate (BBP), DEHP, and MEP may be responsible for declined eGFR and increased ACR even at the exposure levels occurring among general adults.	Sci Total Environ Vol.791 Pages 148343	10.1016/j.scitotenv.2021.148343	34126474	ヒト	-	-	-	-	-	-	横断研究	1	1	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-
統合_0476	H. Kang, S. Kim, H. Lee, Y. Jeong, J. Lee, I. Lee, H. B. Moon, K. Choi and K. T. Kim	2025	Parabens, bisphenols, and other environmental phenols exposure from cosmetics use in Korean adolescent girls: Findings from a 2-day intervention study	Endocrine-disrupting chemicals (EDCs), such as bisphenols, parabens, and benzophenones, are commonly found in personal care products (PCPs) and pose a significant public health concern, particularly in adolescent girls. This study aimed to investigate the association between PCP use and urinary concentrations of environmental phenols in Korean adolescent girls, focusing on the potential role of PCPs as a major source of EDC exposure. METHODS: We recruited 60 girls aged 13-18 years and collected their first-morning urine samples and questionnaire data on PCP use. Participants recorded the use of 16 PCPs, including 6 skin-cell-repair products, 5 skincare products, sunscreens, cosmetics, and nail tip products, in a subsequent two-day intervention restricting participants' use, leading to subsequent of 72 participants. We measured the changes in urinary chemical concentrations were assessed. Baseline findings showed an association between frequent PCP use and higher urinary concentrations of parabens (e.g., methyl, ethyl, and propyl parabens), bisphenol S (BPS), and benzophenone-3(e.g., benzophenone-3). After the two-day intervention, no significant reductions in EDCs concentrations were observed for the entire study participants (n = 72). However, when excluding adolescents with no baseline PCP use (n = 12), substantial reductions were shown in BPA (by 52.7%), and benzophenones (by 13.4% to 29.3%). This study contributes to the limited research on EDC exposure in adolescent populations and underscores the need for targeted public health interventions and policy measures to protect vulnerable populations from the potential health risks associated with EDC exposure. 統合_0477	G. Kalliora, G. A. Wellenius, L. McCandless, A. M. Calafat, A. Spolin, M. E. Romano, M. R. Karagas, A. Chen, K. Yolton, B. P. Lanphear and J. M. Braun	2020	Exposures to chemical mixtures during pregnancy and neonatal outcomes: The HOME study	INTRODUCTION: Exposure to mixtures of environmental chemicals are prevalent among pregnant women and may be associated with altered fetal growth and gestational age. To date, most research regarding environmental chemicals and neonatal outcomes has focused on the effects of individual agents. METHODS: In a prospective cohort of 388 pregnant women from Cincinnati (2003-2006), we used biomarkers to estimate exposure to 22 phenols, phthalates, metals, organophosphate (op)-metal, organochlorine pesticides, polychlorinated biphenyls, polybrominated diphenyl ethers, perfluoroalkyl substances (PFAS), and environmental tobacco smoke (ETS) during pregnancy. We used Bayesian kernel machine regression (BKMR) to estimate associations between the chemical mixture and birthweight, birthweight z-score, birthweight for gestational age z-score (assessing intrauterine growth), head circumference, and gestational age (assessing intrauterine growth). PIP, posterior probability of inclusion (PIP) ≥ 0.5 identified chemicals with potentially important contributions to the mixture effect. RESULTS: Mixtures of 22 chemicals were associated with lower birthweight, birthweight z-score, and birthweight for gestational age z-score. Three chemicals, three phthalate metabolites, several metals, organophosphate (op)-organochlorine pesticides, polychlorinated biphenyls, and several PFAS had a PIP ≥ 0.5 for one or more outcomes. In the op cluster, chlorpyrifos was the most important chemical (PIP = 0.9) and 3,5,6-trichloro-2-pyridinol (TCPY) had a PIP = 0.5. Of the 3 chemicals in the cluster 2 had inverse associations with birthweight and birthweight z-score: 2,5-dichlorophenol (PIP = 0.5) and 2,4,5-trichlorophenol (PIP = 0.5). In the ETS cluster, cotinine had the largest PIP (PIP = 0.9) and had a positive association with birthweight and birthweight z-score. On average, infants born to women in clusters 1 (1,2 cm BW, CI: -1.9, 0.6) and 2 (0.6 cm BW, CI: -1.1, 2.1) had lower birth length than infants in cluster 3. Each 1 ng/mL increase in TCPY, one of the most important chemicals in the op cluster, was associated with a 0.2 cm (CI: -0.4, 0.0) lower birth length. Cotinine was also associated with shorter birth length. Cluster membership, PC scores, and individual chemicals were not associated with other birth outcomes. CONCLUSIONS: We used two methods of characterizing multiple chemical exposures in this cohort identified inverse associations of select organochlorine compounds, phenols, and cotinine with birth length, but not other neonatal outcomes. 統合_0478	J. Jurewicz, J. Majewska, A. Berg, K. Owczarek, M. Zajicek, D. Kaleta, A. Wasik and D. Rachoń	2021	Serum bisphenol A analogues in women diagnosed with the polycystic ovary syndrome - is there an association?	Due to the endocrine-disrupting effects of bisphenol A (BPA) several governmental authorities have banned its use and the manufacturers had to find alternative substances with a similar chemical properties. This led to the increase in the use of so-called BPA-analogues, which however also turn out to possess mild estrogenic and an androgenic properties and thus, may cause fertility problems and are hormone-dependent-related disorders. The aim of this study was to evaluate the potential association between the exposure to BPA and its two analogues: BPS and BPF, with the diagnosis of polycystic ovary syndrome (PCOS), which remains the most common female endocrinopathy. Serum concentrations of BPA, BPS and BPF were measured using high performance liquid chromatography method with tandem mass spectrometry (HPLC-MS/MS). Women with PCOS (n = 120) were compared with healthy controls (n = 120). Women with PCOS had significantly higher serum BPA concentrations (median 0.38 ng/mL [25th-75th percentile: 0.26-0.58] vs. 0.28 ng/mL [0.18-0.39], P = 0.0023). Since BPS and BPF concentrations did not differ between the studied groups. There was however a negative correlation between serum BPA and BPS (r = -0.252, P = 0.0001) and between BPA and BPF (r = -0.200, P = 0.001) in women with PCOS. So concentrations, some found between the serum BPA, and other metabolic parameters such as serum lipids, insulin, DHEA-S, androstenedione and FAI. When studying the association between serum BPA analogues and PCOS it turned out that women whose serum BPA concentrations were in the first tertile were more likely to be diagnosed with this endocrinopathy (OR 95% CI: 1.11; 0.58; 2.48). P = 0.8017). This association was also statistically significant when adjusted for age, education, BMI, smoking, income, and alcohol consumption (adjusted OR (95% CI): 2.17 (1.03; 3.71). P = 0.039). These results point to the potential association between the exposure to BPA and the diagnosis of PCOS. The role of BPA is not clear and remains further studies. Yoo	2022	Profile of Environmental Chemicals in the Korean Population-Results of the Korean National Environmental Health Survey (KoNEHS) Cycle 3, 2015-2017	The Korean National Environmental Health Survey (KoNEHS) program provides useful information on chemical exposure, serves as the basis for environmental health policies, and suggests appropriate measures to protect public health. Initiated on a three-year cycle in 2009, it reports the concentrations of major environmental chemicals among the representative Korean population. KoNEHS Cycle 3 included children and adolescents. Into the analysis, where the blood and urine samples of 6357 participants were measured for major metals, phthalates, phenols, and other organic compounds. Lead, mercury, cadmium, metabolites of DEHP, and DnBP, and 2-phenylphenol, and levels of the Korean adult population tended to decrease compared to previous survey cycles but remained higher than those observed in the US or Canada. Both bisphenol A (BPA) and many trans-nuclear acid concentrations have increased over time. Heavy metal concentrations (blood lead, and cadmium) in children and adolescents were approximately half that of adults, while some organic chemicals, such as BPA and DEHP, were high. BPA showed higher levels than the US or Canada, whereas BPF and BPS showed lower detection rates in the study. However, as these are increasingly used as substitutes for BPA, further research is necessary. As environmental chemicals may affect childhood health and development, additional analysis should ensure exposure sources and routes through continuous observations. 統合_0480	M. K. Jung, H. S. Choi, J. Suh, A. Kwon, H. W. Chae, W. J. Lee, E. G. Yoo and H. S. Kim	2019	The analysis of endocrine disruptors in patients with central precocious puberty	BACKGROUND: A few studies have reported a positive association between phthalate exposure and pubertal timing, but several conflicting reports exist. The main objective of the study was to determine whether phthalate exposure was associated with central precocious puberty (cPP). METHODS: This case-control study enrolled girls with central precocious puberty (CPP) and girl controls. Of pre-pubertal girls and 31 pubertal girls) were enrolled. Nineteen girls were included. For phthalate metabolites (creatinine-adjusted) and bisphenol A (BPA) were measured in the first spot urine samples of these 50 girls in the early CPP group, 31 girls in the progressive CPP group, and 19 girls in the control group. Differences in the urinary concentrations of phthalate metabolites and BPA among the groups were analyzed. RESULTS: Urinary concentrations of total phthalate (DEHP) were 51.2, 79.2, 106.1, 54.2, and 54.2 μg creatinine in the pre-pubertal control group, early CPP group, progressive CPP group, pubertal control group, and 11.1, 38.7, 21.1, and 30.3 μg/g creatinine in the pubertal control group, respectively. The urinary concentration of the four phthalates was significantly lower in the CPP group than in the pre-pubertal control group (P = 0.0001). Conversely, there was no significant difference in the urinary concentration of the five phthalates between the CPP and pubertal control groups (P values: 0.077 for MEHP, 0.752 for MEHHP, 0.188 for MEOHP, and 0.982 for MnBP). In addition, the BPA level was not significantly different between the CPP and pubertal control groups (BPA median values: 0.91 μg/g creatinine, the CPP group; 1.7 μg/g creatinine, the pubertal control group; P value = 0.892). CONCLUSIONS: Our study showed that there was no significant difference in the urinary phthalate levels between the CPP and pubertal control groups. Moreover, phthalate metabolites were significantly lower in the CPP group than in the pre-pubertal control group. Further investigation about endocrine disruptors and pubertal progression is needed. 統合_0481	H. Jin, J. Xia, L. Mao, M. Zhao, X. Bai, J. Wen, T. Shen and F. Wu	2020	Bisphenol analogue concentrations in human breast milk and their associations with postnatal infant growth	Many studies show that bisphenol A (BPA) is widespread in human breast milk. However, the occurrence of other bisphenol analogues (BPAs), including bisphenol S (BPS), bisphenol F (BPF), and bisphenol AF (BPAF), in breast milk is still not well known. In this study, breast milk samples were collected from 350 mothers in Hangzhou, China, with the aims to determine the occurrence of BPS, BPF, and BPAF in these samples and to investigate their effects on postnatal growth of infants through breast milk consumption. BPA (mean 2.6 ng/mL, range = 1.00–18 ng/mL) was the most abundant BPA in breast milk, followed by BPS (0.19 ng/mL, <LOD–1.1 ng/mL) and BPAF (0.082 ng/mL, <LOD–0.58 ng/mL). BPF was not detected in all breast milk samples. We found that breast milk concentrations of BPA were significantly correlated with infant's weight or height gain rate. Daily intakes (DIs) of BPs via the consumption of breast milk were calculated for infants, and the mean DI values were 105 ng/kg bw, 10 ng/kg bw, and 23 ng/kg bw for BPA, BPS, and BPAF, respectively. Overall, this study firstly demonstrates that the lactation exposure to BPA through breast milk consumption may affect the postnatal growth of infants. Xia	2020	Prenatal exposure to bisphenol A and its alternatives and child neurodevelopment at 2 years	While increasing evidence has shown that prenatal bisphenol A (BPA) exposure is adversely associated with child neurodevelopment, little is known about the neurodevelopmental effects of BPA alternatives, such as bisphenol S (BPS) and bisphenol F (BPF). We aimed to evaluate the relationships of repeated measurements of bisphenol exposure during pregnancy with child neurodevelopment. From 2012-2015, 650 mother-child pairs were recruited from the Wuhan Maternal and Child Health Cohort in China. Urinary concentrations of BPA, BPS, and BPF were measured in maternal samples collected in each trimester. Children were assessed using the Ages & Stages Questionnaires, Third Edition at 2 years. A structural equation model, a psychomotor development index accurate, decrease urinary quartiles of BPS were associated with infant's weight or height gain rate. Daily intakes (DIs) of BPs via the consumption of breast milk were calculated for infants, and the mean DI values were 105 ng/kg bw, 10 ng/kg bw, and 23 ng/kg bw for BPA, BPS, and BPAF, respectively. Overall, this study firstly demonstrates that the lactation exposure to BPA through breast milk consumption may affect the postnatal growth of infants. 統合_0483	W. Jiang, Y. Huang, H. Jin, Y. Gan, Q. Zhang, X. Hu, Y. Tian, J. Zhang and C. The Shanghai Birth	2025	A prospective exposome-based gene-environment interaction study on the effects of prenatal environmental exposure on fetal growth in the Shanghai Birth Cohort	BACKGROUND: Both environmental exposure and type 2 diabetes (T2D) genetic susceptibility affect fetal growth. However, most previous studies used single exposure rather than an exposome strategy to explore the joint effects of environmental exposure and genetic susceptibility on fetal growth. METHODS: Based on the Shanghai Birth Cohort, we established the association between a broad range of prenatal environmental factors and fetal growth and further evaluate the effect modification of maternal and fetal T2D genetic susceptibility on the identified exposures. METHODS: From 1,150 mother-newborn pairs from the Shanghai Birth Cohort, we estimated the associations between 19 prenatal exposure measures (including outdoor environment, residential environment, chemical exposures, lifestyle factors, and psychosocial status) and fetal growth, measured by birth weight for gestational age z-score (BWZ). Single-exposure models, mixture models, and interaction models were used to assess the primary pooled learning and weaker (none) were applied jointly to screen for BWZ-associated exposures. Multivariable linear regression models were used to assess the interactions of BWZ-associated exposures with maternal and fetal T2D genetic risk scores (GRSs). RESULTS: Higher prenatal exposure to ambient temperature (AT) (β = 0.08, 95 % CI: 0.03, 0.13), fine particulate matter (PM2.5) (β = 0.07, 95 % CI: 0.02, 0.12), and 2,4-dinitrophenol (DNP) (β = 0.06, 95 % CI: 0.01, 0.11) was associated with increased BWZ. In contrast, we found significant decreases in urinary concentrations of environmental phenol replacements, including bisphenol S (β: 3.9, 95 % CI: 7.9, 0 and bisphenol F (β: 6, 95 % CI: 1.8, 10.2). DNCH metabolites, 1cyclohexane-1,2-dicarboxylic acid monohydroxy isononyl ester (MHNCH) (β: 20, 95 % CI: 7.5, 32.5) and 1,2-cyclohexane dicarboxylic acid monocarboxy isooctyl ester (MCNCH) (β: 15.1, 95 % CI: 4.2, 26.1), were also positively associated with BWZ. Moreover, we found significant interactions between maternal T2D GRS and exposure to AT, PM2.5, and DNP. Additionally, we found that the effects of maternal T2D GRS on BWZ were modified by exposure to several environmental phthalate metabolites. Maternal phthalate, mono-2-ethyl-5-carboxypentyl terephthalate (MECPTP) (β = 0.4, 95 % CI: 0.8, 1.6), and mono-2-ethyl-5-oxohexyl terephthalate (MEOHTP) (β = 0.4, 95 % CI: 0.8, 1.6) metabolites were associated with increased BWZ. Moreover, we found that the effects of fetal T2D GRS on BWZ were modified by exposure to several environmental phthalate metabolites, including mono-2-ethyl-5-carboxypentyl terephthalate (MECPTP) (β = 0.4, 95 % CI: 0.8, 1.6), mono-2-ethyl-5-oxohexyl terephthalate (MEOHTP) (β = 0.4, 95 % CI: 0.8, 1.6), and mono-2-ethyl-5-hydroxyhexyl terephthalate (MEHHTP) (β = 0.4, 95 % CI: 0.8, 1.6). CONCLUSIONS: Our study identified several prenatal environmental exposures within the outdoor environment, phenols, and metallicells that were associated with fetal growth. Mother-newborn pairs with high T2D genetic susceptibility were particularly vulnerable to the environmental insults. https://doi.org/10.1289/EHP10802. 統合_0484	V. S. Jiang, A. M. Calafat, P. L. Williams, J. E. Chavarro, J. B. Ford, I. Souter, R. Hauser and L. Minguez-Alarcon	2023	Temporal trends in urinary concentrations of phenols, phthalate metabolites and phthalate replacements between 2000 and 2017 in Boston, MA	Endocrine disrupting chemicals (EDCs) can adversely affect human health and are ubiquitously found in everyday products. We examined temporal trends in urinary concentrations of EDCs and their replacements. Urinary concentrations of 11 environmental phenols, 15 phthalate metabolites, phthalate replacements such as two diisononyl cyclohexane-1,2-dicarboxylate (DINCH) metabolites, and tricitrates were quantified using isotope-dilution tandem mass spectrometry. This ecological study included 998 male and 829 female patients who were predominantly White Caucasian (82 %) with an average age of 36 years and a BMI of 25.0 kg/m2 seeking fertility treatment at a Boston, MA clinic between 2000 and 2017. Geometric means (GM) and 95 % confidence intervals (95 % CI) were calculated for each year. Temporal trends were investigated using multivariable linear regression models. We observed significant increases per year in urinary concentrations of traditional phenols, parabens, and triclosan, such as bisphenol A (β = 0.04, 95 % CI: 0.03, 0.06), benzophenone-3 (β = 0.05, 95 % CI: 0.04, 0.06), methylparaben (β = 0.04, 95 % CI: 0.03, 0.05), dichlorophenols (β = 0.03, 95 % CI: 0.02, 0.04), 2,5-dichlorophenol (β = 0.04, 95 % CI: 0.03, 0.05), and triclosan (β = 0.04, 95 % CI: 0.03, 0.05). Significant increases were also observed for several phthalate metabolites, including monoethyl phthalate (MEP) (β = 0.04, 95 % CI: 0.03, 0.05), monobenzyl phthalate (MBzP) (β = 0.03, 95 % CI: 0.02, 0.04), and mono-2-ethylhexyl phthalate (MEHP) (β = 0.02, 95 % CI: 0.01, 0.03). Significant increases were observed for several phthalate replacements, including bisphenol S (β: 3.9, 95 % CI: 7.9, 0 and bisphenol F (β: 6, 95 % CI: 1.8, 10.2). DINCH metabolites, 1cyclohexane-1,2-dicarboxylic acid monohydroxy isononyl ester (MHNCH) (β: 20, 95 % CI: 7.5, 32.5) and 1,2-cyclohexane dicarboxylic acid monocarboxy isooctyl ester (MCNCH) (β: 15.1, 95 % CI: 4.2, 26.1), were also positively associated with BWZ. Moreover, we found significant interactions between maternal T2D GRS and exposure to AT, PM2.5, and DNP. Additionally, we found that the effects of maternal T2D GRS on BWZ were modified by exposure to several environmental phthalate metabolites. Maternal phthalate, mono-2-ethyl-5-carboxypentyl terephthalate (MECPTP) (β = 0.4, 95 % CI: 0.8, 1.6), and mono-2-ethyl-5-oxohexyl terephthalate (MEOHTP) (β = 0.4, 95 % CI: 0.8, 1.6), and mono-2-ethyl-5-hydroxyhexyl terephthalate (MEHHTP) (β = 0.4, 95 % CI: 0.8, 1.6) metabolites were associated with increased BWZ. Moreover, we found that the effects of fetal T2D GRS on BWZ were modified by exposure to several environmental phthalate metabolites, including mono-2-ethyl-5-carboxypentyl terephthalate (MECPTP) (β = 0.4, 95 % CI: 0.8, 1.6), mono-2-ethyl-5-oxohexyl terephthalate (MEOHTP) (β = 0.4, 95 % CI: 0.8, 1.6), and mono-2-ethyl-5-hydroxyhexyl terephthalate (MEHHTP) (β = 0.4, 95 % CI: 0.8, 1.6). 統合_0485	S. Jiang, G. Yang, S. Zhou, X. Zhang, C. Peng and Q. Lu	2021	Bisphenol A, S, and F exposure, ESR1/2, CAT, and eNOS genetic polymorphisms, and the risk of hypertension	While bisphenol A (BPA) exposure was inconsistently associated with hypertension risk, little is known about whether its alternatives bisphenol S and F (BPS and BPF) have similar hypertensive effects. Furthermore, epidemiologic studies on the genetic susceptibility to the hypertensive effects of bisphenols are scarce. We conducted a case-control study in 539 pairs of hypertension cases and matched controls. Urinary bisphenols, estrogen receptor 1/2 (ESR1/2) polymorphisms, catalase (CAT) rs769214 and rs7943316, and endothelial nitric oxide synthase (eNOS) rs2070744 and rs1799983 were measured. Logistic regression models were used to assess the associations of bisphenols and their interactions with genetic polymorphisms with hypertension risk. Cumulative effects of multiple exposures associated with hypertension risk. Centers of rs2070744 C allele in ESR2 were associated with increased hypertension risk. Significant associations of BPA exposure with increased hypertension risk were suggested in individuals with the major allele of rs2798050 in ESR2, rs769214 in CAT, and rs1799983 in eNOS. Besides, rs7943316 in CAT might modify the association of BPA exposure with hypertension risk. Individuals with specific genotypes in ESR1/2, CAT, and eNOS might be more susceptible to the hypertensive effects of BPA. 統合_0486	S. Jiang, Y. Wang, Z. Wang, Y. Xu, X. Li, M. Sun and B. Li	2024	Bisphenol A and its alternatives bisphenol S and F exposure with serum uric acid levels, hyperuricemia, and gout prevalence among US adults: a nationally representative cross-sectional study	BACKGROUND: Recent studies suggested inconclusive associations between bisphenols exposure and hyperuricemia risk. Our objective was to assess the potential association of bisphenol A (BPA) and its substitutes bisphenol S (BPS) and F (BPF) exposure with serum uric acid levels, hyperuricemia, and gout prevalence among US adults. METHODS: Data from the National Health and Nutrition Examination Survey (NHANES) 2013–2016 cycles were used. Multivariate linear regression models were used to explore the associations of urinary bisphenols concentrations with SUA levels, hyperuricemia, and gout prevalence. In total population and different age groups. The nonlinear dose–response relationship between BPA/BPS/BPF and SUA levels was examined using restricted cubic spline (RCS) model was used to explore the dose–response relationship. RESULTS: In total population, doubling of urinary BPS and 2.58% concentrations showed associations with an increment of 2.66 μmol/L (95% CI: 0.562, 4.76) and 0.24 μmol/L (95% CI: 0.08, 0.39) in SUA levels, respectively. The RCS model indicated a significantly "J"-shaped dose–response relationship between BPS exposure and SUA levels. Compared to the reference group of urinary BPS, males in the highest quartile (Quartiles: 1.536, μmol/L (95% CI: 0.76, 29.37) rise in SUA levels. For females, doubling of urinary BPS concentrations was associated with a 1.38 μmol/L (95% CI: 0.03, 2.73) increase in SUA levels. Doubling of urinary BPS concentrations was associated with a 1.08 (95% CI: 1.01, 1.16) increased risk of hyperuricemia. Compared with the reference group of BPS, individuals in the second and third tertile had an adjusted OR of 1.28 and 1.43 for hyperuricemia, had a 1.01 and 1.09 rate for hyperuricemia, had a 1.01 and 1.09 rate for hyperuricemia, and had a 1.01 and 1.09 rate for hyperuricemia of BPF, respectively, with a monotonic curve. No significant associations of BPF exposure with hyperuricemia risk or blood pressure levels were found. BPA and BPS exposure were suggested to be associated with increased hyperuricemia risk and blood pressure levels, with different dose–response relationships. Our findings have important implications for public health but require confirmation in prospective studies. Lu	2020	Association of bisphenol A and its alternatives bisphenol S and F exposure with hypertension and blood pressure: A cross-sectional study in China	Epidemiological studies have investigated the associations of bisphenol A (BPA) exposure with hypertension risk or blood pressure levels, but findings are inconsistent. Furthermore, the association between its alternatives bisphenol S and F (BPS and BPF) and hypertension risk are not yet known. We conducted a cross-sectional study in 1,017 eligible participants without hypertension-related diseases, with complete data about blood pressure levels, hypertension diagnosis, and urinary bisphenols concentrations. Multivariable logistic and linear models were respectively applied to examine the cross-sectional associations of urinary bisphenols concentrations with hypertension risk and blood pressure levels. The dose–response relationship was explored by the restricted cubic spline model. Compared with the reference group of BPA, individuals in the middle and high exposure groups had 1.61 and 1.89 times the risk of hypertension, respectively. Each 1-unit increase in ln-transformed BPA was associated with 1.18 (95% CI: 1.03, 1.36) increased risk of hypertension. Compared with the reference group of BPS, individuals in the second and third tertile had an adjusted OR of 1.49 and 1.83 for hypertension, had a 1.01 and 1.09 rate for hypertension, had a 1.01 and 1.09 rate for hypertension, and had a 1.01 and 1.09 rate for hypertension of BPF, respectively, with a monotonic curve. No significant associations of BPF exposure with hypertension risk or blood pressure levels were found. BPA and BPS exposure were suggested to be associated with increased hypertension risk and blood pressure levels, with different dose–response relationships. Our findings have important implications for public health but require confirmation in prospective studies. 統合_0488	J. Jiang, B. Chen, B. Tang, J. Li, C. Zhang, D. Tan, T. Zhang and Q. Wei	2024	Urinary phenols and parabens exposure in relation to urinary incontinence in the US population	BACKGROUND: Our study aimed to investigate the impact of urinary concentrations of personal care products (PCPs)-related phenols (PPs) and parabens (PBs), including Triclosan (TCS), Bisphenol A (BPA), Benzophenone-3 (BP-3), Butylparaben (BPB), Ethylparaben (EPB), Methylparaben (MPB), and Propylparaben (PPB), on urinary incontinence (UI) occurrence. METHOD: We conducted a cross-sectional analysis, using data from the National Health and Nutrition Examination Survey (NHANES) spanning the years 2007 to 2016. Regression analysis was employed to investigate the relationship between exposure to PCPs-related substances, various levels of exposure, and UI within both the general population and the female demographic. Additionally, the Bayesian Kernel Machine Regression (BKMR) model was used to assess the effects of mixtures on UI. RESULTS: Our analysis comprised 7,890 participants who self-reported their diagnosis. Among them, 12,80% experienced stress urinary incontinence (SUI), 11.80% reported urge urinary incontinence (UUI), and 10.23% had mixed urinary incontinence (MUI). Following the adjustment for confounding factors, the highest quartile of TCS exposure was associated with a 1.28-fold increase in the risk of SUI (OR:1.28, 95% CI: 1.01–1.61, p = 0.042), an increased risk of UUI (OR:1.23, 95% CI: 1.01–1.49, p = 0.038), and MUI (OR:1.26, 95% CI: 1.01–1.56, p = 0.039). TCS exposure displayed a negative correlation with the risk of MUI (OR:0.67, 95% CI: 0.49–0.91, p = 0.016). No significant links were observed between parabens and urinary incontinence. Notably, among the female population, our investigation revealed that BPA exposure heightened the risk of MUI (OR:1.30, 95% CI: 1.00–1.68, p = 0.045). Participants in the highest tertile of BPA exposure demonstrated elevated likelihoods of SUI and MUI compared to those in the lowest tertile. In the BKMR analysis, negative trends were observed between the mixture and the risks of UUI and MUI when the mixture ranged from the 25th to the 50th and 75th to the 95th percentile (p < 0.05), respectively. Additionally, a positive trend was identified between the mixture and MUI when it was in the 50th to 75th percentile. CONCLUSION: In conclusion, our findings suggest that exposure to BPA, TCS, and BP-3 may contribute to the development of urinary incontinence. 統合_0489	C. Jiang, J. Guan, X. Tang, Y. Zhang, X. Li, Y. Li, Z. Chen, J. Zhang and J. D. Li	2024	Prenatal low-dose Bisphenol A exposure impacts cortical development via cAMP-PKA-CREB pathway in offspring	Bisphenol A (BPA) is a widely used plastic/ion known to cause various disorders. Despite a global reduction in the use of BPA-containing products, prenatal exposure to low-dose BPA, even those below established safety limits, has been linked to neurological and behavioral deficits in childhood. The precise mechanisms underlying these effects remain unclear. In the present study, we observed a significant increase in the number of neurons in the cortex of mice exposed to BPA during embryonic development. Transcriptomic analysis via RNA sequencing revealed an aberrant activation of the cAMP/PKA/CREB pathway in offspring exposed to BPA. The use of KT5, a selective PKA inhibitor, effectively reversed the deficits in the proliferation and migration of cortical neurons. Furthermore, offspring from dams exposed to low-dose BPA exhibited motor-like behaviors, including hyperactivity, anti-depressant-like responses, and reduced anxiety. While BPA-mediated hyperactivity, it didn't affect the other behavioral changes. These results suggest that the overactivation of PKA plays a causative role in BPA-induced changes in neuronal development. Our data also indicate that neuro-like behaviors induced by prenatal low-dose BPA exposure may be influenced by both altered neuronal development and abnormal PKA signaling in adulthood. 統合_0490	L. L. Jia, Y. L. Luan, H. M. Sher and Y. Guo	2022	Long-term stability of several endocrine disruptors in the first morning urine samples and their associations with lifestyle characteristics	Parabens, triclosan (TCS), bisphenols, benzophenones, and phthalates are typical endocrine disruptors (EDCs) with short half-lives in the human body. The concentration levels of these EDs in a spot urine sample are frequently used in exposure assessment studies, and the reproducibility of urinary levels of these nonpersistent EDs should be considered. In the present study, we consecutively collected 50 day first morning void (FMV) urine samples, as well as daily questionnaires, in six recruited participants and measured the urinary concentrations of six parabens, TCS, nine bisphenols, five benzophenones, and ten phthalate metabolites by using high-performance liquid chromatography-triple quadrupole mass spectrometry. The intraclass correlation coefficients (ICCs) and Spearman's rank correlation coefficients (rs) were calculated to assess the reproducibility and stability of the urinary levels. The ICCs ranged from 0.06 (mBP, MEP, BPA, BPS, BPAF, BPF, 4HB, 4HB-S, BP-1, BP-2, BP-3, BP-8, MEHP, MEOHP, MEHHP, MECPP, MCPP, MBP, MiBP, MBzP, MEHHP, MEO

Navrátilová	2022	The Bisphenols Found in the Ejaculate of Men Does Not Pass through the Testes	Exposure to bisphenols is related to negative effects on male reproduction. The bisphenols exposure is associated with several males of action including negative impact on the blood-testis barrier (BTB) function or spermatogenesis. Bisphenol A (BPA) is a well-known endocrine disruptor, which is commonly used in the production of plastics. Its analogs, bisphenol S (BPS) and bisphenol F (BPF), also disrupt the blood-testis barrier in the crucial. Therefore, in this work, we compared the concentrations of BPA, bisphenol S (BPS) and bisphenol F (BPF) in the urine and seminal plasma of these men using liquid chromatography-tandem mass spectrometry (LC-MS/MS). We found that the median of urinary and seminal plasma content of bisphenols did not differ in normozoospermic men or men after vasectomy. From the obtained data, it can be concluded that the pathways of transport of bisphenols into seminal plasma are not primarily through the testicular tissue, but this pathway is applied similarly to other routes of neurotoxicity by a corresponding equivalent value ratio. To a much greater extent than through testicular tissue, bisphenols enter the seminal plasma mainly as part of the secretions of the accessory glands. 統合_0494	Y. Jeong, S. Mok, S. Kim, I. Lee, G. Lee, Y. Kho, K. Choi, K. T. Kim and H. B. Moon	2024	Comparison of urinary exposure profiles to phthalates and bisphenol analogues in kindergartners in Korea: Impact of environmental choices on children's health	Phthalates and bisphenols (BPs) are well-known endocrine-disrupting chemicals (EDCs) that are widely used in diverse consumer and personal care products. Despite their vulnerability, children are frequently exposed to phthalates and BPs in their surrounding environments. Although pre-school children spend most of their time in kindergarten, no comprehensive assessment of children' exposure to EDCs has been conducted according to kindergarten types. Therefore, in this study, we investigated the urinary concentrations of phthalate metabolites and BPs in kindergartners attending eco-friendly and conventional kindergartens. Potential contaminant profiles were investigated according to kindergarten type and the associations between urinary concentrations and dietary habits were assessed. Di-(2-ethylhexyl) phthalate (DEHP) metabolites, such as mono-(2-ethyl-5-carboxypentyl) phthalate (median: 47.1 ng/mL) and mono-(2-ethyl-5-hydroxyhexyl) phthalate (8.83 ng/mL) had the highest levels, indicating that they were the primary contaminants to which the children were exposed. Urinary concentrations of phthalate metabolites and bisphenols (BPS) were higher in children from conventional kindergartens than eco-friendly kindergartens. Consequently, bisphenol S (BPS) concentrations were significantly higher in children from the eco-friendly kindergarten than in those from conventional kindergartens, implying that eco-friendly plastics might contain BPS as a replacement for BPA. The estimated daily intakes of DEHP metabolites were also significantly higher in children from conventional kindergartens. Our findings suggest that children's exposure to phthalates and BPs is associated with their dietary habits and lifestyle-related metabolites, indicating potential adverse health outcomes from phthalate exposure in children. The study highlights the need for targeted interventions to reduce EDC exposure in children, especially in settings where alternative chemicals may still pose health risks. Lepeule	2021	Pregnancy exposure to synthetic phenols and placental DNA methylation - An epigenome-wide association study in male infants from the EDEN cohort	In utero exposure to environmental chemicals, such as synthetic phenols, may alter DNA methylation in different tissues, including placenta - a critical organ for fetal development. We studied associations between prenatal urinary biomarker concentrations of synthetic phenols and placental DNA methylation. Our study involved 282 mother-son pairs from the French EDEN cohort. Nine phenols were measured in spot urine samples collected during pregnancy. DNA methylation was measured in placental samples using Illumina's Infinium HumanMethylation450 BeadChip. We performed robust linear regressions to test for associations between each phenol and each placental CpG site, adjusted for potential confounders. We also performed a robust regression on each sex-stratified dataset and ran an adjusted interaction term analysis to study SEHSD, and identified differentially methylated regions (DMRs). We performed mediation analysis to test whether placental tissue heterogeneity mediated the associations between urinary phenol concentrations and DNA methylation. We identified 68 significant DMRs (<5 CpGs) associated with triclosan (37 DMRs), 2,5-dichlorophenol (6), benzophenone-3 (5), methyl- (3) and propylparaben (1), 4- and 2-MePh (one association) and several with phenol concentrations. Out of the 68 identified DMRs, 17 (for 14 genes) were hypomethylated. Among these genes (AFF1, FTSJD2, SH3BP5, MAN1B1, PHF20, SOX2, ATP6V1C1) were represented a significant enrichment. Other identified DMRs encompassed genes encoding proteins responsible for cell signaling, transmembrane transport, cell adhesion, inflammatory, apoptotic and immunological processes. Sex-stratified analyses revealed sex-specific associations. Some associations were also mediated by placental tissue heterogeneity. Modelling in vitro suggested that placental cell heterogeneity may partly explain these associations. This is the first case-study describing the genome-wide methylome of placental DNA methylation associated with pregnancy exposure to synthetic phenols in their precursors. Our results suggest that cell heterogeneity might mediate the effects of triclosan exposure on placental DNA methylation. Additionally, the enrichment of important genes within the DMRs suggests mechanisms by which certain exposures, mainly in triclosan, could affect fetal development. Philippat	2021	Prenatal exposure to a wide range of environmental chemicals and child behaviour between 3 and 7 years of age - An exposome-based approach in 5 European cohorts	BACKGROUND: Studies looking at associations between environmental chemicals and child behaviour usually consider only one exposure or family of exposures. OBJECTIVE: This study explores associations between prenatal exposure to a wide range of environmental chemicals and child behaviour at 3 and 7 years of age. METHODS: We included 1,277 mother-child pairs from five European birth cohorts. We measured 69 exposure biomarkers from eight chemical families in maternal blood or urine collected during pregnancy. We used the Strengths and Difficulties Questionnaire (SDQ) to evaluate child behaviour between three and seven years of age. We assessed associations of SDQ scores with exposures using an adjusted least absolute shrinkage and selection operator (LASSO) considering all exposures simultaneously and an adjusted exposure-wide association study (EWAS) considering each exposure independently. RESULTS: LASSO selected only copper (Cu) as associated with externalizing behaviour. In the EWAS, bisphenol S (BPS), cotinine (COT), and Cu were associated with SDQ externalizing behaviour (BPS: 1.66, 95%CI: 1.18;2.13) and more in boys (phthalate SMHP: 1.99, 1.06; 95%CI: 1.28;2.72) were associated with greater risk of externalizing behaviour problems. Cu (95% 0.98; 95%CI: 0.52;1.44). Prenatal exposure to BPS, COT, and Cu was also associated with greater risk of hyperactivity/inattention problems at 7 years (BPS: 0.98; 95%CI: 0.52;1.44). These associations were mainly seen among women with insufficient/low/high iodine during pregnancy. Internalizing scores in association with exposure to diethyl thiophosphate (DETP; 1.99; 1.12; 95%CI: 1.04;2.20) but the effect size was driven by the smallest cohort. Internalizing scores improved with increased concentration of perfluorooctane sulfonate (PFOS; 95% 0.92; 95%CI: 0.85;1.00); however the association was driven by the two smallest cohorts with the lowest PFOS concentrations. DISCUSSION: This study added evidence on deleterious effects of prenatal exposure to BPS and DETP on child behaviour. Other associations should be interpreted cautiously since they were not consistent with previous studies or they have not been studied extensively. Hong	2021	Associations Between Thyroid Hormone Levels and Urinary Concentrations of Bisphenol A, F, and S in 6-Year-old Children in Korea	OBJECTIVES: Bisphenol A (BPA) is used in the electrical, mechanical, medical, and food industries. Previous studies have suggested that BPA is an endocrine disruptor. Regulation of BPA has led to increased use of bisphenol F (BPF) and bisphenol S (BPS). However, few studies have investigated the associations of BPF and BPS with thyroid dysfunction in children. Our study investigated the associations of prenatal BPA and early childhood BPA, BPF, and BPS concentrations with thyroid function in 6-year-old children. METHODS: We measured urinary BPA, BPF, and BPS concentrations in 1,562 mother-child pairs in Korea. Of the cohort, We measured urinary BPA, BPF, and BPS concentrations and thyroid hormone levels (thyroid stimulating hormone, total T3, and free T4) in 761 6-year-old children. We examined the associations between urinary bisphenol concentrations, and percentage change of thyroid hormone concentrations using multivariable linear regression. We also compared thyroid hormone levels by dividing the cohort according to BPA, BPF, and BPS concentrations. RESULTS: The associations between prenatal BPA and total T3 levels were statistically significant in all models, except for girls. Urinary as a creatinine. The associations between urinary BPA and BPF concentrations and levels of all thyroid hormones were not statistically significant. However, we observed that boys' free T3 levels (-1.981; 95% confidence interval; -3.82 to -0.13) were associated with higher urinary BPF concentrations. In girls only, CONCLUSIONS: Our findings identified significant associations between prenatal BPA exposure and total T3 levels in all children and between BPF exposure and free T3 levels in girls only. 統合_0498	M. Jamka, S. Kunik, A. Makarewicz-Bukiewska, A. Milkowska-Chobrzda, M. Wasilewicz-Gwiździe and J. Walkowiak	2024	No Differences in Urine Bisphenol A Concentrations between Subjects Categorized with Normal Cognitive Function and Mild Cognitive Impairment Based on Montreal Cognitive Assessment Scores	A link between bisphenol A (BPA) exposure and cognitive disorders has been suggested. However, the differences in BPA concentrations between subjects with and without cognitive impairment have not been analyzed. Therefore, this observational study aimed to compare urine BPA levels in subjects with normal cognitive function (NCF) and mild cognitive impairs (MCI). A total of 84 MCI subjects and 84 well-matched NCF individuals were included in this study. Cognitive functions were assessed using the Montreal Cognitive Assessment (MOCA) scale. Urine BPA concentrations were evaluated by gas chromatography-mass spectrometry and adjusted for creatinine levels. Anthropometric parameters, body composition, sociodemographic factors, and physical activity were also assessed. Creatinine-adjusted urinary BPA levels did not differ between the NCF and MCI groups (1.8 (1.2–2.7) vs. 2.2 (1.4–3.6) µg/g creatinine, p = 0.328). However, there were significant differences in MOCA results between groups since the study population was divided into subjects with normal cognitive function and MCI. Urinary BPA concentrations were not correlated with MOCA scores. Additionally, education levels were independently associated with MCI. In conclusion, urine BPA levels are not significantly different between subjects with MCI and NCF, but these findings need to be confirmed in further studies. 統合_0499	P. Jamsekornkul, N. Numcharikrat, S. Anoopkanthonghkul, K. Soongswang and V. Supornsilchai	2025	Increased maternal urinary bisphenol F levels associated with reduced anogenital distance in male newborns	BACKGROUND: Bisphenol exposure during pregnancy has been linked to a range of adverse reproductive outcomes. However, the full extent of the effects of bisphenol analogs, particularly bisphenol A (BPA), bisphenol S (BPS), and bisphenol F (BPF), on fetal development, especially anogenital distance (AGD), a sensitive marker of reproductive development, remains unclear. We conducted this study to research to investigate associations among maternal and neonatal urinary bisphenol analogs, BPA, BPS, BPF, and AGD. METHODS: This prospective cohort study enrolled 80 mother-newborn pairs in Bangkok, Thailand, from April 2023 to January 2024. Maternal urine samples were collected during the third trimester, and newborn urine samples were collected within 24 h after birth. Urinary bisphenol concentrations were measured using liquid chromatography-tandem mass spectrometry. Correlations were analyzed by Pearson's correlation test and linear regression analysis. RESULTS: High maternal urinary BPF concentrations were negatively associated with anoscrotal distance, anofrontal distance, and penile length in male newborns (t = -0.963, -0.860 and -0.965, respectively; p < 0.05). No significant associations were found for BPA or BPS. Frequent maternal consumption of carbonated drinks was associated with higher neonatal BPS levels, while maternal obesity was positively correlated with maternal BPA concentrations. No significant correlation was observed between maternal and neonatal bisphenol concentrations, nor between neonatal bisphenol levels and AGD. CONCLUSIONS: This study is the first to report a negative association between maternal BPF exposure and AGD in male newborns. These findings highlight the potential endocrine-disrupting effects of BPF on fetal development and emphasize the need for further research. 統合_0500	A. Jamal, N. Rastkari, R. Dehghaniafshar, R. N. Nodeh, S. Nasseri, H. Kashani, M. Shamsipur and M. Yunesian	2020	Prenatal urinary concentrations of environmental phenols and birth outcomes in the mother-infant pairs of Tehran Environment and Neurodevelopmental Disorders (TEND) cohort study	Daily exposure to environmental phenols can lead to potential undesirable effects on the health of pregnant women and fetuses. The present study is aimed to evaluate the relationship between maternal urinary concentrations of phenols in pregnancy and anthropometric birth outcomes. The studied population comprised of 189 pregnant women participating in the Tehran Environment and Neurodevelopmental Disorders (TEND) prospective cohort study, which had been ongoing since March 2016 in some hospitals and health-care delivery centers in Tehran, Iran. Concentrations of bisphenol A, triclosan, 4-nonylphenol, and parabens were determined in spot urine samples of pregnant mothers in the first trimester. Weight, height, and head circumference at birth were also recorded from the mothers' medical records. Multivariable linear regression was used to examine the relationships between log-concentrations of phenols and birth outcomes. Whereas analyzed all samples regardless of newborns' gender, none of the urinary concentrations of phenols were associated with birth weight, length, and head circumference. However, after stratification by gender, urinary concentrations of BPA, triclosan, and propylparaben were associated with birth weight. BPA, triclosan and propylparaben was respectively related to a decrease of 141 (n = 93); (-8.5, -1.1) in boys' height and 0.4 cm (95%CI: -0.8, -1.1) in boys' length in the adjusted models for covariates. Also, the changes in head circumference, per log-unit increase of triclosan, methylparaben, and butylparaben led to a reduction of 1.6 cm (95% CI: -3.17, 0.03), increase of 0.8 cm (95% CI: -0.01, 1.6) and 1.7 cm (95% CI: 0.08, 1.3) in head circumference at birth respectively. Our results suggested that prenatal triclosan and parabens exposure might be associated with head circumference at birth. Furthermore, our observations unusually strengthen pattern between maternal triclosan and parabens exposure during pregnancy and fetal growth. However, these findings must be interpreted while taking into account the limitations of this study. 統合_0501	A. Jala, B. Varghese, R. Dutta, R. Adela and R. M. Borkar	2022	Levels of parabens and bisphenols in personal care products and urinary concentrations in Indian young adult women: Implications for human exposure and health risk assessment	Limited information is available about the levels of exposure of paraben and bisphenols emerging from personal care products (PCPs) use in Indian women and the risk associated with it. In this study, liquid chromatography-tandem mass spectrometry (LC-MS/MS) was used to determine the concentrations of 4 parabens (methyl-, ethyl-, propyl-, and butyl paraben) and 5 bisphenols (BPA, BPB, BPE, BPF, and BPS) in 1 PCPs samples (n = 110) obtained from Indian market and in the urine samples of young adult females (n = 50). The concentrations measured in PCPs and urine samples were used to determine the estimated daily intake. The mean concentrations of 4 parabens and 5 bisphenols in PCPs ranged from 58.0 to 238 × 10(6) ng/g and 2.71–148 ng/g, respectively. In urine sample analyzed, the mean concentrations of 4 parabens and 5 bisphenols ranged from 0.007 to 390 ng/mL and 0.01–33.8 ng/mL, respectively. There was no significant correlation of BPA with age, BMI and waist-to-hip ratio (WHR), but significant correlations (p < 0.05) were observed between urinary paraben and bisphenol concentrations. A statistically significant difference (p < 0.05) exists between the BMI and WHR groups for bisphenol concentrations. Estimated daily intake and hazard index for parabens and bisphenols were found to be essentially harmless for Indian young adult females. Hitherto, this is the first study to show that Indian young adult females were exposed to parabens and bisphenols. The study provides evidence on PCPs usage contribution to the urinary concentrations of EDCs. 統合_0502	R. B. Jain	2021	Concentrations of bisphenol A and its associations with urinary albumin creatinine ratios across the various stages of renal function	Data from National Health and Nutrition Examination Survey for 2003-2016 for US adults aged ≥ 20 years, N = 10,922 were used to study variabilities and associations with urinary albumin creatinine ratio (UACR) in the adjusted concentrations (ADJ) of urine bisphenol A (BPA) across various stages of renal function (RF). RF stages considered were RF 1: (eGFR ≥ 90 mL/min/1.73 m2); RF 2: (60 ≤ eGFR < 90 mL/min/1.73 m2); RF 3A: (45 ≤ eGFR < 60 mL/min/1.73 m2); RF 3B/4/5 (15 ≤ eGFR < 45 mL/min/1.73 m2). Irrespective of gender, race/ethnicity, and smoking status, UACRs for BPA were located on U curves with point of inflection at RF 3A, and RF 3B/4/5 respectively. A similar U curve was observed for those school dropouts but for those with advanced, BPA levels continued increasing with RF 3B/4/5. Same is true for RF 3A, and RF 3B/4/5 respectively. A similar U curve was observed for those school dropouts but for those with advanced, BPA levels continued increasing with RF 3B/4/5. Same is true for dyslipidemia was found to be associated with statistically significantly higher concentrations of BPA in urine. Shape of concentration curves for BPA across RF stages is determined by the balance of actively mediated excretion and reabsorption operating on both sides of renal proximal tubules during each stage of RF. Shape of concentration curves for BPA across various stages of RF was age and race/ethnicity dependent. Associations between BPA and UACR were found to be negative (p < 0.02), positive (p = 0.25), negative (p = 0.93), and negative (p = 0.01) respectively at RF 1, RF 2, RF 3A, and RF 3B/4/5 respectively. 統合_0503	U. Jain, N. Gupta, R. Mathur, S. Nimesh and S. K. Mathur	2020	A Study on Impact of BPA in the Adipose Tissue Dysfunction (Adiposopathy) in Asian Indian Type 2 Diabetes Mellitus Subjects	A surge to increase the production via usage of chemicals at both industrial and agricultural arenas has forced humans to be routinely and imprudently exposed to a wide variety of endocrine disrupting chemicals. The overall aim of the study was to evaluate possible relation that might exist between bisphenol A (BPA) and the adipose tissue hormones, and further impact on adiposopathy. In the present study, the role of BPA, an "endocrine disruptor" with respect to adiposopathy was evaluated in type 2 diabetes mellitus patients. For the study, 100 healthy control subjects and 100 newly diagnosed diabetes patients were recruited. Fasting venous blood samples was analyzed for several biochemical parameters, such as serum glucose, lipid profile, insulin, adiponectin, leptin, TNF- α, IL-6, IL-1, free fatty acid. Concentrations of BPA were also measured both in serum and urine samples. It was found that serum BPA concentrations were found to be significantly higher in diabetic subjects in comparison to the control subjects. Results of BPA were found to be positively correlated with HbA1c, fasting insulin, HOMA-IR, and negatively correlated with adiponectin in diabetic subjects. Also, it was found to be positively correlated with leptin and negatively correlated with adiponectin in diabetic subjects. Therefore, the current study suggested more deleterious effect of BPA in diabetes and its pathophysiology. 統合_0504	M. H. Jacobson, Y. Wu, M. Liu, T. M. Attina, M. Naidu, R. Kanthikeel, K. Kannan, B. A. Warady, S. Furth, S. Vento, H. Trachtman and L. Trasande	2020	Serially assessed bisphenol A and phthalate exposure and association with kidney function in children with chronic kidney disease in the US and Canada: A longitudinal cohort study	BACKGROUND: Exposure to environmental chemicals may be a modifiable risk factor for progression of chronic kidney disease (CKD). The purpose of this study was to examine the impact of serially assessed exposure to bisphenol A (BPA) and phthalates on measures of kidney function, tubular injury, and oxidative stress over time in a cohort of children with CKD. METHODS AND FINDINGS: Samples were collected between 2006 and 2014 from 369 children participating in the Chronic Kidney Disease in Children (CKiD) prospective cohort study. Urinary concentrations of BPA (median 2.2 ng/mL; interquartile range [IQR] 0.9-4.8) and nine DEHP, DBP, and butylbenzyl phthalate metabolites (median 211 ng/mL; IQR 122-361) and urine DBCPA, and parabens had a median age of 11.8 years (interquartile range [IQR] 7.4-15.6) at the baseline visit. In urine samples collected serially over an average of 3.0 visits (standard deviation [SD] 1.6), concentrations of BPA, phthalic acid (PA), and phthalate metabolites were measured as well as biomarkers of tubular injury (kidney injury molecule-1 [KIM-1] and neutrophil gelatinase-associated lipocalin [NGAL]) and oxidative stress (8-hydroxy-2′-deoxyguanosine [8-OHdG] and F2-isoprostanes). Glomerular filtration rate (eGFR) was estimated using the bedside Schwartz equation. Linear mixed models were fit to estimate the associations between urinary concentrations of 5 chemical exposure measures (i.e., BPA, PA, and 4 phthalate metabolite groups) and clinical renal outcomes and urinary concentrations of biomarkers. Models were adjusted for age, sex, race/ethnicity, household income, baseline eGFR, and urinary creatinine concentration. Models were also stratified by sex and by age (<12 years versus ≥12 years) to examine whether associations differed by sex and age, and urinary creatinine. Urinary concentrations of BPA, PA, and phthalate metabolites were associated with increases in NGAL (β = 0.13 [95% CI: 0.05, 0.21]; p = 0.001), KIM-1 (β = 0.10 [95% CI: 0.03, 0.18]; p = 0.005), 8-OHdG (β = 0.09 [95% CI: 0.02, 0.16]; p = 0.01), and F2-isoprostanes (β = 0.08 [95% CI: 0.01, 0.15]; p = 0.03). Associations between urinary BPA concentrations and kidney injury biomarkers were stronger in females than in males (p-interaction = 0.04 for NGAL and p-interaction = 0.03 for KIM-1). Associations between urinary BPA concentrations and kidney injury biomarkers were also stronger in children <12 years of age than in children ≥12 years of age (p-interaction = 0.03 for NGAL and p-interaction = 0.04 for KIM-1). For example, a 2× increase in urinary BPA concentrations was associated with an increase in NGAL (β = 0.13 [95% CI: 0.05, 0.21]; p = 0.001), KIM-1 (β = 0.10 [95% CI: 0.03, 0.18]; p = 0.005), 8-OHdG (β = 0.09 [95% CI: 0.02, 0.16]; p = 0.01), and F2-isoprostanes (β = 0.08 [95% CI: 0.01, 0.15]; p = 0.03). Associations between urinary PA concentrations and biomarkers were also observed but were generally weaker than those observed for BPA. For example, a 2× increase in PA concentrations was associated with an increase in NGAL (β = 0.08 [95% CI: 0.01, 0.15]; p = 0.03), KIM-1 (β = 0.06 [95% CI: 0.00, 0.13]; p = 0.06), 8-OHdG (β = 0.04 [95% CI: -0.02, 0.11]; p = 0.2), and F2-isoprostanes (β = 0.04 [95% CI: -0.02, 0.11]; p = 0.2). Limitations of this study include utilization of spot urine samples for exposure assessment of non-persistent compounds and lack of specific information on potential sources of exposure. CONCLUSIONS: Although BPA and phthalate metabolites were not associated with clinical renal endpoints such as eGFR in preteens, there was a consistent pattern of increased tubular injury and oxidative stress over time, which have been shown to affect renal function in the long term. This raises concerns about the potential for clinically significant changes in renal function in relation to exposure to common environmental toxicants at current levels. 統合_0505	M. H. Jacobson, M. Woodward, W. Bao, B. Liu and L. Trasande	2019	Urinary Bisphenols and Obesity Prevalence Among U.S. Children and Adolescents	Bisphenol A (BPA) has been recognized as an endocrine-disrupting chemical and identified as an obesogen. Although most adolescents, human exposure to BPA has been declining owing to its substitution with other bisphenols. Thus, structurally similar substitutes, bisphenol S (BPS) and bisphenol F (BPF), have raised similar concerns, although fewer studies have been conducted on these newer derivatives. We used data from the U.S. National Health and Nutrition Examination Surveys from 2013 to 2014 to evaluate associations between BPA, BPS, and BPF and body mass outcomes among children and adolescents aged 6 to 19 years. Concentrations of BPA, BPS, and BPF were measured in urine samples collected from 1,852 participants. Body mass outcomes included body mass index (BMI) z-score, overweight, and obesity, according to the 2000 US norms. Multivariate models, also stratified as a priori on socioeconomic/height status of a child, BPA, BPS, and BPF were dichotomized to FOUR, BY ISO, and FIVE of urine samples, respectively. Log-transformed urinary BPS concentrations were associated with an increased prevalence of general obesity (OR, 1.16; 95% CI, 1.01 to 1.32) and abdominal obesity (OR, 1.13; 95% CI, 1.02 to 1.27). BPF detection (vs not detected) was associated with an increased prevalence of abdominal obesity (OR, 1.39; 95% CI, 1.01 to 1.92) and continuous BMI z-score (β = 0.30; 95% CI, 0.02 to 0.57). BPA and total bisphenols were not statistically significantly associated with general obesity, abdominal obesity, or any body mass outcome. These results suggest that BPA substitute chemicals are correlated with obesity in contemporary children. 統合_0506	A. Ishtiaq, M. A. Nasrullah, J. S. Khan, S. Malik, U. Tareen, M. Anees, A. Sultan and I. Murtaza	2023	A cohort study investigating the role of Bisphenol A in the molecular pathogenesis of breast cancer	BACKGROUND: Breast cancer is an abnormal division of breast cells. Bisphenol A (BPA), an environmental toxicant, is identified as an emerging risk factor for breast cancer development. However, to the best of our knowledge, no previous study has investigated the BPA levels in breast cancer patients in Pakistan. The present study sought to explore the role of BPA in tumor growth among the Pakistani population. METHODS: The study was a hospital-based, case-control study conducted between January 2019 and December 2020. A total of 100 breast cancer patients and 100 healthy controls were recruited. Immunohistochemical expression analysis of tumor markers were performed. RESULTS: The level of BPA in the serum samples of breast cancer patients was significantly higher than control. Histopathological analysis of breast cancer tissue samples revealed distinct subtypes of tumor, such as ductal carcinoma in situ (DCIS) and invasive ductal carcinoma (IDC). There was a significant increase in ROS level with a significant decrease in the levels of superoxide dismutase (SOD) and catalase (CAT) enzymes in malignant breast tissue samples as compared to control tissue samples. We found upregulated expression of p53, ZR75-and MKI67 genes at mRNA level in malignant breast tissue samples by 2.77 folds, 328 folds and 16 folds, respectively. p53 protein expression in malignant breast tissue samples was also enhanced at the translational level. CONCLUSION: Current findings suggest a relationship between BPA and the progression of breast cancer among the Pakistani population. 統合_0507	N. Irvine, R. C. Bell, F. B. Subhan, C. J. Field, J. Liu, A. M. MacDonald, D. W. Kinniburgh, J. W. Martin, D. Dewey and G. England-Mason	2024	Maternal pre-pregnancy BMI influences the associations between bisphenol and phthalate exposures and maternal weight changes and fat accumulation	BACKGROUND: Bisphenols and phthalates are two classes of endocrine-disrupting chemicals (EDCs) thought to influence weight and adiposity. Limited research has investigated their influence on maternal weight changes, and no prior work has examined maternal fat mass. We examined the associations between exposure to these chemicals during pregnancy and multiple maternal weight and fat mass outcomes. METHODS: This study included a sample of 338 women enrolled in a Canadian prospective pregnancy cohort. Second trimester urinary concentrations of 2 bisphenols and 12 phthalate metabolites were quantified. Self-reported and measured maternal weights and measured skinfold thicknesses were used to calculate pre-pregnancy BMI, gestational weight gain (GWG) at 3 months and 5- to 9-years postpartum weight retention, and changes in fat mass loss, and late postpartum fat mass retention. Adjusted robust regressions examined associations between chemicals and outcomes in the entire study population and sub-groups stratified by pre-pregnancy body mass index (BMI) (underweight/normal weight, overweight, obese). RESULTS: Pre-pregnancy BMI was associated with greater GWG (β = 0.07 kg/week per BMI unit, 95% CI: 0.04, 0.10), greater maternal fat at 3- to 5-years postpartum (β = 0.65, 95%CI: -0.07, 1.62). Among women with overweight or obese pre-pregnancy BMIs, MEHP and MEP were positively associated with weight retention at 3 months and 5- to 9-years postpartum, respectively (B's = 0.12 to 0.63, 95%CIs: 0.02, 1.07). DEHP metabolites and MCNP were positively associated with late pregnancy fat mass gain and late postpartum fat mass retention (B's = 0.03 to 0.16, 95%CIs: 0.001, 0.31). Further, the nature of EDCs was positively associated with late pregnancy fat mass gain. CONCLUSION: In this cohort, pre-pregnancy BMI was a key determinant of the associations between second trimester exposure to bisphenols and phthalates and maternal weight changes and fat accumulation. Investigations of underlying physiological mechanisms, windows of susceptibility, and impacts on maternal and infant health are needed. 統合_0508	L. M. Iribarne-Durán, L. Serrano, F. M. Peinado, M. Peña-Caballero, J. A. Hurtado, F. Vela-Soria, M. F. Fernández, C. Freire, F. Artacho-Cordón and N. Olea	2022	Biomonitoring bisphenols, parabens, and benzophenones in breast milk from a human milk bank in Southern Spain	BACKGROUND: Human breast milk is considered the optimal source of nutrition for infants. Milk from breast milk banks offers an alternative to infant formulas for vulnerable hospitalized neonates; most likely to benefit from the protective properties of breast milk. However, breast milk can contain contaminants, including endocrine disrupting chemicals (EDCs), including bisphenols, parabens (PBs), and benzophenones (BPs), in samples from a human milk bank in Granada, Southern Spain and to explore sociodemographic, reproductive, and lifestyle factors related to their concentrations in the milk. METHODS: Concentrations of three bisphenols (bisphenol A (BPA), bisphenol F (BPF), and bisphenol S (BPS)), four PBs (methyl- (MeP), ethyl- (EtP), propyl- (n-PrP), and butyl paraben (n-BuP)), and four BPs (BP-1, BP-2, BP-3, and 4-hydroxybenzophenone (4-OH-BP)) were analyzed in 50 breast milk samples donated to the milk bank between 2017 and 2019 by solid-phase extraction and liquid chromatography-tandem mass spectrometry. Multiple linear and logistic regression models were fitted. RESULTS: Detectable concentrations were found in at least one of the analyzed compounds in all breast milk samples and in all four compounds in over 70% of them. The most frequently detected compounds were EtP (90.0%), BP-3 (76.0%), EtP (92.2%), n-PrP (56.0%), and BPA (92.2%). Median concentrations ranged between <0.53 ng/mL (n-PrP) and 1.87 ng/mL (BP-1) and 539 ng/mL (BP-3). Six samples contained detectable concentrations of BPF, BPS, or most BPs (BP-1, BP-3, BP-8, and 4- hydroxy-BP). Breast milk paraben concentrations were associated with parity, the utilization of deodorants, mouthwash, skin care products, and cosmetics, and the intake of nutritional supplements. CONCLUSIONS: Results reveal the widespread presence of BPA, PBs, and BP-3 in donor breast milk samples, highlighting the need for preventive measures to enhance the benefits of breast milk from milk banks and from breastfeeding women in general. 統合_0509	L. M. Iribarne-Durán, F. M. Peinado, C. Freire, I. Castilleo-Rosales, F. Artacho-Cordón and N. Olea	2022	Concentrations of bisphenols, parabens, and benzophenones in human breast milk: A systematic review and meta-analysis	BACKGROUND: Breast milk is the main source of nutrition for infants but may be responsible for their exposure to environmental chemicals, including endocrine disrupting chemicals. AIM: To review available evidence on the concentrations of bisphenols, parabens, and benzophenones in human breast milk. METHODS: A literature search was conducted in PubMed, Web of Science, Scopus, Science Direct, and Access databases, conducting a comprehensive search of peer-reviewed original articles published during the period 1980-2020, including epidemiological and methodological studies. Inclusion criteria were met by 55 studies, which were compiled by calculating weighted detection frequencies and arithmetic mean concentrations of the chemicals. Then risk of bias was assessed using the NORMO-I checklist. RESULTS: Among the 55 reviewed studies, concentrations of bisphenols were assessed by 27 (15.0%), PBs by 21 (11.6%), and BPs by 28 (15.6%). Weighted detection rates were 43.6% for bisphenol A (BPA), 37.1-63.6% for PBs, and 39.5% for benzophenone 3 (BP-3). Weighted mean concentrations were 2.2 ng/mL for BPA, 0.2-13.2 ng/mL for PBs, and 26.4 ng/mL for BP-3. Mean concentrations ranged among studies from 0.1 to 1,900 ng/mL for BPA, 0.1-1,000 ng/mL for PBs, and 0.1-1,000 ng/mL for BPs. Sample sizes ranged from 1 to 1,200 donors. Risk of bias was moderate in 38 studies (69.1%). Greater concentrations were observed in samples collected after 2010. Characteristics of these chemicals were associated with source demographic and lifestyle factors in eight studies (14.5%). Two epidemiological studies showed moderate/serious risk of bias. CONCLUSIONS: This systematic review contributes the first overview of the widespread presence and concentrations of bisphenols, PBs, and BPs in human breast milk, revealing geographical and temporal variations. The methodological heterogeneity of published studies underscores the need for well-conducted studies to assess the magnitude of exposure to these chemicals from human milk.	Sci Total Environ Vol.806 Issue Pt 1 Pages 150437	10.1016/j.scitotenv.2021.150437	34583069	ヒト	-	-	-	-	-	-	バイオモニタリング	1	1	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-
統合_0510	M. N. Suzuma, W. L. Shaiver, C. C. Hong, C. B. Ambrosone and T. O. Chang	2022	Urinary Concentrations of Triclosan, Bisphenol A, and Brominated Flame Retardants and the Association of Triclosan with Demographic Characteristics and Body Fatness among Women with Newly Diagnosed Breast Cancer	Background: Triclosan, bisphenol A (BPA), and brominated flame retardants are environmental estrogenic endocrine-disrupting compounds that may influence the prognosis of breast cancer. We examined the urinary concentrations of these compounds and their associations with demographic characteristics and body fatness in a population of women with newly diagnosed breast cancer. Methods: Overnight urine collection and questionnaire data were collected from 286 women with stage 0-IIIA breast cancer. Urinary concentrations of triclosan, BPA, and BDE-47 were measured using high-performance liquid chromatography-tandem mass spectrometry. Regression analyses were conducted to examine associations of urinary compound concentrations with age, menopausal status, race/ethnicity, body mass index (BMI), waist circumference, and body composition. Results: Triclosan, BPA, and TBBA were detected in urine samples from 98.5%, 6.6%, and 3% of patients, respectively. TBBPA was undetectable. Among patients with quantifiable values, the geometric mean concentrations were 35.9 μg/L (77.50 pg/g creatinine) for triclosan and 0.83 μg/L (1.98 pg/g creatinine) for BPA. Body mass index ≥ 30 vs. <30 kg/m2 was associated with lower triclosan creatinine-corrected urinary concentrations, of triclosan (−40.66, 95% confidence interval [CI] = −77.19 to −2.82; p = 0.0353). The observed association was predominantly in postmenopausal women (−64.01, 95% CI = −88.28 to −13.98%). Creatinine-corrected urinary concentrations of triclosan were lower in Black women than in White women. Conclusions: In this study population, women with newly diagnosed breast cancer had triclosan exposure. Assessments of the implications of urinary concentrations of triclosan for women should consider body fatness and menopausal status. 統合_0511	U. Ihenacho, C. Guilherme, L. R. Wilkens, A. A. Franke, C. Tseng, Y. Li, M. Sangaramoorthy, M. C. Derouen, C. A. Heiman, D. O. Stram, L. Le Marchand, I. Chang and A. H. Wu	2023	Association of Endocrine Disrupting Chemicals With the Metabolic Syndrome Among Women in the Multiethnic Cohort Study	Metabolic syndrome (MetS) is associated with a high risk of cardiovascular disease, a leading cause of death among women. MetS is a diagnosis of at least 3 of the following: high blood pressure, high fasting glucose, high triglycerides, low high-density lipoprotein (HDL) cholesterol, and abdominal obesity. Exposure to endocrine disrupting chemicals (EDCs) may contribute to MetS and its components. We examined associations between EDCs and MetS in a cross-sectional analysis within the Multiethnic Cohort Study. We evaluated the associations between 6 classes of urinary EDCs: bisphenol A (BPA), triclosan, parabens, and phthalates1 and MetS among 1,728 women. Multivariable logistic regression was used to estimate odds ratios and 95% CI for the association between tertiles of each EDC and MetS adjusting for age, body mass index (BMI), racial and ethnic group, and exam center. Stratified analyses by race and ethnicity and BMI were conducted. We identified 539 (31%) women. We did not detect statistically significant associations of MetS with BPA, triclosan, or phthalate metabolite excretion. MetS was inversely associated with total parabens (Ptrend = .002). Although there were no significant associations between parabens and MetS components, parabens were inversely associated with HDL (Ptrend = .03). Associations between parabens and MetS varied by race and ethnicity and BMI. These findings suggest an inverse association between parabens and MetS in larger multiethnic studies. Prospective analyses to investigate suggested differences in associations by race, ethnicity, and BMI are warranted. 統合_0512	A. Iglesias-González, M. Schweitzer, P. Palozzi, F. Peng, S. Haan, E. Lateifer and B. M. R. Appenzeller	2022	Investigating children's chemical exposome - Description and possible determinants of exposure in the region of Luxembourg based on hair analysis	The specific physiology and behaviour of children makes them particularly vulnerable to chemical exposure. Specific studies must therefore be conducted to understand the impact of pollution on children's health. Human biomonitoring (HBM) is a powerful approach to assess the internal exposure to chemicals. Hair is a non-invasive matrix that can be used to investigate both recent exposure and chronic exposure. The present study aims at assessing chemical exposure and investigating possible determinants of exposure in children living in Luxembourg. Hair samples were collected from 296 children before 12 years and tested for 163 compounds (109 pesticides, 47 PCBs, 7 PBDEs and Dibutylbenzils). Moreover, anthropometric parameters, information on diet, residence, and presence of pets at home was collected through questionnaires. Correlations, regressions, t-tests, PLS-DA and MANOVAs, were used to investigate exposure patterns. Twenty-nine to 88 (median = 61) compounds were detected per sample. The highest median concentration was observed for BPA (128.6 pg/mg). Twenty-three biomarkers were detected in ≥ 90% of the samples, including 15 in all samples. 22 pesticides, BPA and BPS. Exposure was higher at younger ages. ISO (OR = 1.07 per pg/mg, p = 0.0001) and DCPP (OR = 1.03, p = 0.0001) were significantly associated with the presence of pets at home. Consumption of fish (OR = 1.03, p = 0.0001), eggs (OR = 1.02 pg/mg) or sweetbread, or urban (+0.001) residence area (e.g. Arlon/central 0.28 pg/mg) or pesticide, or urban (-0.03), and feeding pets (e.g. hamster 0.23 pg/mg) or pets, or urban (-0.002) were identified as determinants of exposure. The present study demonstrates that children are simultaneously exposed to multiple pollutants from different chemical classes, and confirms the suitability of hair to investigate exposure. These results set the basis for further investigations to better understand the determinants of chemical exposure in children. 統合_0513	E. Broc, S. W. Thurston, E. S. Barrett, N. B. Buck, R. H. N. Nguyen, S. Sathyanarayana, A. Reich-enberg, B. R. Collett, S. H. Swan and S. F. Evans	2022	Prenatal bisphenol A exposure in relation to behavioral outcomes in girls aged 4-5 and modification by socio-demographic factors in The Infant Development and Environment Study (TIDES)	Bisphenol A (BPA) is a polymer used in the production of polycarbonate plastics and epoxy resins. Its estrogen mimic, prenatal BPA exposure has been associated with mental behavioral outcomes in children however, findings are inconsistent. We investigated associations between prenatal BPA exposure and behavioral outcomes in girls aged 4-5 years and modification by socio-demographic factors. We measured maternal urinary BPA and behavior in 4-5 year old girls, and to assess whether socio-demographic factors modify this relationship.Mothers enrolled in The Infant Development and Environment Study (TIDES) provided a single spot urine at enrollment (median gestational age 27 weeks) and completed the Behavior Assessment System for Children-2 (BASC-2) and Social Responsiveness Scale-1 (SRS-2) when their daughters were 4-5 years of age. Maternal BPA was measured in urine samples using high performance liquid chromatography-tandem mass spectrometry. We used multivariable linear regression analyses to estimate associations between maternal urinary log(10)-transformed BPA concentration and BASC-2 subscale and composite scores and SRS-2 Total Score. To examine the role of socioeconomic status and race/ethnicity, we stratified by maternal education (≤ high school, > high school) and child's race/ethnicity (Black, White, Hispanic, Other).Participants were 175 girls from three enrollment centers in Minnesota (n = 60), California (n = 57), and New York (n = 58). Participants from these centers were recruited from three distinct populations: those enrolled at the University of Washington, University of Minnesota, and University of California San Francisco, a low-population, more similar higher socioeconomic demographic characteristics. Across all centers, no associations were seen between BPA and BASC-2 or SRS-2 scores. When stratified by income, BPA was significantly associated with greater social impairment as measured by the SRS-2 Total Score (β coefficient=39.9, confidence interval(CI) 5.7,74.1, N=25) in BMC participants (N = 60). In non-BMC participants (N = 115), BPA was significantly associated with lower BASC-2 Internalizing composite (-5.0 [-9.4,-0.6]) and Depression subscale scores (-5.6 [-9.7,-1.5]) within-a-association-s were seen between BPA and SRS-2 scores. Our findings suggest that sociodemographic factors may modify the impacts of maternal prenatal BPA on behavioral endpoints. 統合_0514	M. Hwang, K. Choi and C. Park	2022	Urinary levels of phthalate, bisphenol, and paraben and allergic outcomes in children: Korean National Environmental Health Survey 2015-2017	BACKGROUND: Phthalates, bisphenols and parabens have been widely used in household and personal care products. Their endocrine disrupting, sensitizing and antimicrobial properties might play a role in the occurrence of allergic diseases. However, the effects of these chemicals, particularly on humans, are relatively underexplored. OBJECTIVES: This study aimed to report the concentrations of phthalate, bisphenol and paraben in urine of Korean children, and assess their relationship with allergic outcomes. METHODS: Data obtained from nationally representative Korean children, a total of 1,668 children between 3 and 11 years of age included in the Korean National Environmental Health Survey (5th round of KoNEHS 2015-2017), were analyzed. Associations of urinary phthalate metabolites, bisphenols, and parabens levels with atopic dermatitis and allergic rhinitis were examined by logistic regression analysis. RESULTS: Urinary concentrations of phthalate metabolites, bisphenols, and parabens were higher in children than in adults. Urinary metabolites of DEHP, DBP, and DEP, and BzP and PrP in preschool children, and MEP in school children, were associated with BzP and PrP in preschool children. Urinary metabolites of DEHP, MnP and PrP in school children. The association of urinary chemicals with atopic dermatitis and allergic rhinitis were different by gender, especially in preschool children. CONCLUSIONS: Urinary phthalates, BPA and parabens levels in the Korean children were related with atopic dermatitis and allergic rhinitis. Considering the importance of allergic diseases in children, the public health implications of exposure to these chemicals warrant further studies. Given the cross-sectional design and confounding variables, the results of this study should be interpreted with caution. 統合_0515	T. Husøy, M. Andreassen, H. Hjertholm, M. H. Carlsen, N. Norberg, C. Sprong, E. Papadopoulou, A. K. Sakhi, A. Sabaredzovic and H. Dirven	2019	The Norwegian biomonitoring study from the EU project EuroMix: Levels of phenols and phthalates in 24-hour urine samples and exposure sources from food and personal care products	BACKGROUND: Exposure to multiple chemicals occurs daily through several routes; diet, inhalation and dermal contact. Real life exposure assessment is needed to understand the risk. Therefore, a human biomonitoring (HBM) study was performed to examine the plausibility of source to dose calculations for chemical mixtures in the Horizon 2020 EuroMix project. OBJECTIVES: To provide a detailed description of the design of the EuroMix HBM study in Norway, and present levels of phenols and phthalates in 24-hour urine samples and exposure sources from food and personal care products. METHODS: Spot-adapted diaries on their food consumption, PCP- and toiletting-d' each and male, Urine samples were collected over the same 24-hour period. Urinary levels of four parabens, five bisphenols, eight replacement/transplacement (1 (OMB), triclosan (TCS), triclocarban (TCC) and metabolites of eight phthalates and 1,2- cyclohexane dicarboxylic acid diisononyl ester (DINCH) were analysed by ultra high performance liquid chromatography coupled to tandem mass spectrometry (UHPLC-MS/MS). Associations between urinary biomarker concentrations and questionnaire data were investigated by univariate correlation analysis and multivariate partial least squares regression analysis (PLS-R). The detection limit for the metabolites of phthalates, and DINCH, and bisphenol A (BPA) and TCS was more than 98 (BPA, which bisphenol S (BPS) and bisphenol F (BPF) were only found in 39% and 4% of the urine samples, respectively. Bisphenol B (BPB), bisphenol AP (BPAP) and TCC were not detected. Food groups associated with phthalate exposure were meat, bread, beverages and butter and oil. Food determinants for phthalate exposure were snacks, butter and oil, fruit and berries and other foods. The only positive association between the use of PCPs and phenols was found between BPA and hydroxy-fatty- Phthalate exposure was associated with the use of shower gel, hand cream (females), toothpaste, and in males cream (females) and shaving products (males). CONCLUSIONS: For participants in the Norwegian EuroMix study, exposure to phenols and phthalates was mainly from food. Personal care products were identified as important exposure sources for some chemicals. This indicates a complex pattern of exposure to numerous chemicals from multiple sources, depending on individual diet and PCP preferences. Hao	2022	Prenatal Bisphenol A Exposure and Early Childhood Behavior and Cognitive Function: A Chinese Birth Cohort Study	INTRODUCTION: Biomonitoring of bisphenol A (BPA) in human blood is still scarce, although already noticeable. We aimed to examine the associations between prenatal serum BPA concentrations and behavior and cognitive function in preschool children.METHODS: A total of 1,782 mother-child pairs with complete demographic information, blood samples, and psychological measurements were included from the China Baby Birth Cohort (C-ABCS). We detected serum BPA concentrations and assessed children's neurodevelopment using a set of psychometric scales. RESULTS: The median prenatal maternal serum BPA concentration was 0.23 (IQR, 0.16–0.33) ng/mL, with a detection frequency of 99.7%. Compared with the girls with the lowest serum concentrations, those with higher BPA concentrations had lower IQ scores. Every 10-fold increase in maternal BPA concentrations was associated with a 3.66 (95% CI: 1.82, 5.50) unadjusted difference in children's full-scale IQ (FSIQ) score, implement [relative risk (RR) = 3.66, 95% confidence interval (CI): 1.82, 5.50], emergent metacognition (beginner (RR = 1.78, 95% CI: 1.07, 2.50), conduct problem (RR = 1.68, 95% CI: 1.12, 2.25), peer relationship problem (RR = 1.68, 95% CI: 1.12, 2.25), and hyperactivity (RR = 1.68, 95% CI: 1.12, 2.25). Boys were more susceptible to BPA exposure than girls. Children whose mothers had concentrations had an increased risk of conduct problem compared with those with the lowest concentrations (RR = 1.78, 95% CI: 1.07, 2.50). Interaction = 0.012). After stratification by age, high prenatal BPA concentrations were associated with increased ADHD (RR = 4.43, 95% CI: 1.54, 12.80) among children aged 3 years, not among children aged 5 years. CONCLUSION: Our study revealed the sex-specific and age-specific impacts of prenatal BPA exposure on preschool children's cognitive and behavioral development. 統合_0517	Y. S. Huang, P. L. Hung, L. J. Wang, C. M. Tsai, C. K. Tsai, M. M. Tsai and H. R. Yu	2024	Distinct Impacts of Prenatal and Postnatal Phthalate Exposure on Behavioral and Emotional Development in Children Aged 1.5 to 3 Years	Development is a continuous process, but few studies have assessed the simultaneous impact of prenatal and postnatal phthalate exposure on children's behavioral and emotional development. A total of 190 mother-child pairs were recruited from the Taiwan Maternal and Infant Cohort Study. Urinary concentrations of 11 phthalate metabolites were measured in maternal samples collected during the second trimester and in children's samples collected at 1.5 years old. Behavioral problems were assessed using the Child Behavior Checklist (CBCL). Data ratios (DRs) represent a 1-unit increase in log10-transformed creatinine-corrected maternal urine concentrations. Prenatal maternal urinary MnBP levels were associated with total problems (DR = 1.90, 95% CI: 1.08–33.33, p < 0.02), anxiety (DR = 3.56, 95% CI: 1.28–101.18, p < 0.01), and sleep problems (DR = 11.36, 95% CI: 1.27–96.72, p < 0.01). These findings suggest that prenatal and postnatal exposure to dibutyl phthalate (DBP), metabolized as MnBP, distinctly affects children's behavioral development.	Toxics. 2024 Oct 31;12(11):795.	10.3390/toxics12110795	39590974	ヒト	発達神経	-	-	-	-	-	コホート研究	1	1	-	-	-	-	1	1	1	-	-	-	-	-	-	-	-	-	-	-	-
統合_0518	Y. J. Huang, C. A. Chuang, Y. C. Chang, M. F. Tseng, Y. S. Chiou and C. L. Shih	2024	Advanced metabolomics-based approach to reveal new insights into Bisphenol A metabolism and its presence in human excreta and water bodies in Taiwan	Bisphenol A (BPA) is an environmental contaminant and can be detected in foodstuffs. Hence, investigating BPA metabolism in humans is crucial because certain BPA metabolites may exhibit similar or even greater toxicity than does the parent compound. In this study, we used an advanced metabolomics-based data processing approach along with ultrapermeant liquid chromatography-mass spectrometry (UPLC-MS) to identify BPA metabolites. In human liver enzyme incubation samples, and those metabolites, were further detected in human excreta and water body samples in Taiwan. The first stage involved screening full-scan MS files from the incubation samples into feature information; this stage revealed 1890 and 2027 features with clear recursive relationships in the BPA and isotopically labeled BPA incubation datasets, respectively. The second stage involved using stable isotope tracing to identify isotopic pairs from the two datasets; this stage revealed 290 isotopic pairs. An additional dose–response experiment was conducted to confirm that all these features will be increased in response to increasing BPA concentrations. Finally, the third stage involved using the online METLIN database to search for the 290 isotopic pairs and their corresponding MS/MS spectra for further analysis. To confirm these features as possible BPA metabolites, we compared the isolated MS1 MS/MS spectra between BPA and isotopically labeled BPA incubation samples. The results revealed 75 isotopic pairs with matching isotopically labeled MS/MS spectra. Among these identified features, one feature's m/z value matched to that of a previously reported BPA metabolite, and the other 74 features were novel. However, only 2 of them had proposed structures. We further investigated whether these features could be detected in humans or Taiwanese water bodies. Furthermore, 13 and 7 novel metabolites were identified in human urine and fecal samples, respectively. 17 novel metabolites were identified in the water samples. These findings indicate some of these novel metabolites are present not only in humans but also in various water bodies across Taiwan. Additional research is needed to assess these BPA metabolites, suggesting they may have toxic properties. Further research is warranted to investigate the occurrence of these newly discovered metabolites and assess their potential human health risks. Chan	2021	Prenatal Bisphenol a Exposure, DNA Methylation, and Low Birth Weight: A Pilot Study in Taiwan	Prenatal exposure to bisphenol A (BPA) may increase the risk of abnormal birth outcomes, and DNA methylation might mediate these adverse effects. This study aimed to investigate the effects of maternal BPA exposure on maternal and fetal DNA methylation levels and explore whether epigenetic changes are related to the associations between BPA and low birth weight. We collected cord blood samples originating from 162 mother–infant pairs in Taiwan. Maternal urinary BPA concentrations were measured using high-performance liquid chromatography–tandem mass spectrometry (HPLC–MS/MS). Long interspersed nuclear element-1 (LINE-1) and pyrosequencing of the H19 gene were used to quantify maternal and fetal DNA methylation levels, respectively. Eighty-seven CpGs with the most differentially methylated probes possibly interacting with BPA exposure or birth weight were selected using two multiple regression models. Ingenuity pathway analysis (IPA) was utilized to narrow down 19 candidate CpGs related to disease categories, including developmental disorders, skeletal and muscular disorders, skeletal and muscular system development and function, and organismal development. Finally, we examined the correlations between the methylation levels of these CpGs and birth weight using linear regression models. Higher maternal urinary BPA concentrations were associated with lower birth weight. Similarly, in the epigenome-wide findings, differential methylation of cord blood CpGs, mostly in the epigenetic regulatory genes, was significantly associated with low birth weight. Analysis of the epigenome-wide findings also revealed that maternal BPA exposure was correlated with cord blood DNA methylation in cord blood of the 6 CpGs. However, the adjusted odds ratio for the dehydrogenase/reductase member 9 (DHRS9) gene, at the 2nd CG site, in the hypermethylated group was significantly associated with low birth weight. These results support a role of BPA, and possibly DHRS9 methylation, in fetal growth. However, additional studies with larger sample sizes are warranted. 統合_0520	S. Huang, D. Wang, Z. Qi, C. Long, G. Li and Y. Yu	2023	A large-scale nationwide study of urinary phenols in the Chinese population	Bisphenol A (BPA), tetrabromobisphenol A (TBBPA), and their substitutes are commonly used in everyday products. However, large-scale internal exposure levels of them in China, the factors influencing on them, and the associated health risks remain unclear. This study investigated the urinary concentrations of BPA, TBBPA, and their substitutes in 1,000 Chinese adults and explored the factors influencing on them, and the associations between some bisphenol analogues, as well as TBBPA and its substitutes, i.e., tetrachlorobisphenol A and 2,2′-oxydiethanol-3,3′-dibromobisphenol. The concentrations of 13 bisphenols ranged from <LOD to 38 μg/L and from <LOD to 2.35 μg/L, respectively. BPA and bisphenol S were the main environmental phenols. Residents in eastern China were more exposed to bisphenols, which may be due to the regional production of BPA and the diversity of food consumption patterns of the residents. Education level and age were significantly correlated with bisphenol exposure. Subjects with a bachelor's degree or aged 30–50 years appeared to be more exposed to bisphenols, especially for BPA. Subjects who consumed bottled water and takeaways also had higher levels of bisphenols. Based on RQs, the health risk assessment showed that no subjects had hazard quotients (HQs) > 1 for BPA, TBBPA, and their substitutes, which indicated that 0.6 % of the Chinese general population had a potential non-carcinogenic risk from BPA. This large-scale nationwide study is beneficial for governmental decision-making and the prevention of phenol exposure.	Sci Total Environ Vol.894 Pages 164850	10.1016/j.scitotenv.2023.164850	37331384	ヒト	-	-	-	-	-	-	バイオモニタリング	1	1	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-
統合_0521	S. Huang, Z. Li, C. Wu, X. Zhao, J. Xiang, W. Xiao, H. Su, R. Zhang, Z. Xu, Q. Su, X. Lu, Q. Wang and Z. Su	2025	Divergent effects of EDCs on bone maturation: Role of body mass index and puberty	Exposure to endocrine-disrupting chemical (EDC) mixture and its association with bone maturation in children remain unclear. In this case-control study, the relationship between EDC exposure and accelerated bone maturation (AcBM) in 1,302 children was investigated. Urinary concentrations of 16 EDCs, including bisphenols, parabens, and phthalates, were measured. Bone maturation, as well as current bisphenols, was determined. Logistic regression, weighted quantile sum, Bayesian kernel machine regression, mediation effect analysis, and quantile regression. Girls with advanced BA had significantly lower median concentrations of mono-isobutyl phthalate (MiBP), mono(2-ethyl-5-hydroxyhexyl) phthalate, and BP. Only total monoethyl phthalate (MEP), total bisphenols (BPA, BPF, and BPS), MiBP, and TBBPA were detectable in boys. In girls, mono-methyl phthalate (MMP), MiBP, MEP, and total EDCs were negatively associated. Together, correlations were observed between several phthalate metabolite concentrations and height for the BA standard deviation score. Body mass index (BMI) mediated the associations between mono-methyl phthalate concentration and BPA with advanced BA. The findings reveal that MMP, MiBP, BPA, MEP, and BP exposure exert divergent effects and external sensitivity differences on accelerated bone maturation, with BMI and potential stage playing mediating roles. These findings have significant public health implications, given the prevalence of EDCs and the increasing trends in overweight/obesity, earlier puberty initiation, and accelerated bone maturation.	Ecotoxicol Environ Saf. 2025 Sep 1:302:118525.	10.1016/j.ecoenv.2025.118525	40554108	ヒト	骨	-	-	-	-	-	-	横断研究	1	1	-	-	-	1	1	1	-	-	-	-	-	-	-	-	-	-	-	-
統合_0522	H. Huang, J. Liang, P. Tang, C. Yu, H. Fan, Q. Liao, J. Long, D. Pan, X. Zeng, S. Liu, D. Huang and X. Qiu	2022	Associations of bisphenol exposure with thyroid hormones in pregnant women: a prospective birth cohort study in China	Bisphenols are endocrine-disruptive chemicals that disrupt thyroid hormone homeostasis. However, evidence on the effects of bisphenol mixtures on thyroid hormones are insufficient. Therefore, the present study aimed to explore the effects of bisphenol substitutes and bisphenol mixtures on thyroid hormones during pregnancy. The study was conducted among 600 pregnant women in the Guangxi Zhuang Birth Cohort (GZBC), China. In multiple linear regressions, compared with the low exposure group, bisphenol S (BPS) concentrations in the middle exposure group led to a 10.90% (95% CI: -18.26%, -3.09%) decrease in triiodothyronine (T3) levels; the first trimester (simultaneously with T3/BPS) levels in the middle exposure group led to an 8.36% (95% CI: -15.81%, -0.51%) decrease in T3 levels, in the first trimester (simultaneously with BPS) levels in the high exposure group led to higher free thyroxine (FT4) levels (9.66%, 95% CI: 1.75%, 18.00%) in the second trimester. Bisphenol F (BPF) in the middle exposure group led to higher FT3 levels (8.99%, 95% CI: 0.03%, 17.31%) in the second trimester. Bisphenol A (BPA) in the high exposure group led to higher FT4 levels (8.66%, 95% CI: 0.03%, 17.31%) in the second trimester. Bayesian kernel machine regression (BKMR) models showed a U-shaped dose-response relationship between bisphenol S (BPS) and free triiodothyronine/FT3 (fT3/fT4) (p = 0.02) as well as BPS and FT3 (p = 0.05). Nonlinear relationships were also observed between the bisphenol mixture and FT3. Overall, maternal bisphenol exposure affected thyroid hormone levels during pregnancy. This study provides evidence that BPB, BPF, BPE, and TBBPA are unsafe substitutes for BPA, as well as the overall effect of bisphenols on adverse health in human beings. 統合_0523	L. Hua, W. Liu, Y. Liu, M. Yang, B. Wang, H. Zhu, L. Zhu, Y. Yao, Y. Zhang and H. Zhao	2022	Occurrence and profile characteristics of environmental phenols in human urine from a rural area in Northwestern China	Many environmental phenols, such as bisphenols, benzophenones and parabens, are known as endocrine disrupters and can adversely affect human health. However, the knowledge of human exposure to common environmental phenols in Chinese rural areas is insufficient. In this context, 180 urine samples were collected from participants in a rural area in Northwest China and were analyzed for nine bisphenols, three benzophenones and four parabens. Bisphenol A (BPA), bisphenol S (BPS), benzophenone-3 (BP-3), 4-hydroxybenzophenone, methylparaben (MeP), and butylparaben (BuP) were detected in more than 50% of the urine samples, with median concentrations of 0.568 ng/mL, 0.221 ng/mL, 0.191 ng/mL, 1.30 ng/mL, 0.1820 ng/mL, 20.0 ng/mL, 4.51 ng/mL and 1.90 ng/mL, respectively. A significant positive correlation was observed between BPA and BPS (r_s = 0.2, p < 0.01). Females had significantly higher urinary concentrations of BPA, BPS, BP-3, MeP and PrP than males (p < 0.05). Urinary concentrations of BPA, BPS, MeP and PrP could be influenced by age. Other demographic information, such as annual household income, education and occupation was not associated with the exposure level of the targeted phenols in adults. The estimated daily intakes of the analytes except BPA were all below their respective tolerable/acceptable daily intake levels. This study profiles the demographic differences in the exposure to environmental phenols in general populations from rural areas and provides information on risk assessments. 統合_0524	Y. Hu, S. Lai, Y. Li, X. Wu, M. Xing, X. Li, D. Xu, Y. Chen, J. Xiang, P. Cheng, X. Wang, Z. Chen, H. Ding, P. Xu and X. Lou	2023	Association of urinary bisphenols with thyroid function in the general population: a cross-sectional study of an industrial park in China	Bisphenols (BPs) are potential thyroid disruptors that are widely used in many consumer products, leading to their widespread exposure to the general population. Current cross-sectional and case-control studies have found associations between exposure to BPs and serum thyroid function, but the results were contradictory. The objectives of this study are to describe demographic characteristics, BP exposure levels, and thyroid function measurements in potentially exposed and control districts and to investigate the association of urinary BPs with thyroid function. Data were collected from a general population aged 3-79 years (N = 282) recruited by the Zhejiang Human Biomonitoring Program (ZHBP). The concentrations of 10 kinds of BPs in urine and serum free triiodothyronine (FT3), total thyroxine (TT4), total thyroxine (TT4), thyroid-stimulating hormone (TSH), thyroglobulin (Tg), thyroglobulin antibodies (TgAb), thyroid peroxidase antibodies (TPOAb), and thyrotropin receptor antibody (TRAb) in serum were measured. Multiple linear regression models and restricted cubic spline (RCS) models were used to explore the associations between urinary BPs and thyroid function. The detection rates of BPA, BPF, BPS, BPAF, BPB, BPP, BPZ, BPAP, BPBP, and BPFL were 99.65%, 99.29%, 99.65%, 0.00%, 0.00%, 0.00%, 0.00%, 0.00%, 0.00%, and 0.00%, respectively, in 567 (76.3%, 215/282), 0.00% (0/282), 0.00% (0/282), and 0.00% (0/282) of the population in the exposed area and 83.89%, 61.27%, and 10.66% of the population in the control area. Among individuals, serum TT3 was negatively associated with urinary BPA (β = -0.035, 95% CI: -0.071, -0.000, P = 0.021). Among male females, FT3 and Tg levels were negatively associated with the urinary BPA (β = -0.035, 95% CI: -0.061, -0.002, P = 0.018; 95% CI: -0.061, -0.002, P = 0.018; 95% CI: -0.061, -0.002, P = 0.018;

Shen	2023	Environmental endocrine disruptor Bisphenol A induces metabolic derailment and obesity via upregulating IL-17A in adipocytes	BACKGROUND: Bisphenol A (BPA), a ubiquitous environmental endocrine disruptor, has been extensively demonstrated to be associated with metabolic disorders, including obesity and type 2 diabetes mellitus. However, the underlying mechanism underpinning for the environmental etiology of chronic metabolic disorders has not been sufficiently elucidated. OBJECTIVES: This study is designed to explore the toxicological pathogenesis of chronic inflammation in BPA exposure during obesity. METHODS: We investigated the role of IL-17A in the association of BPA exposure and obesity from human cross-sectional study to animal models, including 3T3-L1 adipocytes, C57BL/6 mice, IL-17A knockout mice and IL-17A neutralizing antibody treated mice. RESULTS: Urinary BPA levels were positively correlated with BMI (β = 0.31, 95% CI: 0.02, 0.60), metabolic disorders and levels of interleukin-17A (IL-17A) in human adipose tissue (all P < 0.05). Consistently, BPA exposure induced obesity and IL-17A production in mice. Moreover, BPA-induced IL-17A secretion from BPA-exposed aggravated body weight gain and insulin resistance, concurrent with much heightened inflammatory responses in the adipose tissue including increase in IL-17A and macrophage polarization towards M1 stage. Genetically modified IL-17A ablated mice (IL-17A(-/-)) showed improved adipose tissue inflammation response. Improved macrophage polarization homeostasis by along with insulin sensitivity in both WT(C) group alone or much more significantly the HFD + BPA group. Moreover, mediation analysis in human epidemiological investigation demonstrated that plasma IL-17A attributed up to 30.03% mediating role in the associations between BPA exposure and obesity risk (OR(CI)=0.03(0). This research paradigm from human to animal provides strong evidence for the elucidation of IL-17A mediating inflammation and insulin resistance in obesity. Such findings reiterate the obesogenic risk of environmental endocrine disruptor BPA in metabolic disorders and unveils the potential toxicological mechanisms underpinning such effect. 統合_0533	X. Hong, G. Wang, X. Liu, M. Wu, X. Zhang, X. Hua, P. Jiang, S. Wang, S. Tang, X. Shi, Y. Huang and T. Shen	2022	Lipidomic biomarkers: Potential mediators of associations between urinary bisphenol A exposure and colorectal cancer	Previous research reported associations between bisphenol A (BPA) exposure and some malignant tumor incidences, yet the underlying mechanism remains largely uncertain. This investigation was aimed to explore the association of BPA exposure burden with colorectal cancer (CRC) and the role of some tissue lipid biomarkers between BPA and CRC. A case-control study was conducted in CRC cases were significantly higher than those in controls (P value < 0.05). BPA was positively correlated with all three cancer CRC biomarkers, with an unadjusted odds ratio (OR) of 4.65 (96% confidence interval (95% CI): 3.21, 6.14). Moreover, the mediation analysis revealed that the associations between BPA exposure and CRC were partially mediated by phosphatidylcholine (PC) (C32:1), phosphatidylethanolamine (PE) (C36:2), diacylglycerol (TG) (C52:2) dimensionless mediation contributions of 21.9%, 18.7%, 16.4%, and 17.9%, respectively. In the association between BPA exposure and CRC. Our work provides novel findings that cancer tissue metabolites may be playing vital mediating roles in the associations between BPA exposure burden and CRC risk. These findings contribute to better understanding of the etiology of CRC induced by environmental stressors. 統合_0534	S. Hong, O. J. Kim, S. K. Jung, H. L. Jeon, S. Kim and J. Ki	2024	The Exposure Status of Environmental Chemicals in South Korea: The Korean National Environmental Health Survey 2018-2020	In South Korea, a Human Biomonitoring (HBM) program, known as the Korean National Environmental Health Survey (KoNEHS), was launched in 2009. This study aims to provide an overview of environmental chemical exposures in South Korea based on data from the KoNEHS cycle 3 (2018-2020). To ensure population representativeness, Koreans aged 3 years and older were recruited from 60 sites across the country. A total of 1893 participants joined in the collection of biospecimens, which were subsequently analyzed for 33 environmental chemicals or their metabolites, including nine that were not tested in the previous cycle. The five most common PFASs were detected in more than 90.7% of the participants. The 95th of serum PFOS was the highest in adults at 10.1 μg/L (10.9, 16.0) and was the lowest in children at 3.1 μg/L (3.0, 3.4). In adults, there was a general decrease in the detection rate and concentration of some heavy metals and phthalate metabolites. In children and adolescents, the detection rate of BPA in urine decreased, while the rate of its substitutes BPF and BPS increased, and the rate of propyl paraben in urine decreased significantly. The results of the KoNEHS cycle 3 indicate that exposure levels to certain environmental chemicals are still high, highlighting further monitoring and re-going surveys to determine their trends, especially for newly investigated substances, such as PFASs. Ko	2024	The associations between maternal and fetal exposure to endocrine-disrupting chemicals and asymmetric fetal growth restriction: a prospective cohort study	Recent evidence has revealed associations between endocrine-disrupting chemicals (EDCs) and placental insufficiency due to altered placental growth, syncytialization, and trophoblast invasion. However, no epidemiologic study has reported associations between exposure to EDCs and asymmetric fetal growth restriction (FGR) caused by placental insufficiency. The aim of this study was to evaluate the association between EDC exposure and asymmetric FGR. This was a prospective cohort study including women admitted for delivery to the Maternal-Fetal Center at Seoul St. Mary's Hospital between October 2020 and October 2022. Maternal urine and blood samples were collected, and the levels of bisphenol A (BPA), monoethyl phthalate, and perfluorooctanoic acid in each specimen were measured. Multivariable and multinomial logistic regression analyses were conducted to evaluate associations between the levels of EDCs and fetal growth parameters, including the head circumference (HC)/abdominal circumference (AC) ratio as an asymmetric parameter. The levels of EDCs were compared between the asymmetric FGR group and the control group. Among 1,200 participants, 1,179 were included in the analysis after excluding 21 participants who withdrew consent. The asymmetric FGR group showed significantly higher maternal and fetal BPA levels compared to the normal growth group (maternal urine BPA, 1.98 μg/g creatinine vs. 1.71 μg/g creatinine [p = 0.006]; cord blood BPA, 1.98 μg/L vs. 0.86 μg/L [p < 0.001]). In conclusion, fetal exposure levels of BPA show linear associations with asymmetric fetal growth patterns. High maternal and fetal exposure to BPA might be associated with asymmetric FGR. 統合_0536	S. Hong, S. K. Choi, J. H. Wie, J. E. Shin, Y. S. Ju, Y. H. Kim, B. S. Kang, O. Kim, S. Won, H. J. Yoon, H. S. Kim, I. Y. Park, M. Yang and H. S. Ko	2025	Effects of Endocrine Disrupting Chemicals on Fetal Weight: Exposure Monitoring Among Mothers with Gestational Diabetes Mellitus and Their Fetuses	Gestational diabetes mellitus (GDM) requires lifestyle changes that may alter exposure to endocrine-disrupting chemicals (EDCs). This study aimed to assess maternal and fetal exposure to EDCs including bisphenol A (BPA), essential phthalates (DEHP), and perfluorooctanoic acid (PFOS) during the GDM-19 pandemic and to evaluate their associations with fetal growth. Maternal urine and blood samples were collected from 58 GDM and 116 non-GDM pregnancies using EPCC-MELMS. Significant correlations were found between maternal urine and cord blood levels of BPA and MEP. Cord blood BPA levels were significantly higher in the GDM group (β = 0.34, p = 0.001), and maternal BPA exposure was associated with increased fetal weight (β = 0.08, p = 0.001). These findings suggest that GDM may enhance placental transfer of BPA. Cord blood triclosan (β = -2.66, p = 0.001), indicating increased susceptibility to obesogenic effects. PFOA was present in all cord blood but only 61% of maternal urine samples. These findings underscore the dual impact of GDM-related lifestyle changes: reduced EDC transfer to the fetus, yet persistent metabolic vulnerability. 統合_0537	S. A. Holmboe, L. Schaub Henriksen, H. Frederiksen, A. M. Andersson, L. Priskorn, N. Jørgensen, A. Juul, J. Toppari, N. E. Skakkebæk and K. M. Main	2022	Prenatal exposure to phenols and benzophenones in relation to markers of male reproductive function in adulthood	INTRODUCTION: Environmental exposure during fetal life may disrupt testicular development. In humans, a limited number of studies have investigated whether these adverse effects persist into adulthood. Using data from a prospective, population-based birth cohort study, The Copenhagen Mother Child cohort, the objective was to assess if there is an association between fetal exposure to selected phenols and benzophenones and markers of testicular function in adult men. METHODS: Pregnant women were recruited in 1997-2000. Their sons were examined clinically at 18-20 years of age, with focus on adult testicular function (congenital absence (CAT), semen quality and reproductive hormones). In total, 351 18-20-year-old men were included, whose mothers during pregnancy had a serum sample drawn and analyzed for bisphenol A (BPA) and benzophenone-3 (BP3). Associations between maternal BPA and BP3 and CAT, semen quality, and reproductive hormones were analyzed using logistic and linear regression analyses. RESULTS: In univariate analyses, increased levels of maternal BPA were associated with higher total sperm count (TSC) and higher total testosterone (TT). In multivariable analyses, increased levels of maternal BPA were associated with higher total sperm count (TSC) (adjusted percentage difference (95%CI) 27.5 (2% to 6%,35%) and TT: 33% (18%,63%), compared to T1) and benzophenone-3 (BP-3): 17.3% (-2%,39%), T3: 18% (-6%,45%)), while no clear association was seen to total testosterone (TT). Higher levels of BPA and BP-3 were associated with a lower T/T ratio, although only significant for BPA up to tertile 2 (T2). As associations were seen to GEU in markers of semen quality, CONCLUSION: In conclusion, high exposure to BPA and BP-3 was associated with a compensated reduced Leydig cell function but no other changes in markers of reproductive health. As maternal levels of BPA and BP-3 were not correlated, separate effects may be at play. Larger studies, as long-term reproductive consequences of prenatal exposure are warranted to validate our findings.	Front Endocrinol (Lausanne). 2022 Dec 9:13:1071761.	10.3389/fendo.2022.1071761	36568115	ヒト	精巣	-	-	-	-	-	-	コホート研究	1	1	-	-	-	-	-	-	1	1	1	-	1	-	-	-	-	-	-	-	-	-	-
統合_0538	A. Hirke, B. Varghese, S. Varade and R. Adela	2023	Exposure to endocrine-disrupting chemicals and risk of gestational hypertension and preeclampsia: A systematic review and meta-analysis	Prenatal exposure to endocrine-disrupting chemicals has been linked to gestational hypertensive (GH) and preeclampsia (PE). However, the results were conflicting and inconclusive. We conducted a systematic review and meta-analysis for an overview of these relationships. We searched PubMed and Google Scholar for studies investigating bisphenol A, phthalates, and per-or-poly-fluoroalkyl substances and GH or PE. Pooled odds ratio (OR) with a 95% confidence interval (CI) were calculated for risk estimate using the generic inverse variance method. A total of 16 studies were included in the present analysis. The pooled results demonstrated that exposure to phthalates (OR = 1.16, 95% CI: 1.03, 1.31, I^2 = 0%, $P_{heterogeneity}$ = 0.46) and PFAS (OR = 1.14, 95% CI: 1.01, 1.28, I^2 = 0%, $P_{heterogeneity}$ = 0.46) during pregnancy were associated with a similar increased risk of PE. There was no significant association observed with perfluorooctanoic acid (PFOA), perfluorooctanesulfonic acid (PFOS), perfluorohexanesulfonic acid (PFHxS), perfluorononanoic acid (PFNA), and perfluoroundecanoic acid (PFUnDA) and PE. For GH, a statistically significant positive association was found with PFOA (OR=1.18, 95% CI: 1.01, 1.39) and PFHxS (OR=1.19, 95% CI: 1.02, 1.39). Among various phthalates analyzed only mono-ethyl phthalate (MEP, OR=1.37, 95% CI: 1.11, 1.70) showed an association with GH. From our analysis, bisphenol A exposure during pregnancy did not show a significant association with the risk of PE. Our findings indicated that exposure to PFASs, such as PFOA, PFOS, and PFHA during pregnancy is associated with an increased risk of PE and PFOA and PFHxS with GH. We also found that MEP was associated with GH. Most of the results were available in semi-finite analysis. Since most of these associations have limited evidence, more research is needed to confirm these findings.	Environ Pollut. 2023 Jan 15:317:120828.	10.1016/j.envpol.2022.120828	36481468	ヒト	生殖発生(メタアナリシス)	-	-	-	-	-	-	メタアナリシス	1	1	-	-	-	-	-	-	1	1	1	-	1	-	-	-	-	-	-	-	-	-	-
統合_0539	M. Herrero, M. C. G. Sauca, N. González, M. Marquina, F. Barbosa, J. L. Domingo, M. Nadal and J. L. Reuta	2023	Dermal exposure to bisphenols in pregnant women's and baby clothes: Risk characterization	Textile manufacturing consists of a multiple-step process in which a wide range of chemicals is used, some of them remaining in the final product. Bisphenols (BPs) are non-intentionally added compounds in textiles, which can be released from clothes and exposure to humans can occur through dermal contact. The aim of this study was to assess the dermal exposure to bisphenol A (BPA), bisphenol S (BPS) and bisphenol F (BPF) in clothes of newborn and baby. BPA, BPF, and BPS (< LOQ) in clothes commercialized in Spain for pregnant women, newborn and children. In addition, exposure assessment and risk characterization were also carried out. Traces of BPA were found in all the samples, with a median concentration of 7.32 ng/g. The highest values were detected in textile samples made of polyester. Regarding natural fibers, higher concentrations of BPs were observed in garments made of conventional cotton than in those made of organic cotton, with a significant difference for BPA (1.24 vs. 0.38 ng/g, p < 0.05). Although toddlers have the highest dermal exposure to BPA per body weight ratio, pregnant women showed higher exposure to BPs than children. Hence, the non-carcinogenic risks associated to BPA exposure were below the unity, even under the upper bound scenario. However, risks could be underestimated because other exposure routes were not considered in this study. The use of BPA has been restricted in some food related products, therefore, BPA should also be regulated in the textile industry. 統合_0540	J. G. Hernández-Pérez, A. Valenzuela-Sánchez, D. S. López and L. Torres-Sánchez	2025	Racial/ethnic disparities in the association of environmental exposure to phthalates and bisphenols mixtures with diabetes mellitus: NHANES 2013-2016	We evaluated the association between urinary concentrations of phthalates/bisphenols mixtures and diabetes mellitus (DM) and yearly-controlled DM, stratified by sex, and race/ethnicity in 2715 adults from the 2013 to 2016 National Health and Nutrition Examination Survey. DM was self-reported or defined by glucose levels/hypoglycemic use. Poorly controlled DM was defined by HbA1c > 9%. Principal component analyses allowed to identify phthalates/bisphenols mixtures. Multivariable logistic regression models were fitted. Mexican American and Other Hispanic participants had the highest prevalence of DM (20.8%). Urinary concentrations of phthalates/bisphenols were higher in Mexican American than non-Hispanic White participants. Exposure to mixtures and "other races" participants. Conversely, the LOW/MH+ mixture was associated with higher DM odds, mainly among Mexican Americans. Racial/ethnicity seems to determine the association between the different exposure mixtures and DM prevalence and poorly-controlled DM. 統合_0541	L. Heras-González, J. A. Latorre, M. Martínez-Beltrán, D. Espino, F. Olea-Serrano and M. Maricalvi-Arcas	2020	The relationship of obesity with lifestyle and dietary exposure to endocrine-disrupting chemicals	Phytoestrogens are natural components of plants, including numerous foods that form part of the habitual diet of humans and animals. They have similar estrogenic effects to those of synthetic endocrine disruptors such as monomers of plastic materials, e.g., polycarbonates and epoxy resins. The most frequently used monomer is bisphenol A (BPA), which has been found to migrate from drink and food packaging, plastic baby bottles, and the coating of cans. Numerous studies have associated exposure to endocrine disruptors with obesity, classifying them as obesogens. The objectives of this study were to estimate the dietary exposure to phytoestrogens and BPA in a population of schoolchildren in Granada (southern Spain) and to assess the relationship between exposure to these substances and obesity. The sample was composed of 81 children (39 boys and 42 girls) between 10 and 12 years old. The effects of the additional estrogenic burden on fighting overweight, as well as definitive conclusion has been reached. Thus, some authors consider that exposure to these substances could contribute activity to be positive at certain stages of life, whereas others regard it as posing a risk at any age. In the present population of children, the likelihood of normal weight versus obesity was significantly related to the total isoflavone intake (OR = 0.11; p = 0.039) as well as to the energy expenditure on physical activity, with lesser activity implying a greater risk of obesity (OR = 1.016; p = 0.001). Further research is warranted on the obesogenic effects of exposure to endocrine disruptors present in foods. Maricalvi-Arcas	2022	Influence of BPA exposure, measured in saliva, on childhood weight	INTRODUCTION: Endocrine disrupters such as bisphenol A (BPA), BPA-glycidyl methacrylate, and other BPA-acrylate-based derivatives have been related to type 2 diabetes, the metabolic syndrome, and obesity, among other metabolic disorders. The objective of this study is to examine the influence of BPA exposure by saliva analysis and daily physical activity on the risk of overweight/obesity in schoolchildren from southern Spain. METHODS: The study included 300 children (53.3% girls) aged 7-10 years. Participants completed a questionnaire with four sections: participant data, including demographic information and family habits; semi-quantitative food frequency questionnaire; anthropometric variables; and physical activity variables. All participants underwent dental examination, when the presence of sealants/composites in each tooth and other dental characteristics were recorded. Saliva samples were collected from 150 children. RESULTS: The prevalence of overweight/obesity was 35.3%. The total consumption (GP + BCP) was higher in boys (OR = 1.01; p = 0.009) and living in towns with higher income (p = 0.0002). In children, we observed lower daily BPA indices in those who were less physically active (p = 0.008) and living in towns with higher income (p = 0.0002). In children, we observed lower daily BPA indices in those living in towns with higher income (p = 0.0002) and following a less western dietary pattern (p = 0.002), and higher daily BPA indices in those who were less physically active (p = 0.021). No significant associations were observed between daily BPA indices and BMI or AC. Despite this, the application of the daily BPA index identified factors associated with dietary BPA exposure and women's further examination in Spain and other understudied populations. Zhong	2023	Interaction of metabolism-related pathway gene variants with bisphenol A exposure on serum lipid profiles	Bisphenol A (BPA) can be metabolized by metabolic enzymes and may induce abnormal lipid metabolism. We hypothesized that BPA exposure and its interaction with metabolism-related genes might be associated with serum lipid profiles. A cross-sectional study was conducted among 1,000 participants in Wuhan, China, from 2013 to 2014. Urinary BPA, serum lipid profiles, and 15 single-nucleotide polymorphisms (SNPs) in metabolism-related genes were measured. Linear regression and multivariate logistic regression models were used to examine the associations of BPA and SNPs with lipid levels. Multiple linear regression was used to analyze the interactions between BPA exposure and metabolism-related genes on serum lipid profiles. In the discovery stage, both in BPA and in SNPs Q-rs4646994 AA genotype, but not in individuals carrying rs4986938 AG or CC genotypes. The interaction between BPA exposure and metabolism-related genes (ADYBP1 rs4986938 and PON1 rs662) was also significant. In the discovery stage, both in BPA and in SNPs Q-rs4646994 AA genotype, but not in individuals carrying rs4986938 AG or CC genotypes. The interaction between BPA exposure and metabolism-related genes (ADYBP1 rs4986938 and PON1 rs662) was also significant. 統合_0546	H. He, Y. Dang, H. Wan, N. Sher, J. Li, Q. Zeng, J. Chang, Q. Lu, X. Miao, J. Tian and R. Zhong	2022	Urinary bisphenol A and its interaction with CYP17A1 rs743572 are associated with breast cancer risk	OBJECTIVE: Bisphenol A (BPA), a common endocrine disruptor, can be activated by cytochrome P450 (CYP) metabolizing enzymes and might influence the development of breast cancer (BC). We hypothesized that BPA exposure and its interaction with CYP-related genes might be associated with BC risk. METHODS: A case-control study was conducted among 1,000 participants in Wuhan, China, from 2013 to 2014. Urinary BPA was measured using high-performance liquid chromatography-high-resolution mass spectrometry. A set of tested CYP1 gene polymorphisms was genotyped using the Sequenom MassARRAY system. A multivariate logistic regression model was used to examine the associations of BPA and BPA-SNP interaction on BC risk. RESULTS: BC patients had a higher urinary BPA concentration than healthy individuals (P = 0.001). Each 1-unit increase in log-transformed urinary BPA was associated with a 46 % increased BC risk (95 % confidence interval (CI): 1.16, 1.77, P = 0.001). Individuals with the CYP17A1 rs743572 AA genotype showed a significantly higher BC risk than those with the GG genotype (OR = 1.45, 95 % CI, 1.01-2.08, P = 0.04). A significant BPA-CYP17A1 rs743572 interaction was found to be associated with a higher risk of BC (P-interaction = 0.026). Compared with low-BPA individuals carrying the rs743572 GG genotype, high-BPA individuals carrying the rs743572 AA genotype had the highest BC risk (OR = 2.13, 95 % CI, 1.31-3.47, P = 0.003, COCLI-03069). The positive association of BPA exposure with BC risk might be modified by CYP17A1 rs743572, providing evidence for the interaction effect of environment genes on the etiology of BC. 統合_0547	G. Hatem, A. M. Faria, M. B. Porto, J. P. Taiwaks, A. Salomoa, C. Costa and J. Madureira	2025	Association between exposure to airborne endocrine disrupting chemicals and asthma in children or adolescents: A systematic review and meta-analysis	Various studies have explored the association between Endocrine Disrupting Chemicals (EDCs) exposure and children's and adolescents' respiratory health, showing potential long-term effects and links to asthma. This systematic review explores the association between exposure to seven EDC groups during school age and adolescence and asthma onset or exacerbation while highlighting the predominant compounds underlying these associations. Following PRISMA guidelines, 3 databases were searched, and 2,000 publications were identified. After applying inclusion and exclusion criteria, 15 studies were selected for review. Meta-analyses for Bisphenols (Bisphenol A and S) and Parabens (methyl- and butyl-) were performed, yielding pooled Odds Ratios (OR) and their 95% Confidence Intervals (CI). Risk of bias was assessed using the newcastle-ottawa scale, and the quality of evidence for each outcome was measured using the GRADE approach. The review included 66893 children and adolescents from 10 observational studies, most with a low risk of bias in the studied domains. The pooled OR for asthma onset was significant for phthalates in dust samples (OR=1.31, CI:1.03-1.65). Due to limited studies, the overall pooled effects for the other groups could not be computed. Individual studies also found significant associations between asthma onset and urinary concentrations of Bisphenols (OR=1.13, CI:1.08-1.18) and co-exposure to Bisphenols and Parabens (OR=1.09, CI:1.03-1.16), with asthma onset included adverse effects (OR=1.36, CI:1.05-1.58) and rhinitis (OR=1.23, CI:1.01-1.51), urinary Bisphenol S (OR=1.82, CI:1.32-1.70), Bisphenol A (OR=1.57, CI:1.07-2.30) and parents (OR=2.08, CI:1.93-5.26), and exposure to Bisphenols (OR=1.13, CI:1.08-1.18) and Parabens (OR=1.09, CI:1.03-1.16) and asthma onset (OR=1.36, CI:1.05-1.58). Exposure to EDCs was significantly associated with asthma onset and exacerbation in children and adolescents, namely for phthalates, bisphenols A and S, parabens, alcohol, and zinc. Further research is recommended to focus on the impact of synergistics and co-exposure to other indoor air pollutants. 統合_0548	C. Hartmann, T. Jamnik, S. Weiss, M. Gödl, Y. Fareed, Y. Salmaa, D. Braun, M. Flasch, B. Warth and M. Uhl	2023	Results of the Austrian Children's Biomonitoring Survey 2020 part A: Per- and polyfluorinated alkylated substances, bisphenols, benzophenones, triclosan, polycyclic aromatic hydrocarbon metabolites, and cotinine Each of the children was exposed to 22 Cl substances simultaneously. Correlations were found between compounds of the same and of divergent substance groups, supporting the strong need to consider multiple exposures and mixture effects. Eight compounds, including perfluorohexanoic acid (PFHxA), perfluorooctanoic acid (PFOA), methyl paraben (4-MeP), and bisphenol A (BPA), could be quantified in >90% of the samples. Perfluorooctane sulfonic acid (PFOS) was detected in all urine samples. The PFAS group the median of detectable substances ranged between <0.0002 µg/l for perfluorodecanoic acid (PFDA) and 0.002 µg/l for PFHxA. For other environmental contaminants investigated, a maximum urinary level of 0.5 µg/l was found for BPA, 0.2 µg/l for triclosan (TCS), 0.3 µg/l for benzophenone-3 (BP-3), and 0.4 µg/l for 4-MeP. Cotinine was detected in 97% of the urine samples. Cotinine or an acceptable daily intake is currently in force. Based on a recently proposed TDI for BPA, daily intakes of all children exceeded this value. A cumulative risk assessment for four parabens and showing exceedances of acceptable exposures. The results demonstrate simultaneous exposure to several different chemicals, with the majority showing impact on the endocrine system being of particular concern with respect to mixture effects. Further assessments with a stronger focus on mixtures are warranted. The results also highlight the need of policy actions as foreseen in the EU Chemicals Strategy for Sustainability. 統合_0549	J. C. Hartle, R. S. Zawadski, J. Rigdon, J. Lam and C. D. Gardner	2022	Development and evaluation of a novel dietary bisphenol A (BPA) exposure risk tool	BACKGROUND: Exposure to endocrine disrupting chemicals such as bisphenol A (BPA) is primarily from the diet through canned foods. Characterizing dietary exposures can be conducted through biomonitoring and dietary surveys, however, these methods can be time-consuming and challenging to implement. METHODS: We developed a novel dietary exposure risk questionnaire to evaluate BPA exposure and compared these results with BPA levels in urine. The questionnaire was administered to 100 participants in 2015 and 2016. Participants were classified as high BPA exposure or low BPA exposure based on their responses. A high BPA exposure foods score identified from the dietary results and used to estimate BPA exposure. Linear regression models estimated the association between BPA exposure and questionnaire responses. A composite risk score was developed to summarize questionnaire responses. RESULTS: In questionnaire data, 35% of participants ate canned food every week. A composite exposure score validated that the dietary exposure risk questionnaire captured known BPA exposure. In the linear regression models, utilizing questionnaire responses, ca. 15 % dietary recall data participants eating canned foods ≥ 2 times/week (vs. never consumed) 0.79 more servings (p = 0.001) of high BPA exposure foods, and those eating canned foods 3 + times/week (vs. never) consumed 0.89 more servings (p = 0.013) of high BPA exposure foods. Participants eating ≥ 3 servings/day (vs. never consumed) 0.86 more total grams of high BPA exposure foods (p = 0.046). CONCLUSIONS: Dietary exposure risk questionnaires are effective and inexpensive approach in 24-hour dietary recalls to quantify dietary BPA exposure with low participant burden. TRIAL REGISTRATION: The trial was prospectively registered at clinicaltrials.gov as NCT02560909 on April 8, 2015.	BMC Nutr Vol.8 Issue 1 Pages 143	10.1186/s40795-022-00634-4	36474269	ヒト	-	バイオモニタリング	1	1	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-
統合_0550	M. E. U. Haq, M. S. H. Akash, S. Sabir, M. H. Mahmood and K. Rehman	2020	Human exposure to bisphenol A through dietary sources and development of diabetes mellitus: a cross-sectional study in Pakistani population	Bisphenol A (BPA) is considered as xenoestrogen, a crucial component utilized for the manufacturing of plastic products. It has a potential to disrupt the endocrine system and induces endocrine related metabolic disorders. The present study investigated the role of BPA exposure in development of diabetes mellitus in Pakistani population. A total of 1000 participants (500 diabetic and 500 healthy) was conducted. BPA was conducted on 300 participants among which 50.70% participants were diabetic and 38.21% were non-diabetic. We developed a structured questionnaire to gathered sociodemographic data, and collected their urine and blood samples for the estimation of BPA and various biomarkers as risk factors of DM, respectively. Pearson correlation coefficient was determined for urinary BPA levels and DM risk factors. Urinary BPA values were adjusted for confounders. Sociodemographic data shows that urinary BPA level was significantly higher (p < 0.05) in obese people (BMI > 27) living in semi-urbanized areas. BPA was detectable in 70% of study participants. Urinary BPA level was found to be higher in diabetic participants compared with that of non-diabetics. A significant correlation is observed between BPA exposure and DM risk factors. We found that urinary BPA concentration was significantly associated with DM (OR = 1.14, 95% CI = 1.05-1.24, p = 0.002). Diabetic participants (OR = 1.14, 95% CI = 1.05-1.24, p = 0.002) who consume rice more frequently (OR = 1.14, 95% CI = 1.05-1.24, p = 0.002) were found to be at risk of DM. Our study adds to the growing body of evidence supporting the role of BPA exposure as a risk factor for DM and may be associated with higher glycemic index, increased pro-inflammatory and oxidative stress biomarkers, dyslipidemia, and impaired functioning of the liver and kidney. Heating food in plastic containers and consumption of packed food items are the main sources of BPA exposure which are positively associated with DM.	Environ Sci Pollut Res Int Vol.27 Issue 21 Pages 26262-26275	10.1007/s11356-020-09044-0	32361967	ヒト	-	横断研究	1	1	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-
統合_0551	K. Hao, J. Luo, J. Sun, H. Ge and Z. Wang	2021	Associations of urinary bisphenol A and its alternatives bisphenol S and F concentrations with depressive symptoms among adults	BACKGROUND: Bisphenol A (BPA) and bisphenol F (BPF), as substitutes for bisphenol A (BPA), are synthetic compounds detected increasingly frequently in plastics and resins. BPA, BPS, and BPF are endocrine disruptors with similar effects on depressive symptoms. This study aims to evaluate the effects of these compounds on depressive symptoms in adults. METHODS: We used data from the U.S. National Health and Nutrition Examination Survey (NHANES) 2007-2016 for BPA (N = 7,280) and NHANES 2013-2016 for BPS and BPF (N = 2,707). BPA, BPS, and BPF were detected in urine samples. Depressive symptoms were examined using a two-item patient health questionnaire (PHQ-9). Logistic regression models were used to investigate the effects of urinary BPA, BPS, and BPF. Systemic biomarkers and multiple logistic regression models were used to investigate the association between maternal BPA exposure (continuous [ln-transformed or divided into tertiles] and the relative differences in ADHD and ASD problems scores and the odds (OR) of an ADHD and autism score above the 90th percentile. RESULTS: In the prospective Odense Child Cohort, BPA was measured in urine samples collected in gestational week 28 and adjusted for osmolality. ADHD and ASD symptoms were assessed with the use of the ADHD rating scale and ASD scale, respectively, derived from the Child Behavior Checklist completed when children were 5 and 7 years old. RESULTS: In the general population, urinary BPA, BPS, and BPF concentrations, an depressive symptoms. RESULTS: In the general population, no significant association was observed between urinary BPA, BPS, and BPF and depressive symptoms. However, in stratified analyses, urinary BPS was positively associated with depressive symptoms in participants aged 20 years or younger (OR: 1.61, 95% CI: 1.01, 2.56, P = 0.045) and in participants with a family income-to-poverty ratio ≤ 1.30 (OR: 1.61, 95% CI: 1.01, 2.56, P = 0.045). In addition, urinary BPA was negatively associated with depressive symptoms (OR: 0.14, 95% CI: 0.03-0.59) in elderly women (≥65 years old). CONCLUSIONS: This study indicated that exposure to BPA and BPS was positively associated with depressive symptoms, especially in men. However, BPF was negatively associated with depressive symptoms in elderly women. 統合_0552	J. B. Hansen, N. Bilenberg, C. A. G. Timmermann, R. C. Jensen, H. Frederiksen, A. M. Andersson, H. B. Kyhl and T. K. Jensen	2021	Prenatal exposure to bisphenol A and autistic- and ADHD-related symptoms in children aged 2 and5 years from the Odense Child Cohort	BACKGROUND: Bisphenol A (BPA) is a non-persistent chemical with endocrine disrupting abilities used in a variety of consumer products. Fetal exposure to BPA is of concern due to the elevated sensitivity, which children have to endocrine disrupting chemicals. OBJECTIVES: To investigate the association between prenatal exposure to BPA and Attention Deficit Hyperactivity Disorder (ADHD) symptoms and symptoms of Autism Spectrum Disorder (ASD) in 2 and 5 year old Danish children. METHODS: In the prospective Odense Child Cohort, BPA was measured in urine samples collected in gestational week 28 and adjusted for osmolality. ADHD and ASD symptoms were assessed with the use of the ADHD scale and ASD scale, respectively, derived from the Child Behavior Checklist completed when children were 5 and 7 years old. RESULTS: In the general population, no significant association was observed between maternal BPA exposure (continuous [ln-transformed or divided into tertiles] and the relative differences in ADHD and ASD problems scores and the odds (OR) of an ADHD and autism score above the 90th percentile. In stratified analyses, urinary BPA was positively associated with ADHD symptoms in children aged 5 years (β = 0.13, 95% CI: 0.01, 0.25, p = 0.032) and in children aged 2 years (β = 0.16, 95% CI: 0.02, 0.30, p = 0.028). Urinary BPA was also positively associated with ASD symptoms in children aged 5 years (β = 0.13, 95% CI: 0.00, 0.26, p = 0.045). In addition, urinary BPA was associated with an increased OR of maternal urine samples were though the highest exposure tertile had the highest OR (OR = 1.7, 95% CI: 0.63-4.59) for children aged 2 years, no ADHD at age 5 years, or ADHD at age 5 years were found. Trends of elevated Odds Ratios (ORs) were seen among 5 year old children within the 3rd tertile of BPA exposure with an ASD score above the 75th percentile (OR = 1.60, 95% CI: 0.97-2.65), being stronger for girls (OR = 3.17, 95% CI: 1.30-8.28). A dose-response relationship was observed between BPA exposure and ASD score at 5 years of age (p-trend 0.08) in both boys and girls, but only significant in girls (p-trend 0.03). CONCLUSION: Our findings suggest that prenatal BPA exposure even in low concentrations may increase the risk of ASD symptoms which may predict later social abilities. It is therefore important to follow-up these children at older ages, measure their own BPA exposure, and determine if the observed associations persist. 統合_0553	W. M. Hussein, R. Al Rukibat, S. Janat-ar and M. Burkan Al-Zghou	2021	Exposure assessment of bisphenol A by drinking coffee from plastic cups	BACKGROUND: Human exposure to plastic and Bisphenol A (BPA) is very wide in food or beverage containers and baby bottles that have contacted polycarbonate and epoxy resin. Currently a traditional beverage in Arabian culture is served in plastic cups instead of glass cups on different occasions. OBJECTIVE: To evaluate the possible BPA load from the grade 5 drinking coffee plastic cups into the coffee and whether the use of a plastic cups instead of glass ones to serve hot Arabian coffee poses a health risk. MATERIALS AND METHODS: Oral administration of such coffee to three different groups of rats were undertaken. Each group consisted of 10 rats. The first group received 1 ml of coffee served in glass cups, the second group received 1 ml of coffee served in plastic cups, and the third group received 1 ml of coffee that had been left in plastic cups. Three concentrations of Bisphenol A were measured weekly later. Comprehensive examination was conducted and representative tissue samples were subjected to histopathological evaluation. RESULTS: In the control group receiving water kept in a glass cup had 24 ± 2 µg/L serum concentration and the second group rat 36 ± 4 µg/L in which the third group was 29 ± 6 µg/L. No significant parameter changes or histopathological findings were present in the studied animals. CONCLUSION: Bisphenol A can be leached from food-grade plastic cups into hot drinks within short period of time causing a significant impact to public health. 統合_0554	D. Ham, M. Ha, H. Park, Y. C. Hong, Y. Kim, E. Ha and S. Bae	2024	Association of postnatal exposure to mixture of bisphenol A, Di-n-butyl phthalate and Di-(2-ethylhexyl) phthalate with Children's IQ at 5 Years of age: Mothers and Children's environmental health (MOCEH) study	Early childhood is important for neurodevelopment, and exposure to endocrine disruptors such as bisphenol A (BPA) and phthalates in this period may cause neurodevelopmental disorders and delays. The present study examined the association between exposure to mixtures of BPA and three metabolites of phthalates in early childhood and IQ at 5 years of age. The Mother and Children's Environmental Health (MOCEH) study is a prospective birth cohort study conducted in Korea on 1751 pregnant women enrolled from 2006 to 2010. After excluding those without relevant data, 57 children were included in the final analysis. We measured urinary concentrations of BPA and phthalate metabolites during the second trimester and at 3 months. Intelligence was assessed using the Korean-Wechsler Intelligence Scale for Children-IV at the age of 5 years. Weighted quantile sum (WQS) regression and quantile g-computation were used to examine the associations between individual endocrine disrupting chemicals and the IQ at the children. Weighted Quantile Sum (WQS) regression and quantile g-computation were used to assess the association between exposure to mixtures of BPA and phthalate metabolites and IQ at 5 years of age. In the WQS regression model, a one-IQR increase in the mixture was associated with children's IQ (β = -4.93, 95% CI: -9.63, -0.23). In quantile g-computation, a one-quantile increase in the mixture was associated with lower IQ (β = -5.13, 95% CI: -9.68, -0.58). Among the components, MEP (β = -3.08, 95% CI: -6.18, 0.02) and MBP (β = -2.04, 95% CI: -4.08, 0.00) were associated with lower IQ (β = -5.13, P-value = 0.026) and BPA (β = -5.13, P-value = 0.026) were associated with lower IQ (β = -5.13, P-value = 0.026). Prenatal exposure to mixtures of BPA and phthalate metabolites was

Covaci	2021	Determinants of exposure levels of bisphenols in flemish adolescents	The broadly used industrial chemical bisphenol A (BPA), applied in numerous, consumer products, has been under scrutiny in the past 20 years due to its widespread detection in humans and the environment and potential detrimental effects on human health. Following implementation restrictions and phase-out initiatives, BPA is replaced by alternative bisphenols, which have not received the same amount of research attention. As a part of the fourth cycle of the Flemish Environment and Health Study (FLEHS IV, 2016-2020), we monitored the internal exposure to six bisphenols in urine samples of 225 adolescents (14-15 years old) from Flanders, Belgium (Dutch-speaking northern region of Belgium). Additionally, information on potential determinants of exposure was collected via questionnaires. Urinary concentrations of BPA and seven bisphenol analogs (BPS, BPF, BPAF, BPB, BPZ, BPP, BPM) were determined using automated solid-phase extraction coupled to ultra-high performance liquid chromatography-tandem mass spectrometry. Since chemicals with similar structures may co-occur in consumer products, we investigated the co-occurrence between bisphenol compounds. Additionally, we explored the temporal trends in the concentrations of bisphenols between 2011 and 2020 by comparing the current results with those from previous cycles of the FLEHS. Creatinine corrected concentrations were used to account for urine dilution. Bisphenol concentrations were detected in almost all samples (>90%), except for BPAF (<LOD) and BPZ (<LOQ). Median concentrations were 0.70 µg/g creatinine for BPA, 0.11 µg/g creatinine for BPS, 0.10 µg/g creatinine for BPF, and 0.01 µg/g creatinine for BPB. Co-occurrence between bisphenols was observed, with BPA and BPS showing the strongest correlation (Spearman's rho = 0.69). Multivariate regression models revealed that urinary BPA concentrations were significantly associated with higher concentrations of the oxidative stress biomarker, 8-hydroxy-2'-deoxyguanosine (8-OHdG). BPA and BPF levels were higher in children from families with lower household income. Bisphenol concentrations were significantly influenced by some other personal (e.g. household income), food intake (e.g. vegetables and cow milk) and indoor housing characteristics (e.g. flooring). This is the first study to report longitudinal time trends of bisphenols in Japan. The presented findings imply that further research on bisphenols is warranted in the future to monitor whether these time trends continue. Covaci	2020	Biomonitoring and temporal trends of bisphenols exposure in Japanese school children	The widely used chemical bisphenol A (BPA), applied in various consumer products, has been under scrutiny in the past 20 years due to its widespread detection in humans and potential detrimental effects on human health. Following the implementation of restrictions and phase-out initiatives, BPA has been replaced by other structurally similar bisphenols, which have not yet received the same level of research attention. In this study, we aimed to 1) investigate the internal exposure to seven bisphenols in morning void urine samples collected from 7-year old children from Hokkaido, Japan and 2) assess possible time trends in the concentrations of bisphenols between 2013 and 2017. Information on demographic, indoor environment and dietary characteristics of participants was acquired through a self-administered questionnaire. All bisphenols were detected in >50% of samples, except for BPAF (<LOD) and BPZ (<LOQ). Median concentrations were 0.70 µg/g creatinine for BPA, 0.11 µg/g creatinine for BPS, 0.10 µg/g creatinine for BPF, and 0.01 µg/g creatinine for BPB. Co-occurrence between bisphenols was observed, with BPA and BPS showing the strongest correlation (Spearman's rho = 0.69). Multivariate regression models revealed that urinary BPA concentrations decreased significantly over the study time period (around 0.9 µg/g creatinine per year). Levels of BPS and BPF were higher in autumn compared to winter. Higher urinary BPF levels were significantly associated with higher concentrations of the oxidative stress biomarker, 8-hydroxy-2'-deoxyguanosine (8-OHdG). BPA and BPF levels were higher in children from families with lower household income. Bisphenol concentrations were significantly influenced by some other personal (e.g. household income), food intake (e.g. vegetables and cow milk) and indoor housing characteristics (e.g. flooring). This is the first study to report longitudinal time trends of bisphenols in Japan. The presented findings imply that further research on bisphenols is warranted in the future to monitor whether these time trends continue.	Environ Res Vol.191 Pages 110172	10.1016/j.envres.2020.110172	32919958	ヒト	-	-	-	-	-	-	バイオモニタリング	1	1	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-
統合_0560	Z. Guo, X. Ren, P. Liu, Y. Deng, J. Biar, Y. Ga, B. Xu, X. Tang, X. Li, H. Huang, J. Liu and S. Lu	2024	Co-exposure to parabens, bisphenol A, and triclosan and the associations with dyslipidemia in Chinese older adults: The mediation effect of oxidative stress	Dyslipidemia is a prevalent metabolic disorder in older adults and has negative effects on cardiovascular health. However, the combined effect of parabens, bisphenol A (BPA), and triclosan (TCS) exposure on dyslipidemia and the underlying mechanisms remain unclear. This cross-sectional study recruited 881 individuals ≥65 years in Shenzhen, China. Morning spot urine samples were collected and analyzed for four parabens, BPA, TCS, and 8-hydroxy-2'-deoxyguanosine (8-OHdG), a typical biomarker for oxidative stress, using mass spectrometry. Blood samples were tested for lipid levels using an automated biochemical analyzer. Quantile-based g-computation (qgcomp), weighted quantile sum (WQS) regression, and Bayesian kernel machine regression (BKMR) models were used to assess the joint effects of the mixtures. Mediation analysis was then conducted to explore the role of oxidative stress. Results showed that exposure to parabens, BPA, and TCS was positively linked with hypercholesterolemia (OR: 1.17, 95%CI: 1.04-1.31, P = 0.009), hypertriglyceridemia (OR: 1.19, 95%CI: 1.06-1.33, P = 0.003), dyslipidemia (OR: 1.17, 95%CI: 1.04-1.31, P = 0.009), low high-density lipoprotein cholesterolemia (OR: 1.18, 95%CI: 1.05-1.33, P = 0.005), Methylparaben (MeP), n-propyl paraben (PrP), and butylparaben (BtP) were the major contributors. 8-OHdG mediated 9.9% and 13.9% of the overall effect of the examined chemicals on hypercholesterolemia and hypertriglyceridemia, respectively (all P < 0.05). Our study indicated that co-exposure to parabens, BPA, and TCS is associated with dyslipidemia and oxidative stress partially mediates the association. Future research is needed to explore additional mechanisms underlying these relationships.	Environ Res Vol.262 Issue Pt 1 Pages 119835	10.1016/j.envres.2024.119835	39181298	ヒト	-	-	-	-	-	-	横断研究	1	1	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-
統合_0561	Y. Guo, C. Liu, Y. H. Dang, J. Ning, L. Yu and J. L. Wu	2023	Association between Bisphenol A exposure and body composition parameters in children	BACKGROUND: Although there is evidence linking Bisphenol A (BPA) exposure to obesity, research examining its relationship with body composition parameters in young children is limited. METHODS: A cross-sectional investigation was conducted on 280 preschool children aged between 3 and 6 years in Guangzhou, China. BPA exposure was assessed through urine samples using ultra-high performance liquid chromatography-tandem mass spectrometry. Body composition parameters were measured using bioelectrical impedance analysis. Multivariate linear regression models (MLR), BKMR, and WQS were employed to assess the relationship between BPA exposure and body composition parameters. RESULTS: The geometric mean (GM) of urinary BPA concentration was 1.49 μg/L, and creatinine-adjusted BPA concentration was 0.92 μg/g (CR 0.92). After adjusting for confounders, each 1-fold increase in BPA levels was significantly associated with body mass index (BMI) (β = 0.19, 95%CI: 0.04, 0.34), BMI z-score (β = 0.11, 95%CI: 0.04, 0.18), fat mass (β = 0.43, 95%CI: 0.03, 1.82), and percent body fat (β = 3.44, 95%CI: 1.17, 5.71) after adjusting for potential confounding factors. Similarly, adjusted models with log2-BCI transformed creatinine-adjusted BPA concentrations as a continuous variable showed similar trends. Positive linear associations were observed between quartiles of BPA concentrations and body composition parameters, with the highest coefficients in the fourth quartile. CONCLUSION: Our study provides further evidence of positive correlations between BPA exposure and body composition parameters in children aged 3 to 6 years. These findings highlight the potential health risks associated with obesity-related body composition parameters in young children. Further investigations are needed to confirm this association and explore the underlying mechanisms. Sun	2023	Association of a mixture of phthalates and phenols with frailty among middle-aged and older adults: A population-based cross-sectional study	BACKGROUND: Frailty is a complex geriatric syndrome caused by degenerative changes in the body or various chronic diseases. The use of personal care and consumer products is associated with a wide range of health outcomes, but its relationship with frailty remains unknown. Therefore, our primary aim was to explore the potential links between exposure to phenols and phthalates, either separately or in combination, and frailty. METHODS: The exposure levels of phthalates and phenols were evaluated through the measurement of metabolites in urine samples. Frailty status was assessed by a 36-item frailty index with values ≥ 0.25 indicating frailty. Weighted logistic regression was used to explore the relationship between individual chemical exposure and frailty. In addition, multi-pollutant strategies, WQS, BKMR, and qgcomp, were used to examine the joint effect of chemical mixture on frailty. A series of subgroup analyses and sensitivity analyses were conducted as well. RESULTS: In the multivariate logistic regression model, each unit increase in natural log-transformed MEP, MBP, MBzP, MEHP, MEHHP, MEOHP, MECPP, MCPP, 2,4-DCP, and 2,5-DCP was significantly associated with a 1.09-, 1.11-, 1.08-, 1.08-, 1.08

Köhler-Vallant, Z. Dellosen, S. Wells and M. Uhl	2021	Gene Variants Determine Placental Transfer of Perfluoroalkyl Substances (PFAS), Mercury (Hg) and Lead (Pb), and Birth Outcome: Findings From the UmMuKi Bratislava-Vienna Study	Prenatal exposure to perfluoroalkyl substances (PFAS), bisphenol A (BPA), lead (Pb), total mercury (THg), and methylmercury (MeHg) can affect fetal development. Factors influencing placental transfer rate of these toxins are poorly investigated. Whether prenatal exposure to pollutants has an effect on birth weight is incompletely understood. We therefore aimed (1) to determine placental transfer rates of PFAS, BPA, Pb, Thg, and MeHg, (2) to analyze relationships between fetal exposure and birth outcome and (3) to analyze gene variants as mediators of placental transfer rates and birth outcome. Two hundred healthy pregnant women and their newborns were recruited in Vienna (AUT) and Bratislava (SVK) between 2012 and 2014. PFAS, BPA, Pb, Thg, and MeHg were measured in maternal blood, cord blood, and term placenta. Genotyping was performed for some placental transfer genes. Associations between exposure and birth outcome were assessed by survey-regression models. Data and tissue samples from 200 mother–child pairs were interviewed by trained PhDs or from maternal and newborn blood. Genotype information was determined by real-time PCR for five maternal and newborn blood. Genotype information was determined by real-time PCR for five maternal and placental genes. Genotype–phenotype associations were analyzed by categorical regression and logistic regression analysis. Specific gene systems were associated with altered placental transfer of PFOS (ABCA3 rs4149561, ABCG2 rs2231142, GST TyrRNAse, GSTT1 del, ABCC1 rs246221 and PLTP rs7679; dual (dual). A certain combination of these gene polymorphisms (ABCC1 rs246221, ABCG2 rs2231809, HFE H63dDGal) was over-represented in newborns small for gestational age. 95% of Austrian and 75% of Slovakian mothers had levels exceeding the HBM guidance value (1.7 µg/L) of the German HBM Commission for PFOA. 13% of newborns and 38% of women had Pb levels above 35 µg/kg, an exposure limit for the BMBS (50 of 52 µg/L set by the European Food Safety Authority (EFSA). Our findings point to the need to minimize perinatal exposures to protect fetal health, especially those genetically predisposed to increased transplacental exposure. Seven	2021	Effects of Bisphenol A Released From Composite Fillings on Reproductive Hormone Levels in Men	OBJECTIVES: Composite resins are the most preferred filling material because of their excellent aesthetic qualities. However, a filling material should also be biocompatible as well as aesthetic. The aim of this study was to determine the short-and long-term effects of bisphenol A (BPA) levels and to examine the effects of serum BPA on reproductive hormone levels after healthy men were treated with composite fillings. METHODS: Eighteen healthy males each received 2 composite restorations. Saliva and blood samples of subjects were collected before resin application and 1 day and 1, 3, and 5 weeks after the resin was applied. BPA amounts in samples were analyzed by high-performance liquid chromatography. Serum testosterone, luteinizing hormone, follicle-stimulating hormone, and prolactin levels were measured by chemiluminescence assay kits. Statistical analysis of data was made using Friedman, Wilcoxon signed-ranks, and Mann-Whitney U tests (α = 0.05). RESULTS: The amount of BPA released from the composite resins over time was not significantly elevated in either saliva or serum (P > 0.1). In addition, serum BPA levels were significantly higher than saliva BPA levels for both composites. (P < .05), but saliva and serum BPA levels were not statistically different when comparing the 2 composites. (P > .05). CONCLUSIONS: BPA from composite resins used in this study did not significantly alter serum hormone levels. 統合_0573	A. Guilbert, M. Rolland, I. Pin, C. Thomsen, A. K. Sakhi, A. Sabaredzovic, R. Slama, K. Guldvik and C. Philippat	2021	Associations between a mixture of phenols and phthalates and child behaviour in a French mother–child cohort with repeated assessment of exposure	BACKGROUND: Synthetic phenols and phthalates can interfere with biological pathways involved in brain development. Despite the high within-subject temporal variability of urinary concentrations observed for their metabolites, studies investigating effects of phenols and phthalates on child behaviour often relied on a limited number of spot biospecimens to assess exposure. Besides, the majority did not consider relative effects, i.e. effects of the whole mixture of chemicals. METHODS: We measured 2 phenols (bisphenol A and triclosan) and 5 phthalate metabolites (monoethyl phthalate and 4 low-molecular-weight phthalates) in 2 urine samples collected during pregnancy in 420 mother–child pairs from the French SEPAGES cohort. Child behaviour was evaluated at two years using the Child Behaviour Checklist 1.5-5 (CBCL). Associations between a mixture of biomarkers of exposure and externalizing and internalizing behaviour scores were studied using adjusted Weighted Quantile Sum (WQS) regressions with a repeated holdout validation (100 repetitions). RESULTS: The mixture was associated with higher scores on the externalizing and internalizing behaviour scores in the whole population, indicating greater risk of behavioural problems. Overall baseline for children suggested stronger associations in girls than boys. On average, girls in the highest WQS quintile had CBCL externalizing T-scores 3.42 (95% CI: 0.86, 5.98) higher than girls in the lowest quintile, and internalizing T-scores 3.32 (95% CI: 0.22, 6.41) higher. Boys had 1.47 (95% CI: -0.82, 3.76) and 1.17 points (95% CI: -0.86, 3.40) higher scores for the associations observed in girls were bisphenol A (weight of 28%), triclosan (17%) and monoethyl phthalate (MEP, 16%) for the externalizing score and MEP (39%), mono-benzyl phthalate (MBzP, 19%) and mono-n-butyl phthalate (MnBP, 16%) for the internalizing score. DISCUSSION: Our results suggest adverse associations between in utero exposure to a mixture of phenols and phthalates and child behaviour, mainly in girls. Public health consequences may be substantial due to the widespread exposure of the population to these compounds. 統合_0574	L. Gu, Z. Wang, Y. Pan, H. Wang, L. Sun, L. Liu, W. . i. Zhong and W. B. Zhang	2023	Associations between mixed urinary phenols and parabens metabolites and bone mineral density: Four statistical models	Phenols and parabens widely exist in personal care and consumer products and have been proved to be endocrine disrupting chemicals that could disturb bone metabolism. The current studies focusing on the associations between phenols and parabens with bone mineral density (BMD) does contradictory conclusions. Considering the bias might be due to not considering the effects of mixed exposure, we conducted the first cross-sectional study to investigate the associations of both single and mixed metabolites of phenols and parabens with BMD in three populations by setting up four models: generalized linear regression model (GLM), weighted quantile sum (WQS) regression, quantile g-computation (QGC) and Bayesian kernel machine regression (BKMR) in the National Health and Nutrition Examination Survey (NHANES) database. We found that the association between the mixtures and total femur's BMD in men was significantly negative. Bisphenol A (BPA) was shown to contribute most to the negative association in the BKMR model, and this negative association was also confirmed in the GLM model with -β coefficient (95% CI) being -0.022 (-0.041, -0.003). The relationships between the mixtures and femoral neck and trochanter BMD in postmenopausal women were significantly positive. Benzophenone-3 (BP-3) played the most significant role in the positive association with trochanter BMD, as confirmed by the WQS, qgcomp and BKMR models, and this positive association was also verified by the GLM model with β coefficient (95% CI) being 0.01 (0.00, 0.02). In conclusion, the association between the mixed phenols and parabens and BMD was negative in men and positive in postmenopausal women with BP-3 as the main gender-specific. This study might provide new ideas for the prevention and treatment of osteoporosis and the control of personal care and consumer products containing phenols and parabens in the future. 統合_0575	M. N. Grohs, J. E. Reynolds, J. Liu, J. W. Martin, T. Pollock, C. Lebel and D. Dewey	2019	Prenatal maternal and childhood bisphenol a exposure and brain structure and behavior of young children	BACKGROUND: Bisphenol A (BPA) is commonly used in the manufacture of plastics and epoxy resins. In North America, over 90% of the population has detectable levels of urinary BPA. Human epidemiological studies have reported adverse behavioral outcomes with BPA exposure in children; however, corresponding effects on children's brain structure have not yet been investigated. The current study examined the associations between prenatal maternal and childhood BPA exposure and white matter microstructure in children aged 3 to 5 years, and investigated whether brain structure mediated the association between BPA exposure and child behavior. METHODS: Participants were 96 mother-child dyads from the Alberta Pregnancy Outcomes and Nutrition (APrON) cohort. Maternal urine samples were collected during pregnancy and from children at 3 years of age (one sample/participant) to quantify BPA concentrations. Diffusion tensor imaging (DTI) scans at age 3 (n = 67) and 5 (n = 51) were used to assess white matter microstructure. Maternal and childhood BPA and children's functional anisotropy and mean diffusivity of 12 isolated white matter tracts were investigated, controlling for urinary creatinine, child sex, and age at the time of MRI. Post-hoc analyses examined alterations in white matter associated the relationship of BPA and children's scores on the Child Behavior Checklist (CBCL). RESULTS: Prenatal maternal urinary BPA was significantly associated with child mean diffusivity in the splenium and right inferior longitudinal fasciculus. Splenium diffusivity mediated the relationship between maternal prenatal BPA levels and children's internalizing behavior (indirect effect: β = 0.04, 95% CI = 0.01, 0.08). Maternal prenatal BPA was also associated with altered splenium diffusivity and white matter microstructure. CONCLUSIONS: This study provides preliminary evidence that the neural correlates of BPA exposure in humans. Our findings suggest that prenatal maternal exposure to BPA may lead to alterations in white matter microstructure in preschool-aged children, and that such alterations mediate the relationship between early life exposure to BPA and internalizing problems. 統合_0578	V. Gounden, R. N. Naidoo and A. Chuturgoon	2024	A pilot study: relationship between Bisphenol A, Bisphenol-glucuronide and total 25 hydroxy vitamin D in maternal-child pairs in a South African population	INTRODUCTION: Exposure to Bisphenol A (BPA) during early development particularly in utero has been linked to a wide range of pathology. Over the last two decades the importance of vitamin D in maternal and child health has been highlighted. The aim of this pilot study was to examine the relationship of BPA and its naturally occurring metabolite BPA glucuronide (BPA-g) with 25-hydroxy vitamin D (25(OH)D) levels in South African mother-child pairs. METHODS: Third trimester serum maternal samples and matching cord blood samples were analysed for BPA and BPA-g using liquid chromatography tandem mass spectrometry (LC-MS/MS) and 25(OH)D and 25(OH)D2 using high-performance liquid chromatography. A total of 98 maternal and child pairs were analysed. RESULTS: More than fifty percent of maternal-child pairs were noted to be vitamin D deficient (<50 nmol/L). Rank correlation demonstrated a significant positive relationship between maternal and cord blood BPA (p = 0.002) and maternal BPA levels (p = 0.02) respectively. A significant positive association between maternal and cord BPA-g concentrations. Analysis of covariance after controlling for confounders showed a significant relationship between cord BPA-g levels and cord 25(OH)D levels (p-0.01) as well as between maternal BPA-g levels (p-0.02) and cord total 25(OH) levels (p-0.02). DISCUSSION: The findings of the current study indicate a possible relationship with BPA/BPA-g and fetal/early infant Vitamin D levels that needs to be further investigated in this population.	Front Endocrinol (Lausanne). 2024 Nov 28:15:1108969	10.3389/fendo.2024.1108969	39669493	ヒト	その他(ビタミンDレベル)	-	-	-	-	-	-	横断研究	1	1	-	-	-	1	1	1	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-
統合_0579	P. González-Palacios, V. Ramírez, C. Murteiagudo, A. Zafra-Gómez and A. Rivas	2025	Bisphenol A exposure and behavioral outcomes in children: A systematic review and meta-analysis of evidence limited to the BASC assessment tool	BACKGROUND: The growing concern about exposure to endocrine disrupting chemicals (EDCs), and their effects on human health, especially the possible neurobehavioral effects in children, makes a review of the scientific evidence on the subject important. The study conducts a systematic review and applies meta-analysis to determine whether there is a relationship between bisphenol exposure and behavioral development in children, as measured by the Behavioral Assessment System for Children (BASC). METHODS: In June-and-July 2023, Scopus, Web of Science, and Medline and Embase via Ovid were searched to search for studies within the scope of this study. A total of 1967 articles were found, of which 19 were analyzed. Finally, 13 studies met the inclusion criteria for systematic review and 7 for the meta-analysis. The studies measured in the meta-analysis were grouped into three categories: externalizing behaviors, internalizing behaviors, and behavioral symptoms index. The Newcastle-Ottawa Scale was used to assess the quality of the studies. Most of the studies found no significant associations, and no consistency in the results obtained. The heterogeneity in the design of the studies made it impossible to perform sensitivity results in the application of meta-analysis. CONCLUSIONS: There is a non-based differentiation in the behavioral effects associated with bisphenol exposure, as bisphenols affect boys and girls differently, potentially through mechanisms involving estrogen receptors, among other biological pathways. SIGNIFICANCE: Our study highlights the need to improve and homogenize the design and results of epidemiological studies, to extract data effectively. More results are needed to be able to draw conclusions. 統合_0580	N. González, M. Marquès, S. C. Cunha, J. O. Fernandes, J. L. Domingo and M. Nadal	2020	Biomonitoring of co-exposure to bisphenols by consumers of canned foodstuffs	For new occupationally exposed adults, dietary intake is the main route of exposure to bisphenols (BPs), with canned foodstuffs playing a key role. This study was aimed at biomonitoring bisphenol S (BPS) and 5 more BP analogues (BPA, BPE, BPF, BPAP and BPZ) in pool urine and blood samples of a cohort of adults, who followed a diet based on a high consumption of canned food. To the best of our knowledge, this is the first study aimed at assessing the co-exposure of BP analogues in food and biological samples after a two-day duplicate diet study. The recruitment and dietary exposure was 3.27 and 0.180 µg/kg body weight/day for the canned food consumers (CFC) group, and 0.0 and 0.0 µg/kg body weight/day for the non-canned food consumers (NCFC) group. BPA was detected in 100% of the urine samples of the CFC group, 78% for the canned diet group and 50% for the control group, while in blood it could be only quantified in 6% of the samples. The identification of other analogues was also scarce, as it could be the result of other potential exposure sources, such as personal care products (PCPs) or air inhalation. After 2 days, the excretion of BPA was considerably higher in the canned diet group subjects than those in the control group (7.03 vs. 1.89 µg/day), confirming that diet was indeed foodstuffs are the main route of exposure to BPs. Anyhow, the temporary tolerable daily intake (t-TDI) established by the EFSA was not exceeded, even by those consumers with a diet rich in canned food. Moreover, spot urine samples provided accurate information about exposure and excretion of BPA, being the 6 h, instead of 24 h, the optimal sampling interval, when the collection of spot urine samples is not possible.	Environ Int Vol.140 Pages 105760	10.1016/j.envint.2020.105760	32371307	ヒト	-	-	-	-	-	-	バイオモニタリング	1	1	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-
統合_0581	N. González, S. C. Cunha, C. Monteiro, J. O. Fernandes, M. Marquès, J. L. Domingo and M. Nadal	2019	Quantification of eight bisphenol analogues in blood and urine samples of workers in a hazardous waste incinerator	Bisphenol A (BPA) has been widely used in the manufacture of polycarbonate plastic and epoxy resins. In recent years, producers have started replacing BPA by other chemical analogues, such as bisphenol -S (BPS) and -F (BPF), all of them under the label "BPA-free". However, despite bisphenol (BP) analogues have a very similar structure, their endocrine disrupting properties could differ from those of BPA. Unfortunately, information on human exposure to BPA substitutes is still very limited. The present study was aimed at assessing the occurrence of eight BPs (BPA, BPS, BPF, BPE, BPB, BPAP, BPZ and BP-4) in biological samples from a controlled cohort of workers in a hazardous waste incinerator (HWI) located in Catalonia (Spain). Firstly, a chemical method to quantify simultaneously the eight BPs in blood and urine was optimized, being samples quantified by means of gas chromatography coupled to mass spectrometry (GC-MS). Furthermore, a biomonitoring study was performed by collecting samples of total blood and urine of 39 people working in the HWI. Among the 8 BP analogues assessed, BPA presented the highest levels in both biological samples, with mean total (free + conjugated) BPA concentrations of 5.48 and 0.66 µg/L in blood and urine, respectively. Free vs. total BPA levels presented a mean percentage of 79% in blood and 39% in urine. Beyond BPA, traces of BPB were also found in a single sample of blood. Furthermore, none of the remaining BP analogues was detected in blood or urine. Despite BPA has been regulated, it is still very present in the environment, being human exposure to this chemical still an issue of concern for the public health. 統合_0582	S. Gorkowski, M. Tarczyński, E. Demitzaki, K. Makowska and J. Wojtkiewicz	2022	Hair Sample Analysis of Residents from Olsztyn, Northeastern Poland, to Evaluate Levels of Bisphenol S and Bisphenol A: A Pilot Study	BACKGROUND:Bisphenol A (BPA) and its analogue bisphenol S (BPS), widely utilized in numerous fields of industry, may come into the environment and into human organisms. Hitherto, BPA was regarded as the bisphenol with the greatest significance in terms of human exposure and health consequences. However, due to the restrictions imposed on BPA, BPS has become more frequently used in many technologies. Their analysis has been increasingly used for biomonitoring of treatments in humans, but information about the coexistence of BPA and BPS in human hair is extremely scarce. The present study aimed to examine hair samples from 26 individuals from Olsztyn, northeastern Poland, to evaluate the levels of these 2 industrial pollutants. MATERIAL AND METHODS: The method used in the research was liquid chromatography with a fluorescence detector (LC-FLD). BPA was found in 77% of analytes examined and its concentrations ranged from 50 to 915 pg/mg (median 57 pg/g). The BPS concentrations were higher - from 120 to 1884 pg/mg (median 86.7 pg/g). We also found that gender, age, and the presence of artificial hair color had an effect on the BPA and BPS levels in the hair. CONCLUSIONS:This study has shown that hair samples may be useful in assessing the levels of bisphenols, and that exposure to BPS may be greater than that to BPA in this area. The investigations also revealed that hair analysis is a useful approach for the biomonitoring of BPA and BPS levels in human organisms. 統合_0583	S. Gömar-Oliete, S. Rötzer, U. Rolle-Kampczyk, U. Sack, M. von Bergen, M. Barta, A. C. Zenclussen and G. Herberth	2025	Prenatal exposure to mixtures of phthalates and bisphenol A and eczema risk: findings in atopic and non-atopic children from the LINA birth cohort	BACKGROUND: We investigated whether maternal exposure to phthalate and bisphenol A (BPA) mixtures is associated with eczema in children, as most studies have only addressed single chemical exposures. METHODS: Nine phthalate metabolites and BPA were quantified in urine at gestational weeks 30 (6 (n = 620) and infant, inhalant, and food allergen specific immunoglobulin (IgE) levels (u/L) and IgG were measured in serum from 5-year-old children of the LINA cohort (n = 319). The association of prenatal exposure to phthalates and BPA, both single and mixed, with eczema and IgE was assessed in children stratified by atopy status. Three independent statistical models adjusted for covariates were used: logistic regression' also in the sex-stratified analysis - weighted quantile sum (WQS) regression, and Bayesian kernel machine regression (BKMR). RESULTS: Prenatal exposure to phthalate mixtures was associated with eczema in atopic children (OR: 1.3, 95% CI: 1.05-1.62) and non-atopic children (OR: 1.3, 95% CI: 1.09-1.62) and the sum of di-2-ethylhexyl phthalate metabolites (OH6, 1-3, 6-OX) were significantly associated with eczema exclusively in atopic boys. The BKMR suggested a positive trend between chemical exposure and IgE values in the atopic subgroup. In the WQS model, the mixtures' positive effect on eczema among atopic children was significant (1.46, 1.06-2.01) with MBzP (59.9 %), monoethyl phthalate (13.3 %), and BPA (13.8 %) being the main contributors, which jointly modulate antibody-mediated immunity and inflammatory gene pathways in the host epigenetic profile. CONCLUSIONS: Maternal exposure to mixtures of phthalates and BPA differentially impacts eczema risk among atopy-stratified children. This in utero chemical-gene interaction analysis in atopic children identified genes involved in immune cell activation and Ig production. Compared to non-atopic children, individual phthalates were significantly associated with eczema in atopic boys, suggesting that chemicals may have a larger effect size in predisposed populations. 統合_0584	M. Goldney, M. A. Adgent, D. R. Stevens, H. B. Chin, K. K. Ferguson, A. M. Calafat, S. Trevino, E. G. Ford, V. A. Stallings, W. J. Rogan, D. M. Umbach, D. D. Baird and D. P. Sandler	2024	Environmental phenol exposures in 6- to 12-week-old infants: The Infant Feeding and Early Development (IFED) study	BACKGROUND: Exposure to phenols, endocrine-disrupting chemicals used in personal care and consumer products, is widespread. Data on infant exposures are limited despite heightened sensitivity to endocrine disruption during this developmental period. We aimed to describe distributions and predictors of urinary phenol concentrations among U.S. infants ages 6–12 weeks. METHODS: The Infant Feeding and Early Development (IFED) study is a prospective cohort study of healthy term infants enrolled during 2010-2012 in the Philadelphia region. We measured concentrations of seven phenols in 282 urine samples, collected during the 1- or 2-month study visit, using online SPE-HPLC-MS/MS. We estimated geometric means (GMs) and 95% confidence intervals (CIs) for detectable phenols and examined associations with demographic and feeding characteristics using multivariable linear regression models. RESULTS: Median concentrations (μg/L) were: BP-3 in benzophenone-3, 0.4 for benzophenone-1, 2.2 for triclosan, 1.0 for 2,5-dichlorophenol, 0.7 for BPA, and 0.3 for 2,4-dichlorophenol. Geometric mean methylparaben concentrations were approximately 10 times higher than published estimates for U.S. children and adults. Triclosan was detected in 98% of samples, and concentrations were 2 to 3 times higher than published estimates for U.S. children and adults. Concentrations of 2,5-dichlorophenol (DCP) and mean concentrations of benzophenone-3 (1.70%) and triclosan (1.90%) but not BPA (0.16%) in milk from mothers of White mothers. Triclosan concentrations were higher in breastfed infants (1.9-fold) and lower in infants whose mothers had a high school education or less (-62%). Phenol concentrations were generally higher in summer samples. CONCLUSIONS: Widespread exposure to select environmental phenols among this cohort of healthy U.S. infants, including much higher paraben concentrations compared to those reported for U.S. children, supports the importance of expanding population-based biomonitoring programs to infants and toddlers. Future investigation of exposure sources is warranted to identify opportunities to minimize exposures during these sensitive periods of development. 統合_0585	J. Goerdten, L. Yuan, I. Huybrechts, V. Nawaz, U. Nöthlings, W. Ahrens, A. Scalbert and A. Fouque	2022	Reproducibility of the Blood and Urine Exposome: A Systematic Literature Review and Meta-Analysis	Endogenous and exogenous metabolite concentrations may be susceptible to variation over time. This variability can lead to misclassification of exposure levels and in turn to biased results. To assess the reproducibility of metabolites, the intraclass correlation coefficient (ICC) is commonly used in human exposure omics studies. Data on 15 single-metabolites are reported, and the ICCs of 10 metabolites were meta-analyzed. The reproducibility of the single-metabolites ranged from poor to excellent (ICC: 0.00–0.93). Pooled ICCs were 0.69 (95% CI: 0.61, 0.76) for 2,5-dichlorophenol, 0.68 (95% CI: 0.61, 0.74) for 2,4-dichlorophenol, 0.67 (95% CI: 0.60, 0.73) for benzophenone-3, 0.67 (95% CI: 0.60, 0.73) for mono(2-ethyl-5-hydroxyhexyl) phthalate (MEHHP), more than phthalate (MBzP), mono-(3-ethyl-5-oxohexyl) phthalate (MEOHP), methylparaben, and propylparaben, low to moderate (ICC median: 0.51; range: 0.31–0.85), and for 25-hydroxyvitamin D (25(OH)D), it is excellent (ICC: 0.93; 95% CI: 0.90–0.95). Pharmacokinetics, mainly the half-life of elimination and exposure patterns, can explain reproducibility. This review describes the reproducibility of the blood and urine exposome, provides a worst-dataset of ICC estimates, and hence constitutes a valuable resource for future reproducibility and clinical epidemiologic studies. 統合_0586	M. Gérard-Walton, C. Wavembsung, P. L. Williams, L. Souter, J. B. Ford, J. E. Chavarro, R. Hauser and L. Mínguez-Alarcón	2025	Using mixture and exposome methods to assess the associations and interactions of chemical biomarkers with semen parameters	BACKGROUND: Although epidemiologic studies have found associations between several chemical biomarkers and semen parameters, only a few studies have evaluated their combined effects and interactions. OBJECTIVES: To assess the individual and combined associations between urinary biomarkers of exposure to BPA, phthalates, and phenols and semen parameters. METHODS: Two mixture/exposome models, including exposome-wide association studies (ExWAS), Deletion/Substitution/Addition algorithm (DSA), Bayesian Kernel Machine Regression (BKMR), and the non-linear interaction model (NLI-interaction), were used to evaluate associations between 33 chemical biomarkers (urinary bisphenol A, four parabens, triclosan, 17 phthalate metabolites, and total mono-(hydroxyl and oxo)-paraben). Sperm count, motility, and morphology were measured in 1,540 samples from 1,044 men from the LIFE Study. Multivariable linear regression models were used to estimate associations between exposure mixtures and semen parameters. RESULTS: In BKMR, when modeling the mixture from the 10th to 90th percentile, the chemical mixture was negatively associated with percent normal sperm morphology (-1.43%; 95% CrI: -2.68, -0.19). In DSA NLI, mono-(2-ethyl-5-oxohexyl) phthalate (MEOHP) (-0.28; 95% CI: -0.53, -0.02; p = 0.03) and mono-(3-carboxypropyl) phthalate (MCPP) (-0.28; 95% CI: -0.53, -0.03; p = 0.03) were associated with lower sperm motility. In ExWAS, MEOHP (-0.28; 95% CI: -0.53, -0.03; p = 0.03) and mono-benzyl phthalate (MBzP) (-0.18; 95% CI: -0.36, 0.00; p = 0.05) were associated with lower sperm motility. Using DSA NLI, mono-(carboxyoctyl) phthalate (MCOP) (-0.68; 95% CI: -1.36, -0.01; p = 0.05) was associated with lower sperm morphology. In ExWAS, MCOP (-0.68; 95% CI: -1.36, -0.01; p = 0.05) was associated with lower sperm morphology. In DSA NLI, mono-(2-ethyl-5-hydroxyhexyl) phthalate (MEHHP) (-0.28; 95% CI: -0.56, 0.00; p = 0.05) was associated with lower sperm motility. In ExWAS, MEHHP (-0.28; 95% CI: -0.56, 0.00; p = 0.05) was associated with lower sperm motility. DISCUSSION: Among 33 biomarkers tested, two and nine were associated with lower sperm motility and morphology, respectively. Two mixture/exposome models identified MEOHP as associated with lower sperm motility. Two mixture/exposome models identified MCOP as associated with lower sperm morphology. Two mixture/exposome models identified MEHHP as associated with lower sperm motility. Two mixture/exposome models identified MCPP as associated with lower sperm motility. In ExWAS, MEHHP was associated with lower sperm motility. In ExWAS, MCOP was associated with lower sperm morphology. In DSA NLI, MEHHP was associated with lower sperm motility. In DSA NLI, MCOP was associated with lower sperm morphology. In DSA NLI, MCPP was associated with lower sperm motility. In DSA NLI, MEOHP was associated with lower sperm motility. In DSA NLI, MEOHP was associated with lower sperm motility. In DSA NLI, MEOH

統合_0597	P. Gangadaran, B. Bharti, S. V. Attri, V. S. Malik and A. Pintal	2024	Biomonitoring Study of Urinary Bisphenol A Levels and Impact of Bottle-Feeding Practices Among Infants and Children From Northern India	OBJECTIVES: To compare the urinary bisphenol A (BPA) levels in bottle-fed and never-bottle fed infants and under-five children and to determine the impact of bottle feeding practices and sociodemographic factors on urinary BPA levels. METHODS: A community-based cross-sectional study was carried out on children aged between 2 to 60 months attending the hogarwali centres in Chandigarh. RESULTS: Urine samples were collected from 1,000 children (mean age: 19.5 ± 14.5 months; 53.5% boys). Urinary BPA was detected in 70.5% of children, with a median concentration of 0.90 ng/mL (0.90 and 56.34 ng/mL at lower bottle-fed children (n = 82; 90.2% [P = 0.69]). On multivariate regression analysis, there were no significant predictors for high (> 75th percentile) urinary BPA levels. Only the urinary BPA levels >75th percentile showed higher trend for significance among children from middle/higher socioeconomic background in reference to lower socioeconomic strata (adjusted OR 1.82; 95% CI 0.91, 3.63; P = 0.07) and among children whose feeding bottles were brushed once or twice daily in reference to a group with no daily brushing (adjusted OR 2.65; 95% CI 0.96, 7.30; P = 0.07). CONCLUSIONS: Although feeding with plastic bottle did not emerge as a statistically significant risk factor for BPA exposure, yet detection of BPA levels among majority of study children signals urgent need for unmasking exposure to other sources given the potential long-term toxicity of BPA among infants and young children. Rivas	2023	Levels of Bisphenol A and its analogs in nails, saliva, and urine of children: a case control study	INTRODUCTION: A growing number of studies link the increase in overweight/obesity worldwide to exposure to certain environmental chemical pollutants that display obesogenic activity (obesogens). Since exposure to obesogens during the first stages of life has been shown to have even more intense and permanent effect on lean shown, it is important to study their possible role in childhood. The objective here was to study the association of Bisphenol A (BPA) and 13 BPA analogs in children, using three biological matrices (nails, saliva and urine), and overweight and obesity (n = 160). METHODS: In this case-control study, 99 overweight/obese children and 61 normal-weight children, aged 3-12 years, were recruited. Nail, saliva and urine samples were collected and analyzed by ultra-high performance liquid chromatography-tandem mass spectrometry (UHPLC-MS/MS). Logistic regression was used to study the association between overweight/obesity and Bisphenol exposure. RESULTS: The results suggested that BPF in nails is associated with overweight/obesity in children (OR=3.67 p < 0.029). In saliva, however, the highest detected concentrations of BPAP presented an inverse association (OR=0.66; p = 0.033) with overweight/obesity. No associations of statistical significance were detected between exposure to BPFs in the other analogs and overweight/obesity in any of the biological matrices. Zafra-Gómez	2024	Dietary bisphenols exposure as an influencing factor of body mass index	BACKGROUND: Over the past three decades, there has been a significant increase in the prevalence and incidence of overweight and obesity worldwide. The obesogen hypothesis suggests that certain external agents, including endocrine disrupting chemicals (EDCs), can disrupt metabolic homeostasis, leading to an increased susceptibility to obesity. Bisphenols (BPs) are EDCs that have been shown to have significant influence by accumulation by promoting the transformation of endogenous into adipocytes. This study aimed to assess the possible contribution of dietary bisphenol exposure to the risk of developing overweight and obesity in a sample of Spanish children according to sex. METHODS: Dietary and anthropometric data were collected from 175 controls and 126 cases schoolchildren aged 5-13 years. Dietary exposure to BPA and BPS was estimated by combining occurrence data with consumption data. Urinary concentrations of BPA and BPS were determined by ultra-high-performance liquid chromatography-tandem mass spectrometry (UHPLC-MS/MS). RESULTS: For females, cases had significantly higher exposure to BPA from meat and eggs compared to controls (median = 104.56; interquartile range (IQR) = 174.39-30.17 vs. 30.17; 30.17-0.00 ng·d-1·kg-1 bw-1; p = 0.006). Diet quality was higher for controls (6.21 (2.12) vs. 4.80 (2.24) p < 0.001) among males independently of a high or low exposure to bisphenols. However, higher diet quality was observed for female controls with a high exposure of total bisphenols (6.79 (2.56) vs. 5.31 (2.01); p < 0.011). Females exposed to high levels of BPA from meat and eggs had higher likelihood of being overweight and obese (adjusted Odds Ratio = 2.73; 95% confidence interval = 1.08-7.20). However, no consistent associations were found in males. CONCLUSIONS: High BPA levels from meat and eggs were positively associated with overweight and obesity in females. The dietary intake of BPA in the schoolchildren in the present study was much higher than the acceptable daily intake established by EFSA for the last year.	Environ Health. 2024 Oct 29;23(1):93.	10.1186/s12940-024-01134-7	39472930	ヒト	代謝	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-
統合_0600	P. Gajjar, Y. Liu, N. Li, J. I. P. Buckley, A. Chen, B. P. Lanphear, H. J. Kalkwarf, K. M. Cecil, K. Yolton and J. M. Braun	2022	Associations of mid-childhood bisphenol A and bisphenol S exposure with mid-childhood and adolescent obesity	BACKGROUND: Bisphenol A (BPA) is a suspected obesogen that has been associated with adiposity in children. Bisphenol S (BPS), a structural analog of BPA, is used as a BPA substitute and may have similar health effects as BPA. However, few studies have examined whether BPS is associated with childhood adiposity. METHODS: We quantified urinary BPA and BPS concentrations in 315 children age 8 years from the HOME Study, a prospective pregnancy cohort enrolled in Cincinnati, Ohio (2003-2006). We measured body mass index (BMI), waist circumference, and triceps skinfold thickness at age 8 years and BMI z-score, waist-to-height ratio, and fat mass/height2 at age 12 years (n = 241). We assessed associations between concentrations at age 12 years (n = 159). Using multivariable linear regression, we estimated covariate-adjusted associations of BPA and BPS with adiposity measures at ages 8 and 12 years and adipose-positive concentrations at age 12 years. RESULTS: Each SD fold increase in urinary BPA concentrations were inversely associated with percent body fat at age 8 years (β = -1.2; 95% confidence interval [CI]: -1.6, -1.0) and 12 years (β = -1.4; 95% CI: -1.8, 0.9). In contrast, urinary BPS concentrations were positively associated with percent body fat at age 8 years (β = 1.1; 95% CI: -0.6, 2.7), but not at 12 years (β = 0.1; 95% CI: -1.7, 1.8). Urinary BPA and BPS concentrations were not associated with severe adiposity or leptin concentrations. CONCLUSIONS: We did not observe evidence that urinary BPA or BPS concentrations during childhood were associated with greater mid-adiposity at ages 8 and 12 years in this cohort. 統合_0601	Z. Fu, H. Jin, W. Mao, S. Yin, L. Xu and Z. Hu	2024	Conjugated metabolites of bisphenol A and bisphenol S in indoor dust, outdoor dust, and human urine	Bisphenol A (BPA) and bisphenol S (BPS) have been widely spread in the global environment. However, for conjugated BPA and BPS metabolites, limited studies have investigated their occurrence in environmental matrices and human samples. In this study, we developed a method for the analysis of 12 conjugated BPA and BPS metabolites in indoor and outdoor dust, and human urine using ultra-high performance liquid chromatography-tandem mass spectrometry (UHPLC-MS/MS). Three BPA metabolites were found in ambient indoor and outdoor dust, and BPA sulfate (mean 0.79 and 1.12 ng/g, respectively) and BPA glucuronide (0.63 and 0.66 ng/g) being were dominant. BPS conjugates accounted for a mean of 42 and 66% of total BPS burst of conjugated BPA and BPS metabolites) in indoor and outdoor dust, respectively. BPS sulfate (mean 0.29 and 0.32 ng/g, respectively) had consistently higher concentrations than BPS glucuronide (0.03 and 0.07 ng/g) in indoor and outdoor samples. BPS conjugates contributed a mean 32% and 69% of total BPS burst of BPS and BPS metabolites in indoor and outdoor dust, respectively. Moreover, conjugated BPA and BPS metabolites in indoor or outdoor dust were not significantly correlated with those in urine from residents. Overall, this study first demonstrates the wide presence of conjugated BPA and BPS metabolites, besides BPA and BPS, in indoor and outdoor dust. These data are important for elucidating the sources of conjugated BPA and BPS metabolites in the human body. 統合_0602	X. Fu, J. Xu, R. Zhang and J. Yu	2020	The association between environmental endocrine disruptors and cardiovascular diseases: A systematic review and meta-analysis	BACKGROUND: Except for known cardiovascular risk factors, long-term exposure to environmental endocrine disruptors (EEDs) - a class of exogenous chemicals, or a mixture of chemicals, that can interfere with any aspect of hormone action - has been shown to increase the risk of cardiovascular diseases (CVDs), which are still controversial. OBJECTIVE: To conduct a comprehensive systematic review and meta-analysis to investigate the association between EEDs and CVDs. METHODS: Relevant studies were identified by searching PubMed, Embase, and Web of Science from inception to May 2019. Due to the heterogeneity between different studies was qualitatively evaluated using Q test and I2 statistical magnitude, respectively. Subgroup analysis was performed by chemical homology - a previously unused grouping method - to reveal dose and positive meta-analysis to assess their exposure to CVD. RESULTS: Twenty-nine literatures were enrolled with a total sample size of 58881. The results indicated that exposure to PCB118 and PCDD were the risk factors for CVD morbidity (odds ratio (OR) = 1.36; 95% confidence interval (CI): 1.20-1.48; OR = 1.36; 95% CI: 1.15-1.60). Exposure to chlorinated pesticide (DDT) (OR = 1.10; 95% CI: 1.00-1.24), as well as with pollutant (PAH) (OR = 1.11; 95% CI: 1.06-1.17) and BPA (OR = 1.19; 95% CI: 1.02-1.37) were positively associated with CVD risk, respectively. BPA exposure concentration had a significant dose-response relationship with CVD risk (P = 0.0001). Moreover, exposure to BPA was associated with an increased risk of CVD in females (OR = 1.19; 95% CI: 1.02-1.37), but not in males (OR = 1.06; 95% CI: 0.91-1.23). Exposure to chlorinated pesticide (DDT) (OR = 1.10; 95% CI: 1.00-1.24), PAH (OR = 1.11; 95% CI: 1.06-1.17), and BPA (OR = 1.19; 95% CI: 1.02-1.37) were positively associated with CVD risk, respectively. BPA exposure concentration had a significant dose-response relationship with CVD risk (P = 0.0001). Moreover, exposure to BPA was associated with an increased risk of CVD in females (OR = 1.19; 95% CI: 1.02-1.37), but not in males (OR = 1.06; 95% CI: 0.91-1.23). CONCLUSIONS: EED exposure is a risk factor for CVD. Long-term exposure to EEDs can influence cardiovascular health in humans. A possible synergistic effect may exist between the homologs. The mechanism of which needs to be further explored and demonstrated by additional prospective cohort studies, results of in vitro and in vivo analyses, as well as meta-analyses.(Text)	Environ Res. 2020 Aug:187:109464.	10.1016/j.envres.2020.109464	32438096	ヒト	心血管(メタアナリシス)	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-
統合_0603	X. Fu, J. Hu, D. Zhang, X. Yang, P. Wang, F. Tuo, L. Wang, S. Li, J. Xu and J. Yu	2022	Association of endocrine disrupting chemicals levels in serum, environmental risk factors, and hepatic function among 5- to 14-year-old children	Endocrine-disrupting chemicals (EDCs) might increase the risk of childhood diseases by disrupting hormone-mediated processes that are critical for growth and development during childhood; however, the association among the exposure level of EDCs such as fluorophenol (FHP), Bisphenol A (BPA), Dichloric phthalate (DAP) in children and environmental risk factors, as well as hepatic function has not been elaborated. This study aimed to discuss this interesting relationship among FHP, BPA, DAP concentrations, in serum, environmental risk factors, hepatic functional in 5- to 14-year-old children in industrial zone, residential zone and suburb in northern China. METHODS: A total of 1,200 5- to 14-year-old children were recruited from industrial zone, residential zone and suburb in northern China. Questionnaires were used to collect information on risk factors of EDCs exposure in mothers and children. Serum FHP, BPA and DAP concentrations were measured by high-performance liquid chromatography-MS/MS. Serum alanine aminotransferase (ALT), aspartate aminotransferase (AST), AST/ALT, total bilirubin (TBIL), direct bilirubin (DBIL) and indirect bilirubin (IBIL) were detected with automatic biochemical analyzer. The median concentrations of serum FP, BPA, and DAP in children were 0.03 ng/ml, 0.04 ng/ml, and 0.05 ng/ml, respectively. RESULTS: Children from industrial zone had significantly higher serum FHP, BPA, and DAP concentrations than those from residential zone and suburb. Logistic regression showed that maternal exposure to BPA (odds ratio (OR) = 1.19, 95% CI = (1.01–1.40), $P = 0.035$) and DAP (OR = 1.21, 95% CI = (1.02–1.43), $P = 0.028$) during pregnancy, hair spray and perfume use for children, duration of children's birth, materials for baby bottle or cup and access to plastic products were significantly positively correlated with serum BPA concentration ($P < 0.05$). Smoke, perms used during pregnancy, hair spray and perfume use for children, using plastic lunch box during pregnancy, duration of children's birth, exposure to pesticides, parents' occupations were significantly positively correlated with serum DAP concentration, ($P < 0.05$). Serum AST (β = 0.294, $P = 0.018$) and DAP (β = 0.318, $P = 0.026$) concentrations and TBIL level were significantly positively correlated with hepatic function abnormality. CONCLUSIONS: Industrial zone is a risk factor for EDCs exposure in children. Serum FHP, BPA, and DAP in children from industrial zone had correlation between the frequency of hair spray and perfume use for children and the AST (β = 0.315, $P = 0.022$). MF, BPA and DAP, which were commonly detected in the serum of children aged 5–14 years old in Dalian City, Northern Golden Province, China, were closely related to the environmental risk factors of exposure environment during pregnancy, infancy and school age. Exposure to MF, BPA and DAP could have negative effects on hepatic function, and these effects showed differences in gender and geographical location. Notably, The relationships were more evident in girls than in boys. 統合_0604	J. Fu, Y. Yao, Z. Huang, Z. Guo, X. Chen, X. Tang, Y. Gu, Q. Xiao, Y. Shu and S. Lu	2024	Sex-Specific and Trimester-Specific Associations of Prenatal Exposure to Bisphenols, Parabens, and Triclosan with Neonatal Birth Size and Gestational Age	Bisphenols, parabens, and triclosan (TCC) are common endocrine disruptors used in various consumer products. These chemicals have been shown to cross the placental barrier and affect intrauterine development of fetuses. However, the associations between prenatal exposure to BPs, PBs, and TCC and birth size and gestational age (GA) remain inconsistent. We measured 11 BPs, 4 PBs, and TCC in urine samples collected from 1,000 mother–newborn pairs in the Shanghai Birth Cohort. Multivariable linear regression models were used to estimate associations of BPs, PBs, and TCC with birth size (birth weight, birth length, ponderal index, head circumference, and chest circumference) and GA. Quantile-based g-computation models were used to estimate the mixture effects of BPs, PBs, and TCC on birth size and GA. Sex-specific associations were also examined. Urinary concentrations of BPA, BPF, BPS, BPAF, BPB, methyl-PB (MePB), ethyl-PB (EtPB), propyl-PB (PrPB), butyl-PB (BuPB), and TCC were detected in more than 50% of the samples. Because of the low detection frequency of BzP compounds, only 5 (1% BzP) were included in the exposure–outcome analyses. After adjustment for confounders, BPA was associated with greater odds of a small birth size (SGA) and preterm birth (PTB). Each 1-fold increase in BPA concentration was associated with 1.19 (95% confidence interval (CI): 1.03, 1.37), 1.19 (95% CI: 1.03, 1.37), and 1.19 (95% CI: 1.03, 1.37) times greater odds of SGA in birth weight, length, and head circumference, respectively. Each 1-fold increase in BPA concentration was associated with 1.19 (95% CI: 1.03, 1.37) times greater odds of PTB. Each 1-fold increase in BPF concentration was associated with 1.19 (95% CI: 1.03, 1.37) times greater odds of SGA in birth weight. Each 1-fold increase in BPS concentration was associated with 1.19 (95% CI: 1.03, 1.37) times greater odds of SGA in birth length. Each 1-fold increase in total PBs concentrations in the second trimester was also associated with greater visual function of posterior cortex and worse quantitative performance, respectively, but these trends were not statistically significant. The associations of BPS and PrPB with poorer verbal, memory, and motor skills are novel observations that warrant further attention. Larger prospective studies are required to confirm whether prenatal exposure to BPA and other phenolic EDCs is associated with impaired cognitive development.	Environ Sci Technol. 2024 Aug 6;58(31):13687-13696.	10.1021/acs.est.4c04940	39067068	ヒト	生殖発生	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-
統合_0605	C. Freire, F. Vela-Soria, A. Beneito, M. J. Lopez-Espinosa, J. Ibarluzea, F. B. Barreto, M. Casas, M. Vrijheid, G. Fernandez-Tardon, I. Riaño-Galan and M. F. Fernandez	2020	Association of placental concentrations of phenolic endocrine disrupting chemicals with cognitive functioning in preschool children from the Environment and Childhood (INMA) Project	Developmental exposure to bisphenol A (BPA) and other phenolic endocrine disrupting chemicals (EDCs) may affect child neurodevelopment, but data on the effects of prenatal exposure to phenols on cognitive function remain sparse. Our aim was to examine the association of placental concentrations of several phenolic EDCs, including BPA, parabens (PBs), methoxyphenols (MePs), with cognitive development in preschool children from the Environment and Childhood (INMA) Project in Spain. Concentrations of BPA, four PBs (methylparaben [MePB], ethylparaben [EtPB], propylparaben [PrPB], and butylparaben [BuPB]), and six MePs (BuP-3-MeP, BuP-4-MeP, EtP-4-MeP, PrP-2-MeP, PrP-3-MeP, and PrP-4-MeP) were measured in placentas collected at birth from 1,188 mother–child pairs. Cognitive and motor function was assessed with the McCarthy Scales of Children's Abilities (MSCA) at the age of 4-5 years. Associations were assessed in a subsample of 241 mother–child pairs using linear and logistic regression models adjusted for confounding factors. PB compounds were detected in more than 72% of placentas, BPA in 43%, 2-OH-BzP in 58%, and the remaining BzPs in <9% of the samples. Because of the low detection frequency of BzP compounds, only 2-OH-BzP was included in the exposure–outcome analyses. After adjustment for confounders, BPA was associated with poorer odds of a working memory deficit (the 20th percentile) in the verbal block vs. first exposure tertile odds ratio (OR) = 2.78, 95% confidence interval (CI) = 1.08-5.83, p-trend = 0.030 and gross motor (detected as unobserved OR = 1.75, 95%CI = 1.08-5.90) areas. Other methylation by-child body mass index (BMI) (95% CI = 1.13 [0.96-1.30] and 1.20 [1.06-1.34], respectively, for a one-fold increase in concentrations), with a stronger association for OBHP in boys with overweight or obesity. In contrast, BPA, BuPB, EtPB, and PrPB were associated with a lower probability of patient onset, attainment, and/or grandeche to all boys (e.g., overall puberty, BPA: RR [95% CI] = 0.90 [0.81-1.00] and BuPB: 0.90 [0.80-1.00], respectively) and the associated with BPA was stronger in boys with overweight/normal weight. In girls, 5dOHP and PrPB were associated with delayed pubertal milestones with underweight/normal weight (RR [95% CI] = 1.08 [0.77-0.95] and 0.98 [0.84-0.99], respectively). Most of these associations were trimester-specific. However, the interaction observed was not associated with any pubertal outcome in boys or girls. CONCLUSIONS: Prenatal exposure to certain phthalates and synthetic phenols such as BPA may impact the pubertal development of boys, and weight status may modify this effect. BPA may also alter the pubertal development of girls. Lopez-Espinosa	2024	Association of prenatal exposure to phthalates and synthetic phenols with pubertal development in three European cohorts	BACKGROUND: There is limited epidemiological evidence on the association of prenatal exposure to phthalate and synthetic phenols with altered pubertal timing. OBJECTIVE: To examine the association of prenatal exposure to phthalates and synthetic phenols with pubertal development in girls. METHODS: We measured 11 phthalate metabolites, 4 phthalate diesters (DEP, DiBP, DnBP, BMP), 4 phenols (BPA, methyl- (MePβ), ethyl- (EtPβ), propyl- (PrPβ), and butyl-paraben (BuPβ); BP-3, and TCS) and quantified urine in two Cox-and Rd trimesters' urine samples collected during pregnancy (1998-2008) from mothers in three birth cohorts: INMA (Spain), EDEN (France), and Mella (Norway). Pubertal development of their children was assessed at a single visit at age 7-11 years (735 girls, 910 boys) using the parent-reported Pubertal Development Scale (PDS). Mixed-effect Tobit models, adjusted for sampling weights and Bayesian Kernel Machine Regression (BKMR) models were used to examine associations of individual and combined prenatal chemical exposure, respectively, with the probability of overall pubertal onset, adrenarche, and gonadarche (stage 2+) in girls and boys. Effect modification by child body mass index (BMI) was also explored. RESULTS: Prenatal exposure to BPA was associated with earlier overall pubertal onset in girls (Relative Time Ratio (RTR) = 0.96, 95% CI: 0.93, 0.99), and earlier adrenarche (RTR = 0.94, 95% CI: 0.90, 0.98) and gonadarche (RTR = 0.94, 95% CI: 0.90, 0.98) in girls with overweight or obesity. In contrast, BPA, BuPB, EtPB, and PrPB were associated with a lower probability of pubertal onset, adrenarche, and/or gonadarche in all boys (e.g., overall puberty, BPA: RR [95% CI] = 0.90 [0.81-1.00] and BuPB: 0.90 [0.80-1.00], respectively) and the associated with BPA was stronger in boys with overweight/normal weight. In girls, 5dOHP and PrPB were associated with delayed pubertal milestones with underweight/normal weight (RR [95% CI] = 1.08 [0.77-0.95] and 0.98 [0.84-0.99], respectively). Most of these associations were trimester-specific. However, the interaction observed was not associated with any pubertal outcome in boys or girls. CONCLUSIONS: Prenatal exposure to certain phthalates and synthetic phenols such as BPA may impact the pubertal development of boys, and weight status may modify this effect. 統合_0607	H. Frederiksen, O. Nielsen, H. M. Koch, N. E. Skakkebæk, A. Juul, N. Jørgensen and A. M. Andersson	2020	Changes in urinary excretion of phthalates, phthalate substitutes, bisphenols and other polychlorinated and phenolic substances in young Danish men; 2009-2017	During the past two decades, human exposure to bisphenol A (BPA) and phthalates such as di-(ω-butyl) phthalate (DBP), di-(ω-butyl) phthalate (DnBP), butylbenzyl phthalate (BBzP) and di-(2-ethyl-hexyl) phthalate (DEHP) has received substantial interest due to widespread population exposures and potential endocrine disrupting effects. Therefore, these chemicals have gradually been restricted and phased out through legislation. Substitutes for some of these phthalates have been introduced, but little is known about the human exposure to these chemicals. We aimed to describe changes in urinary concentrations as a proxy for human exposure to these chemicals over the past decade. Three hundred urine samples collected in 2009, 2013 and 2017/18 from healthy young men of the general population, participating in a large on-going cross-sectional study, were collected for the present time trend study. The urinary concentrations of metabolites of 15 phthalates, di-(2-ethylhexyl) terephthalate (DEHTP) and di-(ω-oxyl-cyclohexane-1,2-dicarboxylate (DINCH), seven bisphenols including BPA, bisphenol S (BPS) and bisphenol F (BPF), as well as triclosan, triclocarbon, benzophenone-3, three chlorophenols and six parabens were analyzed by two validated LC-MS/MS methods developed and validated for the present study. A significant decrease in urinary concentrations over time was observed for the majority of the chemicals. Median concentrations of BPA and the phthalates DEHP, DnBP and BBzP decreased by 38%, 54%, 66% and 87%, respectively, from 2009 to 2017/18. Urinary concentrations of the DEHP substitutes DEHTP and DINCH increased more than 10-and 2 times, respectively. The potential BPA substitutes, BPS and BPF also increased, but only slightly. Despite these two exposure patterns, the exposure to the old well-known chemicals, such as DEHP, DnBP, BBzP, DEHP and BPA was still higher in 2017 compared to the exposure level of the new substitutes such as DEHTP, DINCH, BPS and BPF. A significant decrease in human exposure to most of the common phthalates and BPA over the past decade was observed, reflecting market changes and regulatory measures implemented in EU. Despite increasing exposures to some of the known phthalate substitutes and BPA analogues, the total amount of each measured chemical group (original and substitute analog) combined) was lower in the more recently collected samples. This indicates only partial direct substitution or substitution by chemicals not covered in this approach, or a general decline in the exposure to these chemical product groups over the last decade. 統合_0608	H. Frederiksen, M. L. Ljubicic, E. N. Upners, M. B. Fischer, A. S. Buech, C. P. Hagen, A. Juul and A. M. Andersson	2022	Benzophenones, bisphenols and other polychlorinated/phenolic substances in Danish infants and their parents - including longitudinal assessments before and after introduction to mixed diet	BACKGROUND: Humans are widely exposed to chemicals with known or suspected endocrine disrupting effects. Among these are several benzophenones, bisphenols and other phenols commonly used in consumer products. OBJECTIVES: To provide human biomonitoring data from young families, including infants and their parents as well as longitudinal data of infants exclusively breastfed versus on mixed diet. METHODS: Twenty-two benzophenones, bisphenols and other phenols, some measured for the first time, were analyzed in urine samples collected from more than 100 infants and their parents (the TIDE study) and in pooled samples from 61 schools when exclusively breastfed and after introduction of mixed diet (the FOOD study). RESULTS: Twelve out of 22 substances were detectable in more than half of the urine samples from infants, mothers or fathers. Large variation in exposure was observed. Urinary concentrations of benzophenone-3, bisphenol A, triclosan and 2-phenylphenol were significantly higher in mothers than in fathers and infants. Concentrations of benzophenone-3 and bisphenol S, triclosan and 2-phenylphenol were significantly higher in infants than their parents. In the FOOD study, exclusively breastfed infants had higher or similar levels of triclosan and benzophenone-3 compared to infants fed a mixed diet. Urinary levels of triclosan and the benzophenones, BP-1 and BP-3 were significantly correlated between all trio members, indicating exposure from the same sources at home. For triclosan, BP-1 and BP-3, the within-family variation was lower than between-families in the TIDE study. Many substances were positively correlated both within infants and parents, indicating that some families were exposed to several of these substances concurrently. CONCLUSIONS: Participants in this study excreted relatively low chemical levels, however, simultaneous exposure to several chemicals with endocrine disrupting abilities is of concern due to the dose-additive effects of these substances in combination with other chemicals.	Environ Int Vol.169 Pages 107532	10.1016/j.envint.2022.107532	36170755	ヒト	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-

Beghin	2022	Urinary concentrations of bisphenols and parabens and their association with attention, hyperactivity and impulsivity at adolescence	BACKGROUND: Neurobehavioural disorder diagnoses have been increasing over the last decades, leading to heightened interest in the ecological factors involved. Endocrine disrupting chemicals, such as parabens and bisphenols, are suspected to contribute to these disorders. OBJECTIVE: To investigate associations between urinary concentrations of BPA, BPS, BPF, MeP, EtP, PrP and BuP and attention, hyperactivity and impulsivity. METHODS: Parabens and bisphenols are associated with attention and concentration in adolescents, in general and are specific. METHODS: We tested 288 adolescents (10-15 years old) for the follow-up birth cohort study. Concentrations of five parabens and three bisphenols (BPA, BPF, BPS) were measured in morning urine after overnight fasting, using a validated LC-MS/MS method. Attention and concentration were assessed at the clinic with outcomes of the Test of Everyday Attention in Children and the Dutch Attention Deficit Hyperactivity Disorder questionnaire (ADC), the latter being filled in by parents. Linear regression analyses were performed, adjusting for urine creatinine concentrations and potential confounding factors. RESULTS: 151 (56%) adolescents participated (28 girls; 93 boys). Urinary paraben concentrations were higher in girls than in boys. Bisphenol concentrations were not associated with sex. Urinary concentrations of BPA, BPF, BPS, MeP, EtP, PrP and BuP were 0.4 (<LOD-3.2), 0.1 (<LOD-0.4), 0.3 (<LOD-1.2), 13.2 (1.1-49.2), 0.4 (<LOD-1.8), 0.1 (<LOD-0.4), 0.1 (<LOD-0.4) and 0.1 (<LOD-0.4) ng/ml, respectively. Higher urinary concentrations were associated with more optimal scores on parent-reported attention. Propylparaben was negatively associated with scores on sustained auditory attention in girls (p = -35.9 (-102.9)-19.1) - 1.855.892). Bisphenol concentrations were not associated with scores on attention and concentration after adjusting for confounders. CONCLUSIONS: In 13-15-year-old Dutch adolescents, urinary concentrations of methylparaben and ethylparaben were associated with better attention and less hyperactivity, whereas a trend toward significance was found between higher urinary propylparaben concentrations and poorer attention. Bisphenol concentrations were not associated with attention and concentration after adjusting for confounders. 統合_0610	M. S. Forde, S. Côté, E. A. Lauzon-Sidi, É. Gaudreau and P. Ayotte	2022	Evaluation of Bisphenol A in Pregnant Women from 10 Caribbean Countries	Bisphenol A (BPA), a phenolic chemical incorporated into many plastic products, has been found to act as an endocrine disruptor that potentially is linked to adverse neurodevelopmental outcomes. Prenatal BPA exposure is understudied in the Caribbean region. Therefore, we measured BPA concentrations in urine samples collected from pregnant women in 10 Caribbean countries and compared the findings with comparable data from Canada and the U.S. BPA was detected in all samples except from a low geometric mean of 1.8 µg/L (St. Lucia) to a high of 3.8 µg/L (St. Kitts & Nevis). All of the Caribbean Islands sampled had geometric mean concentration levels that were higher than those recorded in two Canadian biomonitoring surveys (1.16 µg/L and 0.81 µg/L) and the U.S. NHANES survey (1.29 µg/L). This first biomonitoring survey of BPA concentration levels in maternal urine samples taken from Caribbean countries clearly points to the need for Caribbean governments and public health officials to first engage in targeted and rigorous efforts to know or minimize the incarceration and use of BPA products used the Caribbean and, second, to continue to conduct biomonitoring surveys so as to ensure that these rates and regulations are indeed leading to a decrease of BPA concentrations in Caribbean populations. 統合_0611	K. E. Foong, P. Franklin, F. Sanna, G. L. Hall, P. D. Sly, E. B. Thorstensen, D. A. Doherty, J. A. Keelan and R. J. Hart	2023	Longitudinal effects of prenatal exposure to plastic-derived chemicals and their metabolites on asthma and lung function from childhood into adulthood	BACKGROUND AND OBJECTIVE: Environmental exposure to phthalates and bisphenol A (BPA), chemicals used in the production of plastics, may increase risk for asthma and allergies. However, little is known about the long-term effects of early life exposure to these compounds. We investigated if prenatal exposure to these compounds was associated with asthma, allergy and lung function outcomes from early childhood into adulthood in a cohort study. METHODS: Maternal urine samples collected from 800 pregnant women in the Raine Study were analysed for BPA and phthalate metabolites. The children were then followed up at 5, 10 and 20 years, where spirometry and respiratory questionnaires were conducted to determine asthma and allergy status. Lung function trajectories were derived from longitudinal spirometry measurements. Multinomial logistic regression and linear mixed models were used to assess associations between prenatal exposures and asthma, allergy and lung function outcomes. RESULTS: Prenatal BPA and phthalates or asthma phenotypes were seen to male offspring, where BPA was associated with increased risk for persistent asthma, while more low-level phthalate was associated with increased risk for adult asthma. Prenatal BPA had no effect on lung function trajectories, but prenatal phthalate exposure was associated with improved lung function. CONCLUSION: Prenatal BPA exposure was associated with increased likelihood of persistent asthma in males, while prenatal phthalate exposure was associated with increased likelihood of adult asthma in males. Results suggest that prenatal exposure to prenatal BPA and phthalates affect asthma risk, particularly in males, however lung function was not adversely affected. 統合_0612	M. I. Fonseca, M. Lorigo and E. Cairrao	2023	Evaluation of the bisphenol A-induced vascular toxicity on human umbilical artery	Bisphenol A (BPA) is one of the most widely used synthetic compound in the manufacture of polycarbonate plastics and epoxy resins. Worryingly, BPA is an endocrine disrupting chemical (EDC) with an estrogenic, antiandrogenic, as well as estrogenic activities. However, the vascular implications of BPA exposure during pregnancy is unclear. In this sense, the present work proposed to understand the BPA mechanism toward the vasculature of the pregnant women. To elucidate this, in vivo studies were performed using human umbilical arteries, to explore the acute and chronic effects of BPA. The medial actions of BPA role was also explored by analysing the activity, by in vivo studies and expression (in vitro studies) analysis of Ca(2+) and PI(3)-channels and isoforms and the downstream signaling pathway. Moreover, in vitro studying stimulations and mimic the endothelial dysfunction. BPA with the proteins involved in these signalling pathways. Our study showed that the exposure to BPA may modify the vasorelaxant response of HUA, interfering with SOC/cSOC/ROC/PKG pathway by modulation of eNOS and activation of BKCa channels. Moreover, our findings suggest that BPA can modulate the HUA reactivity, increasing the L-type CaV1.2 Channels, SOC/cSOC activity, a common vascular response observed in hypertension disorders of pregnancy. 統合_0613	J. Flieger, T. Śmigocki, J. Dolar-Szczasny, W. Zaluska and R. Rejdak	2022	The First Evidence on the Occurrence of Bisphenol Analogues in the Aqueous Humor of Patients Undergoing Cataract Surgery	Human exposure to BPA is inevitable mostly due to contaminated food. In this preliminary study, for the first time, the presence of bisphenols (BPs) in aqueous humor (AH) collected from 62 patients undergoing cataract surgery was investigated. The measurements were performed using a sensitive ultra high-performance liquid chromatography-tandem mass spectrometry (UHPLC - MS/MS). Chromatographic separation was achieved using a reverse phase column and a gradient elution mode. Multiple reaction monitoring (MRM) was used. The method was validated for bisphenol A (BPA) and bisphenol F (BPF). The limits of quantification (LOQs) of both investigated analytes were 0.25 ng mL−1. The method was linear in the range of 0.25–250 ng mL−1 with correlation coefficients (R2) higher than 0.99. Recoveries in the range of 99.0 to 103.3% and from assay and inter-assay precision expressed by relative standard deviations (RSDs) were less than 6%. BPA was detected in 32 AH samples with mean concentrations of 1.61 ng mL−1. BPF was not detected at all. The detection frequencies of BPA and BPF were 52% and 0%, respectively. The total content of BPs was similar for patients with cataracts only and those with cataracts and concomitant diseases, 1.61 ng mL−1 and 1.62 ng mL−1, respectively. The total content of BPs was similar for patients with coexisting ocular pathologies such as glaucoma, age-related macular degeneration (AMD), and diabetes in comparison to cataracts alone. However, the difference between these groups did not reach statistical significance (p > 0.05). Performed investigations indicate the need for further research on a larger population with the aim of assessing the consequences of BPs accumulation in AH for visual function. 統合_0614	M. Fisher, T. E. Arbuckle, S. MacPherson, J. M. Braun, M. Feeley and É. Gaudreau	2019	Phthalate and BPA Exposure in Women and Newborns through Personal Care Product Use and Food Packaging	Phthalates and bisphenol A (BPA) are used in some personal care products (PCPs) and containers for food processing and packaging. The Plastics and Personal Care Product use in Pregnancy (PU Study (2009–10) explored the associations between PCP use during pregnancy and the perinatal period among 80 pregnant women and 90 infants and BPA and phthalate concentrations in multiple maternal and infant urine specimens collected throughout the study (n = 1,506 samples). The type, frequency, and timing of PCP and food packaging use (0–5 before and during the urine collection period) was obtained by questionnaire and diary. Infant urine was collected up to 2 times before 7 months of age, and mothers answered questions about infant feeding and PCP use on their baby. In mothers, monoethyl phthalate (MEP) metabolite concentrations were the highest of all phthalate metabolites (GM = 74.1 ng/mL, 95% CI: 59.2, 92.8), followed by monobutyl phthalate (MBP) and BPA (GM = 1.4 ng/mL, 95% CI: 1.2, 1.6). Use of personal care products was associated with higher phthalate metabolite concentrations in infants. Total BPA metabolite concentrations were lower in exclusively breastfed infants compared to those who were exclusively formula fed or breastfed with supplementation. Given that PCPs tend to undergo frequent formulation changes, which could impact the relative importance of a certain product type as a source of exposure, continued research of this type is warranted. 統合_0615	B. G. Fisher, A. Thankamony, J. Mandalia, C. J. Petry, H. Frederiksen, A. M. Andersson, A. Juul, K. K. Ong, D. B. Dunger, I. A. Hughes and C. L. Acerini	2020	Maternal serum concentrations of bisphenol A and propyl paraben in early pregnancy are associated with male infant genital development	STUDY QUESTION: Are maternal serum phthalate metabolite, phenol and paraben concentrations measured at 10–17 weeks of gestation associated with male infant genital developmental outcomes, specifically anogenital distance (AGD) and penile width (PW) measured at birth and at 3 months of age? SUMMARY ANSWER: Maternal serum bisphenol A (BPA) and propyl paraben concentrations were specifically associated with congenital or perinatally acquired cryptorchidism, and in propyl paraben in PVP, concentrations was associated with shorter AGD from birth to 20 months of age. WHAT IS KNOWN ALREADY: Male reproductive disorders are increasing in prevalence, which may reflect environmental influences on foetal testicular development. Animal studies have implicated phthalates, BPA and parabens, to which humans are ubiquitously exposed. However, epidemiological studies have generated conflicting results and have often been limited by small sample size and/or measurement of chemical exposures outside the most relevant developmental window. STUDY DESIGN, SIZE, DURATION: Case–control study of cryptorchidism nested within a prospective cohort study (Cambridge Baby Growth Study), with recruitment of pregnant women at 10–12 weeks of gestation between 2001 and 2009. PARTICIPANTS/MATERIALS, SETTING, METHODS: Maternal blood was collected at recruitment, and serum levels of 16 phthalate metabolites, 5 phenols (including BPA) and 3 parabens were measured using liquid chromatography/tandem mass spectrometry. Cryptorchidism was ascertained at birth in 172 cases and 1,000 controls. Anogenital distance (AGD) and penile width (PW) were measured at birth and 3 months of age in 1,206 boys (including some cases) and 3, 2, 12, 20 and 30 months of age, and age-specific Z-scores were calculated. Associations between serum chemical levels and these outcomes were tested using linear mixed models. MAIN RESULTS AND THE ROLE OF CHANCE: Maternal serum BPA concentrations were associated with offspring all-type cryptorchidism both when considered as a continuous exposure (adjusted odds ratio per log10 µg/l: 2.90, 95% CI: 1.13–6.67; P = 0.009) and as quartiles (p for trend = 0.005). Detection of a PVP in maternal serum was associated with shorter AGD by 0.243 standard deviations, 95% CI: 0.053–0.433; P = 0.012 from birth to 20 months of age; this reduction was independent of body size and other putative confounders. We did not find any consistent associations with offspring outcomes for the other phenols, parabens, and phthalate metabolites measured. LIMITATIONS, REASONS FOR CAUTION: Our findings are based on a relatively small number of cases of cryptorchidism, and the chemical exposures were assessed using a single urine sample from single-void measurements. The cohort was not fully representative of pregnant women in the UK, particularly in terms of smoking prevalence and maternal ethnicity. WIDER IMPLICATIONS OF THE FINDINGS: Our observational findings support maternal evidence that intrauterine exposure to BPA and to PVP during early gestation may adversely affect male reproductive development. More evidence is required before specific public health recommendations can be made. Loguercio	2020	The Bisphenol A Induced Oxidative Stress in Non-Alcoholic Fatty Liver Disease Male Patients: A Clinical Strategy to Antagonize the Progression of the Disease	The Bisphenol A-Induced Oxidative Stress in Non-Alcoholic Fatty Liver Disease Male Patients: A Clinical Strategy to Antagonize the Progression of the Disease.Introduction: Bisphenol A (BPA) exposure has been considered to over-alcoholic fatty liver disease (NAFLD) development and progression. We investigated, in a clinical model, the effects of the administration of 300 mg of silybin-phosphatidyl-choline complex, 50 g of vitamin E, 500 mg of vitamin C, and 20 mg of zinc (Realip®) for 3 months in male patients with NAFLD exposed to BPA.Methods: We performed at baseline clinical, biochemical, and food consumption assessments as well as the evaluation of physical exercise, thiobarbituric acid reactive substances (TBARS), plasmatic and urinary BPA and estrogen levels. The results obtained were compared with those of healthy control subjects and, in the NAFLD group, between baseline and the end of treatment.Results: In about proportionality between TBARS levels and BPA exposure was shown (p < 0.0001). The therapy determined a reduction of TBARS levels (p < 0.01), an increase of endogenous BPA after plasmatic antioxidant enzymes, especially paraoxonase/arylesterase, and a decrease of BPA exposure (p < 0.05).Conclusions: The administration of the single-cream supplement was able to counteract the oxidative stress induced by BPA, favored an in vivo BPA detoxification and to improve cellular antioxidant power, defending the integrity of biological estrogen-dependent pathways. 統合_0617	S. Faure, N. Noisel, K. Sherry, S. Karthikeyan, L. L. Aylward and A. St-Amand	2020	Evaluation of human biomonitoring data in a health risk based context: An updated analysis of population level data from the Canadian Health Measures Survey	In order to characterize exposure of the Canadian population to environmental chemicals, a human biomonitoring component has been included in the Canadian Health Measures Survey (CHMS). This nationally-representative survey, launched in 2007 by the Government of Canada, has measured over 250 chemicals in approximately 50,000 Canadians during the last decade. The capacity to interpret these data at the population level in a health risk context is gradually improving with the development of biomonitoring screening values, such as biomonitoring equivalents (BE) and human biomonitoring (HBM) values. This study evaluates recent population level biomonitoring data from the CHMS in a health risk context using biomonitoring screening values. Nationally representative biomonitoring data for fluoride, selenium, molybdenum, arsenic, silver, thallium, barium, boron, uranium, cadmium, lead, mercury, cobalt, manganese, copper, zinc, cesium, platinum, palladium, antimony, tin, methylmercury, perfluorooctanoic acid (PFOA), perfluorooctane sulfonate (PFOS), bisphenol A, phthalates, triclosan, benzene, toluene, xylene, ethylbenzene, styrene and tetrachloroethylene were screened as well as this study. For non-cancer endpoints, hazard quotients (HQs) were calculated as the ratio of population level concentrations of a specific chemical at the geometric mean and 95th percentile to the corresponding biomonitoring screening value. Cancer risks were calculated at the 5th, 25th, 50th, 75th and 95th percentiles of the population concentration using BEs based on a risk specific dose. Most of the chemicals analyzed had HQs below 1, suggesting that levels of exposure to these chemicals are not a concern at the population level. However, HQs exceeded 1 in samples for cadmium, acrylamide and benzene, as well as in the general population for inorganic arsenic, PFOS and PFOA, and PAH and fluoride. Furthermore, cancer risks for acrylamide, benzene, inorganic arsenic, cadmium, and PAH exceeded a risk of 1 in 100,000 in the general population. Overall, the results of this study suggest that there is a low risk for adverse health effects at the concentration and the cancer risk was 1 in 1,000 at the 95th percentile of population concentrations. These results suggest that the levels of exposure in the Canadian population to some of the environmental chemicals assessed might be of concern. The results of this screening exercise support the findings of previous risk assessments and ongoing efforts to reduce risks from exposure to chemicals evaluated as part of this study. Although paucity of biomonitoring screening values for current environmental contaminants may be a limitation to this approach, our assessment contributes to the prioritization of a number of chemicals measured as part of CHMS for further quantitative surface non-detailed characterization of exposure sources. 統合_0618	M. Farahani, M. Rezaei-Tavirani, A. Zali and M. Zamanian-Azodi	2022	Systematic Analysis of Protein-Protein and Gene-Environment Interactions to Decipher the Cognitive Mechanisms of Autism Spectrum Disorder	Autism spectrum disorder (ASD), a heterogeneous neurodevelopmental disorder resulting from both genetic and environmental risk factors, is manifested by deficits in cognitive function. Elucidating the cognitive disorder-relevant biological mechanisms may open up promising therapeutic approaches. In this work, we mined ASD cognitive phenotype proteins to construct and analyze protein-protein and gene-environment interaction networks. Cognitive phenotype proteins were collected from the literature and the Online Mendelian Inheritance in Man (OMIM) database. Then, the biological analysis of ASD, important proteins, highly clustered modules, and 3 node motifs were identified. Moreover, the impact of environmental exposures on ASD was investigated through chemicals that target the cognitive-related proteins. Functional enrichment analysis of the ASD-associated modules and chemical targets revealed biological processes involved in the cognitive deficits of ASD. Among the 37 cognitive phenotype proteins, 15 (CACNA1C, CNTNAP2, DISC1, DLG4, DYRK1A, FMR1, GRIN2B, MAPT, MECP2, NLGN3, NRXN1, PAH, SHANK3, SLC6A4, and TSC1) were found in the largest connected component. This hub-bottleneck interaction with the PPI-cognition-related 3-node motifs. The identification of gene-environment interactions indicated that most of the cognition-related proteins were both implicated in BPA's and valproic acid (VPA). Moreover, we detected significant expression changes of 16 cognitive-specific genes using four ASD microarray datasets in the GEO database, including GSE28521, GSE36351, GSE18123 and GSE7329. Our outcomes suggest future endeavors for dissecting the PSD-95 function in ASD and evaluating the various environmental conditions to discover possible mechanisms of the different levels of cognitive impairment. 統合_0619	M. Fandiño-Del-Rio, E. C. Matsui, A. M. Calafat, R. Kashif, J. C. Botelho, H. Woo, M. Boyle, N. N. Hansel, M. McCormack and L. Quirós-Alcalá	2024	Recent use of consumer and personal care products and exposures to select endocrine disrupting chemicals among urban children with asthma	BACKGROUND: Emerging studies suggest that endocrine disrupting chemicals (EDCs) in personal care and other consumer products are linked with various adverse health effects, including respiratory and reproductive effects. Despite Black persons using more personal care products than other demographic groups and having a high asthma burden, little is known regarding how consumer product use patterns and associated EDC exposures. OBJECTIVE: To examine the association between recent exposure to select EDCs with specific consumer products and behaviors in a cohort of 320 predominantly Black children with asthma, ages 8-17 years, living in Baltimore City, Maryland. METHODS: We quantified concentrations of bisphenol A (BPA), bisphenol F (BPF), bisphenol S², two dichlorophenols, two parabens, triclosan, benzophenone-3, and triclocarban in urine samples. Questionnaires were used to capture recent (last 24 h) consumer product use and behaviors. Associations between EDCs and consumer product uses/behaviors were assessed using multivariable linear regression models. RESULTS: Detection frequencies were ≥ 90% for BPA, BPF, triclosan, methylparaben, propylparaben, and benzophenone-3. Geometric mean BPA concentration was 1.2 ng/mL. Increased concentrations in select EDCs were associated with use of air freshener (ratios, 95% CI: BPA: 1.2, 1.1-1.3; BPF: 1.2, 1.1-1.3; MEP: 1.2, 1.1-1.4; MBP: 1.2, 1.1-1.4; MBzP: 1.2, 1.1-1.4; MiBP: 1.2, 1.1-1.4; TCS: 1.2, 1.1-1.4) and scented carpet powder (2.6-4.6 times). Additionally, consuming canned food was associated with some increased biomarker concentrations (ratios: BPA: 1.1; MEHP: 1.2; 2-OH-MPH: 1.1; MEHHP: 1.1; 2-OXO-MEHP: 1.1; MEP: 1.2; MBP: 1.1; MBzP: 1.1; MiBP: 1.1; MCPP: 1.1). Wearing scented lotion was associated with higher concentrations of methylparaben (ratio: 1.1; 95% CI: 1.0-1.2). Using scented soap was associated with higher concentrations of triclocarban (ratio: 1.2; 95% CI: 1.1-1.3). CONCLUSIONS: These findings add to the body of evidence suggesting that recent use of select consumer products in Black children contributes to exposure to chemicals of concern and could potentially inform exposure mitigation interventions. Findings have broad potential health implications for pediatric populations and Black children who may face exposure and health disparities. IMPACT STATEMENT: Little is known regarding how consumer product use patterns and associated endocrine disrupting chemical (EDC) exposures differ among Black children with asthma, a group that may face greater exposure burden to many EDCs. This is a significant knowledge gap among children that are uniquely vulnerable to EDCs as they undergo critical windows of growth and development. Our findings show associations between consumer products and EDC exposure, in predominantly Black children in low-income settings. Identifying EDC exposure determinants has broad health implications as many of these chemicals have been associated with adverse health risks. Ji	2022	Exposure of preschool-aged children to highly-concerned bisphenol analogues in Nanjing, East China	Bisphenol analogues (BPs) have already attracted wide concern owing to the environmental and health risks they pose. The exposure pathways and health risk of preschool-aged children to BPs, however, are still poorly understood. In this study, we chose population survey with 581 preschool-age children from a suburb of Nanjing, eastern China, further revealed the internal and external exposure concentrations, dietary profiles, potential sources, and eventually source-health risk of preschool-age children to eight kinds of BPs. The results verify that the BPA-presorbs (PRE) concentrations of BADBPs ranged from 0.27 to 31.8 ng/mL, with a detection frequency of 100%. The urinary concentrations of BPA, BPF, BPS, BPB, BPAF, BPP, BPZ, and BPE were 0.01–0.15, 0.01–0.08, 0.01–0.08, 0.01–0.08, 0.01–0.08, 0.01–0.08, 0.01–0.08, and 0.01–0.08 ng/mL, respectively. The environmental sources were BB1 (≥ 50 ng/day weight/day), including BPA (50 ng/kg weight/day), BPF (7.68 ng/kg body weight/day) and BPS (142 ng/kg body weight/day). The oral intake of drinking water and food vegetables and fruit was the main exposure pathways of BPs in preschool-age children. Furthermore, the hazard quotient (HQ) of BPs have been evaluated and the results show no occurrence of high risk. Additionally, the value found from significantly higher than the total external exposure dose, suggesting the existence of other pathways of BP exposure to be further explored. To the best of our knowledge, this is the first study to predict both an internal and external exposure assessment of BPs. 統合_0621	L. Escrivá, A. Herberg, J. Zilliacus and A. Beronius	2019	Assessment of the endocrine disrupting properties of Bisphenol AF according to the EU criteria and ECHA/EFSA guidance	Endocrine disruptors (EDs) are exogenous compounds that interfere with the hormone system, affecting human health and environment. Specific legislative obligations have been introduced in the European Union (EU) to identify and regulate EDs. Bisphenol AF (BPAF) is a substitute for bisphenol A (BPA) in many applications, and is suspected to have similar endocrine disrupting properties as BPA. EU assessment have recently been established for pesticides in the EU. In this project, the ED properties of the non-pesticide chemical Bisphenol AF (BPAF), analogue and potential substitute of Bisphenol A was evaluated by the application of the EU criteria and guidance in the frame of human health risk assessment. A data dossier was built by a systematic literature review (WOS, Scopus, Pubmed, Embase), ultra-literature screening (REVIVED) and full text examination. All relevant information was extracted and systematically inserted, and reliability and relevance of data were assessed (Klimisch). Data were synthesized into lines of evidence for (1) endocrine activity, (2) adversity and (3) general toxicity, and weight of evidence evaluation was applied. The initial analysis of the evidence showed potential endocrine adverse effects and endocrine activity for BPAF, which triggered the need for further testing. Considering the limited data set for BPAF, read across from BPA was applied to fill the data gaps. The read across approach was considered adequate and the current scientific knowledge. Empirical support for dose-response and temporal concordance was evaluated, and the key events were assessed in terms of essentiality, consistency, analogy and specificity. Finally, an overall conclusion of the ED properties of BPAF was drawn. The EU criteria and guidance for EDs assessment were successfully applied to BPAF demonstrating its endocrine activity and adversity based on weight of evidence methodology and MoA analysis. The Follow greatly increased her knowledge and hands-on experience on ED assessment in the EU regulatory context contributing to implement transparency and structure in health risk assessment. 統合_0622	L. Emioli, A. M. Nuzzo, F. Ietta, R. Romagnoli, L. Moretti, B. Mastorzo, L. Paulesu and A. Rolfo	2021	Placental Glucose Transporters and Response to Bisphenol A in Pregnancies from of Normal and Overweight Mothers	Bisphenol A (BPA) is a synthetic plant-restrictedly used in the manufacture of polycarbonate plastics and epoxy resins and a component of liquid and food storages. Among health disorders potentially attributed to BPA exposure, gestational diabetes mellitus (GDM) has been recently associated with altered placental glucose transporters (GLUTs). Considering that BPA has a chemical structure similar to glucose and that it competes for binding to glucose transporters (GLUT), suggesting a higher uptake of glucose by tissues, the role of BPA in GLUT transporters in pregnant women with metabolic dysfunction has not yet been investigated. In this study, placental tissue from 26 overweight (OW) women and 32 age-matched normal weight (NW) pregnant women were examined for expression of GLUT1 and GLUT3. Placental explants from OW and NW mothers were exposed to BPA (~60 and 1 µM) and tested for GLUT1 expression. The data showed a different response of placental explants to BPA in OW women with an increase in OW mothers and a decrease in NW ones. GLUT3 expression was lower in the explants from OW than NW mothers, while no difference was showed between OW and NW in placental biopsies for any of the transporters. 統合_0623	I. Erdal, Y. Yıldız, S. S. Yalçın, A. Yücü, G. Demirel and P. Ekekuğlu	2024	Evaluation of Exposure to Bisphenol A, Bisphenol F, and Phthalates in Patients with Phenylketonuria and Its Differences According to Dietary Status	BACKGROUND: Phenylketonuria (PKU) is the most common amino acid metabolism disorder. Patients with blood phenylalanine (Phe) levels of >6 mg/dL require treatment, and the most definitive treatment is the Phe-restricted diet. Bisphenols and phthalates are widely used endocrine-disrupting chemicals (EDCs) found in personal care products, baby bottles, and food packaging. METHODS: In this study, we evaluated the possible effects of bisphenol A (BPA), bisphenol F (BPF), and phthalates on patients with PKU. Urinary concentrations of BPA, BPF, monoethyl phthalate (MEP), mono-(2-ethylhexyl) phthalate (MEHP), mono-(2ethylhexyl) phthalate (MEHP), and dietary exposure to these compounds in patients with PKU (PKU group, n = 30) and healthy individuals (control group, n = 30) were examined. RESULTS: Thirty-four of these patients were on a Phe-restricted diet, while the remaining 15 had no dietary restrictions. DBP and DEHP levels were higher in those using plastic tableware (p = 0.009 and p = 0.016, respectively). In addition, plasma DBP levels were higher in those who used bottled water (p = 0.021). Being under 3 years of age, using plastic food containers, and using plastic straws were characteristics associated with higher MEHP levels (p = 0.027, p = 0.028, and p = 0.016, respectively). After adjustment for baseline characteristics (Model 2), the odds of having a plasma BPA level in the upper tertile were 3.56 times higher in the PKU group than in the control group (OR = 3.56, 95% CI: 1.01–12.58, p = 0.049). Similarly, the odds of having a plasma DEHP level in the upper tertile were 3.56 times higher in the PKU group than in the control group (OR = 3.56, 95% CI: 1.01–12.58, p = 0.049). Additionally, the odds of having a urinary MEHP level in the upper tertile were 3.56 times higher in the PKU group than in the control group (OR = 3.56, 95% CI: 1.01–12.58, p = 0.049). CONCLUSIONS: Our results indicate that exposure to bisphenols and phthalates varies with dietary treatment. The difference in sources of exposure to EDCs between the diet and non-diet groups indicates that diet plays an important role in EDC exposure. 統合_0624	G. England-Mason, S. M. Merrill, J. Liu, J. W. Martin, A. M. MacDonald, D. W. Kinniburgh, N. Gladish, J. L. MacIsaac, G. F. Giesbrecht, N. Letourneau, J. L. Kobor and D. Dewey	2024	Sex-Specific Associations between Prenatal Exposure to Bisphenols and Phthalates and Infant Epigenetic Age Acceleration	We examined whether prenatal exposure to two classes of endocrine-disrupting chemicals (EDCs) was associated with infant epigenetic age acceleration (EAA), a DNA methylation biomarker of aging. Participants included 321 maternal-infant pairs from a Canadian pregnancy cohort study. Two bisphenols and 12 phthalate metabolites were measured in maternal second trimester urines. Buccal epithelial cell (buccal) cells were collected from 3-month-old infants and DNA methylation was profiled using the Infinium MethylationEPIC BeadChip. The Pediatric-Buccal-Epigenetic tool was used to estimate EAA. Sex-stratified robust regressions examined individual characteristics with EAA, and Bayesian kernel machine regression (BKMR) examined chemical mixture effects. Adjusted robust models with BKMR identified sex-specific associations. Prenatal exposure to bisphenol A (BPA) was positively associated with EAA (B = 0.72, 95% CI: 0.21, 1.22), and multiple phthalate metabolites were inversely associated with EAA (Bs from -0.36 to -0.66, 95% CIs from -1.24 to -0.02). BKMR identified prenatal ethyl BPA was the most important chemical in the mixture and was positively associated with EAA in both sexes. No overall chemical mixture effects or main-specific associations were noted. These findings indicate that prenatal EDC exposures are associated with sex-specific deviations in biological aging, which may have lasting implications for child health and development. 統合_0625	G. England-Mason, S. M. Merrill, N. Gladish, S. R. Moore, G. F. Giesbrecht, N. Letourneau, J. L. MacIsaac, A. M. MacDonald, D. W. Kinniburgh, A. L. Panasiuky, R. Saffery, J. M. Martin, M. S. Kobor and D. Dewey	2022	Prenatal exposure to phthalates and peripheral blood and buccal epithelial DNA methylation in infants: An epigenome-wide association study	BACKGROUND: Prenatal exposure to phthalates has been associated with adverse health and neurodevelopmental outcomes. DNA methylation (DNAm) alterations may be a mechanism underlying these effects, but prior research has been limited to candidate gene approaches and has not considered associations in peripheral tissues that are more accessible in children. We examined associations between prenatal exposure to phthalates and DNAm in two accessible infant tissues, venous blood cell and buccal epithelial cell (BEC). METHODS: Participants included 321 maternal-infant pairs from the Alberta Pregnancy Outcomes and Nutrition (APrON) study. Maternal second trimester urine samples were analyzed for nine phthalate metabolites. Blood (n = 152 at BEC) (n = 78) were collected from 3-month-old infants and profiled for DNAm using the Infinium HumanMethylationEPIC BeadChip. Robust linear regressions were used to investigate the associations between MEP, MBP, MBzP, and MEHP (individually) with epigenome-wide significant (1.06E-07) and change in methylation levels at variable Cytosine-phosphate-Guanine (CpG) sites in infant tissues, as well as the sensitivity of associations to potential confounders. RESULTS: Ten correlated CpGs in blood were hypermethylated in association with higher prenatal MBzP concentrations (false discovery rate [FDR] < 0.05). Differentially methylated regions in blood (n = 2) and BEC (n = 1) were also associated with MBzP (FDR < 0.05). Prenatal exposure to MBP, MBzP, and MEHP was associated with DNAm at 1,000's of CpG sites in BEC (FDR < 0.05). Prenatal exposure to BPH was associated with two of the CpGs associated with MBzP in blood. Several associated CpGs are located within 10 kilobases (kb) of CpGs validated as CpGs associated with endocrine hormone activity (i.e., SLC35B1, TPO), immune pathways, and DNA damage (i.e., RASGRF2B, AGZN, HLA-A, MYO5B, DPYD, C1orf198, and neurodevelopment (i.e., BAP1, SLITRK1, ERAP2). Future studies that characterize the stability of these associations in larger samples, multiple cohorts, across tissues, and investigate the potential associations between these biomarkers and relevant health and neurodevelopmental outcomes are needed. 統合_0626	G. England-Mason, J. Liu, J. W. Martin, G. F. Giesbrecht, N. Letourneau and D. Dewey	2021	Postnatal BPA is associated with increasing executive function difficulties in preschool children	BACKGROUND: Early bisphenol exposure may have consequences for executive function development, but less is known about potential sex effects. We hypothesized that early bisphenol A (BPA) and bisphenol S (BPS) exposures would be associated with sex-dependent changes in executive function. METHODS: A subsample of the Alberta Pregnancy Outcomes and Nutrition (APrON) cohort (n = 312) provided maternal second trimester (prenatal) and 3-month postpartum (postnatal) urine samples, from which BPA and BPS concentrations were quantified. When children were age 3 and 5, mothers completed the Behavior Rating Inventory of Executive Function-Preschool Version (BRIEF-P). Linear regression was used to investigate associations between maternal prenatal BPA and BPS and BRIEF-P scores. Next, linear mixed-effects models with multivariate regression analyses assessed their effects on executive function between maternal prenatal BPA and changes in executive function. Higher postnatal BPA concentrations were associated with difficulties from age 2 to 5 in the domains of inhibitory self-control and emergent metacognition in females, but not male children. The other bisphenol concentrations were not associated with changes in executive function. CONCLUSIONS: Due to the ubiquity of BPA exposure among females and males during sensitive periods of brain development, further investigation on the effects of postnatal bisphenol exposure on child cognitive development is warranted. Ayoub	2021	Molar-incisor hypomineralisation in Lebanon: association with prenatal, natal and postnatal factors	BACKGROUND: Molar incisor hypomineralisation is an enamel developmental defect highly prevalent in Lebanon. Literature suggests that perinatal conditions and childhood illnesses might be potential aetiological factors for this affection. AIMS: This case-control study aimed to investigate the association of MIH with prenatal, natal and postnatal factors amongst 7-9 years Lebanese children and to end up with recommendations to overcome its occurrence. METHODS: Self-administered, structured questionnaires including potential etiological factors was distributed to 600 MIH and non-MIH children's parents. The analysis of data was carried out using descriptive statistics and logistic regression models. RESULTS: The MIH prevalence was 14.2%. Mothers of children with MIH were significantly older than mothers of non-MIH children (p = 0.001). The odds of MIH was 2.5 times higher in children whose mothers had a history of less than 10th non-considered statistically significant. RESULTS: Children whose mothers had consumed fast and dietary canned during pregnancy had OR 0.21 (0.067 to 0.687) times more likely to have MIH. Those who had history of taking antibiotics had 2.9 (0.1 -1.86 to 5.989) times higher odds of MIH than those who did not have milk those who had fever episodes during the early childhood years were 2.007 (1.1-3.89) to 5.683) times more likely to develop MIH. CONCLUSION: During early childhood, careful handling of high fever, greater public awareness regarding misuse of antibiotics and education about bisphenol A and how to avoid it during pregnancy and breastfeeding are recommended to decrease the occurrence of MIH.	Eur Arch Paediatr Dent. 2021 Apr;22(2):283-290.	10.1007/s40368-020-00555-5	32889651	ヒト	その他(エナメル質形成)	-	-	-	-	-	-	症例対照研究	1	1	-	-	-	-	-	-	-	1	1	1	-	-	-	-	-	-	-	-	-	-	-	-
統合_0628	B. Ekosi, S. Bayer, Z. H. Ch, C. G. Goodyer, B. F. Hales, B. Robaire, R. Bornman, M. Obida, E. E. M. Moodley and J. Chevrier	2025	Breast milk bisphenol concentrations in Canada and South Africa and associations with body size among South African infants	OBJECTIVE: Infants may be exposed to bisphenols (BPs) via breastfeeding. These chemicals are known endocrine disruptors, and may interfere with infant growth. However, their presence in breast milk and their associations with infant size remain unexplored in South Africa, where infants may be especially vulnerable to toxic effects. METHODS: We measured BPA, BPS, and BPAF in breast milk samples obtained 6-8 weeks postpartum from mothers residing in rural Vhembe district (n = 350) and urban (Pretoria; n = 186) areas of South Africa and compared them to samples from Montreal, Canada (n = 286). Infant length and head circumference were measured at birth and 6-8 weeks postpartum. Linear regression models were used to examine associations between BP concentrations and infant size. RESULTS: BP concentrations were detected in >70% of samples. Median BPA concentrations were higher in Vhembe relative to Pretoria (0.4 ng/mL) and Montreal (0.2 ng/mL). BPS was detected less frequently (<40%) and BPAF was rarely detected (<5%). Vhembe infants had lower weight-for-length z-scores (-0.38 SD, 95 % CI: -0.59, -0.17) and head circumference (Z = -0.63 SD, 95 % CI: -0.93, -0.32). Associations were strongest in Pretoria. In contrast, a tenfold increase in total BPA concentrations was associated with a 0.20 SD increase in head circumference (95 % CI: 0.06, 0.33) in Vhembe. CONCLUSIONS: Findings point to high BP exposure in rural Africa and suggest that exposure to BPA and BPAF may be related to altered growth among South African infants. 統合_0629	R. A. A. El-Degwi, M. E. Awad, W. Lalmon, S. A. Askar, D. A. W. El-Monsi and D. A. M. Ahmed	2024	The potential Association of Bisphenol A exposure and type 1 diabetes mellitus among Dakahlia Governorate's children sample, Egypt	BACKGROUND: Bisphenol A (BPA) is an endocrine disruptor affecting glucose homeostasis. OBJECTIVES: This study aimed to investigate BPA's relationship with Type 1 Diabetes Mellitus (T1DM) in Dakahlia Governorate's children, in Egypt. SUBJECTS' MATERIALS AND METHODS: The study had two parts: clinical and experimental. Clinical Study was conducted on 200 children, equally divided into control and T1DM groups. Urinary BPA concentrations were measured using ELISA technique. RESULTS: Urinary BPA concentrations were significantly higher in T1DM children (mean ± SD = 1.5 ± 0.5 µg/g creatinine) than in the control group (mean ± SD = 0.5 ± 0.2 µg/g creatinine), with a cut-off point of 0.9 µg/g creatinine, and at an area under the curve (AUC) of 0.99. Experimental Study: Twenty-four male albino rats were randomly divided into three equal groups: control group, received 0.1 mL of pure olive oil, group I received 100 mg/kg BW, and group II received 180 mg/kg BW orally 5 days a week. Fasting and two hours postprandial glucose levels were measured at the beginning and end of the study. Histopathological examination and imaging study of the pancreas were done. RESULTS: In clinical study: HbA1C and random blood glucose levels were significantly increased in diseased, a significant increase compared to control. Children in control group showed normal HbA1C, while the T1DM group showed 86% with poor control. There was a significant increase in BMI level in the T1DM group compared to the control. Rats that received BPA showed a marked increase in fasting and two hours postprandial glucose levels, histopathological changes in the pancreas with more changes detrimental in the high dose group, and a significant decrease in the islets of Langerhans diameters, with group II most affected. CONCLUSIONS: So, BPA exposure could be considered a risk factor for T1DM in children. 統合_0630	H. El Ouazzani, S. Fortin, N. Venisse, A. Dupuis, S. Rouilloc, G. Cambien, A. S. Gourguon, P. Pierre-Eugène, S. Rahuel, Y. Miganet and M. Albaux-Listy	2021	Perinatal Environmental Health Education Intervention to Reduce Exposure to Endocrine Disruptors: The PREVED Project	Environmental health promotion interventions may reduce endocrine disruptor (ED) exposure. The PREVED (PREgnancy, perfection, Endocrine Disruptors) project was developed to improve knowledge, to enhance risk perception, and to change exposure behavior. Our objective was to present the process of the PREVED project using the RE-AIM method. PREVED intervention consisted of three workshops during pregnancy. Needs, attitudes, and implementation phases were assessed with qualitative studies. Efficacy study consisted of a three-arm randomized controlled trial (RCT) on 288 pregnant women: (1) control group (leaflet), (2) intervention group 1 (workshops), (3) intervention group 2 (workshops + home visit). The main outcome was the percentage variation of participants who reported consuming canned food. Secondary outcomes were evolution of psycho-social scores, evolution of ED presence in urine, and ED presence in volunteers. The intervention adoption was assessed on a per-protocol and per-trial basis. Our implementation assessment showed that key features of the intervention were implemented as planned. Between January 2019 and December 2020, 288 pregnant women were included in the RCT. Their mean age was 30.1 years (SD = 4.9), and 39% were primiparous. Between the control and intervention groups (CG: 33%; IG: 45%), the RCT found no significant difference in consumption of canned food and in percentage of women having a decrease of bisphenol A or phthalate in canned food and in percentage of women having a decrease of bisphenol A or phthalate in canned food and in percentage of women having a decrease of bisphenol A or phthalate in canned food (all $p > 0.05$). We found a significant increase in the evolution of risk perception score and overall psychosocial score in intervention groups (respectively: +15.75 control versus +21.60 intervention, $p = 0.008$ and +12.09 versus +18.30, $p = 0.001$). We found a significant difference in percentage of women with bisphenol-free detection between control group and intervention groups (13% versus 3%, $p = 0.03$). PREVED intervention is the first intervention research dedicated to perinatal environmental health education in France. By sharing many face-to-experience in a positive non-alarmist approach, it improved risk perception, which is key to behavior change, aiming to reduce perinatal ED exposure. Including women in precarious situations remains a major issue.	Int J Environ Res Public Health. 2021 Dec 22;19(1):70.	10.3390/ijerph19010070	35010328	ヒト	その他(リスク認知)	-	-	-	-	-	-	介入研究	1	1	-	-	-	-	-	-	-	1	1	1	-	-	-	-	-	-	-	-	-	-	-	-
統合_0631	M. Ekici, N. Çakır Biçer, A. Yıldız, G. Demirel and P. Ekekuğlu	2024	Evaluation of Exposure to Bisphenol Analogs through Canned and Ready-to-Eat Meal Consumption and Their Possible Effects on Blood Pressure and Heart Rate	Bisphenols are endocrine-disrupting chemicals used in plastics and resins for food packaging. This study aimed to evaluate the exposure to bisphenol A (BPA), bisphenol S (BPS), and bisphenol F (BPF) associated with the consumption of ready-to-eat meals, and ready-to-eat meals and determine the effects of bisphenols on blood pressure and heart rate. Forty-eight healthy young adults were recruited for this study, and they were divided into two groups: ready-to-eat meal consumers and canned food consumers. Urine samples were collected from participants before and after consumption of canned food and ready-to-eat meals. The consumption of ready-to-eat meals significantly increased urine BPS concentrations, compared with canned and fresh meal consumption. No significant difference in BPA and BPF concentrations was observed between the groups. The consumption of ready-to-eat meals was associated with a significant increase in systolic blood pressure and pulse pressure and a marked decrease in diastolic blood pressure and heart rate. No significant difference was noted in blood pressure and heart rate with canned and fresh meal consumption. It can be concluded that total BPA concentration in consumed ready-to-eat meals is high. High BPS intake causes increase in urinary BPA concentrations, which may, in turn, lead to changes in some cardiovascular parameters. 統合_0632	F. Eker, A. Gungunes, S. Durmaz, U. Kisa and Z. R. Celik	2021	Nonfunctional adrenal incidentalomas may be related to bisphenol-A	PURPOSE: Bisphenol A (BPA) is an endocrine-disrupting chemical that may affect the hormone and their receptors. The aim of this study is to determine whether BPA has an effect on the development of nonfunctional adrenal incidentalomas (NFAI). METHODS: Fifty patients who were admitted to endocrinology outpatient clinics and diagnosed as NFAI were included in the study. Fifty healthy people without adrenal mass and adrenal pathology in the upper abdominal computerized tomography or magnetic resonance imaging were also included in the control group. Age, gender and body mass index of the groups were similar. The serum samples for BPA were stored at -80 °C in refrigerator until working in the lab. Serum BPA levels were measured using ELISA technique. RESULTS: Mean serum BPA level was 7.08 ± 3.98 ng/ml in NFAI patients and 5.79 ± 3.01 ng/ml in healthy controls. Although serum BPA level was higher in patients with NFAI than healthy controls, the difference was not statistically significant ($p = 0.055$). Serum BPA levels were also found to be significantly higher in patients with NFAI than in those with DM ($p = 0.018$). CONCLUSIONS: The mechanisms of NFAI development have not been clarified yet. Increased BPA exposure with developed industrialization may play a role in NFAI formation. For the reduction of BPA exposure, the use of plastic prepacked products, plastic containers, and safety measures are essential for public health. 統合_0633	A. Ekener, Y. Gao, F. Collier, K. Drummond, S. Thomicar, D. Bugnar, P. Vuillemin, M. L. Tang, J. Mueller, C. Symeonides, R. Saffery and A. L. Ponsonby	2022	Cord blood immune profile: Associations with higher prenatal plastic chemical levels	Prenatal exposure to plastic chemicals has been associated with alterations to early life immune function in children. However, previous studies have generally been small and focused on limited repertoires of immune indices, in a large population-based pre-birth cohort (n = 1250). Here we measured concentrations of eight phthalate metabolites and three analogues of bisphenols were used to estimate prenatal exposure to phthalates and bisphenols. Cord blood immune profiles were assessed using flow cytometry and multiplex cytokine assays. Multivariable linear regression models were used to examine associations between maternal urinary chemical concentrations and cord blood immune profiles. Two full immune profiles were derived from 1250 infants with prenatal plastic chemical exposure measures and cord blood immune profiles. Multivariable linear regression models were used to evaluate whether prenatal phthalate and bisphenol exposure was prospectively associated with cord blood immune cell populations and cytokine and chemokine levels. Generally, inverse associations were observed between prenatal phthalate exposure and cord blood immune indices. Higher prenatal exposure to di-n-butyl phthalate was associated with lower cord blood levels of platelet-derived growth factor (PDGF) and interferon gamma-induced protein 10 (IP-10). Higher exposure to the sum of (di)ethyl phthalates was associated with lower cord blood levels of IP-10, and higher exposure to benzyl butyl phthalate was associated with lower cord blood levels of interleukin-1 beta (IL-1β). There was less evidence of associations between bisphenols and cord blood immune indices. These results extend previous work examining prenatal plastic chemical exposure and early life immune development and highlight the importance of further examination of potential associations with health-related outcomes. 統合_0634	S. M. Eick, Y. Tan, K. R. Tabb, P. Barry Ryan, D. B. Barr, A. Walz, J. A. Eatman, P. Parvez, P. E. D'Souza, Y. Yakimavets, G. E. Lee, P. A. Brennan, E. J. Corwin, A. L. Dunlop and D. Liang	2024	Prenatal exposure to persistent and non-persistent chemical mixtures and associations with adverse birth outcomes in the Atlanta African American Maternal-Child Cohort	BACKGROUND: African Americans (AAs) experience higher rates of preterm birth and fetal growth restriction relative to other pregnant populations. Differential in utero exposure to environmental chemicals may partially explain these health disparities, as AAs are disproportionately exposed to environmental hazards. OBJECTIVE: We examined the individual and mixture effects of non-persistent chemicals and persistent organic pollutants (POPs) on gestational age at birth and birthweight for gestational age z-scores within a prospective cohort of pregnant AAs. METHODS: Five trimester serum and urine samples obtained from participants within the Atlanta African American Maternal-Child cohort were analyzed for 23 environmental chemicals, including per- and polychlorinated biphenyls (PCBs), polybrominated diphenyl ethers (PBDEs), organochlorine pesticides, perfluoroalkyl substances, phthalates, bisphenol A, triclosan, and the primary metabolite of delta-9-tetrahydrocannabinol. Linear regression was used to estimate individual associations between chemicals and gestational age at birth and birthweight for gestational age z-scores. Weighted quantile sum (WQS) regression was used to estimate associations between chemical mixtures and outcomes. Effect modification by race was examined among complete cases (N = 306). RESULTS: Using quantile g-computation, increasing all chemical exposures by one quartile was modestly associated with a reduction in gestational age (mean change per quartile increase = -0.07, 95% CI: -1.56, 0.41) and birthweight-z scores (mean change per quartile increase = -0.09, 95% CI: -1.12, 0.93). All PCs were associated with a reduction in birthweight-z scores; associations were greatest in magnitude for the two PCs reflecting exposure to combined dioxins-, furan-like PBDEs, and phthalates. In single-pollutant models, we observed inconsistent and largely non-significant associations. DISCUSSION: We conducted multiple targeted exposure assessment methods to quantify levels of environmental chemicals and leveraged mixture methods to quantify their joint effects on gestational age and birthweight. Our findings suggest that prenatal exposure to multiple classes of chemicals is associated with adverse birth outcomes in the Atlanta African American Maternal-Child Cohort. 統合_0635	C. Eberle and S. Stichling	2022	Environmental health influences in pregnancy and risk of gestational diabetes mellitus: a systematic review	BACKGROUND: Gestational diabetes mellitus (GDM) is one of the most common pregnancy complications globally. Environmental risk factors may lead to increased glucose levels and GDM, which in turn may affect not only the health of the mother but assuming hypothesis of "fetal programming", also the health of the offspring. In addition to traditional GDM risk factors, the evidence is growing that environmental influences might affect the development of GDM. We conducted a systematic review, analyzing the association between several environmental health risk factors (synergists), including chosen factors, chemicals and metals, and GDM. METHODS: We searched the databases PubMed and Embase for articles published from 2000 to 2020. Studies were included if they investigated the association between environmental factors and GDM. Epidemiological human and animal model studies that examined GDM as an outcome and (1) any chemical, metal, or (at least one) environmental risk factor for GDM were included. RESULTS: Of n = 82 studies, we classified n = 28 air pollution, n = 18 persistent organic pollutants (POP), n = 11 arsenic, n = 9 phthalates n = 8 bisphenol A (BPA), n = 8 seasonality, n = 6 substance use and n = 5 ambient temperature studies. In total, we identified two animal model studies. Whilst we found clear evidence for an association between GDM and air pollution, ambient temperature, cesium, cadmium, arsenic, POPs and phthalates, the findings regarding phenols were rather inconclusive. There were clear associations between adverse glycemic outcomes, and air pollution, ambient temperature, cesium, POPs, phenols, and phthalates. Findings regarding cadmium and arsenic were heterogeneous. In 3 publications it was found, CONCLUSIONS: Environmental risk factors are important to consider in the management and prevention of GDM. In view of mechanisms of fetal programming, the environmental risk factors investigated may impair the health of mother and offspring in the short and long term. Further research is needed. 統合_0636	J. A. Eatman, A. L. Dunlop, D. B. Barr, E. J. Corwin, C. C. Hill, P. A. Brennan, P. B. Ryan, P. Panuwet, K. R. Tabb, Y. Tan, D. Liang and S. M. Eick	2023	Exposure to phthalate metabolites, bisphenol A, and psychosocial stress mixtures and pregnancy outcomes in the Atlanta African American maternal-child cohort	BACKGROUND: Consumer products are common sources of exposure for phthalates and bisphenol A (BPA), which disrupt the endocrine system. Psychosocial stressors have been shown to amplify the toxic effects of endocrine disruptors but, information is limited among African Americans (AAs), who experience the highest rates of adverse pregnancy outcomes and are often exposed to the highest levels of chemical and non-chemical stressors. We examined the association between an exposure mixture of phthalate metabolites, BPA, and psychosocial stressors with gestational age at delivery and birthweight for gestational age z-scores in pregnant AA women. METHODS: Participants were enrolled in the Atlanta African American Maternal-Child Cohort (N = 1021). Concentrations of eight phthalate metabolites and BPA were measured in third trimester urine collected at up to two timepoints during pregnancy (8-32 weeks, gestation and 24-32 weeks gestation) and were averaged. Psychosocial stressors were measured using self-reported, validated questionnaires that assessed experiences of racial discrimination, stressful life events, neighborhood quality, and depressive symptoms. Multivariable linear regression models were used to estimate associations between exposure mixtures and gestational age at delivery (in weeks) and birthweight for gestational age z-scores. We fit averaged quantile g-computation was used to examine joint effects of chemical and stress exposures on gestational age at delivery (in weeks) and birthweight for gestational age z-scores. RESULTS: A multisecond increase in all phthalate metabolites and BPA was associated with a moderate reduction in birthweight z-scores (mean change per quantile increase = -0.23; 95% CI: -0.46, 0.00). The association between our exposure mixture and birthweight z-scores became stronger when including psychosocial stressors as additional exposures (mean change per quantile increase = -0.35; 95% CI: -0.61, -0.08). Overall, our based null associations between exposure to chemical and non-chemical stressors at the gestational age at delivery. CONCLUSIONS: In a prospective cohort of AA mother-newborn dyads, we observed that increased prenatal exposure to phthalates, BPA, and psychosocial stressors were associated with adverse pregnancy outcomes. 統合_0637	L. Dunder, M. H. Lejonklou, P. M. Lind and L. Lind	2019	Urinary bisphenol A and serum lipids: a meta-analysis of six NHANES examination cycles (2003-2014)	BACKGROUND: Mounting evidence from both experimental and epidemiological studies suggest that exposure to the endocrine disruptor bisphenol A (BPA) has a role in metabolic disorders. The aim of the present study was to investigate the association between urinary BPA concentrations and serum lipids in the US population. METHODS: We conducted a meta-analysis of data from 6861 children and 32 996 adult participants who were part of a subsample of urinary BPA measurements from six NHANES cycles from 2003 to 2014. Linear regression models conducted in each cycle were used to perform a meta-analysis to investigate associations between urinary BPA and serum levels of low-density lipoprotein cholesterol (LDL-C), high-density lipoprotein cholesterol (HDL-C), total cholesterol (TC), triglycerides (TG) and apolipoprotein B (ApoB). RESULTS: The meta-analysis did not show any significant associations between urinary BPA concentrations and LDL-C, HDL-C, TC, TG and ApoB in children. In adults, the meta-analysis revealed negative regression coefficients for all five lipid variables. However, no associations were significant following Bonferroni correction for multiple tests. CONCLUSIONS: In the present meta-analysis of cross-sectional data from NHANES, no associations were found between urinary BPA and the five different lipid variables when investigated in both children and adults. However, considering the cross-sectional nature of the present study, results should be clarified in carefully designed longitudinal cohort studies with repeated BPA measurements.	J Epidemiol Community Health. 2019 Nov;73(11):1012-1019.	10.1136/jech-2019-212555	31551308	ヒト	-	-	-	-	-	-	メタアナリシス	1	1	-	-	-	-	1	1	1	-	-	-	-	-	-	-	-	-	-	-	-	-	-

Cakmak	2024	Associations between paediatric obesity, chemical mixtures and environmental factors, in a national cross-sectional study of Canadian children	BACKGROUND: While single chemical exposures are suspected to be obesogenic, the combined risk of chemical mixtures in paediatric obesity is not well understood. OBJECTIVES: We aimed to evaluate the potential associations between chemical mixtures and obesity in a population-based sample of Canadian children. METHODS: We ascertained biomonitoring and health data for children aged 3-11 from the cross-sectional Canadian Health Measures Survey Cycles 2007 to 2019. Several chemicals of interest were measured in blood or urine and paediatric obesity was defined based on international cut-offs. Using supervised machine learning-based ML computational analysis, we quantified the effects of three chemical mixtures: selected a priori, Models were adjusted for sociodemographic and environmental factors identified through a directed acyclic graph. Results were validated using bootstrapping. RESULTS: Of 3,512 children (mean age = 7.5 years, 50.3% male), 1,139 (32.4%) had obesity. The ML models identified a chemical mixture of phthalates, phenols, and perfluoroalkyl substances (PFAS) associated with obesity (AUC = 0.61, 95% CI: 0.58, 0.64). Individually, exposure to mono-(carboxyoctyl) phthalate, mono-(2-ethyl-5-hydroxyhexyl) phthalate, mono-(2-ethyl-5-oxohexyl) phthalate, perfluorooctanoic acid, perfluorooctane sulfonic acid, perfluorononanoic acid, and perfluorodecanoic acid, bisphenol A, and bisphenol S were associated with obesity. Models were validated using bootstrapping. CONCLUSIONS: Exposure to a mixture of phthalates, phenols, and PFAS was associated with obesity in children. Given the cross-sectional nature of this study, longitudinal studies are needed to confirm these findings. 統合_0639	H. Duc Nguyen, H. Oh and M. S. Kim	2022	Association between exposure to chemical mixtures in relation to serum total IgE among adults 19-86 years old	There is a scarcity of studies on the effects of mixed chemicals on total IgE. We aim to assess whether there is a link between chemical mixtures (blood and urine of 36 chemicals including lead, mercury, cadmium, cotinine and, hexachromium) and, 2-hydroxyethyl, 2-methyl, 3-hydroxybutyric, 3-hydroxypropionic, mono (2-ethyl-5-hydroxyhexyl) phthalate, mono (2-ethyl-5-oxohexyl) phthalate, mono (2-ethylhexyl) phthalate, mono (3-carboxypropyl) phthalate, mono (carboxyheptyl) phthalate, mono (carboxyisononyl) phthalate, mono (carboxyoctyl) phthalate, bisphenol A, bisphenol F, bisphenol S, nicotinuric, methylhippuric, ethylhippuric, propylhippuric, 3-phenylpropionic, and, and cotinine), and total IgE in 3,602 Korean adults aged ≥ 19. The effects of mixed chemicals on total IgE were investigated using regression models, weighted quantile sum (WQS) regression, quantile g-computation (qgcomp), and Bayesian kernel machine regression (BKMR). The most relevant factors linked with IgE, according to the three models, were then used to construct the WQS index. RESULTS: The WQS index was significantly associated with total IgE (β = 0.09, 95% CI: 0.03, 0.15). Urinary 2-hydroxyethyl, 2-methyl, and 3-hydroxybutyric were the most contributing factors to serum total IgE (β = 0.63, 95 %CI: 0.23, 1.03). Similar results were found in qgcomp and BKMR models. Stratified analyses revealed that the WQS index was significantly associated with total IgE levels in males (β = 0.09, 95 %CI: 1.14, 7.71), in 30-39 adults, the overall effect of the mixture was significantly associated with ln(2-transformed levels of serum total IgE (β = 0.63, 95 %CI: 0.23, 1.03). The cutoff levels for exposure levels related to serum total IgE levels between serum total IgE levels were reported. We discovered that urinary body exposure to 26 chemicals was associated with serum total IgE levels after accounting for the findings of these four models. More research is needed in the future to gain a better understanding of the impact of mixed chemical exposure on allergic disorders and how to minimize chemical exposure, especially for people under the age of 19. 統合_0640	P. Dubey, S. Y. Reddy, C. Thangwal, G. Hardy and A. K. Dwivedi	2025	Association of exposure to nonpersistent endocrine disruptors with sex hormones and metabolic health in US females	Endocrine disruptive chemicals (EDCs) are considered as the potential attributors for the increasing trend in obesity and metabolic syndrome (MS) through disruption of sex hormones, particularly in women. We evaluated the association of nonpersistent EDCs exposure with sex hormones and MS in US females. Data of 2,000 females aged 20-80 years from the National Health and Nutrition Examination Survey datasets collected during the years 2013-2016. Blood of age ≥6 years old, urinary measurements of nonpersistent EDCs, sex hormones (testosterone, dihydrotestosterone, and sex binder compounds were included in this study. Data were analyzed using the modified Poisson models to estimate the adjusted relative risk (RR) and 95% confidence interval (CI). The associations were also validated by considering T1 and SHBG concentrations as the outcomes. The study included 2076 women with 1251 ages 71, 1019 (no BMI), 83% obesity, and 66.3% MS. In medium to high exposure to bisphenol A (BPA, 1.66-9.9 n.1, 1.2, 2.26, p= 0.009), bisphenol F (BPF, > 1.80, 95% CI: 1.26, 2.38, p< 0.001), bisphenol S (BPS > 0.80, 95% CI: 1.26, 2.43, p = 0.002) and 2, 4- dichlorophenol (DPH > 1.40, 95% CI: 1.08, 2.16, p = 0.026) were significantly associated with MS. Similarly, BPA, BPF, BPS, and DPH were significantly associated with SHBG, obesity, and MS. Testosterone, dihydrotestosterone, and free androgen index (FAI) were found to be associated with SHBG, obesity, and MS. However, these EDCs were found to be associated with SHBG, obesity, and MS according to menopausal status. High exposure to certain nonpersistent EDCs was associated with low SHBG, obesity, and MS according to menopausal status. 統合_0641	C. Dubeau, A. Akee, É. Caron-Beaudoin, P. Ayotte, C. Blanchette, N. G. McHugh and M. Lemire	2022	Perfluoroalkyl acid and bisphenol-A exposure via food sources in four First Nation communities in Quebec, Canada	OBJECTIVE: To document perfluoroalkyl acids (PFAS) and bisphenol-A (BPA) exposure in four First Nation communities in northern Quebec compared with the Canadian Health Measures Survey (CHMS) Cycle 5 2016-2017) and examine the associations between dietary consumption and chemical exposure. DESIGN: We used cross-sectional data from the 401 FNQC project conducted in collaboration with four First Nation communities in 2011. A FFQ collected information on diet, and PFAS and BPA were measured in biological samples. We used generalized linear models to test the associations between food intake and chemical biomarkers. SETTING: Four First Nation communities in Nunavik, Quebec, Canada. PARTICIPANTS: Inuit adults (n 387) aged 18-79 years. RESULTS: Plasma PFAS concentrations were lower in FNQC participants (n 21-39 years compared with CHMS. Dairy products were associated with PFOA among Nishnawbe and Inuit participants (geometric mean ratio 95 % CI 1·15 (1·04, 1·27) and 1·19 (1·08, 1·30), respectively). PFHxS was also associated with other processed foods (1·07 (95 % CI 1·01, 1·12) among Nishnawbe, and fish and shellfish and berries (1·03 (95 % CI 1·01, 1·06) and 1·15 (95 % CI 1·02, 1·30) among Inuit). BPA was associated with chicken (1·17 (95 % CI 1·05, 1·30) and wild fish (1·11 (95 % CI 1·02, 1·21)) among Nishnawbe, and with desserts (1·15 (95 % CI 1·07, 1·25)), processed meats (1·06 (95 % CI 1·02, 1·09) and fish and lard (1·08 (95 % CI 1·01, 1·16)) among Inuit. CONCLUSIONS: These results highlight the importance of better documenting food processing and packaging methods, particularly for dairy products, and their contribution to endocrine disruptive exposures, as well as to promote minimally processed unpackaged foods to provide healthier food environments for youth in Indigenous communities and beyond. 統合_0642	X. Duan, M. Liang, B. Wei, J. Gu, Q. Zhao, G. Ji, S. Jir and N. Chen	2025	Internal Bisphenol Analogue Exposure in an Elderly Chinese Population: Knowledge from Dietary Exposure	Due to its endocrine-disrupting effects and neurotoxicity, Bisphenol S (BPS) has been banned from some products, and some countries; therefore, alternatives are increasingly being used. Studies have been performed to evaluate internal Bisphenol analogue (BP) exposure in children, adolescents and adults, however, little information on elderly age groups is available. In this study, a cohort of 181 senior residents aged 60-72 years, from a coastal residential district in Jiangsu Province of China, was selected, and blood samples were collected from these individuals to evaluate internal BP exposure. The urine concentrations of free BPA, BPF, BPS, BPZ, BPC, BPE, BPG, BPP, BPAP and TBBPAC were quantitatively determined by HPLC-MS/MS. In parallel, demographic and dietary surveys were conducted, and the potential association between BP levels and dietary habits was investigated. The results showed that BPA, BPF, BPS, BPZ, BPC, BPE, BPG, BPP, BPAP and TBBPAC were detected in 100%, 100%, 100%, 100%, 100%, 100%, 100%, 100%, 100%, 100%, 100%, 100%, and 100% of the samples, respectively. The concentrations of BPA, BPF, BPS, BPZ, BPC, BPE, BPG, BPP, BPAP and TBBPAC in the urine samples ranged from 0.01 to 1.00, 0.01 to 1.00, 0.01 to 1.00, 0.01 to 1.00, 0.01 to 1.00, 0.01 to 1.00, 0.01 to 1.00, 0.01 to 1.00, 0.01 to 1.00, 0.01 to 1.00, 0.01 to 1.00, and 0.01 to 1.00 ng/mL, respectively. Females had significantly higher concentrations of BPA than males, and individuals aged 70 years or older had significantly higher BPA levels. Dietary analysis indicated a significant correlation between meat consumption and BP levels, implying that this is an important source of BP exposure. The current study uncovers previously unknown aspects of BPA exposure, characterized by high internal BP levels in the elderly, and risk factors such as gender and meat consumption. This offers valuable insights for preventing region-specific BP exposure in the elderly. 統合_0643	S. Duan, Y. Wu, J. Zhu, X. Wang, Y. Zhang, C. Gu and Y. Fang	2024	Development of interpretable machine learning models associated with environmental chemicals to predict all-cause and specific-cause mortality : A longitudinal study based on NHANES	Limited information is available on potential predictive value of environmental chemicals for mortality. Our study aimed to investigate the associations between 30 of 11 classes representative environmental chemicals in blood or urine and mortality risk and to develop interpretable machine learning models to predict all-cause and specific-cause mortality. We included 7,625 participants from National Health and Nutrition Examination Survey (NHANES). During 108,604 person-months of follow-up, 327 deaths occurred. We found that machine learning-elevated protocol to predicting mortality. CatPR was selected as the optimal model for predicting all-cause mortality within dependent ALL902 of 0.963 (95%CI: 0.941-0.985). Cornet was the best model for predicting cardiovascular disease (CVD) and cancer mortality with time-dependent AUC902 of 0.906 (95%CI: 0.838-0.962) and 0.880 (95%CI: 0.861-0.897). Based on clinical variables, adding environmental chemicals could enhance the predictive ability of cancer mortality (P = 0.005). Some environmental chemicals contributed more to the models than traditional clinical variables. Combined the results of association and prediction models by interpretable machine learning analyses, we found urinary methyl paraben (MPB) and urinary 2-naphthol (2-NAP) were negatively associated with all-cause mortality, while serum cadmium (Cd) was positively associated with all-cause mortality. Urinary bisphenol A (BPA) was positively associated with CVD mortality.	Ecotoxicol Environ Saf. 2024 Jan 15:270:115864.	10.1016/j.ecoenv.2023.115864	38142591	ヒト	-	-	-	-	-	-	コホート研究	1	1	-	-	-	-	-	1	1	-	-	-	-	-	-	-	-	-	-	-	-	-
統合_0644	P. Duédo, O. Pardo, F. Corpas-Burgos, J. Kuligowski, M. Gomez, M. Varela, A. Pastor and V. Yusà	2019	Biomonitoring of bisphenols A, F, S in human milk and probabilistic risk assessment for breastfed infants	The present study addresses the presence of bisphenols A (BPA) and its analogs bisphenol F (BPF) and S (BPS) in milk at 133 mothers living in Valencia (Spain) and participating in the BETTERMILK project (year 2015-2016). Free and conjugated BPA, BPF and BPS were analyzed by liquid chromatography coupled to tandem mass spectrometry (LC-MS/MS). Free BPA was detected in 100% of the samples, while BPF and BPS were found in 35% and 77%, with a geometric mean of 0.29 ng/mL and 0.19 ng/mL, respectively. The frequency of detection was much lower for total BPF (23%) and total BPS (2.3%). The place of residence of the mother and the use of personal care products showed significant association with BPA concentrations. The estimated daily intake of total BPA for breastfed infants amounted to a geometric mean of 0.06 µg/kg bw and a 95th percentile of 1.0 µg/kg bw, below the tolerable daily intake of 4 µg/kg bw/day established by EFSA. To our knowledge, this is the largest biomonitoring study of bisphenols in human milk in Europe.	Sci Total Environ Vol.668 Pages 797-805	10.1016/j.scitotenv.2019.03.024	30870748	ヒト	-	-	-	-	-	-	バイオモニタリング	1	1	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-

Ot Behalf Of The Biowat Task	2021	Biomonitoring of Phthalates, Bisphenols and Parabens in Children: Exposure, Predictors and Risk Assessment	Exposure to emerging contaminants, such as phthalates, bisphenols and parabens in children has been associated with possible neurodevelopment and endocrine alterations. In the present study, the biomonitoring of biomarkers in children (5-12 years old) from the Valencia Region (Spain) have been implemented using urines from the INMA, program. More than 75% of the children studied (n = 162) were internally exposed (>LOQ) to bisphenols and parabens, and the whole population assessed (n = 197) were exposed to at least one phthalate. The geometric means (GM) of the concentrations of bisphenol A, methyl paraben and propyl paraben were 0.9, 1.4 and 2.8 ng/mL, respectively. Regarding phthalates, monoethyl phthalate GM was 50.3 ng/mL and dietary) butyl phthalate (as the sum of five metabolites) GM was 38.8 ng/mL. Despite the studied population being considered as highly exposed to phthalates and bisphenols, concentrations were in general lower than in previous studies, including children in Spain and in other countries. In most cases, the risk assessment carried out concluded that the internal exposure to phthalates, bisphenols, and parabens is lower than the guidance values established, and, therefore, a health risk derived from the exposure to these compounds in the studied population is not expected. Hao	2020	[A birth cohort study of the association between prenatal serum bisphenol A concentration and infant neurobehavior development]	Objective: To explore the association between maternal bisphenol A (BPA) exposure during pregnancy and neurobehavioral development in infant. Methods: Participants were from the Maternal-Birth Cohort, which was established from October 2008 to October 2010 based on four municipal medical and health institutions in Hefei area. High-performance liquid chromatography-tandem mass spectrometry was applied for the determination of serum BPA concentration in 1 780 pregnant women sampled at their third filling, and during 3 d(7 to 28 d, months age of the infants. Neurobehavioral development were assessed by 0-6 year-old pediatric neurobehavioral scale. Multiple linear regression models were used to analyze the association between maternal BPA exposure and infant neurobehavioral development. Results: The median concentration of BPA in the urine of 931 mother-child pairs had complete data on serum BPA detection during pregnancy and assessment of infant neurobehavioral development status. The median age of pregnant women at their first filling was 29(27-31) years old, and the M (P25,P75) of serum BPA concentration (ng/ml) was 0.23 (0.12, 0.52), with a detection rate of 82.1% (764/931). The age of infants was 13 (10 to 16) months, and 53.5% (498) were boys. The multiple linear regression model showed that the serum BPA level in pregnancy was negatively associated with the development of language and social behavior development in infants, and the regression coefficients (β) were -0.66 (-1.13, -0.19) and -0.60 (-1.07, -0.13), respectively. Conclusion: BPA exposure during pregnancy affects language and social behavior development in infants, and the detection window is between 13 and 16 months old of the infant. Dechant	2025	Sex-Specific Adverse Association of Endocrine Disrupting Chemicals on Peak Anaerobic Power and Skeletal Muscle Mass of Active Young Adults	dos Santos, JM, Kennedy, T., Zhu, J, McPhie, A, Ray, M, Dentici, J, and Dechant, J. Sex-specific adverse association of endocrine disrupting chemicals on peak anaerobic power and skeletal muscle mass of active young adults. J Strength Cond Res XXXX-000-000, 2025-Endocrine disrupting chemicals, such as bisphenol A (BPA) and bisphenol S (BPS), and polycyclic aromatic hydrocarbons (PAHs) are a broad class of lipophilic compounds that induce adverse physiologic outcomes dependent on biological sex. These chemicals stimulate oxidative stress and impact pathways involved in anaerobic and aerobic energy generation, key drivers of athletic performance. This study aims to analyze the association of BPS, BPA, 2-naphthol (a marker of PAH), and oxidative stress with peak anaerobic power (PAP) and anthropometric characteristics. Peak anaerobic power was assessed by the Wingate anaerobic test (WAnT) in 30 active young adults (18-30 years old; 15 males and 15 females). Urinary BPA, BPS, 2-naphthol, and oxidative stress (8-isoprostane) were measured by ELISA, while muscle mass was assessed by ELISA, capillary sample analysis, and body composition analyzer, respectively. Peak anaerobic power was negatively associated to BPS and positively with percentage of skeletal muscle and oxidative stress ($p < 0.05$). Multivariate regression, moderated by normalized lean variables associated to 8-PGF$_{2\alpha}$ such as sex, height, and age, indicated that only BPS was a predictor of PAP ($β = -0.386$, $p = 0.021$). Multivariate of variables were associated to each sex, and PAP was negatively associated to 8-levels of BPS and 2-naphthol in women. Multivariate regression confirmed that these variables are predictors of PAP ($p < 0.01$). Results support the idea of a sex-specific physiologic impact of BPS and 2-naphthol on PAP, independently of levels of oxidative stress and percentage of muscle. Controlling BPS and 2-naphthol exposure could be potential strategy to improve PAP in female athletes. 統合_0648	Z. Dong, L. Hu, J. Wu, C. Xie, S. Geng, J. Wu, C. Zhong and X. Li	2025	Bisphenol A-induced cancer-associated adipocytes promotes breast carcinogenesis via CXCL12/AKT signaling	Bisphenol A (BPA), a commonly used plastic additive, is believed to cause obesity. As an environmental endocrine disruptor, BPA is closely associated with the onset and progression of BC. However, the molecular mechanisms underlying the promotion of breast cancer by BPA remain unclear. As obesity is a significant risk factor for breast cancer, this study aimed at exploring whether BPA facilitates the progression of breast cancer through obesity. In vivo, BPA was found to promote the growth of breast cancer and induce obesity in mice. Additionally, BPA was found to increase the adipocyte area and mass index (AI), suggesting that obesity may be influenced by urinary BPA. 3T3-L1 cells differentiated into mature adipocytes following treatment with DX-BI (4-MAPA and subsequent treatment with ATO conditioned medium acquired properties associated with cancer-associated adipocytes (CAAs). Network pharmacology suggested that CXCL12 may serve as a key target gene in breast cancer progression. Follow-up PCR analysis revealed that BPA induced the expression of MFs-induced CAAs. Overexpression of CXCL12 promoted epithelial-mesenchymal transition (EMT) and ATC cell migration by activating the AKT pathway. In vivo, BPA-induced CAAs secreted high levels of CXCL12, leading to a notably strengthened role in ATC cells. In tissues from the BPA-CAAs group, the expression of CXCL12 markers associated with CAAs, phosphorylated AKT, N-cadherin, and chemerin was markedly elevated, whereas the expression of E-cadherin was reduced. In conclusion, BPA may induce adipose cells to differentiate into CAA-like cells and subsequently advance breast cancer EMT through the CXCL12/AKT pathway. Cedeño Laurent	2022	Influence of living in the same home on biomonitored levels of consumer product chemicals	BACKGROUND: Individuals living in the same home may share exposures from direct contact with sources or indirectly through contamination of the home environment. OBJECTIVE: We investigated the influence of sharing a home on urine levels of ten phenolic chemicals present in some consumer products. METHODS: We used data from Dixie Spring Institute's Detox Me Action Kit (DMAK), a crowdsourced biomonitoring program in the US. Of the 726 DMAK participants, 185 lived in the same home with one or more other DMAK participants (n = 137 pairs, up to six participants in a home). The concentration distributions included values below the detection limit so we used statistical methods that account for left-censored data, including non-parametric correlation estimation and Kaplan-Meier/Spearman regression models. RESULTS: Concentrations were significantly correlated between participants living in the same home for bisphenol A (BPA), benzophenone-3 (BP-3), triclosan, and the parabens methyl- (MeP), ethyl- (EtP), butyl- (BuP), and benzylparaben (BzP). Inferred correlations between participants not living in the same home were significantly lower than those for participants living in the same home for BPA, BP-3, triclosan, MeP, EtP, and BuP. For these chemicals, 1 to 2 ng/mL of the variance in urine concentrations was explained by whether participants lived in the same household, including exposures not asked about, sensitivity to chemical. Random concentrations, even largely influenced by personal behaviors, whereas distinct/spread and bisphenol concentrations were largely influenced by shared home exposures not related to reported behaviors. DISCUSSION: Measuring the influence of personal and household practices on biomonitoring exposures helps pinpoint major sources of exposure and highlights chemical-specific intervention strategies to reduce them.	J Expo Sci Environ Epidemiol Vol.32 Issue 6 Pages 885-891	10.1038/s41370-021-00368-8	34257390	ヒト	-	-	-	-	-	-	-	-	バイオモニタリング	1	1	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-

Rudel	2020	Consumer behavior and exposure to parabens, bisphenols, triclosan, dichlorophenols, and benzophenone-3: Results from a crowdsourced biomonitoring study	Nearly all Americans have detectable concentrations of endocrine-disrupting chemicals from consumer products. In their bodies, and expert panels recommend reducing exposures. To inform exposure reduction, we investigated the influence of behaviors, sex, and household practices on urine concentrations of 10 phenols and parabens. We used data from Detox Me Action Kit (DMAK), a crowdsourced biomonitoring study. We targeted phenolic compounds: specifically parabens, bisphenol A (BPA) and analogs bisphenol F (BPF) and bisphenol S (BPS), the UV filter benzophenone-3, the anti-microbial triclosan, 2,4-dichlorophenol, and 2,5-dichlorophenol and collected survey data on consumer products, cleaning habits, and efforts to avoid tested chemicals. We investigated associations between urine concentrations and survey responses using univariate and multivariate regression models. We recruited 726 participants, 515 women and 211 men, from across the US. Participants reported eating rarely to their exposure to specific chemicals, and overall, participants achieved lower concentrations than the general U.S. population for BPA, triclosan, and benzophenone-3 but not BPF and BPS. Participants who reported avoiding all four ingredient groups (parabens, triclosan, bisphenols, and fragrances were twice as likely as others to be in the lowest quartile of cumulative exposure. Avoiding certain products and reading ingredient labels to avoid chemicals was most effective for parabens, triclosan, and benzophenone-3. Avoiding BPA was not effective for reducing bisphenols exposures. Avoiding certain chemicals in products was generally associated with reduced exposure for chemicals listed on labels. Greater ingredient transparency will help consumers, who read labels to reduce their exposure to a wider range of potentially harmful chemicals. In order to more routinely address public health, labeling policies should be complemented by regulations that exclude harmful chemicals from consumer products. 統合_0651	J. Ding, Y. Liu, Y. Li, Y. Huang, S. Li, F. Wang, D. Chen, B. Lu and N. Lin	2024	Insights into the accumulation and hepatobiliary transport of bisphenols (BPs) in liver and bile	Bisphenols (BPs) are widely distributed in daily life as typical endocrine disruptors. In this study, we examined the distribution of bisphenol A (BPA) and BPA alternatives in liver (n = 139) and bile (n = 102) tissues from the patients with liver cancer, and calculated the hepatobiliary transport efficiency of BPs (TE-B). Several BPs were detected in both liver (median: 0.898 ng/g; range: 0.0256-28.7 ng/g) and bile (median: 0.307 ng/mL; range: 0.0203-59.7 ng/mL), and BPA was the predominant in both liver tissue (38 ng/g) and bile (mean: 0.66 ng/mL). The TE-B (1.4 BPs was reported for the first time. Liver BPA concentrations were significantly correlated with the molecular weight and Log K(ow) of BPs. Furthermore, BPA and 2BPA in liver showed a significant negative correlation with age, and a significant difference was found in BPA in liver and bile in hepatocellular carcinoma (HCC) patients with different sex. Besides, BPA in liver showed a significant positive correlation with the concentrations of total bile acids (TBA) and total cholesterol (TC) in bile, but not with TBA and TC levels in liver. This suggests that BPs may have some correlation with hepatocellular carcinoma. This is the first report on distribution characteristics of BPs in the liver and bile of hepatocellular carcinoma patients, and the first study to report the hepatobiliary transport efficiency of BPs. The results should contribute to the understanding of BPs accumulation in the liver and bile and further relationship with hepatocellular carcinoma. 統合_0652	I. Dimitriadis, I. Souter, P. L. Williams, D. Weller, J. B. Ford, K. Hauser and L. Mínguez-Alarcón	2025	Phenol biomarker concentrations in human ovarian follicular fluid and the associations with in-vitro fertilization outcomes	BACKGROUND: Phenols are a family of short-lived endocrine disrupting chemicals found in a wide range of products and have drawn significant attention because of widespread human exposure and their potential adverse effects on reproductive health. Phenols have been widely detected in several human bodily fluids, particularly in urine and blood. However, there is limited data on phenols in human ovarian follicular fluid (FF). In addition, studies suggest associations between exposure to bisphenols and measures of infertility in humans. Nevertheless, the association of FF concentrations of bisphenols and female fertility has not been investigated. OBJECTIVE: To investigate the associations between FF concentrations of bisphenol A (BPA), bisphenol S (BPS), bisphenol F (BPF), and 2,5-dichlorophenol (2,5-DCP) and in vitro fertilization (IVF) outcomes. METHODS: This analysis includes 220 women who enrolled in the Environment and Reproductive Health (EARTH) Study and underwent one IVF cycle between 2009 and 2019, with available FF, urine and reproductive outcome data. FF concentrations of 2,5-dichlorophenol (2,5-DCP), 2,5-dichloro-phenol (2,5-DCP), methyl paraben (MPB), ethyl paraben (EPB), propyl paraben (PPB), benzyl paraben (BzP), BPA, BPF, BPS, triclosan (TCS), and benzophenone-3 (BP-3) were measured using liquid chromatography-tandem mass spectrometry. Generalized linear models were used to explore the associations between FF concentrations of bisphenols (in tertiles) or dichlorophenol and FF outcomes. RESULTS: Detection frequencies were varied from high (79-96%) for MPB, PPB and BPS, to moderate (32-46%) for BPA, BPF and TCS, to low (1-16%) for 2,5-DCP, 2,5DCP, EPB, BPB, BPF, TCC. Correlations between FF and urine were strong for BPS (~0.80), moderate for BPB (~0.45) and PBP (~0.62), and weak for BPA (~0.21), and none for BPS (~-0.01) and BPS (~-0.07). FF BPS concentrations significantly decreased over time, whereas FF BPA concentrations increased. None of the examined FF phenol/dichlorophenol concentrations were not related to early IVF outcomes (endometrial thickness, total and mature (MII) oocyte yield, fertilization rates). However, significant associations between PPB and BPS and lower implantation, clinical pregnancy, and live birth rates were observed. Similarly, significant associations between BPA and lower implantation rates were observed. CONCLUSION: We observed that most phenols, were detected in FF and there were some correlations with urinary concentrations. We confirmed in FF that phenols such as BPA may be declining, while exposure to new replacements, such as BPS are increasing. However, no overall associations were observed for the examined FF phenol biomarker concentrations with early IVF outcomes and pregnancy outcomes. Further research is needed to examine the potential associations of these phenols in FF, especially the newer ones that are in the rise. 統合_0653	I. Di Nepoli, S. Tagliaferri, E. Sommella, E. Salviati, D. Porri, B. Ragozzi, H. Cena, P. Campiglia, C. La Rocca, R. M. Cerbo and R. De Giuseppe	2021	Lifestyle Habits and Exposure to BPA and Phthalates in Women of Childbearing Age from Northern Italy: A Pilot Study	Background: Endocrine-disrupting chemicals (EDCs) are compounds that interfere with aspects of hormonal signaling. Considerable attention has been paid to their biological effects, especially in women of childbearing age or during pregnancy as EDCs have been reported to cross the placenta becoming concentrated in the fetus' circulation. Lifestyle habits, daily consumption of packaged foods and use of healthcare/cosmetic products are considered the main sources of exposure to EDCs. Methods: A pilot study was carried out to evaluate the urinary concentrations of bisphenol A (BPA) and phthalates in a group of women from Northern Italy. Forty-five women (median age 35, IQR: 30-38) were evaluated for urinary bisphenol A (BPA) and phthalates levels and also studied to EDCs' major determinants of daily exposure (frequency/dietary, physical activity, smoking habits, and weight status. Results: Although 100% of women seemed to have been exposed to common sources of EDCs, they reported a healthy lifestyle. The multivariable model described a positive and significant association between consumption of sources/beverage in plastic containers and (nonetic) phthalate exposure (p = 0.007). Conclusions: Since reproductive age encompasses a critical window for future health and functioning of the "mothers-to-be" and their children, future studies on prenatal dietary BPA and phthalate exposure and the role of consumer product choices in reducing such exposure are recommended. Faggio	2023	Screening of phthalate and non-phthalate plasticizers and bisphenols in Sicilian women's blood	The plastic accumulation and its degradation into microplastics is an environmental issue not only for their ubiquity, but also for the release of intrinsic chemicals, such as phthalates (PAEs), non-phthalate plasticizers (NPPs), and bisphenols (BPs), which may reach body organs and tissues, and act as endocrine disruptors. Knowing plastic additives in biological matrices, such as blood, is a key step to establish a link between human exposure and health outcomes. In this work, the profile of PAEs, NPPs and BPs was determined in Sicilian women's blood with different ages (30-60 years) and interpreted by chemometrics. PAEs (DMP and DEPh), NPPs (DINP and DINCH), BPA and BPS were at higher frequencies and greater levels in women's blood and varied in relation to age. According to statistical analysis, younger females showed higher contents in blood ones than older women, probably due to a more frequent use of higher quantities of plastic products in daily life. 統合_0655	S. Dhar, A. Das and P. Bhattacharjee	2025	A population-based study to understand the association between Bisphenol-A (BPA) and Polycystic Ovarian Syndrome (PCOS): correlating with anthropometric parameters and clinical features	Bisphenol-A (BPA) is one of the most ubiquitous EDCs, possessing a variety of health risks starting from metabolic disorders to cancer. Due to the estrogen-mimicking phenomenon, BPA was associated with female reproductive disorders like polycystic ovarian syndrome (PCOS). This study aims to investigate the possible epigenetic mechanisms behind BPA-mediated PCOS manifestation among young women from West Bengal, India. A cross-sectional study was conducted in Kolkata Metropolitan City, West Bengal, India. Upon consenting participants, 80 women were collected for pathological screening, anthropometric measurements. Followed by this, BPA exposure was measured in serum as well as saliva using ELISA-based technique and subsequently Global DNA methylation status (5-hmC, 5-mC and 5-mC) and HDAC activity were quantified. The mean concentration of BPA in serum was 0.0 ± 0.0 ng/mL, while in saliva, it was 0.0 ± 0.0 ng/mL. Significant differences were observed in BMI, waist circumference, and waist-to-hip ratio between PCOS and non-PCOS groups (p < 0.001). A significant correlation was found between BPA exposure and menstrual irregularity (p = 0.008), and excessive hair growth (p = 0.032). Also, body weight, waist circumference, hip circumference, total fat (%), visceral fat (%), BMI, LH, testosterone, LH: FSH and FAI activity was significantly high (p 0.0001) whereas 5-mC (%) was significantly low (p < 0.001) in PCOS women. Results suggest a potential role of BPA in the alteration of epigenetic mechanisms, which leads to alterations in gene expression levels and eventually causes obesity and hormonal imbalance. Therefore, we hypothesize that BPA may lead to PCOS among women.	J Clin Med Vol.14 Issue 13	10.3390/jcm14134706	40649079	ヒト	-	-	-	-	-	-	-	-	横断研究	1	1	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-

Wojtkiewicz	2019	Association of urinary bisphenols and triclosan with thyroid function during early pregnancy	BACKGROUND: Bisphenols and triclosan are considered as potential thyroid disruptors. While mild alterations in maternal thyroid function can result in adverse pregnancy and child developmental outcomes, there is still uncertainty whether bisphenols or triclosan can interfere with thyroid function during pregnancy. OBJECTIVES: We aimed to investigate the association of urinary bisphenol A (BPA), bisphenol F (BPF), bisphenol S (BPS), and triclosan with early pregnancy thyroid function. METHODS: This study was embedded in the Swedish Environmental Longitudinal, Mother and child, Asthma and allergy study (SELMA), a population-based prospective pregnancy cohort. In total, 1996 participants were included in the current study. Maternal urinary concentrations of three bisphenols and triclosan, collected at median (95% range) 10 (6-16) weeks of pregnancy, as well as serum concentrations of thyroid-stimulating hormone (TSH), free thyroxine (FT4), free triiodothyronine (FT3), total thyroxine (TT4), and total triiodothyronine (TT3) were measured. RESULTS: Higher BPA levels were associated with higher FT4 concentrations (β 0.01; 95% CI: 0.00, 0.02; p 0.05). Higher BPS levels were associated with higher TSH concentrations (β 0.06; 95% CI: 0.01, 0.11; p 0.05). Higher triclosan levels were associated with higher FT4 (β 0.007; 95% CI: 0.001, 0.013; p 0.05) and TT4 (β 0.007; 95% CI: 0.001, 0.013; p 0.05) concentrations. The association of BPA with thyroid function differed by infant sex, with gestational age. The negative association of BPA with FT4/FT3 and TT4/TT3 ratios was only apparent in early but not late gestation (P for interaction 0.003, 0.008, respectively). CONCLUSION: These human data during pregnancy substantiate experimental findings, suggesting that BPA could potentially affect thyroid function and disturbance activities in early gestation. 統合_0658	A. Derakhshan, H. Shu, M. A. C. Broeren, A. Korevaar, C. H. Lindh, B. Demeneix, R. P. Peeters, C. G. Bornehag and T. J. M. Korevaar	2021	Association of endocrine disrupting chemicals exposure with human chorionic gonadotropin concentrations in pregnancy	BACKGROUND: Human chorionic gonadotropin (hCG) is produced by the placenta and plays an essential role in the maintenance of pregnancy. Endocrine disrupting chemicals (EDCs) have the potential to interfere with functions related to the production and secretion of hCG. However, associations between exposure to EDCs and hCG concentrations in humans remain to be elucidated. OBJECTIVES: To investigate the association of urinary, serum and plasma concentrations of EDCs during pregnancy with serum hCG concentrations. METHODS: We utilized data from the Swedish Environmental Longitudinal, Mother and child, Asthma and allergy (SELMA) study. We investigated the association of 19 EDCs measured in early pregnancy urine or blood with serum hCG concentrations using multivariable linear regression models with covariate adjustment and inverse probability and Weighted Quantile Sum (WQS) regression with repeated holdout validation for the EDC-mixture. RESULTS: In 2,109 included women, higher exposure to bisphenol S was associated with lower hCG. Beta (95% CI): -0.05 (-0.11 to -0.00) per doubling of exposure. Urinary concentrations of the phthalate metabolites mono-(3-carboxypropyl) phthalate (MCPP) and mono-(2-ethyl-5-hydroxyhexyl) phthalate (MEHHP) were associated with lower hCG. Beta (95% CI) for a unit (ln) increase: -0.07 (-0.14 to -0.01) and -0.07 (-0.13 to -0.01), respectively. Urinary concentrations of the phthalate metabolite of di-2-ethylhexyl phthalate (DEHP) was associated with a lower hCG. Beta (95% CI) for a unit (ln) increase: -0.07 (-0.14 to -0.01). Likewise, higher plasma concentrations of perfluorooctanoic acid (PFOA) was associated with a lower hCG. In the WQS-regression, each quartile increase in the EDCs-mixture was associated with -0.27 lower hCG (95% CI: -0.36 to -0.19). CONCLUSIONS: Higher exposure to several EDCs during pregnancy was associated with a lower hCG, and despite the small effect sizes, still indicating that the exposure may negatively affect production or secretion of hCG by the placenta. Our results provide the impetus for future experimental studies to investigate the placenta as a target organ for adverse effects of EDCs. 統合_0659	A. Derakhshan, E. M. Philips, A. Gkaniadelar, S. Santos, A. G. Asimakopoulos, K. Kannan, A. Korevaar, H. W. J. Jaddoe, L. Trasande, R. P. Peeters and T. J. M. Korevaar	2021	Association of urinary bisphenols during pregnancy with maternal, cord blood and childhood thyroid function	BACKGROUND: Most pregnant women are exposed to bisphenols, a group of chemicals that can interfere with various components of the thyroid system. OBJECTIVES: To investigate the association of maternal urinary bisphenol concentrations during pregnancy with maternal, newborn and early childhood thyroid function. METHODS: This study was embedded in Generation R, a prospective, population-based birth cohort (Rotterdam, the Netherlands). Maternal urine samples were analyzed for eight bisphenols and bj (BPA, BPF, BPS, BPAF, BPB, BPE, BPP, BPZ). Maternal serum thyroid function (free thyroxine (FT4) and total thyroxine (TT4) were measured in early pregnancy and child TSH and FT4 were measured in cord blood and childhood. RESULTS: The final study population comprised 1,367 mothers, 883 newborns and 682 children. In early pregnancy, BPA was detected in 89% of the women, BPF in 14%, BPS in 25% and BPAF in 1%. Higher BPA concentrations were associated with higher FT4 concentrations (β 0.02; 95% CI: 0.00, 0.04). Higher BPS concentrations were associated with maternal thyroid function. Higher BPS concentrations were associated with a higher maternal TT4 (β 1.99% (0.2 per 1 (natural log) unit increase; 95% CI: 0.03 to 3.92) but there was no association with TSH or FT4. Furthermore, higher BPS was associated with an attenuation of the association between maternal FT4 and TSH (P(interaction) = 0.002). There was no association of early or mid-pregnancy BPA or early pregnancy BPS with cord blood or childhood TSH and FT4. A higher late-pregnancy maternal BPA exposure was associated with a higher TSH in female newborns (P(interaction) = 0.06) and a higher FT4 during childhood in males (P(interaction) = 0.08). CONCLUSIONS: Our findings show that exposure to bisphenols may interfere with the thyroid system during pregnancy. Furthermore, the potential developmental toxicity of exposure to bisphenols during pregnancy could affect the thyroid system in the offspring in a sex-specific manner. Cianfarani	2024	Urinary Bisphenol A and Bis(2-Ethylhexyl) Phthalate Metabolite Concentrations in Children with Obesity: A Case-Control Study	INTRODUCTION: Obesity is a worldwide public health problem. Experimental animal and in vitro studies suggest that the exposure to BPA and phthalates are associated to a higher risk of obesity. OBJECTIVE: The objective of the study was to determine urinary excretion of bisphenol A and phthalates in obese and normal-weight children. METHODS: A case-control study was conducted in 110 children. Sixty-six obese children, 36 girls (mean age 8.42 ± 1.97 years), and 30 boys (mean age 8.61 ± 1.35 years), and 30 normal-weight children, 21 girls (mean age 7.66 ± 1.35 years), and 29 boys (mean age 7.77 ± 1.98 years) were studied. Urinary BPA and phthalate metabolites were measured by high-performance liquid chromatography-tandem mass spectrometry. Urinary creatinine was measured by the Jaffe method. Urinary BPA and phthalates were evaluated through "ad hoc" questionnaires. RESULTS: BPA and DEHP metabolites were detectable in obese and normal-weight children. Obese girls showed significantly higher BPA concentrations in comparison with normal-weight girls (mean, 10.77; 95% CI = 7.62-15.19 vs. 5.66; 95% CI = 3.65-7.71; μg/g creatinine, respectively, p 0.05). The first step of DEHP metabolic rate was significantly higher in obese girls compared with controls (p 0.05). DEHP metabolites correlated significantly with both concentrations in obese girls (p 0.05). A higher risk of obesity was found in children with BPA levels above the median values with the habit to eat food packaged (OR = 11.09; 95% CI = 1.28-96.78). CONCLUSIONS: These findings show that a higher exposure to BPA is associated with the risk of obesity in girls. Further studies are needed to unveil the sweet-effect relationship. 統合_0661	Z. Dong, S. Wang, H. Song, R. Liu and Y. Lv	2025	Bisphenol a monitoring by commercial pregnancy test strips transformed by DNA walking machine	Frequently-occurred food contamination issues bring about a tremendous global demand for point-of-care testing (POCT) devices. Pregnancy test strip (PTS) retains the highest POCT market share and a low cost of $0.3 per test, but challenged by limited analytical sensitivity and inconvenient operation. Herein, we developed a DNA walker machine for PTS enhancement monitoring. Herein, we developed a DNA walker machine assisted commercial PTS method for on-site bisphenol A (BPA) analysis. DNAzyme was operated as the efficient autonomous catalytic walker chain to drive the DNA machine for the amplified signal output of BPA in drink samples. A detection limit of 34 ng/mL was obtained. The POCT strategy constructed in this work has the characteristics of low cost, convenient operation and high analytical sensitivity, represents an attractive option for biosensing and on-site drink safety monitoring. Miao	2021	Bisphenol A exposure, interaction with genetic variants and colorectal cancer via mediating oxidative stress biomarkers	Bisphenol A (BPA) may induce oxidative stress as well as the toxicity of colon cancer cells. We hypothesized that BPA exposure and interactions with genetic variants might be associated with colorectal cancer (CRC) risk, and the association might be partly mediated by oxidative stress. We measured urinary BPA and oxidative stress (8-hydroxy-2'-deoxyguanosine [8-OHdG] and 8-hydroxy-2'-deoxyribonucleic acid [HNE-MA]) in 270 new CRC cases and 538 healthy controls. A set of 26 genetic variations in 12 candidate DNA repair genes and 9 metabolic enzyme genes were genotyped by MassARRAY platform. Multivariate logistic regression models were used to estimate odds ratios (ORs) and 95% confidence intervals (CIs). Urinary BPA levels were significantly associated with CRC risk (OR = 1.59, 95% CI = 1.19-2.13, P = 0.002). The mediation analysis showed BPA increased CRC risk partially mediated 11.45% of the effect of BPA on CRC risk. Moreover, BPA was found to interact with ERCC5 rs17655 and rs2296147 (both P(multiplicative) = 0.05) to increase CRC risk. In brief, our results suggested BPA was associated with CRC risk and the positive association of BPA with CRC risk might be partly mediated by the oxidative stress. 4NP, NB, BPA might increase risk in ERCC5 rs17655 and rs2296147 to increase CRC risk. 統合_0663	M. Deng, T. Gao, L. Tao, W. Tang, X. Wang, Y. Jiang, D. X. Xu, M. Fang and Y. Huang	2023	Are human exposure assessment the same for non-persistent organic chemicals? - from the lens of urinary variability and predictability	Assessment of human exposure to mixtures of non-persistent chemicals from food matrices and consumer products requires accurate characterization and estimation of their prevailing exposure levels, and assessment sampling approaches for these varying chemicals remain disputable. Here, we used high-throughput targeted method to quantify urinary concentrations of 39 most common non-persistent chemicals (9 parabens, 10 bisphenols, 3 triclosan, 7 benzophenones, 2 dichlorophenols, 13 phthalate metabolites and 35 antioxidants) in 328 consecutive spot samples from 15 participants over three consecutive days, 30 samples of which were collected in 24-h urine. Urinary chemicals were detected frequently (detection frequency ≥ 50%) and at relatively high concentrations. Intraclass correlation coefficient (ICC) to assess the reproducibility of targeted chemicals demonstrated that regardless of sampling approaches, All triclosans, most parabens, benzophenones and triclosan showed moderate to high reproducibility (0.60 < ICC < 0.940), with relatively high predictive power of PAREs for 16 to collections. Notably, most phthalates, bisphenols and antioxidants showed low ICC values. Together, our results demonstrates that TWO samples may be adequate for assessing human exposure to parabens, benzophenones, triclosan and dichlorophenols, whereas multiple consecutive urine collections may be advantageous for evaluating exposure to most phthalates, bisphenols and antioxidants. 統合_0664	D. Demicioglu, N. Cirac, S. D. Pektas, T. Edgunlu, M. Unal and D. Yazgan Aksoy	2024	Bisphenol-A and pentachlorophenol sodium levels in patients with rosacea	BACKGROUND/ OBJECTIVES: Rosacea is a common chronic inflammatory skin disorder. Endocrine-disrupting chemicals (EDC) are toxic substances, that may gain entry through the skin and subsequently interfere with hormonal and immune functions. Bisphenol A (BPA) and pentachlorophenol sodium (PCP) are two of these EDCs, incriminated in the pathogenesis of certain inflammatory skin disorders. We aimed to test the hypothesis that BPA and PCP levels are higher in patients with rosacea compared to healthy controls. METHODS: Rosacea (ROS) patients (n = 30; 24 female, 6 male; mean age: 39.2 ± 10.1 years) and sex-matched healthy controls (HC) (n = 30; 24 female, 6 male; mean age: 36.2 ± 10.2 years). Main anthropometric measures, fasting plasma glucose (FPG), insulin, HOMA-IR, lipids, C-reactive protein (CRP), ESR, and liver function tests were quantified and recorded. RESULTS: Serum CRP (SD: 3.2 vs. 3.7, t: 5.4mg/L, respectively, p0.05 for all). Serum BPA levels were 13.8 ± 11.6 and 12.9 ± 19.2ng/mL, and PCS levels were 62.2 ± 45.9ng/mL and 68.6 ± 62.1ng/mL for patients and healthy controls, respectively. There was no significant difference in BPA and PCS levels between the two groups (p > 0.05 for both). No significant association was found among HOMA-IR, CRP, BPA, and PCS levels (p > 0.05 for all). CONCLUSIONS: Although the present study fails to provide presumptive evidence for the role of BPA and PCS in rosacea, the question as to other EDCs might be resolved in its etiopathogenesis remains. This hypothesis requires confirmation in larger-scale future prospective trials. 統合_0665	J. Delaplanx, S. Fosse-Edorh, C. Filtol and C. Pitteloud	2023	Relation of urinary bisphenol concentration and diabetes or prediabetes in French adults: A cross-sectional study	BACKGROUND: International research has recently shown an association between exposure to bisphenol A (BPA) and the risk of diabetes, although limited results are available for exposure to bisphenol S (BPS) and bisphenol F (BPF). The aim of this study was to examine the relationships between impregnation with BPA, BPS, and BPF and the prevalence of diabetes or prediabetes in the French adult population. METHODS: Based on the Esteban cross-sectional study, 850 adults aged 18 to 74 years living in France were included. Urinary concentrations of BPA, BPS, and BPF were measured by liquid chromatography-tandem mass spectrometry. Logistic regression multivariable models were performed and adjusted for known risk factors for diabetes and urine creatinine concentration. RESULTS: The percentage of included individuals with diabetes was 5.2% (95% CI: 3.6%, 7.4%), and 24.2% (95% CI: 20.8%, 27.9%) had prediabetes. Urinary concentrations of BPA, BPS, and BPF were detected in 89.2%, 70.2%, and 11.4% of the adults. A high level of total bisphenol concentration of BPA (≥ µg/L) (> 1.5 WHO) (1.06-1.90), p < 0.001). However, our did not find any significant independent association between urinary BPS and BPF levels and the prevalence of diabetes or prediabetes. CONCLUSIONS: In this sample, considering the diabetes risk factors, diabetes or prediabetes was positively associated with higher urinary BPA concentration but not with urinary BPS and BPF concentrations. However, analysis of prospective longitudinal studies are still necessary to demonstrate a causal link between bisphenol exposure and the risk of diabetes or prediabetes. Silverberg, A. R. Atwater, M. J. Reeder and D. L. Holness	2022	Occupational contact dermatitis: Retrospective analysis of North American Contact Dermatitis Group Data, 2001 to 2016	BACKGROUND: Patch testing is an important diagnostic tool for suspected allergic contact dermatitis (ACD) in occupational settings. OBJECTIVE: Provide an overview of occupational skin disease (OSD) and an analysis of occupational ACD in North American patients undergoing patch testing between 2001and 2016. METHODS: Patients with OSD were analyzed for frequency of allergic reactions, by a screening series of allergens, occupations, and industries. RESULTS: Occupational dermatitis was diagnosed in 1,039 patients (mean age 43.2 years, 57.1% male, 42.9% female). Of these, 1,015 (97.7%) had ACD, 15 (1.4%) had irritant contact dermatitis (ICD), and 9 (0.9%) had OSD. The most common occupationally related allergens included rubber accelerators, preservatives, and epoxy resins. Of OSD, 1,015 (97.7%) were common sites of dermatitis. The occupations most affected were service workers and machine operators. LIMITATIONS: Our cohort may not reflect the general working population. CONCLUSION: This study identified common occupational allergens, exposure sources, and occupations/industries at risk. This information may help the clinician evaluate and manage patients with occupational contact dermatitis. 統合_0667	D. Degirmencioglu Gok, F. Tugge Okutucu, N. Ozturk and H. A. Ceyhun	2024	Association of bisphenol A with cognitive functions and functionality in adult attention deficit hyperactivity disorder	BACKGROUND: Bisphenol A (BPA) has been linked to attention-deficit/hyperactivity disorder (ADHD) symptoms, but the effects on cognitive functions and functionality in adult ADHD have not been investigated. We investigated the associations between serum BPA with cognitive functions and functionality in adult ADHD patients. METHODS: The levels of BPA were measured in 45 adult ADHD patients and 30 well-matched healthy controls. The relationship between plastic exposure and BPA was also evaluated. Stroop test and Wisconsin Card Sorting Test were applied for neurocognitive evaluation and participants were compared in basic cognitive functions including planning, organization, attention/vs, problem solving, cognitive flexibility, variety of attention, information processing speed, the ability to change perceptual set and response under interference. Sheehan disability scale was applied for functionality. The association of BPA with test scores was analyzed statistically. RESULTS: Serum BPA levels in adult ADHD patients were found significantly higher than healthy controls. Adult ADHD patients were also found to have significantly lower functionality and cognitive test scores. BPA levels showed a significant effect on the Stroop test and Wisconsin Card Sorting Test, indicating significant differences between the groups in terms of cognitive functions. However, no significant correlation was found between BPA levels and cognitive functions. CONCLUSIONS: BPA is associated with ADHD and affects functionality in the field of work, but larger-scale further studies are needed for its effect on cognitive functions. 統合_0668	C. D. de Siqueira, A. G. Ademola, A. C. R. de Moraes and F. B. Filippin-Monteiro	2023	Human body burden of bisphenol A: a case study of lactating mothers in Florianopolis, Brazil	Exclusive breast milk is the diet recommended by the World Health Organization (WHO) until 6 months of age. However, breastfeeding has the potential of transferring certain toxic chemicals from the mother to the infant. Bisphenol A (BPA) is a synthetic chemical used as a monomer in polycarbonate plastics and epoxy resins. Information on BPA concentration in the breast milk of lactating mothers is very limited. Also, this study aimed to determine the concentration of BPA in the colostrum of 50 post-term women at a university-affiliated maternity hospital in South Brazil. The results, obtained for all 50 samples, indicated a high concentration of BPA with a median value of 35.28 ng/mL. Furthermore, the concentration of BPA in mothers was influenced by the consumption of foods packaged in plastic packaging, especially when the plastic is heated (p = 0.0001). Based on the estimated daily intake (EDI) of BPA, the median value of 0.0012 ng/kg bw/day was found to be 1,000 times lower than the tolerable daily intake (TDI) established by the European Authority of Food Safety. These data showed a high concentration of BPA in the breastmilk of the lactating mothers which might be through the use of plastic containers as food/drink packages. This is of public health importance as the high concentration of BPA in their breast milk can be an indicator of potentially serious health problems in these mothers and much more in the babies breastfed with BPA-contaminated breast milk. 統合_0669	D. S. Davis, O. L. M. Scandlen, R. Saboy, M. Ghaffarzadeh, T. G. Hannam, A. Lagunov and L. A. Favetta	2024	High seminal BPA in IVF patients correlates with lower sperm count and up-regulated miR-21 and miR-130a	Bisphenol A (BPA) is a widespread industrial chemical, used as the key monomer of polycarbonate plastics and epoxy resins. BPA has been detected in human seminal fluid and has been correlated with changes in sperm quality and reproductive outcomes. However, the mechanisms underlying these changes remain unclear. Here, we investigated the relationship between seminal BPA and sperm quality in IVF patients. According to WHO guidelines, BPA levels in the seminal plasma were then measured through an enzyme-linked immunosorbent assay (ELISA) and compared to sperm quality metrics. The relative miRNA expression of key genes associated to male reproduction, including androgen receptor, miR-34c, miR-21, miR-130a, was then quantified and compared between groups with high or low BPA content. Our results revealed that BPA levels were increased with age and were negatively correlated with sperm counts (p<0.05). The negative correlation revealed significant correlations between patients over age-matched. No other relationships between seminal BPA and motility, morphology or DNA fragmentation levels were observed. qPCR analysis showed that androgen receptor mRNA expression was significantly greater in sperm with high seminal BPA (p<0.05). Moreover, we found that the expression of miR-21 and miR-130a were also upregulated in the higher BPA group (p<0.05). These results display a relationship between BPA content in the semen and male fertility parameters, and provide insights into the molecular mechanisms through which BPA may be affecting male reproductive capability. Ultimately, this research can potentially drive changes to guidelines and exposure limits for BPA exposure. 統合_0670	Y. Dai, J. Ding, Z. Wang, B. Zhang, Q. Guo, J. Gou, X. Qi, X. Ding, C. Wu, J. Zhang and Z. Zhou	2025	Biomonitoring, dietary predictors, drinking water ingestion of 33 endocrine disrupting chemicals in primary school children in China, towards an exposome approach	Exposure to multiple endocrine disrupting chemicals (EDCs) may have some adverse impacts on child health yet, little data is available on the body burdens, co-exposure patterns, health risks, and possible sources of a wide range of EDCs in children. Urine samples (n = 1,000) from primary school children in China were collected and analyzed for 33 EDCs including bisphenols, parabens, phthalates, and 10 toxic and essential elements were quantified in urine. A 24-hour dietary recall survey was conducted to collect dietary information, and tap water and bottled water were collected accordingly. Multivariable linear regression models were applied to estimate associations of dietary information and drinking water types with urinary EDC concentrations. A total of 31 chemicals were detected in more than 50 % of urinary samples. The median urinary ΣEDCs was 1,100 ng/mL. Children from Shanghai had significantly higher urinary concentrations of ΣEDCs, ΣPhthalates, ΣBisphenols, and ΣParabens than those from Guangzhou, Guiyang, and Lanzhou. Consumption of dairy products was positively associated with urinary ΣEDCs and bisphenol concentrations. Meat and meat products were positively associated with ΣPhthalates concentrations. Rice and rice products were positively associated with urinary concentrations of methyl- and ethyl parabens, respectively. Cereal intakes were positively associated with urinary cadmium, arsenic and cobalt levels, and the consumption of aquatic products was to relation to increases of urinary lead and cadmium concentrations. Children who mainly drank filtered water had lower urinary concentrations of chlorophyl-ate metabolites and bisphenol S, while those with bottled water as the main drinking water source had higher 2,4-dichlorophenol concentrations, and lower cadmium levels. In urine, compared to those who mainly drank tap water. Our findings suggested that children in this area were widely exposed to multiple classes of EDCs, and diet and drinking water were potential exposure sources of the analyzed chemicals. Smagulova	2022	Genome-wide distribution of histone trimethylation reveals a global impact of bisphenol A on telomeric binding proteins and histone acetyltransferase factors: a pilot study with human and in vitro data	OBJECTIVE: To assess the genetic and epigenetic effects promoted by Bisphenol A (BPA) exposure in adolescent males from the Spanish INMA- Granada birth cohort, and in human cells. METHODS: DNA methylation was analyzed using MBDBP. Repeat number variation in genomic DNA was evaluated, along with the analysis of H3K4me3 by using chromatin immunoprecipitation followed by high-throughput sequencing (ChIP-seq). Analyses were performed with maternal urine from a child-based of the adolescents, concentrations in urine measurements by in vitro assessments of human HeLa cells exposed to 10 nM BPA, specifically, immunofluorescence evaluation of protein levels, gene expression analysis and ChIP-qPCR analysis. RESULTS: Adolescents in the high urinary BPA levels group presented a higher level of Satellite III (SATIII) repetitive region copy numbers compared to those in the low BPA group. Differentially methylated regions (DMRs) were identified between the two groups, including genes such as ZNF577, ZNF578, ZNF781, ZNF782, ZNF783, ZNF784, ZNF785, ANGEL, ELOF1 and CERKL and SATIII genes. Genome-wide sequencing revealed increased H3K4me3 occupancy of the promoters of genes, revealing histone acetyltransferase factors, DNA binding factors and DNA repair genes. Results were supported in HeLa cells, especially 10 nM BPA in vitro. In accordance with the data obtained in blood samples, we observed higher H3K4me3 occupancy and lower DNA methylation at some specific regions in HeLa cells. In exposed cells, changes in the expression of genes encoding DNA repair factors, (KTA1, ANGEL1 TEP1) were observed, and increased expression of several genes encoding telomeric DNA binding factors (DAXX1, TERT, TPP1, UPF1, ZBTB48) were also found. Furthermore, an increase in ESRL/ERRα was observed in the nuclei of HeLa cells along with increased binding of ESR1 to KAT8, KAT2A and TERT/TP promoters. CONCLUSIONS: Our results suggest that BPA exposure may affect telomere maintenance and DNA repair mechanisms. Our data also suggest that the effects of BPA exposure in cells may be mediated by ERRα. BPA exposure may affect telomere maintenance and DNA repair mechanisms. Our data also suggest that the effects of BPA exposure in cells may be mediated by ERRα. BPA exposure may affect telomere maintenance and DNA repair mechanisms. Our data also suggest that the effects of BPA exposure in cells may be mediated by ERRα. Jurewicz	2021	Urinary Bisphenol A Concentrations and Parameters of Ovarian Reserve among Women from a Fertility Clinic	BACKGROUND: Human exposure to environmentally widespread endocrine disruptors, especially bisphenol A (BPA), has been suggested to affect reproductive health. Animal studies indicate that BPA may play a role in ovarian reserve impairment. However, human studies are inconclusive. The aim of the current study was to assess the effects of environmental exposure to BPA on ovarian reserve. METHODS: The study participants comprised 312 women recruited between 2017–18 years old who attended an infertility clinic for diagnosis, due to the couples' infertility. BPA urinary concentrations were assessed by the validated gas chromatography–ion trap mass spectrometry method. The ovarian reserve was assessed using ovarian reserve parameters: the ovarian volume, AFC (antralia), FSH (follicle-stimulating hormone), AMH (anti-Müllerian hormone), and HTC (antral follicle count). RESULTS: In the current study, the negative association between BPA urinary concentrations and AMH (r = -0.02 and AFC (p > 0.05) levels was found. Exposure to BPA was not related to other examined parameters of ovarian reserve (FSH, HCI, CONCLUSIONS: Our results suggest that BPA exposure may affect ovarian reserve parameters and reduce ovarian reserve. As this is one of the first studies of its kind, the findings need confirmation in a further investigation. 統合_0673	Y. Cui, Y. Hong, Y. Xu, Z. Jin, Y. Ji, Y. Liu, L. Zhao and L. Ren	2024	Associations between urinary level of bisphenol A, phthalates, 8-iso-prostaglandin-F2 α , and emotional and behavioral problems among Chinese adolescents	BACKGROUND: Emotional and behavioral problems (EBPs) of adolescents is a worldwide public health problem. Bisphenol A (BPA) and phthalates (PAEs) are prevalent and potentially toxic to human health. Therefore, this study aimed to investigate the associations between urinary BPA, PAEs, 8-iso-PGF2α and EBPs in Chinese adolescents. METHODS: A cross-sectional study was conducted in 2019. EBPs of adolescents were assessed using the Strengths and Difficulties Questionnaire (SDQ). Urinary concentrations of BPA and seven PAEs metabolites in adolescents were determined by high performance liquid chromatography-tandem mass spectrometry. Urinary 8-iso-PGF2α concentration was detected by enzyme-linked immunosorbent assay (ELISA). Spearman rank correlation analysis, multivariate logistic regression analysis, restricted cubic spline functions were used to explore the relationship between the levels of BPA, PAEs, 8-iso-PGF2α and EBPs. RESULTS: BPA and PAEs metabolites were positively associated with EBPs in Chinese adolescents. Both the 8-iso-PGF2α was significantly non-linearly correlated with emotional symptoms, conduct problems, peer problems and total difficulties. Furthermore, 8-iso-PGF2α may partially mediate the association between BPA, PAEs and EBPs. CONCLUSIONS: Our findings suggested that BPA and PAEs exposure were associated with EBPs in Chinese adolescents. Both the 8-iso-PGF2α was significantly non-linearly correlated with emotional symptoms, conduct problems, peer problems and total difficulties. Furthermore, 8-iso-PGF2α may partially mediate the association between BPA, PAEs and EBPs. CONCLUSIONS: Our findings suggested that BPA and PAEs exposure were associated with EBPs in Chinese adolescents. Both the 8-iso-PGF2α was significantly non-linearly correlated with emotional symptoms, conduct problems, peer problems and total difficulties. Furthermore, 8-iso-PGF2α may partially mediate the association between BPA, PAEs and EBPs exposure characterization matter could not represent their long-term exposure level. CONCLUSIONS: High exposure of BPA and PAEs are associated with EBPs, which may be partly mediated by oxidative stress among adolescents. The results of this study could provide certain ideas for subsequent related research. 統合_0674	Y. P. Cui, P. Yang, C. Liu, P. P. Chen, Y. L. Deng, Y. Miao, Q. Luo, M. Zhang, W. Q. Lv and Q. Zeng	2021	Urinary bisphenol A and its alternatives among pregnant women: Predictors and risk assessment	BACKGROUND: Exposure to bisphenol A (BPA) has been associated with various adverse health outcomes. Recently, an increasing concern on its alternatives such as bisphenol S (BPS) and bisphenol F (BPF) has been aroused due to the restriction use of BPA. Few studies have identified predictors of exposure to BPA alternatives and assessed their health risks. OBJECTIVE: The aim of this study was to identify predictors of BPA and its alternatives exposure among pregnant women and assess the health risks. METHODS: A total of 1,000 pregnant women were recruited from the Wuhan Maternal and Child Health Hospital Cohort, a prospective cohort established Chinese cohort. A questionnaire was conducted to obtain demographic characteristics, dietary habits, and lifestyles. We examined the predictors of creatinine-adjusted urinary BPA and its alternatives concentrations using multivariable linear regression. Risk assessments of exposure to BPA and its alternatives was calculated based on the estimated of daily intake (EDI). RESULTS: Geometric means of creatinine-adjusted urinary BPA, BPS, and BPF were 0.64 ng/mL, 0.08 ng/mL, and 0.05 ng/mL, respectively. Urinary BPA was positively correlated with BPS (r = 0.19, p < 0.001) and BPF (r = 0.14, p < 0.001). Changes' levels of fried food were related to higher concentrations of BPA, and intake of polyethylene was associated with higher concentrations of BPF and BPS. The mean EDI of BPA, 7.9 % of BPS, and 7.8% ranged from 0.625% to 13.139% tried by body weight/day, which were below the tolerable daily intake (TDI) for BPA defined by the European Food Safety Authority (EFSA) (4 ng/kg body weight/day). The maximum hazard index (HI) value was 0.7439. CONCLUSION: Several predictors identified in this study may inform public recommendations to reduce exposure to BPA and its alternatives. Júnior	2025	Co-exposure to multiple endocrine-disrupting chemicals and oxidative stress: Epidemiological evidence of nonmonotonic dose response curves	This study aimed to investigate the effect of multiple exposure to eight classes (parabens, bisphenols, glycolipid ethers, antimicrobials, benzophenones, phthalates, tri and dichlorophenols) of endocrine-disrupting chemicals (EDCs) on oxidative stress biomarkers in pregnant women. A cross-sectional study was conducted with 1,000 pregnant women in the second trimester of pregnancy. Urine samples were collected from each mother-fetal pairs enrolled in the population-based New York University Children's Health and Environment Study (NYU CHES). Bisphenols and phthalates were measured in maternal urine collected repeatedly during pregnancy. Analyses included 25 phthalate metabolites and 9 bisphenols that were detected in 50 % of participants or more. Total biomarkers were summed from electronic ultrasonography records and estimated for each EDC class. Oxidative stress was assessed by 8-hydroxy-2'-deoxyguanosine (8-OHdG) and 8-isoprostane (8-isoPGF2α) concentrations in urine collected during the second trimester of pregnancy. Multivariable linear regression models were used to investigate potential interactions and BKMR was used to explore the joint effects of the mixture. We examined the predictors of creatinine-adjusted urinary BPA and its alternatives concentrations using multivariable linear regression. Risk assessments of exposure to BPA and its alternatives was calculated based on the estimated of daily intake (EDI). RESULTS: Geometric means of creatinine-adjusted urinary BPA, BPS, and BPF were 0.64 ng/mL, 0.08 ng/mL, and 0.05 ng/mL, respectively. Urinary BPA was positively correlated with BPS (r = 0.19, p < 0.001) and BPF (r = 0.14, p < 0.001). Trasande	2023	Maternal urinary bisphenols and phthalates in relation to estimated fetal weight across mid to late pregnancy	BACKGROUND: Bisphenols and phthalates are high production volume chemicals used as additives in a variety of plastic consumer products leading to near-ubiquitous human exposure. These chemicals have established endocrine disrupting properties and may impact cardiometabolic health in the early and later stages of life. OBJECTIVES: To examine associations between urinary bisphenol A (BPA), bisphenol S (BPS), and phthalate metabolites in mother-fetal pairs enrolled in the population-based New York University Children's Health and Environment Study (NYU CHES). Bisphenols and phthalates were measured in maternal urine collected repeatedly during pregnancy. Analyses included 25 phthalate metabolites and 9 bisphenols that were detected in 50 % of participants or more. Fetal biometry data were extracted from electronic ultrasonography records and estimated fetal weight (EFW) was calculated using the Hadlock 4 equation. Linear mixed models were used to examine associations between urinary biomarkers and EFW z-score, adjusting for maternal and paternal covariates. We examined sex differences using stratified models. RESULTS: We found no statistically significant associations were observed across chemicals, phthalates, bisphenols, and sexes. However, within gestational timepoints, we found that among females, the molar sums of the phthalates DEHP and DnOP were generally associated with decreases in EFW among smaller babies and increases in EFW among larger babies. Among males, the opposite trend was observed. However, confidence intervals were generally wide at the tails of the distribution. CONCLUSIONS: In this sample, exposure to bisphenols and phthalates was associated with small sex-specific shifts in fetal growth; however, few associations were observed at the median of fetal weight and confidence intervals in the tails were wide. Findings were strongest for DEHP and DnOP, which are increasingly used as replacements for DEHP, supporting the need for future research on these contaminants. 統合_0687	A. G. Christiansen, O. Carstensen, M. Sommerlund, P. A. Clausen, J. H. Bamkilde, V. Schlünssen, M. Isaksson, S. A. J. Schmidt and H. A. Kolstad	2022	Prevalence of skin sensitization and dermatitis among epoxy-exposed workers in the wind turbine industry	BACKGROUND: A high prevalence of skin sensitization and dermatitis has been reported among workers exposed to epoxy components. OBJECTIVES: To estimate the risk of skin sensitization and dermatitis among workers in the wind turbine industry in Denmark and to identify risk factors for skin sensitization. METHODS: A cross-sectional study among 1,000 randomly selected workers was conducted. A questionnaire-based interview and clinical skin examination, and a nasal wash and blood sample were collected at two wind turbine blade factories in Denmark. Participants underwent a skin examination, were tested with a delayed patch test panel including epoxy-containing products used at the factories, and answered a questionnaire. RESULTS: Screen production workers (EPBs) were sensitized to an epoxy component compared with none of the office workers. Skin sensitization was more frequent among EPBs (odds ratio (OR) 5.3, 95% confidence interval (CI) 1.1-25.5) and laminators (OR 3.2, 95% CI 0.8-12.8) than among office workers. Dermatitis was more frequent among EPBs (OR 3.5, 95% CI 0.9-13.7), blade workers (OR 2.7, 95% confidence interval (CI) 0.8-9.1) and higher among laminators (OR 8.0) than the nonsensitized workers (OR 1.0). Workers sensitized to epoxy components had a higher risk of dermatitis if they had worked more than 5 years in the factories (OR 3.5, 95% CI 1.0-12.7). Nonsensitized workers had a higher risk of dermatitis if they had worked more than 5 years in the factories (OR 2.3, 95% CI 1.0-5.2). Bisphenol A and F were the most frequent sensitizers. One of the four workers sensitized to epoxy components used at the factories did not react to the epoxy resin of the TRIAX mat(TM) panel. CONCLUSIONS: Despite comprehensive skin protection, sensitization and dermatitis are prevalent among highly epoxy-exposed workers in the wind turbine industry in Denmark. Our findings document the need for intensified preventive efforts and emphasize the importance of tailored patch testing. What is already known about this topic? Epoxy components are well-known sensitizers of the skin. A high prevalence of skin sensitization and dermatitis has been reported among workers exposed to epoxy components. Comprehensive protective equipment is recommended when working with epoxy components. What does this study add? Despite comprehensive skin protection, skin sensitization and dermatitis are prevalent among epoxy-exposed workers. We found that 50% of workers sensitized to epoxy products had dermatitis. Only 70% of the sensitized workers were detected by the epoxy mixture the TRIAX test(TM), which emphasizes the importance of tailored testing. 統合_0688	E. U. Chowdhury, H. Banu, M. S. Monshed, I. A. Jahan, S. Khand and M. A. Hassnat	2025	Raised Bisphenol A has a Significant Association with Adverse Reproductive Manifestations Rather than Biochemical or Hormonal Aberrations in Women with Polycystic Ovary Syndrome	BACKGROUND: Bisphenol A (BPA) is a widely used industrial element. Recently it is suspected that BPA may disrupt the endocrine system to influence the manifestations of polycystic ovary syndrome (PCOS). OBJECTIVE: This study aimed to assess serum BPA level and its association with manifestations of PCOS in women. METHODOLOGY: This cross-sectional study included 80 young adults, with PCOS and 80 age-matched healthy controls. BPA, free testosterone, DHEAS, LH, FSH, SHBG, fasting glucose, insulin, and lipid profile were measured. Clinical features, including hirsutism, menstrual irregularities, and glycemic traits, were evaluated. Statistical analyses, including hormone, lipid, biochemical, and hormone receptor binding plastics, dehydroepiandrosterone-sulfate, and BPA. Glucose was measured by glucose oxidase. Subjects by glycemic phosphate dehydrogenase peroxidase, all hormones including SHBG by chemiluminescent immunoassay and BPA by sandwich enzyme-linked immunosorbent assay. Insulin resistance was measured using homeostasis model assessment of insulin resistance. RESULTS: Women with PCOS had significantly higher BPA levels (ng/mL) than the control group (27.30 (19.60, 33.90) vs. 16.0 (13.38, 18.78); median (IQR), p < 0.001). Using the 75th percentile value of the control group, 19 (23.8%) women with PCOS had high BPA levels. Those with high BPA levels had a significantly higher frequency of menstrual irregularities (" abortive among women with PCOS (OR = 3.2, 95% confidence interval (CI) 1.1-9.3, p = 0.032) and hirsutism (OR = 3.5, 95% CI 1.2-10.2, p = 0.021). Women with PCOS and high BPA (OR = 3.2, 95% CI 1.1-9.3, p = 0.032) had higher levels of BPA than those without the features. Serum BPA had no significant association or correlation with any androgenic and metabolic manifestations. CONCLUSION: Raised BPA level may be associated with adverse reproductive features in PCOS.	J ASEAN Fed Endocr Soc Vol.40 Issue 1 Pages 26-31	10.15605/jafes.040.01.14	40416478	ヒト	疫学	-	-	-	-	-	横断研究	1	1	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-
統合_0689	W. C. Chou, J. W. Gaynor, E. M. Graham, B. Kloeppinckx, T. Walker, E. S. Coker, R. F. Wambach and Z. Lin	2025	A Machine Learning-Based Clustering Analysis to Explore Bisphenol A and Phthalate Exposure from Medical Devices in Infants with Congenital Heart Defects	BACKGROUND: Plastic-containing medical devices are commonly used in critical care units and other patient care settings. Patients are often exposed to xenobiotic agents that are leached out from plastic-containing medical devices, including bisphenol A (BPA) and phthalates. Given the potential health implications, there is an urgent need for a comprehensive understanding of this exposure. OBJECTIVES: This multi-institutional study aimed to characterize the exposure to BPA and phthalates from medical devices in infants with congenital heart defects (CHD) undergoing cardiac surgery during the perioperative period. METHODS: We collected daily urine samples from infants with CHD undergoing cardiac surgery during the perioperative period from birth to 6 (1.4) and measured BPA, 402 methoxyphthalate (DEHP) metabolites (MEHP, MEHHP, MEOHP, MECPP), and non-DEHP phthalate metabolites (MBP, MMP, MEP, MCPP, MiBP) using ultra high-performance liquid chromatography-tandem mass spectrometry. Machine learning-based cluster analysis was utilized to analyze these liner dependent data. RESULTS: Utilizing a machine learning-based unsupervised clustering approach, 3 unique clusters of infants undergoing cardiac time series toxicokinetic exposure patterns. These distinct clustering groups correlated with the utilization of extracorporeal membrane oxygenation (ECMO) and cardiopulmonary bypass (CPB) during cardiac surgery. Infants undergoing cardiac surgery with ECMO support had significantly higher urinary concentrations of several BPA and phthalate metabolites compared to those without ECMO use, a trend we observed with non-DEHP metabolites. Moreover, peak concentrations in toxicokinetic profiles demonstrated within the intensity of medical devices. CONCLUSION: Our findings suggest that dynamic changes of urinary BPA and DEHP metabolites corresponded to the type and number of medical devices used in infants. Further studies are needed to investigate the potential toxicological risks of infants with CHD undergoing cardiac surgery exposed to these chemicals in medical devices. https://doi.org/10.1289/EHP14056. 統合_0690	Y. J. Choi, Y. A. Lee, Y. C. Hong, J. Cho, K. S. Lee, C. H. Shin, B. N. Kim, J. I. Kim, S. J. Park, N. Bhagwat, K. Bannerjee and Y. H. Lin	2020	Effect of prenatal bisphenol A exposure on early childhood body mass index through epigenetic influence on the insulin-like growth factor 2 receptor (IGF2R) gene	OBJECTIVES: Epigenetic mechanisms have been suggested to play a role in the link between in utero exposure to bisphenol A (BPA) and pediatric obesity; however, there is little evidence regarding this mechanism in humans. We obtained data on obesity-associated CpG sites from a previous epigenome-wide association study, and then examined whether methylation at these CpG sites was influenced by prenatal BPA exposure. We then evaluated the relationship between CpG methylation status and body mass index (BMI) in a prospective children's cohort at ages 2, 4, 6, and 8 years. METHODS: Methylation profiles of 59 children were longitudinally analyzed at ages 2 and 8 years using the Infinium Human Methylation BeadChip. A total of 956 CpG sites known to be associated with BMI or obesity-associated risk were tested for prenatal BPA levels, repeated-measures linear and logit regression groups based on the BMI percentile of maternal BPA levels (2 ≥6 µg/g creatinine) followed by an analysis of the association between DNA methylation and BMI trajectories. RESULTS: Methylation at cg07600487 (IGF2R) at age 2 years was significantly associated with maternal BPA level (β = 0.004, p = 0.0011, false discovery rate [FDR] = 0.0011). Moreover, the increase of methylation at cg07600487 (IGF2R) at age 2 years, the linear mixed model analysis revealed that BMI during ages 2-8 years significantly increased by 0.49 (95% confidence interval [CI]: 0.082 to 0.91, p = 0.02) kg/m2 in boys. The indirect effect of prenatal BPA exposure on early childhood BMI through methylation at cg07600487 (IGF2R) at age 2 years was marginally significant. CONCLUSIONS: Prenatal exposure to BPA may influence differential methylation of IGF2R at age 2. This result indicates that a possible sensitive period of DNA methylation occurs earlier during development, which may affect BMI and later childhood in a sex-specific manner.	Environ Int. 2020 Oct:143:105929.	10.1016/j.envint.2020.105929	32644488	ヒト	疫学	-	-	-	-	-	コホート研究	1	1	-	-	-	-	-	-	-	1	1	1	-	-	-	-	-	-	-	-	-	-	-
統合_0691	Y. Choi, S. J. Lee, J. Jeon, K. J. Jung and S. H. Jee	2019	Inverse associations of bisphenol A and phthalate metabolites with serum bilirubin levels in Korean population	Bisphenol A (BPA) and phthalates are endocrine disruptors that can induce oxidative stress. Serum bilirubin has antioxidant properties and may serve as a biomarker of oxidative stress. The objective of this study was to explore the relationship of BPA and phthalates with serum bilirubin levels in a Korean population. Urinary concentrations of BPA and six phthalates [mono-n-butyl phthalate (MnBP), mono-iso-butyl phthalate (MiBP), mono-(2-ethyl-5-carboxyl) phthalate (MECPP), mono-(2-ethyl-5-hydroxyhexyl) phthalate (MEHHP), mono-(2-ethyl-5-oxohexyl) phthalate (MEOHP), and mono-benzyl phthalate (MBzP)] were measured in 709 participants. Serum concentrations of BPA and three phthalate metabolites (MnBP, MiBP, and mono-(2-ethylhexyl) phthalate (MEHP)) were measured in 702 participants. After multivariate adjustment, including confounding variables, associations between above chemicals and serum bilirubin levels were analyzed using multivariate linear regression with age, sex, BMI, SGOT, SGPT, GFR, and alcohol intake adjustment. Participants were further stratified by sex. Among the urinary BPA and phthalate metabolites, MnBP, MiBP, MECPP, and MEHHP were detected in more than 95% of the subjects. MnBP, MiBP, MECPP, MEHHP, and MEOHP were positively associated with serum bilirubin levels (β = 0.011, P = 0.003; β = 0.010, P = 0.003; β = 0.008, P = 0.010; β = 0.008, P = 0.010; β = 0.006, P = 0.031, respectively). After stratification by sex, the associations of urinary BPA remained both in male and female, of which urinary phthalates disappeared in female. The association of serum MiBP was disappeared after stratification. Urinary BPA and phthalate metabolites were inversely associated with serum bilirubin levels, whereas serum MiBP showed positive association with bilirubin. These results could provide clues for understanding the mechanisms of endocrine disruptor from oxidative stress to excretion from our body. Park	2020	Thyroxine-binding globulin, peripheral deiodinase activity, and thyroid autoantibody status in association of phthalates and phenolic compounds with thyroid hormones in adult population	Exposure to consumer chemicals such as phthalates and phenolic compounds has been associated with thyroid hormone disruption in humans. However, information related to factors that may influence such associations is limited. We investigated the effects of thyroid autoantibody status and thyroxine-binding globulin (TBG) on the associations between urinary phthalate and phenol biomarkers and thyroid hormones. Environmental Health Survey (KoNEHS) 2015-2017, and measured urinary concentrations of major phthalate metabolites, bisphenol A (BPA), and triclosan, with thyroid hormone related measures, including free and total T3 and T4, TSH, thyroxine-binding globulin (TBG), calculated peripheral deiodinase (DIO) activity, and thyroid autoantibodies of thyroperoxidase (TPO) and thyroglobulin (Tg). Phthalate metabolites were negatively associated with free T3 and positively associated with total T3. These observations could be explained by TBG levels and calculated peripheral DIO activity that were also associated with phthalate exposure. In contrast, BPA was positively associated with total T4 and negatively associated with total T3, without any changes in TBG concentration. Serum TPO and Tg antibodies were not associated with urinary biomarker concentrations. Our results suggest that phthalates and BPA may disrupt thyroid hormone homeostasis via different pathways, and TBG may play a role in phthalate exposure. The results of our observation-level potential underlying mechanisms of phthalates-induced thyroid hormone disruption, and suggests the importance of consideration of thyroid autoimmunity status in association studies for thyroid-disrupting chemicals. 統合_0693	J. Y. Choi, J. Lee, D. A. Huh and K. W. Moon	2022	Urinary bisphenol concentrations and its association with metabolic disorders in the US and Korean populations	Bisphenol A (BPA) is a representative endocrine-disrupting compound used in a vast array of consumer products, and are being frequently substituted by its analogues, bisphenol S (BPS) and bisphenol F (BPF). We aimed to investigate the urinary concentrations of BPA, BPS, and BPF in the US and Korean populations, and to compare the exposure levels between the two countries. We used data from the US National Health and Nutrition Examination Survey (2013-2014) and 2008 Korean adults from the Korean National Environmental Health Survey (2015-2017) cycle and analyzed. We examined the exposure levels of bisphenols, and determined their associations with obesity, high obesity (superobesity threshold (ST)), CC and triglycerides (TG) levels, and hypercholesterolemia prevalence through multiple linear, and binary (ordinal) logistic regression models. In both populations, high BPA levels (several tertiles vs. 2nd, Schindler) showed corresponding associations with (typically) favorable obesity. BPA levels were associated with decreased HDL-C levels (Q3: β = -0.063, p = 0.00 3.01; Q3: β = -0.032, p = 0.02), increased TG levels (Q3: β = 0.221, p = 0.029 [US]; Q3: β = 0.089, p = 0.02), and higher odds for obesity (Q3: OR = 1.58, 95% CI: 1.06, 2.35 [US]; Q3: OR = 1.52, 95% CI: 1.03, 2.24 [Korea]). Similar results were observed for BPS and BPF. Urinary BPA, BPS, and BPF concentrations were significantly associated with metabolic disorders in the US and Korean populations. Increases in HDL-C (Q3: β = -0.048, p = 0.02) and elevated odds for obesity at higher BPF levels (Q3: OR = 1.48, 95% CI: 1.02, 2.15) was observed in US women. The findings of our study indicated that BPS and its analogues, BPS and BPF, are associated with lipid metabolism disorders. In addition to obesity in adults. Given the increase in exposure to BPA alternatives, continuous biomonitoring, and further investigation of their health effects through prospective cohort studies are warranted. 統合_0694	J. W. Choi, H. Jang, J. R. Kuiper, D. H. Bennett, R. J. Schmidt and H. M. Shin	2025	Gestational exposures to mixtures of multiple chemical classes and autism spectrum disorder in the MARBLES study	BACKGROUND: Previous epidemiologic studies on gestational chemical exposures and autism spectrum disorder (ASD) often lack analysis of chemical mixtures or are limited to investigating certain chemical classes. OBJECTIVE: We examined the impact of multi-class chemical mixtures on ASD risk, using data from the MARBLES (Markers of Autism Risk in Babies Learning Early Signs) study. METHODS: Children were clinically assessed at age 3 and classified as ASD, typical development (TD), or non-TD with other neurodevelopmental concerns. In blood or urine from 235 pregnant mothers, we quantified 32 biomarkers across 5 chemical classes: per- and polyfluoroalkyl substances (PFAS), parabens, phthalates, and organophosphate esters (OPFRs). We only analyzed 18 biomarkers detected in >50% of the sample. After identifying clusters with similar chemical profiles via hierarchical clustering, we applied linear discriminant analysis (LDA) to compare ASD exposure summary scores. In covariate-adjusted models, we used LDA scores to assess co-exposure associations with ASD risk and neurodevelopmental scores. RESULTS: Among 220 children (ASD: 51, TD: 116, non-TD: 53), we identified four clusters: Cluster 1 (PFAS), Cluster 2 (parabens), Cluster 3 (PFAS, Cluster 2), and Cluster 4 (phthalates and OPFRs). Clusters 2 and 3 were associated with non-TD (1.07 [1.01, 1.14] and 1.12 [1.05, 1.19], respectively). Cumulative exposure across the four clusters was linked to increased risk of both ASD and non-TD. Postnatal biomarkers within and between clusters were observed. CONCLUSION: This study shows that considering multiple chemical classes resulted in stronger associations with ASD and non-TD risk, compared to when investigated separately in our previous studies. 統合_0695	J. E. Choi, E. J. Choi, S. Lee, B. Park, H. A. Lee, Y. S. Hong, E. Ha, H. S. Kim and H. Park	2025	Relationship of urinary bisphenol A in childhood on thyroid hormone function in adolescents: a cohort study	BACKGROUND: Bisphenol A (BPA) is a type of endocrine-disrupting chemical utilized in the production of plastics. Soy epoxy resins and polycarbonate polymers. BPA exhibits weak estrogenic and potent anti-androgenic effects, and prior research has linked it to disturbances in thyroid function. This study aims to assess the potential association between early childhood exposure to urinary bisphenol A and thyroid hormone levels in adolescence. METHODS: We analyzed data from 1,128 participants in the Mothers and Children's Environmental Health (MOCEH) birth cohort study. Urinary BPA levels were measured at ages 6 months, 1, 2, 3, 4, 5, and 6 years. The concentration of urinary BPA was repeatedly measured for each subject at ages 2-3 years and 7-9 years. Serum levels of free triiodothyronine (T3), free thyroxine (T4), and thyroid-stimulating hormone (TSH) were measured at ages 10-12 years in a subgroup of 128 out of 166 subjects, who had undergone repeated BPA concentration measurements. We utilized the GAS program to analyze possible links between childhood exposure to BPA and thyroid hormone function in adolescents. Additionally, we explored how exposure to BPA during key specific periods influenced changes in thyroid hormone levels. RESULTS: The study found that urinary BPA levels at ages 2-3 years were not notably linked to thyroid hormone levels in adolescents aged 10-12 years. However, BPA levels at ages 7-9 years were significantly associated with free T3 levels in girls aged 10-12 years. Specifically, a 10-fold increase in urinary BPA concentration at ages 7-9 years was associated with a 0.26 pg/mL decrease in free T3 levels in girls aged 10-12 years (95% CI: -0.44, -0.08). However, specifically T3H and free T3. There was a significant decrease in the concentration of free T3 in girls with higher BPA concentrations. CONCLUSIONS: BPA exposure in childhood affects thyroid function in adolescent girls. This relationship may contribute to an increased prevalence of thyroid disorders in adolescents due to environmental influences. 統合_0696	Y. Chow, K. N. Kim, Y. J. Lee, J. I. Kim, B. N. Kim, Y. H. Lim, Y. C. Hong, C. H. Shin and Y. A. Lee	2024	Prenatal and childhood exposure to endocrine-disrupting chemicals and early thelarche in 8-year-old girls: A prospective study using Bayesian kernel regression	BACKGROUND: Studies on the combined effects of persistent and non-persistent endocrine-disrupting chemicals (EDCs) on puberty are insufficient. To date, no studies have analyzed breast development at age 8 years, a key criterion for determining precocious puberty. We investigated the relationship between prenatal or childhood exposure to EDC mixtures and early thelarche, defined as breast development before age 8 years in girls. METHODS: This prospective study included 211 girls, who had undergone an prenatal and 8-year ultrasound examination. Urinary concentrations of 11 EDCs (5 cat, heat, mercury, bisphenol A (BPA), 3 dimethylarsinic acid, and three phthalate metabolites) from the Environment and Development of Children cohort. Prenatal exposure was assessed through samples from pregnant women at 12-27th weeks of gestation. Tanner staging was assessed by a pediatric endocrinologist. The Bayesian kernel machine regression (BKMR) model was used to estimate the overall effect of the mixture and the individual contribution of each EDC to early thelarche. RESULTS: Early thelarche was observed in 63 (29.9%) girls at age 8 years. In the logistic regression models, the risk of early thelarche increased with increasing prenatal exposure to Cd (an inverse relationship was observed for urinary BPA levels (odds ratio (OR) = 1.86, 95% confidence interval [CI] 1.29-2.68) but decreased with prenatal BPA exposure (aOR per IQR = 0.57, 95% CI 0.35-0.92). Some of the 8-year-old chemical exposures were associated with early thelarche. In the BKMR models, an increase in the mixture of prenatal EDCs was associated with a higher risk of early thelarche, with prenatal Cd and inversely associated with prenatal BPA exposure (p = 0.004 for Cd and p = 0.004 for BPA). In the BKMR models, an increase in the mixture of 8-year-old EDCs was associated with a higher risk of early thelarche, with 8-year-old Cd and BPA showing positive associations

Bayen	2024	Biomonitoring of bisphenol A (BPA) and bisphenol analogues in human milk from South Africa and Canada using a modified QuEChERS extraction method	A novel but modified [pH]CHERS extraction method was developed to assess the levels of free and conjugated bisphenols (BPs) in human milk collected between 2018 and 2019 from two regions of South Africa (the Limpopo Province Sheshe district, n = 39; Pretoria, n = 19) and Canada (Montreal, n = 20). Total BPA (free and conjugated) and BPS were the predominant bisphenols detected in samples from Sheshe and Pretoria, with median concentrations of 0.19 and 0.16 ng/mL, respectively. Conjugated BPA and BPS were detected in 100 % and 97 % of the samples from Sheshe, with median levels of 1.03 ng/mL and 0.48 ng/mL, and detection frequencies of 73 % and 89 %, respectively. The free-association analysis of BPA revealed a predominantly conjugated form in the African samples. In contrast, total BPA was detected in only one milk sample from Montreal. Total BPS levels were lower than BPA in South Africa, with detection frequencies of 73 % and 21 % in Sheshe and Pretoria, respectively. In contrast, total BPS was the major BP detected (50 %) in Montreal (up to 3.07 ng/mL). BPAF was found exclusively in South Africa, with detection frequencies for total BPAF of 46 % and 84 % in Sheshe (<MDL–3.01 ng/mL) and Pretoria (<MDL–0.14 ng/mL), respectively. To our knowledge, this is one of the first studies to detect bisphenols in human milk from data-scarce countries such as South Africa and to highlight the notable disparities in the types and levels of bisphenols detected across two distinct countries (Canada and South Africa). 統合_0701	Z. Chen, J. He and W. Shi	2023	Association between urinary environmental phenols and the prevalence of cardiovascular diseases in US adults	Environmental phenols, as endocrine disruptors, are used widely in personal care and consumer products. However, few studies have examined the association between phenol exposure, including bisphenol A (BPA), bisphenol S (BPS), and triclosan (TCS), and cardiovascular disease (CVD). We aimed to investigate the association between urinary phenols and the prevalence of CVD. A total of 3004 participants were measured with liquid chromatography-tandem mass spectrometry (HPLC-MS/MS). The CVD was defined as a composite of 5 self-reported cardiovascular outcomes, including congestive heart failure, coronary heart disease, angina pectoris, heart attack or stroke. Multivariable logistic regression models were used to examine the association between phenols and the prevalence of CVD. A total of 3004 participants were enrolled, and 720 (16.5%) were diagnosed of CVD. The average levels of BPA, BP-3, and triclosan concentrations were 0.38, 0.30, 0.05, and 19.27 ng/mL, respectively. After multivariate-adjusted logistic regression models with increased risk of CVD after adjusting all covariates (odds ratio [OR] 1.06, 95% confidence interval [CI] 1.01 to 1.11, P = 0.01). Compared with the lowest quartile (<1.15), the highest quartile (≥3.09 ng/mL) of BPA was associated with increased risk of CVD (OR 1.31, 95% CI 1.02 to 1.68, P = 0.04). Restricted cubic models confirmed that the association between BPA and the risk of CVD was non-linear (P = 0.005). Only BPA was associated with the risk of CVD, following a J-curve-shaped relationship. Zhu	2023	Mitigating the impact of bisphenol A exposure on mortality: Is diet the key? A cohort study based on NHANES	Bisphenol A (BPA) is a widespread environmental pollutant linked to detrimental effects on human health and reduced life expectancy following chronic exposure. This prospective cohort study aimed to examine the association between BPA exposure and mortality risk, and to investigate the potential mediating role of dietary factors in this relationship. The study included 2,579 participants from the 2003-2016 National Health and Nutrition Examination Survey (NHANES). Urinary BPA levels were employed to assess BPA exposure, and dietary quality was evaluated using the Healthy Eating Index (2015-HEI-2015). All-cause, cardiovascular disease (CVD), and cancer mortality statuses were determined until December 31, 2019, resulting in a cumulative follow-up of 80,066 person-years. The results showed that the highest tertile of urinary BPA levels corresponded to a 39% increase in all-cause mortality and a 42% increase in CVD mortality compared to the lowest tertile. In contrast, the highest HEI-2015 scores was associated with a 29% reduction in all-cause mortality relative to the lowest tertile. Although no significant interaction was found between HEI-2015 scores and urinary BPA levels concerning mortality, the association between HEI-2015 scores and both all-cause and CVD mortality was statistically significant at low urinary BPA levels. Continuous monitoring of BPA exposure is crucial for evaluating its long-term adverse health effects. Improving dietary quality can ward off cause mortality and decrease the risk of all-cause and CVD mortality at low BPA exposure levels. However, due to the limited protective effect of dietary quality against BPA exposure, minimizing BPA exposure remains a vital goal.	Ecotoxicol Environ Saf. 2023 Nov 15:267:115629.	10.1016/j.ecoenv.2023.115629	37890258	ヒト	その他(死亡率)	-	-	-	-	-	-	コホート研究	1	1	-	-	-	1	1	1	-	-	-	-	-	-	-	-	-	-	-	-	-	-
統合_0703	Y. Chen, Z. Zhang, G. He, H. Liang, X. Song, J. Xi, S. Wei, W. Yuan, Z. Wang and M. Miao	2024	Associations of prenatal exposure to bisphenols with infant anthropometry: A prospective cohort study	BACKGROUND: Bisphenols (BPs) have been shown to exhibit developmental toxicities. Epidemiological evidence on prenatal BPs exposure and infant growth primarily confined scope to specific BPs and birth outcomes, with few studies focusing on infant growth and reporting inconsistent findings. The joint effects of prenatal exposure to BPs mixture on infant growth was rarely studied. OBJECTIVE: This study examined associations of prenatal exposure to individual bisphenol A (BPA) and its analogues: Bisphenol F (BPF), bisphenol S (BPS), bisphenol AF (BPAF), and tetrachlorobisphenol A (TCBPA) and their mixture with infant growth. METHODS: Between 2018 and 2020, 1,010 pregnant women were recruited from Wuhan Maternal and Child Health Hospital. Maternal urine samples were collected in each trimester. Infant weight, length, and head circumference were measured at birth, 6 months, and 12 months. Linear mixed-effects models and Bayesian kernel machine regression models (BKMR) were used to analyze associations of exposure to individual BPs and BPs mixture with infants' anthropometric measurements, and to identify the important components among mixture. The risks for rapid growth and overweight of each BP were determined using modified Poisson regression models. RESULTS: The 6 general profile of higher prenatal BPs exposure (mainly BPS, BPF, and BPS) associated with higher anthropometric measurements and higher risks of overweight during infancy was found. We also observed higher risks of rapid growth in infants following prenatal BPs exposure, with risk ratios ranging from 1.40 to 1.95. The joint effects of BPs mixture and single effect of each BP from the BKMR models were consistent with the above findings. Prenatal exposure to BPs was associated with greater weight, length, and head circumference at birth, while it was mainly by BPF. CONCLUSIONS: Prenatal exposure to BPs and their mixture could increase anthropometric measurements of offspring during infancy, with implications of altered growth trajectory in future. 統合_0704	Y. Chen, C. Xu, Y. Huang, Z. Liu, J. Zou and H. Zhu	2024	The Adverse Impact of Bisphenol A Exposure on Optimal Cardiovascular Health as Measured by Life's Essential 8 in U.S. Adults: Evidence from NHANES 2005 to 2016	Background/Objectives: Cardiovascular diseases are the primary cause of global morbidity and mortality, with cardiovascular health (CVH) remaining well below the ideal level and showing minimal improvement in the U.S. population over recent years. Bisphenol A (BPA), a pervasive environmental contaminant, has emerged as a potential contributor to adverse cardiovascular outcomes. This cross-sectional study delves into the impact of BPA exposure on achieving optimal CVH, as assessed by the Life's Essential 8 metric, among U.S. adults. Methods: Analyzing data from 6889 participants in the National Health and Nutrition Examination Survey (NHANES) collected between 2005 and 2016, BPA exposure was quantified through urine BPA levels, while optimal CVH was determined using the American Heart Association's Essential 8 criteria, encompassing behavioral and biological factors. Multivariable logistic regression and propensity score matching were employed to evaluate the association between BPA exposure and CVH. Results: This study reveals that individuals in the highest tertile of BPA exposure (≥2.64 ng/mL) had significantly lower odds of achieving optimal CVH (OR = 0.74, 95% CI: 0.60–0.92, p = 0.006) compared to those in the lowest tertile (<1.15 ng/mL). This association was also identified when urinary BPA was analyzed as a continuous variable and was mirrored in the link between urinary BPA levels and health factor scores. Conclusions: The findings underscore the potential benefits of reducing BPA exposure in enhancing the prevalence of optimal CVH and mitigating the burden of cardiovascular disease. Given the widespread use of BPA, ongoing monitoring of BPA's impact on CVH is essential. Further studies are necessary to elucidate the long-term and causative connections between BPA and CVH. These insights contribute to understanding the complex interplay between environmental factors and CVH outcomes, informing targeted interventions to mitigate cardiovascular disease risk within the population. 統合_0705	Y. Chen, H. Xiao, A. Namat, J. Liu, F. Ruan, S. Xu, R. Li and W. Xia	2022	Association between trimester-specific exposure to thirteen endocrine disrupting chemicals and preterm birth: Comparison of three statistical models	BACKGROUND: Growing evidence indicated that maternal exposure to some endocrine disrupting chemicals (EDCs) may increase the risk of preterm birth (PTB). However, few studies have evaluated the joint effect of EDCs on PTB. OBJECTIVES: This study aimed to evaluate the associations of maternal EDCs mixture in the 1st, 2nd, and 3rd trimesters during pregnancy with PTB, and identify the vital components that mainly contribute to PTB. METHODS: This study included 847 pregnant women that provided urine samples for all three trimesters. Urinary concentrations of thirteen EDC metabolites (three phenols, one phthalate, and four benzoic acids and benzothiazole) were examined. Logistic regression model, quantile g-computation and Bayesian kernel machine regression (BKMR) models were applied to study the associations. RESULTS: Higher urinary concentrations of 2,5-dichlorophenol, 2,4-dichlorophenol, and 3-phenoxybenzoic acid in the 1st trimester were positively associated with PTB (OR (95% CI): 1.38 (1.02, 1.86), 1.36 (1.02, 1.82), and 1.34 (1.02, 1.76), respectively). Quantile g-computation identified that urinary EDCs mixture in the 1st trimester were positively associated with PTB (OR (95 % CI): 1.48 (1.02, 2.16)), and the most heavily weighted component for PTB was BPS (28.7%). Followed by mono-2-ethylhexyl phthalate (MEHP) (17.5%). BKMR model determined a significant association between EDCs mixture in the 1st trimester and PTB when all EDC concentrations were at or above their 55th percentile compared to the median. The BKMR model found that BPS and MEHP were associated with an increase in the estimated probability of PTB, when the other EDCs were held in their 55th and 75th percentiles, respectively, in the 1st trimester. CONCLUSIONS: The results of mixture analysis models indicated that exposure to higher EDCs mixture in the 1st trimester may increase the risk of PTB. BPS was considered as the most contributing factor to PTB among the detected EDCs.	Sci Total Environ. 2022 Dec 10:851(Pt 2):158236.	10.1016/j.scitotenv.2022.158236	36041600	ヒト	生殖発生	-	-	-	-	-	-	コホート研究	1	1	-	-	-	1	1	1	-	1	-	-	-	-	-	-	-	-	-	-	-	-
統合_0706	Y. Chen, J. Wu, R. Li, W. Kang, A. Zhao, Y. Yin, S. Tong, J. Yuan and S. Li	2023	Individual and joint association of phenols, parabens, and phthalates with childhood lung function: Exploring the mediating role of peripheral immune responses	The functioning of the respiratory system can be interfered with by exposure to mixtures of environmental chemicals, however, the evidence is still ambiguous. We evaluated the association of exposure to mixtures of 15 chemicals, including 2 phenols, 2 parabens, and 11phthalates, with the lung function metrics. Based on data from the National Health and Nutrition Examination Survey (NEF-2021), this analysis was conducted among 1,582 children aged 6-18 years. Linear regression, Bayesian kernel machine regression, quantile-based g-computation regression, and a generalized additive model were performed to estimate the associations. Stratification analyses were performed to investigate possible biological pathways mediated by immune cells. Our results indicated that the phenols, parabens, and phthalates mixture was negatively related to lung function parameters. Ben and PP1 were identified as important contributors to negative associations with FEV1/CI, FVC, and PEF, with non-linear relationships observed between BP3 and those outcomes. The most influential chemical was MiBP, followed by MnBP, MEP, and Ben. Additionally, the negative associations between the mixture of PP1 and FEV1/FVC were mediated by eosinophils and monocytes. The findings offer insights into the associations of chemical mixtures with respiratory health and the possible driving mechanisms, which would be of significance in adding novel evidence of the role of peripheral immune responses, as well as calling for remediation actions to be prioritized during childhood. 統合_0707	Y. Chen, M. Miao, Z. Wang, H. Ji, Y. Zhou, H. Liang, G. He and W. Yuan	2023	Prenatal bisphenol exposure and intelligence quotient in children at six years of age: A prospective cohort study	The effects of prenatal bisphenol A (BPA) exposure on children's cognitive development have been reported; however, relevant evidence on BPA analogues was limited, with no consideration of the joint effect of their mixtures. We aimed to investigate the associations of prenatal exposure to BPA and its analogues, including bisphenol S (BPS), bisphenol F (BPF), and bisphenol AF (BPAF), with children's intelligence quotient (IQ) at six years of age. We assessed the associations of prenatal exposure to individual BPs with children's intelligence quotient (IQ) and evaluated the joint effects using the Quantile g-computation model (QGC) and Bayesian kernel machine regression model (BKMR). QGC models showed that higher maternal urinary BPs mixture concentrations were associated with lower scores among boys in a non-linear way; however, no associations were observed in girls. For individual effects, BPA and BPF were associated with decreased IQ scores in boys and some identified as important contributors to the joint effect of BPs. However, associations of BPs with increased IQ scores in girls, and FSIQM with increased IQ scores in both sexes were observed. Our findings suggested prenatal exposure to BPs mixture may affect children's cognitive function in a sex-specific pattern and provided evidence of the neurotoxicity of BPA and BPF.	Chemosphere. 2023 Sep:334:139023.	10.1016/j.chemosphere.2023.139023	37230300	ヒト	発達神経	-	-	-	-	-	-	コホート研究	1	1	-	-	-	-	1	1	-	-	-	-	-	-	-	-	-	-	-	-	-	-
統合_0708	X. Chen, S. Zhang, M. Zhang, W. Zhong, S. Bai, Y. Zhao, C. Li, S. Lu and W. Li	2021	Urinary parabens, bisphenol A and triclosan in primiparas from Shenzhen, China: Implications for exposure and health risks	The usage of parabens, bisphenol A and triclosan in diverse consumer products is in widespread. Nevertheless, there are limited data concerning exposure to these chemicals, in human being, especially in primiparas. Biomonitoring of chemicals in primiparas is useful for the estimation of chemical exposure risks for both primiparas and their offspring. This study aims to investigate urinary levels of parabens, bisphenol A and triclosan of 80 primiparas from Shenzhen, China and to evaluate their potential health risks. Methyl, ethyl, and n-propyl parabens (bisphenol A and triclosan exhibited high detection rates (DRs, ≥ 97%) in urine samples, suggesting that primiparas are exposed to them widely. The median concentrations of methyl, ethyl, and n-propyl parabens, bisphenol A and triclosan in urine were 2.16, 0.65, 0.08, 1.30 and 3.00 μg/L, respectively. Ethyl paraben was the predominant paraben in urine samples. Urinary concentrations of methyl paraben were significantly higher than those of ethyl paraben, n-propyl paraben, bisphenol A and triclosan. Personal care products, plastic containers and urinary concentrations of ethyl paraben or PPL industrial products containers might be an important factor influencing primipara exposure to these four chemicals. Urinary concentrations of methyl paraben were positively associated (p < 0.05) with the time of computer use by participant, suggesting that indoor dust might constitute an important source of parabens. The estimated daily intake of parabens, bisphenol A and triclosan contained with the acceptable daily intakes in a comparatively low level. The based-quotients (HQs) of these chemicals were all less than 1, suggesting no health risks for primiparas from South China. SUPPLEMENTARY INFORMATION: The online version contains supplementary material available at 10.1007/s10311-020-00989-1. 統合_0709	W. J. Chen, C. Robledo, E. M. Davis, J. R. Goodman, C. Xu, J. Hwang, A. E. Jenks, T. Ganea, A. M. Calafat and J. D. Peck	2022	Assessing urinary phenol and paraben mixtures in pregnant women with and without gestational diabetes mellitus: A case-control study	Prior studies have identified the associations between environmental phenol and paraben exposures and increased risk of gestational diabetes mellitus (GDM), but no study addressed these exposures as mixtures. As methods have emerged to better assess exposures to multiple chemicals, our study aimed to apply Bayesian kernel machine regression (BKMR) to evaluate the association between phenol and paraben mixtures and GDM. This study included 600 GDM cases and 737 obstetric patient controls from the University of California Medical Center, San Francisco's late 2000s pregnancy urine samples were retrospectively assayed to quantify concentrations of bisphenol A (BPA), benzophenone-3, triclosan, 2,4-dichlorophenol, 2,5-dichlorophenol, butylparaben, methylparaben, and propylparaben. Multivariable logistic regression was used to evaluate the associations between individual chemical exposures and GDM, adjusting for maternal age, race/ethnicity, pre-pregnancy body mass index, and nulliparity. BKMR was used to evaluate the associations between chemical mixtures and GDM, and to identify the most influential phenol and paraben mixtures within each grouping for the cumulative association among the chemical biomarkers. When analyzing individual chemicals using logistic regression, benzophenone-3 was associated with GDM (adjusted odds ratio (aOR) per interquartile range (IQR) = 1.16, 95% confidence interval (CI) 1.13, 1.18), while BPA was negatively associated with GDM (aOR 0.82, 95% CI 0.77, 0.90). In parallel BKMR analysis, an increase in a combination of all phenol and paraben exposures at the 60th percentile, compared to the 50th percentile, was associated with an increase in the estimated difference in the probability of GDM (0.07, 95% Credible Interval (CrI): 0.00, 0.14). Among other chemicals, butylparaben, followed by triclosan, were identified as the most influential chemicals in the chemical mixture. Benzophenone-3 and triclosan were identified as important contributors to the positive association when accounting for correlated phenols and parabens, suggesting the importance of addressing chemical mixtures in perinatal environmental exposure studies. Additional prospective investigations will increase the understanding of the relationship between benzophenone-3 exposure and GDM development.	Environ Res. 2022 Nov:214(Pt 2):113897.	10.1016/j.envres.2022.113897	35839910	ヒト	生殖発生	-	-	-	-	-	-	症例対照研究	1	1	-	-	-	-	1	1	-	-	-	-	-	-	-	-	-	-	-	-	-	-
統合_0710	S. Chen, Y. Tao, P. Wang, D. Li, R. Sher, G. Fu, T. Wei and W. Zhang	2023	Association of urinary bisphenol A with cardiovascular and all-cause mortality: National Health and Nutrition Examination Survey (NHANES) 2003-2016	Bisphenol A (BPA), one of the most widely consumed endocrine disrupting chemicals, has been found to be associated with a variety of diseases, especially cardiovascular diseases. However, few studies have investigated the association of BPA with long-term health outcomes. This study analyzed data from the National Health and Nutrition Examination Survey (NHANES) 2003-2016. The NHANES data were linked to mortality records through December 31, 2019. Urinary BPA was measured using high-performance liquid chromatography-tandem mass spectrometry (HPLC-MS/MS). Survey-weighted Cox proportional hazards models were used to compare the hazard ratios (HRs) of cardiovascular disease (CVD) and all-cause mortality among participants with different urinary BPA concentrations. This study included 9,852 adults and seven hundred and fifty-six deaths were recorded during the follow-up duration was 9.1 years. During this period, 1,550 all-cause deaths occurred, of which 391 were cardiovascular deaths. Compared to the lowest BPA/Cr quartile group, the adjusted HRs of the highest BPA/Cr quartile group were 1.79 (95% CI: 1.33-2.42) for cardiovascular mortality and 1.21 (95% CI: 1.00-1.47) for all-cause mortality. In addition, there was a significant interaction between sex and BPA/Cr in the CVD-related mortality (P for interaction = 0.044). For the female participants, the adjusted HR for cardiovascular mortality in female participants was 2.82 (95% CI: 1.56-5.10), while that in male participants was only 1.34 (95% CI: 0.79-2.26). Higher urinary BPA is associated with an increased risk of cardiovascular mortality among US adults. The effects of BPA on cardiovascular mortality may be more pronounced in women than in men.	Environ Sci Pollut Res Int. 2023 Apr;30(17):51217-51227.	10.1007/s11356-023-25924-7	36807039	ヒト	その他(死亡率)	-	-	-	-	-	-	コホート研究	1	1	-	-	-	-	1	1	-	-	-	-	-	-	-	-	-	-	-	-	-	-
統合_0711	Q. Chen, Q. Deng, Q. Liao, Y. Liu, Z. Zhang, D. Wu, Y. Lu, J. Qin, Q. Liu, S. Li, Z. Long, X. Xing, Q. Wang, X. Zeng, G. Dong, M. Hou and Y. Xiao	2024	8-OHdG mediates the association of co-exposure to fifty-five typical endocrine-disrupting chemicals with renal function: a cross-section investigation in Southern Chinese adults	Individual typical endocrine-disrupting chemicals (EDCs), including organophosphate triesters (OPEs), parabens, triclosan (TCS), bisphenols, benzophenone (BPs), phthalates (PAEs), and synthetic phenolic antioxidants (SPAs), are associated with renal dysfunction. However, the combined effects and underlying mechanisms of mixed EDC exposure on renal function remain unclear. Two hundred ninety-nine adult participants were recruited from Guangzhou, China, between 2018 and 2019. Fifty-five EDCs and 8-hydroxy-2'-deoxyguanosine (8-OHdG) were measured in urine samples. Renal function was assessed by estimated glomerular filtration rate (eGFR). Multivariate linear regression models and Bayesian kernel machine regression (BKMR) were used to analyze associations of exposure to individual EDCs and their mixtures with renal function. Results: Individual EDCs, including OPEs, parabens, TCS, bisphenols, BPs, PAEs, and SPAs, were widely detected in urine samples. Multivariate linear regression models revealed that exposure to mixtures of individual EDCs was associated with a 3.8% reduction in eGFR. Bisphenol A (BPA) and bisphenol S (BPS) were identified as the primary contributors to this effect. Moreover, 8-OHdG mediated the eGFR decline associated with EDC mixtures, with a mediation proportion of 26.39%. A sex-modified effect was also observed (P = 0.004), indicating that exposure to the mixture of EDCs was linked to more pronounced renal dysfunction in females. Our novel findings suggest that exposure to a typical mixture of EDCs is associated with renal dysfunction in the general adult population of Southern China. Furthermore, 8-OHdG may play a role in the pathogenesis of EDC-induced renal dysfunction.	Environ Sci Pollut Res Int Vol.31 Issue 21 Pages 30779-30792	10.1007/s11356-024-33266-1	38613763	ヒト	-	-	-	-	-	-	-	横断研究	1	1	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-

Zeng	2022	Urinary concentrations of phenols, oxidative stress biomarkers and thyroid cancer: Exploring associations and mediation effects	Phenols have been shown to influence the cellular proliferation and function of thyroid in experimental models. However, few human studies have investigated the association between phenol exposure and thyroid cancer, and the underlying mechanisms are also poorly understood. We conducted a case-control study by age- and sex-matching 1319 thyroid cancer and 1319 controls to investigate the associations between phenol exposures and the risk of thyroid cancer, and further to explore the mediating role of oxidative stress. We found that elevated urinary triclosan (TCS), bisphenol A (BPA) and bisphenol S (BPS) levels were associated with increased risk of thyroid cancer, with the odds ratios (ORs) and 95% confidence intervals (CIs) of 1.30 (1.04, 1.62), 1.30 (1.04, 1.62) and 1.29 (1.03, 1.61) for the highest versus the lowest quartile (Q4 vs. Q1), respectively. Positive associations were also observed between urinary TCS, BPA and BPS and three oxidative stress biomarkers measured by 8-hydroxy-2'-deoxyguanosine (8-OHdG), 8-iso-prostaglandin F2α (8-iso-PGF2α) and 2-nitro-tyrosine (2-nitro-Tyr) (all P < 0.05). Moreover, 8-iso-PGF2α and 8-OHdG were also associated with thyroid cancer risk (all P < 0.05). Mediation analysis showed that urinary 8-iso-PGF2α mediated 28.99%, 47.66% and 31.38% of the associations between TCS, BPA and BPS exposures and the risk of thyroid cancer, respectively (all P < 0.05). Our results suggest that exposure to TCS, BPA and BPS may be associated with increased risk of thyroid cancer and lipid peroxidation may be an intermediate mechanism. Further studies are warranted to confirm the findings. 統合_0713	P. P. Chen, C. Liu, M. Zhang, Y. Miao, F. P. Cui, Y. L. Deng, Q. Luo, J. Y. Zeng, T. Shi, T. T. Lu, W. J. Yin, W. Q. Liu, G. L. Yi, G. Qiu and Q. Zeng	2022	Associations between urinary bisphenol A and its analogues and semen quality: A cross-sectional study among Chinese men from an infertility clinic	Human studies on association between bisphenol A (BPA) exposure and semen quality, mostly based on single urinary measurement, are inconsistent. There is limited human evidence on BPA analogues such as bisphenol F (BPF) and bisphenol S (BPS). We aimed to investigate the associations of urinary BPA, BPF and BPS with semen quality in a cross-sectional study among Chinese men from an infertility clinic. We found that urinary concentrations of BPA, BPF and BPS were associated with semen quality among 968 Chinese men from an infertility clinic. We found that higher BPA exposure was associated with increased odds, while 10% of having below reference semen concentration, low sperm count, progressive motility and total motility (≥75th vs trends < 0.05). Higher BPS exposure was associated with increased 19% of having below reference progressive motility and total motility (both P for trends < 0.05). Use 25% competing extreme quartiles were 1.42 (95% CI: 1.07, 2.02) and 1.67 (95% CI: 1.18, 2.35), respectively. Elevated risks for motility outcomes were also observed when bisphenol mixtures were at a 75th percentile. For semen quality parameters, modest or continuous outcomes, inverse associations with individual BPA and BPS and bisphenol mixtures were still maintained. Our results suggested that higher exposure to individual BPA and BPS and bisphenol mixtures were associated with impaired semen quality. 統合_0714	M. Chen, Y. Yang, K. Barat, Y. Fu, Y. Meng, Y. Zhang, F. Su and M. Zhao	2023	Relationship between bisphenol A and the cardiovascular disease metabolic risk factors in American adults: A population-based study	BACKGROUND: Bisphenol A (BPA) is widely used in personal care and consumer products. However, no study has reported a specific relationship between BPA concentrations and metabolic hazardous elements for cardiovascular diseases (CVDs). Consequently, in this study, we used a 6-years of population-based NHANES data (2011-2016) to analyze the association between BPA concentrations and metabolic risk factors for CVDs. METHODS: A total of 1667 participants were enrolled in our project. The participants in the study were divided into quartiles based on BPA levels (Q1: <0.4 ng/mL; Q2: 0.7-1.3 ng/mL; Q3: 1.4-3.0 ng/mL; Q4: >3.0 ng/mL). This study used multiple linear and multivariate logistic regression models to determine the association among BPA concentrations and CVD metabolic risk factors. RESULTS: When the concentration of BPA was increased by 0.3 ng/mL, the diastolic blood pressure was increased by 0.28 mmHg. In the same time, compared to participants in the first quartile (Q1), those in the fourth quartile (Q4) of BPA concentrations had decreased by 0.13 mg/dL and diastolic blood pressure was increased by 2.08 mmHg. In the same time, compared to participants in the first quartile (Q1), those in the fourth quartile (Q4) of BPA concentrations had 21% higher odds of hypertension, 38% higher odds of obesity, 82.3% higher odds of central obesity, 33% higher odds of elevated HbA1c, 17% higher odds of elevated non-HDL cholesterol, and 60.8% higher odds of diabetes. Compared to the lowest quartile, Q2- CONCLUSIONS: We found that higher concentrations of BPA were associated with a higher metabolic risk for CVDs. Further regulation of BPA may need to be considered for the prevention of CVDs in adults. 統合_0715	M. Chen, C. Lu, S. Zhang, L. A. Tse, X. Hong, K. Liu, Y. Ding, P. Xiao, Y. Tian and Y. Gao	2023	Bisphenol A substitutes and childhood obesity at 7 years: a cross-sectional study in Shandong, China	Bisphenol A (BPA) substitutes, such as bisphenol S (BPS) and bisphenol AF (BPAF), are increasingly used due to restrictions on BPA usage, a known endocrine disrupting chemical and putative obesogen. However, little is known about the potential health effects of BPA substitutes in children. We investigated the associations of urinary BPA, BPS, and BPAF concentrations with childhood obesity at 7 years. A total of 1,793 participants in the 2019-2020 survey. Urinary BPA and its substitutes including BPS, BPAF, bisphenol B (BPB), bisphenol AP (BPAP), bisphenol Z (BPZ), and bisphenol F (BPF) were determined. Anthropometric measures including height, weight, waist circumference, and body fat percentage were assessed, and overweight/obesity was defined as BMI ≥ score ≥ 85th percentile. Linear and logistic regressions were used to continuous and categorical outcomes, respectively. Restricted cubic spline (RCS) models were used to explore the dose-response relationships between BPA substitutes and childhood obesity. The BPA substitutes were widely detected (> 75%) in children's urine samples. A positive association with obesity measures was consistently observed for urinary BPS and BPAF, i.e., BMI z-score, waist circumference, and overweight/obesity. Further analysis from the WQS regression model demonstrated a positive association between bisphenol mixtures and all measures of obesity, with BPAF contributing the greatest weighting to the observed associations. Sex differences might exist as the positive associations were only significant in boys. No significant association was found between obesity and BPA or other BPA substitutes. Our study adds to mounting evidence that BPA substitutes (BPS and BPAF are linked to obesity in children, especially in boys. Further longitudinal studies with larger sample size with continued biomonitoring these chemicals and their obesogenic effects are necessary.	Environ Sci Pollut Res Int Vol.30 Issue 29 Pages 73174-73184	10.1007/s11356-023-27578-x	37188933	ヒト	-	-	-	-	-	-	-	横断研究	1	1	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-

Wu	2025	Association of multiple environmental toxicants with markers of early kidney injury in pregnant women: an exposome approach	Pregnant women are regularly exposed to a variety of environmental toxicants in daily life, posing a potential threat of kidney injury before presence of clinical manifestations. As there is a paucity of studies employing an exposome-based approach of kidney health in pregnant women, this study utilizes the above-mentioned strategy to identify the most significant environmental toxicants associated with early kidney injury in pregnant women. A total of 1,000 pregnant women were recruited from 2012 to 2015 in the Taiwan Maternal Cohort Study. Urine samples collected in the first trimester were successfully collected for study. Sixteen biomarkers of exposure to environmental toxicants, including creatinine measurements of melamine, 8 phthalate metabolites, bisphenol A (BPA), methylparaben (MeP), ethylparaben (EP), propylparaben (PP), and butylparaben (BP), and outcome measurements of NGAL for early² 2- of glycosaminoglycan) and albumin to creatinine ratio (ACR). A two-tier strategy of statistical analysis was employed and data was randomly and evenly split to both training (n = 500) and validation (n = 500) sets. Using an elevated quantile score (EQS) regression in the training set and subsequently a multivariate regression in the validation set, we found that NP was the most important chemical to link with early markers of kidney injury, both ACR and NAG. Our findings indicate that short-term exposure to NP is associated with markers of subclinical kidney injury in pregnant women in Taiwan. Further research is warranted to determine whether NP exposure is linked to clinically-relevant kidney outcomes. Wang	2024	The Role of Placental DNA Methylation at Reproduction-Related Genes in Associations between Prenatal Bisphenol Analogues Exposure and the Digit Ratio in Children at Age 4: A Birth Cohort Study	Placental DNA methylation (DNAm) may be a potential mechanism underlying the effects of prenatal bisphenol analogues (BPA) exposure on reproductive health. Based on the Shanghai Minhang Birth Cohort Study (SMBCS), this study investigated associations of placental DNAm on reproduction-related genes with prenatal BPA exposure and children's digit ratio at age 4 using multivariate linear regression models, and mediation analysis was further used to examine the mediating role of placental DNAm in the associations between prenatal BPA exposure and digit ratio among 305 mother−child pairs. Prenatal exposure to bisphenol A (BPA) was associated with increased 2D:4D ratio in boys, 4D:5D (ring finger) and 2D:5D (index finger) in girls, and 2D:4D (index finger) in children with higher BMI at 4 years old. Placental DNAm of Peroxisomal Biogenesis Factor 13 (PEX13) - Coumestrol pathway were found to associations between higher DNAm at the 5 genes and increased digit ratios. Further mediation analysis showed that about 10% of the effect of BPF exposure on increased digit ratios was mediated by placental PEX13 methylation. In conclusion, the altered placental DNAm status might be a mediator underlying the feminizing effect of prenatal BPs exposure. 統合_0718	J. Chen, M. Miao, X. Song, H. Ji, H. Lian, Y. Chen, W. Yuan and Z. Wang	2025	Tracing impacts of prenatal exposure to bisphenol analogues on child anogenital distance development: A birth-cohort study	Prenatal exposure to bisphenol analogues (BPs) is increasingly common and may affect children's reproductive development. However, human evidence is limited and inconsistent. Based on the Shanghai Minhang Birth Cohort Study that enrolled participants in 2010 at Minhang Maternal and Child Health Hospital in Shanghai, China, we measured BPs in maternal urine samples collected during pregnancy and children's anogenital distance (AGD) boys, AGD3(P) (anus-penis), AGD2(S) (anus-scrotum) girls, AGD2(C) (anus-clitoris), AGD3(P) (anus-fourchette) from birth to 48 months as an indicator of reproductive development. A total of 565 mother−child pairs were included. Boys with detected maternal bisphenol S (BPS), bisphenol F (BPF), bisphenol Z (BPZ) and bisphenol AF (BPAF) tended to have increased AGD3(P) at 3 months, while at 12 months, BPS, BPF, and BPAF were associated with a marginal decrease in AGD3(P). In girls, higher levels of BPS, BPF and BPZ were associated with longer AGD at 48 months, and higher risks of rapid AGD growth. Bayesian kernel machine regression (BKMR) models revealed consistent associations of BPs mixtures with AGD in both sexes, with BPF and BPS identified as major contributors. Our study revealed the lasting, sex-specific impacts of prenatal exposure to BPA and its alternatives on children's reproductive development. 統合_0719	H. Chen, W. Zhang, X. Sun, Y. Zhou, J. Li, H. Zhao, W. Xia, S. Xu, Z. Cai and Y. Li	2024	Prenatal exposure to multiple environmental chemicals and birth size	BACKGROUND: Epidemiological studies addressing the combined effects of exposure to chemical mixtures at different stages of pregnancy on birth size are scarce. OBJECTIVE: To evaluate the association between prenatal exposure to multiple chemicals and birth size. METHODS: We measured 12 chemicals in urine samples collected from 1,000 pregnant women in the third trimester. Principal component analysis was used to create clusters of exposed populations and to decrease correlated components of exposed chemicals. In each trimester, for this study, we assessed the associations of these exposure profiles with birth weight, birth length, and ponderal index using multivariable linear regression. RESULTS: We found that compared with women in cluster 1 (lower urinary chemical concentrations), women in cluster 2 (higher urinary concentrations of metals, biomethanols, bisphenols, and some phenols), and women in cluster 3 (higher urinary concentrations of phthalates) were more likely to give birth to children with higher birth weight (0.23 (95% CI: 0.03, 0.43) lb in the 1st trimester; 0.22 (95% CI: 0.02, 0.42) lb in the 2nd trimester; 0.20 (95% CI: 0.00, 0.40) lb in the 3rd trimester). In addition, prenatal exposure to PCD higher benzophenones (ludwig) was associated with reduced birth length across pregnancy. Compared with women in cluster 1, those in cluster 2 had a 0.11 cm (95% CI: 0.01, 0.21) shorter birth length in the 1st trimester, a 0.12 cm (95% CI: 0.02, 0.22) shorter birth length in the 2nd trimester, and a 0.11 cm (95% CI: 0.01, 0.21) shorter birth length in the 3rd trimester. Exposure to multiple chemicals simultaneously, the actual exposure situation of pregnant women, was associated with birth size, indicating that chemical mixtures should be taken more seriously when studying the health effects of pollutants. Sun	2024	Long-term impacts of endocrine-disrupting chemicals exposure on kidney function: A community-based cohort study	This study explores the extended renal effects of endocrine-disrupting chemicals (EDCs) exposure, a linkage already established with adverse health outcomes, notably chronic kidney disease. To delve deeper, the Chiayi County Community Research Center conducted a longitudinal study on 687 participants, monitoring them for three years. Urine samples from individuals were scrutinized between 2017 and 2019, scores, analyzing 11 EDCs and renal function. Findings revealed elevated mono (2-ethylhexyl) phthalate (MEHP) and bisphenol A levels in higher-dose EDC exposure cases. MEHP notably correlated with increased urinary albumin-to-creatinine ratio (UACR), predicting a ~ 16% decline in estimated glomerular filtration rate. Higher MEHP levels also hinted at declining renal function. UACR escalation linked significantly with specific EDCs. MEHP, methylparaben, nonylphenol, and 4-tert-octylphenol. This research underscores enduring renal hazards tied to environmental EDC exposure, particularly MEHP, emphasizing the urgent call for robust preventive public health strategies. 統合_0721	M. Charlton, E. Seek, Y. Wang, S. S. Mehta-Lee, R. Gordon, M. Liu, L. Trevande and L. G. Kahn	2024	Evaluating associations of bisphenol and phthalate exposure with time to pregnancy and subfecundity in a New York City pregnancy cohort	It is important to understand the impact of consumer chemical exposure and fecundity, a couple's measure of probability of successful conception, given approximately 15% of couples experience infertility. Prior research has generally found null associations between bisphenol and phthalate exposure and fecundability, measured as time to pregnancy (TTP). However, this research has not been paired with current chemical exposures and have often lacked diversity in their study populations. We evaluated the associations between common bisphenol and phthalate chemical exposure groups and TTP as well as subfecundity (TTP>12 months) in the New York City Fertility Study, a preconception cohort study enrolling participants from 2017-2020 who were actively trying to conceive and not using contraception. Using questionnaires, we observed a significant adverse association between total bisphenol exposure and certain phthalate groups on TTP and odds of subfecundity. Furthermore, no evidence exists to examine the joint effects of the chemical groups on the outcomes, we found evidence of a potential interaction between total bisphenol exposure and low molecular weight phthalates on TTP. Future research should continue to update knowledge regarding the complex and potentially interacting effects of these chemicals on reproductive health. 統合_0722	C. H. Chang, C. T. Lu, T. L. Chen, W. T. Huang, P. C. Tseng, C. W. Chang, Y. C. Chen, Y. L. Yu and Y. N. Chiang	2023	The association of bisphenol A and paraben exposure with sensorineural hearing loss in children	Bisphenol A (BPA) and parabens (PBs) are chemicals that are extensively used in personal care products (PCPs). In early childhood development, hearing is critical to speech and language development, communication, and learning. In vitro and in vivo, BPA/PBs exhibited neurotoxicity through elevated levels of oxidative stress. BPA also has the potential to be an ototoxicant. Therefore, this study aimed to determine the association of BPA/PBs with sensorineural hearing loss in children. We recruited 1,000 children aged 6-12 years from 2016 to 2017 in Taiwan and collected their urine samples and pure-tone audiometry data. Urinary BPA and PB concentrations were analyzed by using liquid chromatography-tandem mass spectrometry (LC-MS/MS). Logistic regression models were developed to determine the BPA/PB exposure with sensorineural hearing loss. Children with sensorineural hearing loss had higher BPA concentrations than normal hearing children (0.22 ng/mL vs. 0.12 ng/mL; p = 0.05). After adjustment for covariates, the risk of hearing loss at middle frequencies reached 2.85-fold (95% CI: 1.12-7.99) when BPA concentrations increased by 1 log10. The risk of slight hearing loss reached 2.33-fold (95% CI: 1.09-5.19) when children had a methyl paraben (MP) concentration. This study clarifies the role of exposure to BPA/PBs in hearing loss in children. Future research needs to be expanded to include cohort designs and nationwide studies to identify causality.	Environ Sci Pollut Res Int Vol.30 Issue 45 Pages 100552-100561	10.1007/s11356-023-29426-4	37635162	ヒト	-	-	-	-	-	-	-	横断研究	1	1	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-

Yu	2024	Relationships between bisphenol A and paraben exposure, oxidative stress, and the activity of outer hair cells in the cochlea in children with hearing loss	This study aimed to determine the associations of childhood exposure to bisphenol A (BPA) and parabens (PBs) with oxidative stress and the activity of outer hair cells (OHCs) in the cochlea of children with hearing loss. In 2, A total of 621 children were enrolled from two communities. Urinary concentrations of BPA and four PBs including methyl paraben (MP), ethyl paraben (EP), propyl paraben (PP), and butyl paraben (BP) were quantified by using liquid chromatography-tandem mass spectrometry (LC/MS/MS). Four urinary biomarkers of oxidative stress, 8-hydroxy-2′-deoxyguanosine (8-OHdG), 8-isoprostane (8-iso-PGF2α), 4-hydroxynonenal mercapturic acid (HNE-MA), and 8-nitroguanosine (8-nitro-G) were measured using high-performance liquid chromatography-electrospray ionization-tandem mass spectrometry. Hearing tests were conducted by audiologists in the audiometric test room, and the results were confirmed by an otolaryngologist. The activity of OHCs in the cochlea was measured by distortion product otoacoustic emissions (DPOAEs). The associations of BPA/PBs with oxidative stress and the activity of OHCs in children with hearing loss were investigated by using multivariate logistic regression models. The prevalence of hearing loss was 12.7%. There was a significant negative association between the presence of 8-OHdG (AOR, 0.94; 95% CI: 0.90, 0.98) and the activity of OHCs in the left ear. Significant results were also observed for BPA (24 Hz), MP (1 kHz, 1.5 kHz, 2 kHz), EP (2-8 Hz), and 8-OHdG (2 kHz) in the right ear. This study revealed that exposure to BPA/PBs reduces the activity of OHCs, especially at middle frequencies, in children. Martin	2020	Urine Bisphenol A and Arsenic Levels in Residents of the Cheyenne River Sioux Tribe, South Dakota, with and without Diabetes	INTRODUCTION: Diabetes disproportionately affects American Indians/Alaskan Natives (AI/AN). Bisphenol A (BPA) and arsenic (As), environmental toxicants which may be associated with diabetes, have not been well-studied in this population. Our objectives were to determine if urinary BPA and As are associated with diabetes among adults in the Cheyenne River Sioux Tribe (CRST), and to compare their urinary levels with the general U.S. population. METHODS: We conducted a cross-sectional study of CRST adults ≥ 18 years old in 2013-2014. Urinary BPA and As were measured using high-performance liquid chromatography and inductively coupled plasma mass spectrometry, respectively. We used spot urine samples which were tested for BPA and normalized to urinary creatinine. Multivariate linear and logistic regression models were used to examine associations between urine arsenic species and BPA and diabetes, and linear regression to assess the association between self-reported exposures and BPA and As levels. We used conditional logistic regression to investigate the association between urine arsenic species and BPA and As levels among participants who were discordant with respect to diabetes status. RESULTS: Of the 1,011 CRST participants, 19% had diabetes. The unadjusted geometric mean urine BPA was identified as 0.91 ng/mL for CRST and 1.65 ng/mL for total As, BPA geometric means of CRST participants were higher than NHANES participants within total As geometric means were lower. BPA and As were not associated with case status. CONCLUSION: The results of this study are consistent with others that have reported an association between diabetes and exposure to BPA or As. 統合_0725	A. Chandrakanth, S. Findus, R. Vasantharekha, W. Santosh and B. Seetharaman	2024	Exploring the Effects of Endocrine-Disrupting Chemicals and miRNA Expression in the Pathogenesis of Endometriosis by Unveiling the Pathways: a Systematic Review	Endometriosis, characterized by endometrial-like mucosal tissue outside the uterine cavity, is a reproductive disorder affecting about 10% of women within the reproductive age. The pathogenesis of endometriosis has been associated with endocrine-disrupting chemicals (EDCs) and microRNA (miRNA) expression. However, the exact mechanisms underlying these associations remain unclear. This systematic review aims to explore the same. The investigation focused on studies delineating the correlation between endocrine disruptors, microRNAs, and endometriosis. To optimize the search scope, keywords and subject headings were used as search terms. Then, two authors rigorously screened studies using criteria, selecting 27 studies from various databases. Notably, dioxins, organochlorine pesticides, and polychlorinated biphenyls exhibited a solid connection to endometriosis, while bisphenol A and phthalates yielded conflicting results. The heightened presence of bisphenol A, polychlorinated biphenyls, and phthalates was linked to altered gene expression, including genes like MIR663, MIR21, and MIR886. MicroRNAs like miRNA-31, miRNA-182, and miRNA-183 emerged as vital factors in the onset of endometriosis and progression. Furthermore, elevated expressions of miR-155 by miR-146a were observed in endometriosis patients. Our review underscores the significance of EDCs and miRNAs in endometriosis. Further research is crucial to unravel the intricate molecular mechanisms and to reduce the disruptive exposure and endometriosis and behavior microRNA dysregulation and endometriosis. However, research lacks the combination of all these factors. The review delves into the effects of endocrine-disruptors and microRNAs on the pathogenesis of endometriosis to improve our understanding of the disorder and in finding therapies. Aung	2023	Exploratory profiles of phenols, parabens, and per- and poly-fluoroalkyl substances among NHANES study participants in association with previous cancer diagnoses	BACKGROUND: Some hormonally active cancers have low survival rates, but a large proportion of their incidence remains unexplained. Endocrine-disrupting chemicals may affect hormone pathways in the pathology of these cancers. OBJECTIVE: To evaluate cross-sectional associations between per- and polyfluoroalkyl substances (PFAS), phenols, and parabens and self-reported previous cancer diagnoses in the National Health and Nutrition Examination Survey (NHANES). METHODS: We extracted concentrations of 7 PFAS and 12 phenols/parabens and self-reported diagnoses of melanoma and cancers of the thyroid, breast, ovary, uterus, and testes from NHANES cycles between 2005 and 2016. We used multivariable logistic regression models to estimate associations between chemicals and cancers, adjusting for sociodemographic covariates. We conceptualized race as a social construct proxy of structural racial/ethnic inequities and stratified models by race/ethnicity (Non-Hispanic Black, Mexican American, and other Hispanic participants separately compared to White participants). RESULTS: Previous melanoma in women was associated with higher PFOS (OR:1.27; 95% CI: 1.04, 1.55), PFNA (OR:1.73; 95% CI: 1.09, 2.73), PFHxS (OR:1.76; 95% CI: 1.09, 2.84), BPS (OR: 1.61; 95% CI: 1.07, 2.42), and MeP (OR: 1.61; 95% CI: 1.07, 2.42) exposure. Previous thyroid cancer was associated with higher PFOS (OR:1.74; 95% CI: 1.00, 3.04), PFNA (OR:2.26; 95% CI: 1.30, 3.93), PFHxS (OR:2.29; 95% CI: 1.30, 4.04), PFDeA (OR:1.93; 95% CI: 1.02, 3.65), and BPS (OR: 1.74; 95% CI: 1.00, 3.04). Previous uterine cancer was associated with increased PFOA (OR: 1.43; 95% CI: 1.02, 2.02), while higher ethylparaben was inversely associated (OR: 0.51; 95% CI: 0.27, 0.97). Previous PFAS exposure associated with previous ovarian and uterine cancers in White women, while BPS/4-n-BPP was associated with previous breast cancer among non-White women. IMPACT STATEMENT: Biomarkers across a range of exposure categories (phenols, parabens, and per- and poly- fluoroalkyl substances) were cross-sectionally associated with increased odds of previous melanoma diagnoses in women, and increased odds of previous ovarian cancer was associated with several phenols and parabens. Some associations differed by racial group, which is particularly impactful given the established racial disparities in distributions of exposure to these chemicals. This is the first epidemiological study to investigate exposure to phenols in relation to previous cancer diagnoses, and the first NHANES study to explore racial/ethnic disparities in associations between environmental phenol, paraben, and PFAS exposures and historical cancer diagnosis. Fernández	2021	Dietary Habits and Relationship with the Presence of Main and Trace Elements, Bisphenol A, Tetrabromobisphenol A, and the Lipid, Microbiological and Immunological Profiles of Breast Milk	Breastfeeding is the best way to feed an infant, although it can also be a source of abiotic contaminants, such as heavy metals or bisphenol A (BPA). The early life exposure to these compounds can lead to various toxic effects in both the short and long term. These substances can reach breast milk through the mother's habits, diet, being one of the main routes of exposure. The aim of the present work was to analyze possible associations between the dietary habits of women and the content of major trace elements, BPA, fatty acids, and lipids, and the microbiological and immunological profiles of human milk. Possible associations between the concentrations of BPA in the milk samples and the concentrations of major trace elements in human milk were also studied. The results obtained showed that the consumption of canned drinks is related to the presence of BPA in human milk. Furthermore, some relationships were found between the amount of major trace elements and the microbiological and immunological profile of the milk samples. Finally, the presence of BPA was associated with changes in the immunological profile of human milk. Iribarne-Durán	2024	Exposure to bisphenols, parabens, and benzophenones in colostrum breast milk of Panamanian women: A pilot study from the PA-MAMI cohort	BACKGROUND: Breast milk is the optimal source of nutrition for infants, but can also expose them to endocrine-disrupting chemicals (EDCs), among other environmental contaminants. AIM: To determine concentrations of bisphenols (BPs), parabens (PBs), and benzophenones (BP-1, BP-2, BP-3, BP-8, and 4-hydroxy BP in colostrum milk samples from 30 mothers. And two questionnaire was used to collect data on potential influentially variables, and multiple linear and logistic regression analyses were conducted. RESULTS: Twelve chemicals (100 %) were found in the colostrum samples (BP-3, and bisphenol A (BPA) were detected in all 30 samples (11.1 %). The most frequently detected compounds were BPA (90.7 %), BP-8 (63.0 %), MeP (57.7 %), and BPF (51.7 %). The median concentrations was 3.83 ng/mL for BP-3 and 2.37 ng/mL for BPA. No significant associations were found between the presence of BPs, PBs, and BP-3 in colostrum and maternal factors, including age, BMI, education, and parity. However, the consumption of chewy food, yogurt and chocolate, intake of nutritional supplements, and application of some personal care products, CONCLUSION: Bisphenols, parabens, and benzophenones were widely present in colostrum milk samples from Panamanian women. Preventive measures are needed to maximize the benefits of breastfeeding. Barbonetti	2022	Association between urinary bisphenol A concentrations and semen quality: A meta-analytic study	Although preclinical research has revealed disrupting effects on male reproductive functions of bisphenol A (BPA), as yet clinical studies have led to inconsistent results. The present meta-analysis aims to establish the existence and the extent of the association between BPA exposure and semen quality. A thorough search of PubMed, Scopus and Web of Science databases was carried out. Only studies reporting data from multivariate analyses were included. Pooled effect sizes (ES) were calculated using a random-effects model. Eight studies were included in the meta-analysis, involving a total sample of 2,386 men. Only the expected association between BPA levels and sperm motility reached statistical significance (pooled ES coefficient = -0.82; 95% CI: -1.53 to -0.11; p = 0.02). Pthe heterogeneity I2 (I2 = 63.9%). Yet, such a significance was lost after data adjustment for publication bias, as well as at the sensitivity analysis, when each of the two studies that contributed most to the overall estimate was excluded. In conclusion, the overall estimates of data produced by clinical studies point to a clinically negligible, if any, association between urinary BPA concentrations and semen quality. Further studies in centers at high risk of occupational exposure are warranted to corroborate the herein revealed weak correlation with a more sperm motility. Sturgeon	2025	Urinary Levels of Endocrine-Disrupting Chemicals and Breast Density in Young Women	BACKGROUND: Endocrine disrupting chemicals (EDC) found in many household and personal care products have hormonal properties and effects on the mammary gland. It is unclear whether urinary concentrations of EDCs are associated with higher percent breast density, a major risk factor of breast cancer. METHODS: We conducted a cross-sectional study of 97 college-aged women. We quantified individual levels of bisphenol A (BPA), parabens (MeP, EtP, PrP, BuP), benzophenone-3 (BP3), triclosan (TCS), and dichlorophenols (2,4-DCP, 2,5-DCP) in first morning urine samples. Percent breast density was measured from mammograms that had been retrieved (89% success) per each breast density. Associations between urinary concentrations of individual EDCs and percent breast density were assessed using linear regression. RESULTS: There was no evidence of a statistically significant increase in mean percent breast density in the middle or highest tertile for any EDC measured. There was a suggestion that the mean percent breast density was elevated in individuals in the middle and highest tertile levels of ethyl paraben compared with those in the lowest tertile, with a similar increase in mean percent breast density of 3.6% (1.1, 6.1) and 3.2% (0.7, 5.8) for tertile 2 and 3 (p = 0.24). Similar trends in percent breast density were observed for methylparaben, propylparaben, and butylparaben. CONCLUSIONS: Urinary levels of EDCs were not associated with percent breast density in college-aged women. IMPACT: The estimated effect of EDCs on the breast tissue of young women is unclear and warrants larger studies. La Rocca, A. Gastaldelli and G. Life Persuaded Project	2022	Exposure to Endocrine Disruptors (DiI(2-Ethylhexyl)phthalate (DEHP) and Bisphenol A (BPA)) in Women from Different Residing Areas in Italy: Data from the LIFE PERSUADED Project	Phthalates and bisphenol A (BPA) are plasticizers used in many industrial products that can act as endocrine disrupters and lead to metabolic diseases. During the LIFE PERSUADED project, we measured the urinary concentrations of BPA and DiI-ethylhexylphthalate (DEHP) metabolites in 980 Italian women representative of the Italian female adult population (living in the north, centre, south of Italy in both rural and urban areas). The whole cohort was exposed to DEHP and BPA with measurable levels above limit of detection in more than 90% and 95% of the samples, respectively. The exposure patterns differed for the two chemicals in relation to the different residing areas. Women living in urban areas showed higher exposure to DEHP than women living in rural areas (median 19.8 vs. 14.1 µg/kg bw/day, $p < 0.001$), whereas, no difference between areas was observed for BPA. The estimated daily intake of BPA was 0.11 µg/kg bw per day, about 30 fold below the current temporary tolerable daily intake of 4 µg/kg bw per day established by the EFSA in 2015. The analysis of cumulative exposure showed a positive correlation between DEHP and BPA. Further, the reduction of exposure to DEHP and BPA, through specific legislative measures, is necessary to limit the harmfulness of these substances. 統合_0732	F. Ceri, D. Ciociaro and A. Gastaldelli	2022	Assessment of Exposure to Di-(2-ethylhexyl) Phthalate (DEHP) Metabolites and Bisphenol A (BPA) and Its Importance for the Prevention of Cardiometabolic Diseases	Exposomics analyses have highlighted the importance of biomonitoring of human exposure to pollutants, soon non-persistent, for the prevention of non-communicable diseases such as: obesity, diabetes, non-alcoholic fatty liver disease, atherosclerosis, and cardiovascular diseases. Phthalates and bisphenol A (BPA) are endocrine disrupting chemicals (EDCs) widely used in industry and in a large range of daily life products that humans are exposed to. Exposure to these chemicals is widespread, and it is important to assess the patterns of exposure in diverse subgroups, to implement non-invasive strategies for the prevention of exposure in these subgroups, to prevent non-communicable diseases, such as obesity and diabetes, in childhood and adulthood. This is the goal of the LIFE PERSUADED project that measured the urine concentrations of phthalates, DEHP metabolites, MEHP, MEHHP, MEOHP and MEP. A faster method for the urinary metabolites of BPA was developed. In this paper we describe the method that was set up for the LIFE PERSUADED project and validated during the preliminary test. CONCLUSIONS: Knowing the accurate determination of urinary phthalates and BPA can be achieved running from small sample size (50 mL) using two SID techniques applied in cascade on the same deconjugated matrix. 統合_0733	L. Caporossi, P. Viganò, E. Paci, S. Capanna, A. Alteri, D. Pigini, G. Tranfo and B. Papaleo	2022	A Case-Control Study on the Effects of Plasticizers Exposure on Male Fertility	Male infertility is a serious concern for public health, and the possible role of exposure to plasticizers such as phthalates and bisphenol A in contributing to the condition is widely debated. We have herein enrolled 135 infertility cases attending an infertility center and 211 controls (fathers of a spontaneously conceived newborn) to investigate this issue. The urinary levels of seven phthalates and BPA were analyzed through HPLC-MS/MS. Semen quality was assessed according to the World Health Organization (WHO) guidelines. Associations between urinary concentrations of chemicals and parameters of semen volume, sperm concentration, sperm motility, and sperm morphology were investigated through multivariate logistic regression models. Results showed significantly higher urinary concentrations for all the phthalates in cases, compared to controls, except for monoethyl phthalate (MEP). In cases, MEP, the major urinary metabolite of diethyl phthalate (DEP), was found 3.6-fold higher than in controls (median values: 54.9 ng/mL vs. 15.1 ng/mL, $p < 0.001$). Similarly, the urinary concentrations of the DEHP metabolites were 1.5–2.0-fold higher in cases than in controls. Sperm motility was found to be significantly lower in cases than in controls ($p < 0.001$), while no significant differences between cases and controls were observed for sperm volume, concentration, and morphology. Multivariate logistic regression models showed that the urinary concentrations of MEP, MEHP, MEHHP, MEOHP, and MEP were associated with a significantly higher risk of male infertility, with adjusted odds ratios (ORs) ranging from 1.5 to 2.0 for the highest vs. the lowest tertile. Urinary BPA was not significantly associated with male infertility. Our results suggest that the exposure to DEHP, but not to BPA, may be a risk factor for male infertility. 統合_0734	L. Caporossi, P. Viganò, E. Paci, S. Capanna, A. Alteri, G. Campo, D. Pigini, M. De Rosa, G. Tranfo and B. Papaleo	2021	Female Reproductive Health and Exposure to Phthalates and Bisphenol A: A Cross Sectional Study	The ensemble toxicity of some plasticizers (phthalates and bisphenol A) is documented in the literature and may pose a risk to female reproductive health. The aim of this study was to assess exposure to six phthalates. This was achieved by measuring their respective metabolites (mono-ethylphthalate (MEP), mono-n-butylphthalate (MnBP), mono-n-octylphthalate (MnOP), and monobenzylphthalate (MBzP)), as well as the sum of two of the diethyl hexyl phthalate metabolites (∑ DEHP) and bisphenol A (BPA) via female population with infertility problems, and by conducting a correlation analysis between infertility factors, work activities, and lifestyle habits. The study was carried out on a sample of 150 women who attended a fertility center and 150 women who were recruited among the hospital staff and were used as controls. The urine samples of 286 women was given used to quantify xenobiotics and a questionnaire was collected. Phthalate metabolites and bisphenol A were normalized by HPLC/MS/MS. The data showed significantly higher mean values for MEP in women with recurrent pregnancy loss (RPL) (526.5 ± 1439.3 µg/g of creatinine) and idiopathic infertility (290.0 ± 1962 µg/g of creatinine) than in women with other infertility factors (76.9 ± 115.8 µg/g of creatinine). Similarly, for MnBP levels, women with idiopathic infertility (0.90 ± 3.66 µg/g of creatinine) showed significantly higher values than women with the other infertility factors together (0.35 ± 1.08 µg/g of creatinine). Women with tubal factors of infertility, RPL, and endocrine dysfunctions, show higher values of ∑DEHP (p < 0.022). Considering occupations, women working in commerce showed more than twice as much BPA (0.66 ± 1.08 µg/g of creatinine) than women working in other sectors (0.29 ± 0.46 µg/g of creatinine). Women in the healthcare sector showed the lowest values (0.06 ± 0.16 µg/g of creatinine). The presence of significant correlations between some of these phthalates, DEHP metabolites especially in women with RPL and idiopathic infertility, suggests a possible involvement of these compounds as competing factors in reproductive issues. The study of sources of exposure suggested that the working activity intends, as a cofactor in particular, represents a major one for BPA (p < 0.015).	Toxics Vol.9 Issue 11	10.3390/toxics9110299	34822691	ヒト	-	-	-	-	-	-	横断研究	1	1	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-
統合_0735	L. Caporossi, A. Alteri, G. Campo, E. Paci, G. Tranfo, S. Capanna, E. Papaleo, D. Pigini, P. Viganò and B. Papaleo	2020	Cross Sectional Study on Exposure to BPA and Phthalates and Semen Parameters in Men Attending a Fertility Center	Among the possible risk factors for male reproduction, exposure to phthalates and alkylphenols is widely documented. This study evaluated the possible association between chemical exposure and the quality of the seminal fluid of 150 subjects in a fertility clinic. The urinary levels of seven phthalate metabolites (monoethylphthalate, MEP; monobenzylphthalate, MBzP; mono-n-butylphthalate, MnBP; mono-(2-ethylhexyl) phthalate, MEHP; mono-(2-ethyl-5-hydroxyhexyl) phthalate, MEHHP; mono-n-octylphthalate, MnOP; mono-(carboxyheptyl)phthalate, MCPP) and bisphenol A (BPA), were analyzed by high-performance liquid chromatography tandem mass spectrometry (HPLC/MS/MS). Sperm quality was assessed according to World Health Organization (WHO) guidelines. Associations between urinary concentrations of chemicals and parameters of semen volume, sperm concentration, sperm motility, and sperm morphology were investigated through multivariate logistic regression models. Results showed significantly higher urinary concentrations for all the phthalates in cases, compared to controls, except for monoethyl phthalate (MEP). In cases, MEP, the major urinary metabolite of diethyl phthalate (DEP), was found 3.6-fold higher than in controls (median values: 54.9 ng/mL vs. 15.1 ng/mL, $p < 0.001$). Similarly, the urinary concentrations of the DEHP metabolites were 1.5–2.0-fold higher in cases than in controls. Sperm motility was found to be significantly lower in cases than in controls ($p < 0.001$), while no significant differences between cases and controls were observed for sperm volume, concentration, and morphology. Multivariate logistic regression models showed that the urinary concentrations of MEP, MEHP, MEHHP, MEOHP, and MEP were associated with a significantly higher risk of male infertility, with adjusted odds ratios (ORs) ranging from 1.5 to 2.0 for the highest vs. the lowest tertile. Urinary BPA was not significantly associated with male infertility. A negative association was found between the use of plastic containers for food storage ($p < 0.027$) and semen volume (2.56 vs. 2.36 mL as average values, mean vs. daily). A significant positive correlation emerged ($p < 0.009$) between the consumption of canned food and the levels of MEP (3.81 vs. 6.51 µg/g creat as average values, daily vs. never) and between the use of perfumes and levels of MEP (MEHP vs. BMA µg/g creat, as average values, daily vs. never). To further statistically significant associations were found, even considering the working activity. Some evidence emerged about the possible link between exposure and seminal fluid quality further searched on prospective studies will allow us to confirm the casually hypothesis. 統合_0736	X. L. Cao, N. K. Xu, K. Y. Zhou and C. M. Xu	2022	Association of urinary bisphenol A concentrations with in vitro fertilisation outcomes: a systematic review and meta-analysis protocol	INTRODUCTION: Bisphenol A (BPA) is a common environmental endocrine disruptor. BPA has been reported to be associated with female infertility, which may not only affect natural pregnancy and natural fertility but also affect the outcomes of in vitro fertilisation (IVF). BPA exposure may help to partly explain the unsatisfactory IVF outcomes, but the relationship between the urinary BPA concentrations and IVF outcomes remains controversial. Therefore, we will perform a meta-analysis to identify and review the relationship between urinary BPA concentrations and IVF outcomes. METHODS AND ANALYSIS: A comprehensive literature search on PubMed, Embase, Web of Science, Cochrane Library and Chinese databases (CNKI, Wanfang and VIP) will be performed from the inception to 1 October 2022. Only English and Chinese articles will be included. Two researchers will independently screen the articles, extract the data and assess the quality of the included studies. Any disagreements will be resolved through discussion with a third researcher. In addition, the references of the included literature will also be traced to supplement our search results and to obtain all relevant literature. The Newcastle-Ottawa Scale will be used to assess the methodological quality of the included studies using a star rating system ranging from 0 to 9 stars. Heterogeneity in estimates from different articles will be quantified, and publication bias will be investigated using funnel plots. Finally, a sensitivity analysis will also be conducted to estimate whether our results could have been markedly affected by a single included study. ETHICS AND DISSEMINATION: Ethical approval is not required for this protocol, as participants are not included. Findings will be disseminated through peer-reviewed publications and conference presentations. 統合_0737	G. Cambien, A. Dupuis, M. Belmouaz, M. Bauwens, A. Bacle, S. Ragot, V. Migani, M. Allioux and S. Ayrault-Thevenot	2024	Bisphenol A and chlorinated derivatives of bisphenol A assessment in end stage renal disease patients: Impact of dialysis therapy	Patients with end stage kidney disease treated by dialysis (ESKDD) procure dialysis sessions to remove molecules usually excreted by kidneys. However, dialysis therapy could also contribute to endocrine disruptors (ED) exposure. Bisphenol A (BPA) and chlorinated derivatives of bisphenol A (ClxBPA) are suspected ED. The aim of this study was to compare BPA and ClxBPA exposure between ESKDD patients and healthy volunteers. This is a monocentric, cross-sectional, observational study. We compared BPA and ClxBPA exposure between ESKDD patients, patients with stage 5 chronic kidney disease (CKD5D) on dialysis and healthy volunteers. We also describe the impact of a single dialysis session according to dialysis modalities: Hemodialysis (hemo), online hemodiafiltration therapy (HDF) and materials used with per-post BPA and ClxBPA concentrations. The plasma levels of BPA and four ClxBPA were measured for 60 ESKDD patients, in pre and post dialysis sessions (hemo and HDF) and 15 healthy volunteers. BPA plasma concentrations were 10 times higher for ESKDD patients versus healthy volunteers (median [IQR]: 2.0 [1.0–3.0] ng/mL versus 0.2 [0.1–0.3] ng/mL, $p < 0.001$). ClxBPA plasma concentrations were 30 times higher for CKD5 patients versus healthy volunteers (median [IQR]: 0.3 [0.2–0.4] ng/mL versus 0.01 [0.01–0.02] ng/mL, $p < 0.001$). Post-dialysis BPA concentrations were 50% lower than pre-dialysis ones (1.0 [0.5–1.5] ng/mL versus 2.0 [1.0–3.0] ng/mL, $p < 0.001$). For healthy volunteers, ClxBPA were never detected, or quantified under the CKD5 and ESKDD validation limits. Similar results have been observed on quantified ratio (2 patients: 28.8%) and 2 patients: 57.1%), respectively. Dialysis therapy was ineffective to remove BPA either for HD (-1.96 ± 6.82 ng/mL in pre-dialysis versus 3.4% ± 6.63 ng/mL in post-dialysis) or HDF (1.00 ± 1.63 ng/mL in pre-dialysis versus 1.62 ± 15.98 ng/mL in post-dialysis) regarding per post BPA concentrations ($p > 0.05$). The same result was observed regarding ClxBPA analysis. Presence of polysulfone in dialyzer fibers, unexposed ESKDD patients to BPA in pre-dialysis samples, with 3.0% ± 4.73% for ESKDD patients treated with a polysulfone dialyzer versus 0.78% ± 0.63% ($p = 0.048$) for ESKDD patients treated with another dialyzer membrane. Conclusion: ESKDD patients are highly exposed to BPA and ClxBPA, and dialysis therapy is ineffective to remove BPA and ClxBPA, without a polysulfone dialyzer. This work is to our knowledge the first to investigate the impact of a dialysis session and materials used on BPA and ClxBPA plasma concentrations and to compare these concentrations to those found in CKD5 patients and in healthy volunteers. 統合_0738	L. R. Camara, T. E. Arbuckle, H. Trottier and W. D. Fraser	2019	Associations between Maternal Exposure to Bisphenol A or Triclosan and Gestational Hypertension and Preeclampsia: The MIREC Study	BACKGROUND: Little is known about the association between bisphenol A (BPA) or triclosan (TCS) exposure and hypertension in pregnancy. OBJECTIVE: To investigate potential associations between maternal urinary concentrations of BPA and TCS and gestational hypertension and preeclampsia. METHODS: We conducted a nested case-control study within the Maternal-Infant Research on Environmental Chemicals (MIREC) study, a cohort of pregnant women recruited in the first trimester in South Western Ontario (2008–2011). Urinary BPA and TCS were measured in the first trimester by liquid chromatography–tandem mass spectrometry using a single-void urine sample. Blood pressure was measured during each trimester. Multinomial regression was performed to estimate the adjusted odds ratio (aOR) and 95% confidence intervals (CI) for the associations between these phenols and GH and preeclampsia. RESULTS: BPA and TCS were not associated with GH or preeclampsia. However, in nulliparous women, BPA (0.50–1.30 µg/L) was associated with decreased risk of GH (aOR: 0.43; 95%CI: 0.21–0.88) while creatinine-adjusted BPA was associated with an increased risk of GH (1.50–3.50 µg/L: aOR = 2.58; 95% CI: 1.09–6.13; and > 3.50 µg/L: aOR = 2.76; 95% CI: 1.18–6.45). CONCLUSION: BPA and TCS urinary concentrations were not associated with GH or preeclampsia; however, our results suggest an association between TCS and GH in nulliparous women. Additional studies are required to confirm our results.	Am J Perinatol Vol.36 Issue 11 Pages 1127-1135	10.1055/s-0038-1676489	30551231	ヒト	-	-	-	-	-	-	横断研究	1	1	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-

統合_0739	W. Cai, Q. Yan, Y. Deng and Y. Guo	2025	The correlation of bisphenol A exposure on inflammatory cytokines in preschool children	OBJECTIVE: Based on current evidence suggesting that bisphenol A (BPA) may contribute to obesity through the modulation of inflammatory markers, this study aims to investigate the correlation between BPA exposure and cellular inflammatory factors in preschool children. METHODS: A total of 136 preschool children aged 4-6 years were included. Urine and blood samples were collected. BPA exposure was detected by liquid chromatography-tandem mass spectrometry (LC-MS/MS), and cytokines were detected by flow cytometry. Spearman correlation analysis was used to assess the correlation between urinary BPA exposure and cellular inflammatory factors was analyzed using Spearman's correlation and respectively stratified by gender and BMI. RESULTS: The detection rate of BPA in urine samples was 100 %. The median urinary BPA concentration was 5.08 μg/L (QR:3.21-7.82 μg/L), and the creatinine-adjusted BPA concentration was 3.96 μg/g(QR:2.67-5.68 μg/g). BPA level was negatively correlated with IL-10 (r = -0.167, P = 0.049) and positively correlated with IL-6 (r = 0.176, P = 0.040). After stratification by gender, a significant association between BPA exposure and IL-10 was found in females (r = -0.307, P = 0.003), while no associations was found in males. According to BMI classification, BPA exposure had a significant correlation with IL-6 (r = 0.264, P = 0.041) in children with normal weight. Children in the highest BPA exposure group (Q4) showed a decrease in levels of IL-10, and this effect was significantly expressed in girls. In addition, BPA exposure in overweight/obese children was correlated with increased levels of IL-6. However, the mechanism between BPA and inflammatory factors remains to be further explored. 統合_0740	S. Cai, X. Rao, J. Ye, Y. Ling, S. Mi, H. Chen, C. Fan and Y. Li	2020	Relationship between urinary bisphenol a levels and cardiovascular diseases in the U.S. adult population, 2003-2014	BACKGROUND: Emerging evidence has identified cardiovascular system as a potential target of Bisphenol A (BPA). Although a few studies have revealed the relationship between BPA and the risk of several cardiovascular diseases (CVD) outcome, and CVD risk factors, no published studies have investigated the link between urinary BPA and the risk of stroke. METHODS: Data were derived from the United States National Health and Nutrition Examination Survey (NHANES), with a representative sample ages ≥ 18 years from 2003 to 2014. We performed multivariable logistic regression models to examine associations between quantiles and natural logarithm-transformed urinary BPA concentrations and five specific CVD outcomes and total CVD. RESULTS: In quantile analysis, highest level of urinary BPA was associated with increased prevalence of CVD (OR = 1.37, 95% CI: 1.03, 1.82), CHD (OR = 1.57, 95% CI: 1.08, 2.28), and stroke (OR = 1.70, 95% CI: 1.03, 2.80) after adjusting for confounders. When BPA was transformed BPA concentration was shown to be significantly associated with 39%, 31%, 25%, 29%, 26%, and 15% increased odds ratios of prevalence of congestive heart failure, coronary heart disease (CHD), angina pectoris, MI, stroke and total CVD among total participants, respectively. Similar associations were found in males rather than in females. CONCLUSION: We provided the premier evidence of positive relationship between urinary BPA concentration and stroke in U.S. POPULATION. Urinary BPA levels were also positively correlated with congestive heart failure, CHD, angina pectoris, MI, as well as total CVD. These associations were more evident in males. Well-coordinated and prospective studies are warranted to gain the human effects of BPA on CVD. 統合_0741	M. Büyükeser	2023	Comparison of urine bisphenol A levels in transient tachypnea of the newborn and healthy newborns	BACKGROUND: To investigate the relationship between neonatal urine bisphenol A (BPA) levels and the prevalence and prognosis of transient tachypnea of the newborn (TTN). METHODS: This prospective study was conducted between January and April 2020 in the Neonatal Intensive Care Unit (NICU) of Gaziantep Cengiz Gökçek Maternity and Children Diseases Hospital and Pediatric Hospital. The study group consisted of patients diagnosed with TTN and the control group was made up of healthy neonates housed together with their mothers. Urine samples were collected from the neonates within the first 3 hours postnatally. RESULTS: Urine BPA levels and urine BPA/creatinine ratios were found to be significantly higher in the TTN group than in the control group (p < 0.001 and p = 0.001, respectively). The area under the curve (AUC) was 0.727 (95% confidence interval (CI): 0.647-0.808) with a sensitivity of 76.5% and specificity of 61.5%, and the cut-off value of urine BPA/creatinine to be 3.05 μg/g (95% CI: 2.727-3.333), sensitivity 85.3%, and specificity 96.2%) and the cut-off value for BPA/creatinine was 29.15 μg/g (95% CI: 0.771-1.538), sensitivity 61.5%, and specificity 84.6%) among the 77 TTN patients. CONCLUSIONS: BPA and BPA/creatinine values were higher in the urine of newborns diagnosed with TTN which is a fairly common cause of NICU hospitalization. In samples collected within the first 6 hours after birth, which may be a reflection of intrauterine factors. 統合_0743	J. P. Buckley, H. Kim, E. Wong and C. M. Rebholz	2019	Ultra-processed food consumption and exposure to phthalates and bisphenols in the US National Health and Nutrition Examination Survey, 2013-2014	BACKGROUND: Ultra-processed food has low nutritional quality, is associated with development of chronic diseases, and may increase exposure to chemicals used in food packaging and production. OBJECTIVES: To examine associations between consumption of ultra-processed food and urinary concentrations of phthalates and bisphenols. METHODS: We used data from the National Health and Nutrition Examination Survey (NHANES) 2013-2014 participants (≥18 years), our visualized dataset reported in a 2019 dietary recall according to the NOVA food processing classification system and calculated energy intake from ultra-processed food. Urinary concentrations of mono-benzyl (MBzP), mono-(2-ethylhexyl) (MEHP), mono-(carboxynonyl) (MCNP), mono-(carboxyoctyl) (MCOP), and four metabolites of di(2-ethylhexyl) (1)(3)(4) phthalates and bisphenols A, F, and S were measured in spot urine samples. We estimated percentage of energy intake from ultra-processed food and created tertiles of consumption. We used survey-weighted linear regression models to examine associations between consumption and creatinine-adjusted molar/molar (log) urinary concentrations. We examined effect measure modification by age group, race/ethnicity, and poverty-income ratio and assessed associations with minimally processed food. RESULTS: Ultra-processed food consumption was associated with higher urinary concentrations of MBzP, MEHP, MCNP, MCOP, and BPA. Participants in the highest tertile of energy from ultra-processed food was associated with 81% (95% CI: 54%, 113%) higher urinary MCOP concentrations, with a stronger association among children than adolescents or adults. Ultra-processed sandwiches/hamburgers, French fries/other potato products, and ice cream/popsicles were associated with higher concentrations of multiple chemicals. Higher energy from minimally processed food was associated with lower concentrations of MCPP, MCNP, MCOP, and bisphenols A and F. DISCUSSION: Ultra-processed food consumption may increase exposure to currently used phthalates. Additional research is needed to determine whether minimally processed food diets or changes in food production practices can reduce phthalate and bisphenol exposures, and related health effects, particularly among children who are more vulnerable to toxicants and tend to consume more ultra-processed food than adults. Ferrucci	2024	Association of vitamin D and bisphenol A levels with cardiovascular risk in an elderly Italian population: results from the InCHIANTI study	Few studies have evaluated the association between circulating levels of 25-hydroxyvitamin D (25(OH)D), 1,25-dihydroxyvitamin D (1,25(OH)2D), and the endocrine disruptor bisphenol A (BPA), with risk of cardiovascular disease (CVD). We investigated the association of 25(OH)D, 1,25(OH)2D, and BPA with CVD risk factors and with the presence of subclinical atherosclerosis. Serum vitamin D metabolites, 1,25(OH)2D, 25(OH)D, and the endocrine-disrupting agent BPA, with an estimated 17-y risk score and the European Society of Cardiology-based 10-year CV risk SCORE2/SCORE2-OP using univariate and multiple regression. In 298 individuals, blood samples were tested for serum values of 25(OH)D, 1,25(OH)2D and urinary BPA levels. One hundred eighty individuals (60.2%) were deficient (< 30 ng/ml) in 25(OH)D. Levels of 25(OH)D were inversely correlated with CV risk score (β = -0.0281 for both as well as SCORE2/SCORE2-OP (β = -0.030) for both) while BPA levels were positively correlated with both CV risk scores (p = 0.0003 for both). In a logistic regression model, male gender (odds ratio (OR) 2.1, 95% CI 1.1-3.8, p = 0.022), obesity (OR 2.8, 95% CI 1.2-6.5, p = 0.016) and BPA tertile 3 (23 ng/ml) (OR 2.9, 95% CI 1.4-6.1, p = 0.006) were significantly associated with the presence of subclinical atherosclerosis. Similar results were found for SCORE2/SCORE2-OP. Finally, 25(OH)D and BPA levels were associated with 1,25(OH)2D (OR 1.01 and 1.39, p = 0.008 respectively and 1.25(OH)2D levels (-21 ng/ml were associated with SCORE2/SCORE2-OP at +25% (95% CI 98, 156%; CI 7-43, p = 0.0001). In this cross-sectional analysis, BPA exposure was associated with significantly reduced levels of vitamin D that in turn were significantly associated with increased CV risk. Ferrucci	2022	Association between vitamin D and bisphenol A levels in an elderly Italian population: results from the InCHIANTI study	OBJECTIVE: This study aimed to evaluate the association between the endocrine-disrupting chemical, bisphenol A (BPA) on circulating levels of 25-hydroxy vitamin D (25(OH)D) and other vitamin D metabolites in an elderly population in Italy. METHODS: This was a retrospective analysis of the InCHIANTI Bisheal-In Italy. The association between vitamin D metabolites, namely 1,25(OH)2D, 25(OH)D, quantified between 1990 and BPA levels were evaluated. Multiple regression models were used to examine the association between predictor variables with 1,25(OH)2D or 25(OH)D levels. RESULTS: Samples from 298 individuals aged 72.8 ± 15.7 years, were evaluated. Of these, 180 (60.2%) were deficient (< 30 ng/ml) in 25(OH)D. Levels of 25(OH)D were inversely correlated with CV risk score (β = -0.0281 for both as well as SCORE2/SCORE2-OP (β = -0.030) for both) while BPA levels were positively correlated with both CV risk scores (p = 0.0003 for both). In a logistic regression model, male gender (odds ratio (OR) 2.1, 95% CI 1.1-3.8, p = 0.022), obesity (OR 2.8, 95% CI 1.2-6.5, p = 0.016) and BPA tertile 3 (23 ng/ml) (OR 2.9, 95% CI 1.4-6.1, p = 0.006) were significantly associated with the presence of subclinical atherosclerosis. Similar results were found for SCORE2/SCORE2-OP. Finally, 25(OH)D and BPA levels were associated with 1,25(OH)2D (OR 1.01 and 1.39, p = 0.008 respectively and 1.25(OH)2D levels (-21 ng/ml were associated with SCORE2/SCORE2-OP at +25% (95% CI 98, 156%; CI 7-43, p = 0.0001). In this cross-sectional analysis, BPA exposure was associated with significantly reduced levels of vitamin D that in turn were significantly associated with increased CV risk. 統合_0746	C. G. Bunsell-g, E. Ergdahl, M. Unenge Hallerbäck, S. Wikström, C. Lindh, J. Ruegg, E. Tanner and C. Gennings	2021	Prenatal exposure to bisphenols and cognitive function in children at 7 years of age in the Swedish SELMA study	BACKGROUND: Experimental evidence demonstrates that exposure to bisphenol A (BPA), and the recently introduced alternatives bisphenol S (BPS) and bisphenol F (BPF) alter normal neurodevelopment. More research is needed to evaluate the associations between exposure to individual BPA alternatives, and neurodevelopmental outcomes in humans. OBJECTIVE: The present study examined the individual associations between prenatal BPA, BPS and BPF exposure and cognitive outcomes in children at age 7 years. METHODS: Women were enrolled in the Swedish Environmental Longitudinal Mother and Child, Asthma and Allergy (SELMA) study, at an antenatal median week 10.5, and their children were examined for cognitive function at 7 years of age (N = 800). Maternal urine BPA, BPS, and BPF concentrations were measured in samples collected from children's cognitive function at the age of 7 years was measured using the Wechsler Intelligence Scale for Children-IV (WISC-IV). RESULTS: At three bisphenols were detected in over 90% of the women, where BPA had the highest detection frequency (98%). Maternal urine BPA, BPS, and BPF concentrations were not correlated with each other (Spearman's ρ ≤ 0.2). Higher maternal urine BPA, but not BPS or BPF, was associated with a decrease in all four sub-scales assessing verbal comprehension, perceptual reasoning, working memory and processing speed. This association corresponded to a 2.8 point decrease in the full scale IQ score for an interquartile range (IQR) change in prenatal BPF exposure (IQR: -0.094-0.960 ng/mL). In sex-stratified analyses, significant associations with full scale IQ were found to boys (β = -3.86, 95%CI: -6.56, -1.16), while the associations for girls did not reach significance (β = -1.36, 95%CI: -3.97, 0.22). No significant associations between BPA nor BPS and cognitive were found. DISCUSSION: Prenatal exposure to BPF was significantly associated with childhood cognitive function at 7 years. Since BPF is replacing BPA in numerous consumer products globally, this finding urgently call for further studies.	Environ Int. 2021 May;150:106433.	10.1016/j.envint.2021.106433	33637302	ヒト	-	-	-	-	-	-	コホート研究	1	1	-	1	1	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-
統合_0747	M. M. Borghese, R. Huang, S. MacPherson, E. Gaudreau, S. Gagné, J. Ashby-Mantin, M. Fisher, L. Bouj, M. F. Bouchard and T. E. Arbuckle	2023	A descriptive analysis of first trimester urinary concentrations of 14 bisphenol analogues in the MIREC Canadian pregnancy cohort	BACKGROUND: Concern over the health effects of BPA, particularly for the developing fetus, has led to an increasing use of bisphenol analogues in industrial and consumer products, which may be as hormonally active as BPA. Biomonitoring data for many bisphenol analogues, especially in pregnant populations, are limited. METHODS: We measured concentrations of 13 bisphenol analogues in 1(st) trimester urine samples (n = 1891) from participants in the Maternal-Infant Research on Environmental Chemicals (MIREC) cohort. Bisphenol concentrations were compared between participant characteristics using Spearman correlations, Kruskal-Wallis tests, and multivariable linear regression models. We also examined associations between bisphenol concentrations and maternal occupational and healthcare exposures. RESULTS: Bisphenol A (BPA) was detected in 89% of participants with a specific gravity-standardized geometric mean concentration of 0.88 μg/L. Bisphenol AP (AP), 4,4'-(1-phenylethylidene) bisphenol (BPAP), and bisphenol AF (BPAF) were detected in <5% of participants. Bisphenol F (BPF) and bisphenol S (BPS) were detected in >50% of participants. Specific gravity-standardized geometric mean concentrations of these 5 compounds ranged from 0.053 to 0.168 μg/L. Urine bisphenol analogue concentrations were detected in <5% of participants. Concentrations of BPF (0.134 ng/mL) and BPS were higher in younger women and those with higher pre-pregnancy BMI, lower household income, lower education, and among smokers. We found a similar pattern of differences in BPF by age, education, and smoking status, but not BMI. Bisphenol concentrations were not related to maternal occupational exposures. Bisphenol S was higher among participants who reported working in healthcare, education, or an office setting. Canned food consumption was not related to bisphenol analogue concentrations. CONCLUSION: BP (A, S)(AP, BPC, BPF, and BPS) were frequently detected in 1(st) trimester urine samples in this large pan-Canadian pregnancy cohort. This suggests widespread exposure to these analogues around 2008-2011 and warrants further investigation into associations with health outcomes.	Int J Hyg Environ Health. 2023 Aug;253:114225.	10.1016/j.ijheh.2023.114225	37542835	ヒト	-	-	-	-	-	-	横断研究	1	1	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-
統合_0748	R. Boro, V. Ballicaño, R. Tanzirai, G. Soulikidi, I. Mamela, M. Bugliari, E. Migliore and P. Piccioni	2019	Bisphenol A, Tobacco Smoke, and Age as Predictors of Oxidative Stress in Children and Adolescents	OBJECTIVES: The purpose of this study was to investigate bisphenol A (BPA) and its role in the induction of oxidative stress, and confirm the same for tobacco smoke. METHODS: A total of 135 young, healthy students (7-19 years old) were recruited in Chisenso, Italy. A spot of urine of each subject was analyzed to quantify BPA, cotinine, and 15(S)-isoprostane (8-iso-PGF2α). RESULTS: BPA showed a slight increase of concentration proportional with age, whereas cotinine and 8-iso-PGF2α showed a decrease. Cotinine and 8-iso-PGF2α showed a similar shape. The lower trend was observed for 15(S)-isoprostane and cotinine. The result of Spearman's linear correlation test between these 3 levels and of the effect of BPA on 8-iso-PGF2α (multivariate and log-log OLS) is a U-shape. Therefore, BPA—isoprostane relations are represented inaccurately; even their threshold for each one by set of BPA. An increase of oxidative stress due to BPA was observed, but only from 6 ng/mg of CREA up. Passive tobacco smoke is also able to induce an increase in oxidative stress. CONCLUSION: Preventive regime BPA and passive tobacco smoke represents an important tool for promoting the highest health standard. Ferguson	2024	Prenatal Exposure to Nonpersistent Chemicals and Fetal-to-childhood Growth Trajectories	INTRODUCTION: Prenatal exposure to nonpersistent chemicals, including organophosphate pesticides, phthalates, and bisphenols, is associated with altered fetal and childhood growth. Few studies have examined these associations using longitudinal growth trajectories or considering exposure to chemical mixtures. METHODS: Among 777 participants from the Generation R Study, we used growth models to identify weight and body mass index trajectories using weight and height measures collected from the prenatal period to age 10. We measured exposure biomarkers for organophosphate pesticides, phthalates, and bisphenols, in maternal urine at three timepoints during pregnancy. Multinomial logistic regression was used to estimate associations between averaged exposure biomarker concentrations during pregnancy and growth trajectory membership. We used quantile g-computation to estimate joint associations with growth trajectories. RESULTS: 76 (Median) and DAP-1 (-0.90% CI: -1.32, -0.50) and bisphenol A (DP-1 (-0.90% CI: -1.3, -0.22) were associated with higher odds of a growth trajectory characterized by lower prenatal and higher childhood weight, while exposure to organophosphate pesticides was negatively associated with a trajectory of average prenatal and lower childhood weight. This study is consistent with the hypothesis that nonpersistent chemical exposures disrupt growth trajectories from the prenatal period through childhood.	Epidemiology. 2024 Nov 1;35(6):874-884.	10.1097/ede.0000000000001772	39042458	ヒト	-	-	-	-	-	-	コホート研究	1	1	-	1	1	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-

Meeker, R. Miller, T. G. O'Connor, M. E. Romano, S. Sathyanarayana, A. P. Starling, A. Stroustrup and D. J. Watkins	2025	Racial and ethnic differences in prenatal exposure to environmental phenols and parabens in the ECHO Cohort	BACKGROUND: Research suggests racial/ethnic disparities in prenatal exposure to endocrine disrupting environmental phenols (EPs) in United populations. However, no studies have investigated racial/ethnic disparities in prenatal EP exposure across the U.S. OBJECTIVES: To estimate demographic differences in prenatal urinary EPs among participants in the Environmental Influences on Child Health Outcomes (ECHO) Cohort. METHODS: An analysis of 6588 pregnant ECHO participants was performed, with 7868 specimens collected from 1999-2020. Racial/ethnic identity was self-reported. Urinary levels of 11 chemicals (2,4-DCP1, 2,5-dichlorophenol (2,5-DCP), benzophenone-3 (BP-3), bisphenols A (BPA), F (BPF), and S (BPS), and methyl- (MeP), ethyl- (EtP), propyl- (PrP), and butyl- (BuP) parabens were measured in one or more visits during pregnancy. Ethnic/racial means were adjusted for age, pre-pregnancy body mass index, educational level, gestational age and season at urine collection, and ECHO cohort. RESULTS: Participants were classified as Asian (5%), Black (20%), Hispanic (29%), White (41%), and Multiracial (5%). Asian participants had higher urinary levels of BPA (+0.19 log10 ng/mL), BPF (+0.27 log10 ng/mL), and 2,5-DCP (+0.17 log10 ng/mL) than White participants. Black participants had higher urinary levels of MeP (+0.41 log10 ng/mL), PrP (+0.34 log10 ng/mL), and BuP (+0.29 log10 ng/mL) than White participants. Hispanic participants had higher urinary levels of MeP (+0.24 log10 ng/mL), PrP (+0.24 log10 ng/mL), and BuP (+0.21 log10 ng/mL) than White participants. Multiracial participants had higher urinary levels of MeP (+0.21 log10 ng/mL), PrP (+0.21 log10 ng/mL), and BuP (+0.19 log10 ng/mL) than White participants. EtP was higher among Black (95% CI: 1.7-3.7) and non-Hispanic Other (95% CI: 1.1-3.1) participants. EPs were higher among Asian (95% CI: 1.3-2.1), Black (95% CI: 1.7-2.3), and non-Hispanic Other (95% CI: 1.1-2.1) participants. BPA was higher among Asian (95% CI: 1.3-2.1), Black (95% CI: 1.7-2.3), and non-Hispanic Other (95% CI: 1.1-2.1) participants. BPS was higher among Asian (95% CI: 1.3-2.1) participants. Urinary BuPA, BPA, BPF, and BPS were similar across groups. IMPACT STATEMENT: This multiethnic, observational cohort study investigated whether there are racial and ethnic differences in prenatal exposure to endocrine disrupting environmental phenols and parabens. Among 6588 participants from multiple U.S. cohorts, who provided urine specimens during pregnancy, those who self-reported a racial and ethnic identity other than non-Hispanic White had higher urinary concentrations of 2,5-dichlorophenol, 2,5-dichlorophenol, methyl paraben, ethyl paraben, and propyl paraben and lower urinary concentrations of benzophenone-3 than those reporting as non-Hispanic White. These data show differences in prenatal concentrations of endocrine disrupting environmental phenols and parabens by racial and ethnic identity. Gaillard	2021	Associations of maternal bisphenol urine concentrations during pregnancy with neonatal metabolomic profiles	BACKGROUND: Fetal exposure to bisphenols is associated with altered fetal growth, adverse birth outcomes and childhood cardio-metabolic risk factors. Metabolomics may serve as a tool to identify the mechanisms underlying these associations. We examined the associations of maternal bisphenol urinary concentrations, in pregnancy with neonatal metabolite profiles from cord blood. METHODS: In a population-based prospective cohort study, we measured bisphenol A, F and S concentrations in urine samples collected in mid-pregnancy (median 20.4 weeks of gestation). We measured 158 metabolites in cord blood serum samples, including acylcarnitines, amino acids, non-esterified fatty acids (NEFA), phosphatidylcholines (PC) and sphingomyelins in cord blood. RESULTS: The associations of maternal total bisphenol concentrations with neonatal metabolite profiles were present. Higher maternal average BPA concentrations were associated with higher neonatal mono-unsaturated alkyl/acyl-phosphatidylcholine concentrations, whereas higher maternal average BPS was associated with lower neonatal overall and saturated alkyl/acyl-phosphatidylcholine (p-values < 0.05). Trimester-specific analyses showed that higher maternal BPA, BPF and BPS were associated with alterations in neonatal NEFA, diacyl-phosphatidylcholine, acyl-alkyl phosphatidylcholine, alkyl/acyl-phosphatidylcholine, sphingomyelins and acyl-carnitines, with the strongest effects for third trimester maternal bisphenol and neonatal diacyl-phosphatidylcholine concentrations (p-values < 0.05). Associations were mostly present in girls and were not explained by maternal diet, lifestyle or socio-demographic factors. CONCLUSIONS: Higher maternal bisphenol A, F and S concentrations, in pregnancy are associated with alterations in neonatal metabolite profile, mainly in NEFA, PL and carnitines concentrations. These findings provide novel insight into potential mechanisms underlying associations of maternal bisphenol exposure during pregnancy with adverse offspring outcomes, but need to be replicated among larger, diverse populations. Trasande	2024	Fetal bisphenol and phthalate exposure and early childhood growth in a New York City birth cohort	BACKGROUND: Exposure to endocrine-disrupting chemicals such as bisphenols and phthalates during pregnancy may disrupt fetal developmental programming and influence early life growth. We hypothesized that prenatal bisphenol and phthalate exposure was associated with alterations in adiposity through 5 years. This association might change over time. METHODS: Among 1091 mother-child pairs in a New York City birth cohort study, we measured maternal urinary concentrations of bisphenols and phthalates at three time points in pregnancy and child weight, height, and triceps and subscapular skinfold thickness at ages 1, 2, 3, and 5 years. We used multivariable linear regression models to examine associations of prenatal exposure to individual chemicals and a chemical mixture with child growth outcomes. RESULTS: We observed associations of higher maternal urinary second trimester total bisphenol and bisphenol A concentrations in pregnancy and overall child weight between birth and 5 years only (Beta 0.02 SD (95% confidence interval: 0.00, 0.04) and 0.07 (0.02, 0.12) standard deviation score (SDS) change in weight-for-age(-sex) (kg increase in exposure). We reported an interaction of the exposure with time, and analysis showed associations of higher prenatal bisphenol exposure with greater weight-for-age(-sex) SDS at 1 year (0.07 (0.01, 0.13) SDS) and 2 years (0.06 (0.00, 0.12) SDS) but not at 3 or 5 years. Associations of higher prenatal bisphenol S, bisphenol F, phthalate, mono-(2-carboxymethyl) phthalate, and mono-(2-ethyl-5-carboxypentyl) phthalate, mono-(2-ethyl-5-hydroxyhexyl) phthalate, and mono-(2-ethyl-5-oxohexyl) phthalate concentrations were associated with higher child BMI at 5 years (0.20 (0.05, 0.35), 0.28 (0.06, 0.50), 0.31 (0.07, 0.54), 0.25 (0.01, 0.49), 0.26 (0.03, 0.50), 0.26 (0.03, 0.50), 0.25 (0.02, 0.48), 0.26 (0.03, 0.50), 0.26 (0.03, 0.50) SDS). For a doubled thickness, we observed no associations. DISCUSSION: This study contributes to the evidence suggesting associations of prenatal exposure to bisphenols, and high molecular-weight phthalates, on childhood weight and BMI. Jaddoe	2022	Maternal Phthalate and Bisphenol Urine Concentrations during Pregnancy and Early Markers of Arterial Health in Children	BACKGROUND: Fetal exposure to endocrine-disrupting chemicals such as phthalates and bisphenols might lead to fetal cardiovascular developmental adaptations and predispose individuals to cardiovascular disease in later life. OBJECTIVE: We examined the associations of maternal urinary bisphenol and phthalate concentrations in pregnancy with offspring carotid intima-media thickness and distensibility at the age of 10 y. METHODS: We measured urinary bisphenol A (BPA) and phthalate metabolites in 2 trimesters of pregnancy in 1,550 mothers participating in a population-based birth cohort. Carotid intima-media thickness and distensibility in the children at age 10 y using ultrasound. RESULTS: Maternal urinary bisphenol A concentrations were not associated with child carotid intima-media thickness at age 10 y. Higher maternal average concentrations of total bisphenol, especially bisphenol S, were associated with a lower carotid intima-media thickness [difference: -0.15 standard deviation score (SD) SD; 95% confidence interval (CI): -0.31, -0.00 and -0.23 (95% CI: -0.37, -0.08) per interquartile range (IQR) increase in maternal urinary total bisphenol and bisphenol S concentrations]. Trimester-specific analysis showed that higher maternal third trimester total bisphenol and bisphenol S concentrations were associated with lower child carotid intima-media thickness [difference: -0.23 (95% CI: -0.37, -0.09) and -0.19 (95% CI: -0.33, -0.04) SD per IQR increase in exposure, respectively]. Higher maternal urinary bisphenol S concentrations were associated with lower child carotid distensibility [difference: -0.19 (95% CI: -0.33, -0.04) SD per IQR increase in exposure]. Higher maternal urinary bisphenol concentrations were associated with smaller childhood carotid intima-media thickness. Further studies are needed to replicate this association and to identify potential underlying mechanisms. https://doi.org/10.1289/EHP12093. 統合_0754	S. M. Blaauwendraad, R. H. M. Dykgraaf, R. Gaillard, M. Liu, I. S. Lasen, V. W. V. Jaddoe and L. Trasande	2024	Associations of bisphenol and phthalate exposure and anti-Müllerian hormone levels in women of reproductive age	BACKGROUND: In women, exposure to endocrine-disrupting chemicals might accelerate the depletion of the ovarian reserve and might be associated with an accelerated reproductive aging and fertility. We examined the longitudinal associations of exposure to bisphenols and phthalates, with anti-Müllerian hormone concentrations. METHODS: Pregnant women of 18 years or older that resided in Rotterdam between 2002 and 2006 were eligible for participation in this longitudinal prospective cohort study. We measured urinary bisphenol and phthalate concentrations at three time points: in pregnancy among 1,620 women, of whom 1,321 women had serum anti-Müllerian hormone (AMH) measurements 6 and/or 9 years postpartum. Serum anti-Müllerian hormone regression models to assess the association of urinary bisphenol and phthalate concentrations with AMH after 6 and/or 9 years, and linear mixed effect model to assess the association with AMH over time. Models were adjusted for sociodemographic and lifestyle factors. FINDINGS: In our multivariable linear regression models we observed associations of higher urinary bisphenol A (BPA) concentrations with lower AMH levels after 6 years (-0.07 [95% confidence interval (CI): -0.13, -0.01] ng/mL per interquartile range increase in exposure) and after 9 years (-0.07 [95% CI: -0.13, -0.01] ng/mL per interquartile range increase in exposure). However, these associations did not remain after adjustment for multiple testing. No significant associations of bisphenol S with AMH at present in our models. In our linear mixed effect models, higher mono (2-ethyl-5-hydroxyhexyl) phthalate (mEHHP), mEHHP and mEHP were associated with lower overall AMH levels [difference: -0.07 (95% CI: -0.13, -0.01), -0.09 (-0.16, -0.02), -0.08 (95% CI: -0.14, -0.02), and -0.06 (-0.11, -0.01) μg/L per doubling in mEHP, mEHHP, and mEHP respectively] (all False Discovery Rate-adjusted p-values < 0.05). INTERPRETATION: We identify decreases in indices of ovarian reserve in relationship to prenatal phthalate exposures. Studies are needed replicating our results among large multi-ethnic non-pregnant populations and assessing transgenerational effects of exposure on ovarian reserve. 統合_0755	F. M. Bigambo, M. Zhang, J. Zhang, X. Yang, Q. Yu, D. Wu, X. Wang and Y. Xia	2022	Exposure to a mixture of personal care product and plasticizing chemicals in relation to reproductive hormones and menarche timing among 12-19 years old girls in NHANES 2013-2016	The effects of co-exposure to personal care product and plasticizing chemicals (PCPPCs) on reproductive hormones and menarche timing has rarely been studied. We used Bayesian kernel machine regression (BKMR), adaptive best subset shrinkage and selection operator (adaptive LASSO), and generalized linear model (GLM) to explore the mixture effects of 16 PCPPCs, on reproductive hormones and early menarche among 397 girls aged 12-19 years in the National Health and Nutrition Examination Survey (NHANES) 2013-2016. In the BKMR and adaptive LASSO models, we examined the mixture effects of PCPPCs, two environmental phenols (bisphenol A (BPA) and triclosan (TCS)), four phthalate metabolites (mono-ethyl phthalate (MEP), mono-benzyl phthalate (MBzP), mono-isobutyl phthalate (MiBP), mono-(carboxyoctyl) phthalate (MCOP), and Mono-benzyl phthalate (MBzP)) were positively associated with estradiol (E2), and the mixture of PCPPCs was positively associated with testosterone (T). Mono-(2-ethyl-5-carboxypentyl) phthalate (MECPP), mono-(2-ethyl-5-hydroxyhexyl) phthalate (MEHHP), mono-(2-ethyl-5-oxohexyl) phthalate (MEOHP), and Mono-(2-ethyl-5-carboxypentyl) phthalate (MECPP) were inversely associated with SHBG. In GLM, testosterone (T) (MCP and MECPP) were negatively associated with TT, whereas 2,2-dichlorophenol (2,2-DCP) revealed a positive association with early menarche onset. In conclusion, PCPPCs in the mixture and individually are associated with reproductive hormones and early menarche onset in girls. 統合_0756	F. M. Bigambo, D. Wang, J. Sun, X. Ding, X. Li, B. Gao, D. Wu, W. Gu, M. Zhang and X. Wang	2023	Association between Urinary BPA Substitutes and Precocious Puberty among Girls: A Single-Exposure and Mixed Exposure Approach from a Chinese Case-Control Study	There is an argument that BPA substitutes may have the same or more deleterious health effects as BPA due to their structural similarity. This study explored the association between urinary BPA substitutes and precocious puberty among girls by including 120 girls with precocious puberty (cases) aged 6-10 years and 120 girls without (controls) from Shenzhen Children's Hospital Department of child endocrine genetic metabolism, China, between 2021 and 165 healthy girls (controls) recruited from a primary school. Logistic regression was used to evaluate the effect of single exposures, and Bayesian kernel machine regression (BKMR) and quantile-based g-computation models were used to assess the effect of mixed exposures. The BKMR and quantile-based g-computation models revealed a positive association between the mixture of BPA substitutes and precocious puberty. The odds ratio (OR) = 1.75 95% confidence interval (CI): 1.16, 2.76, p = 0.010, OR = 1.46, CI: 1.06, 2.06, p = 0.020, and OR = 1.67, CI: 1.18, 2.36, p = 0.007, respectively. The BKMR and quantile-based g-computation models revealed consistent associations for single-exposure and their non-insufficient evidence for the associations of the mixed exposure of bisphenols with precocious puberty. In conclusion, BPA substitutes such as BPS, TBBPA, and BPF, may be associated with an increased risk of precocious puberty in girls.	Toxics. 2023 Nov 6;11(11):905.	10.3390/toxics11110905	37995557	ヒト	生殖(思春期発達)	-	-	-	-	-	-	-	症例対照研究	1	1	-	-	-	-	1	1	1	-	-	-	-	-	-	-	-	-	-	-	-	-
統合_0757	F. M. Bigambo, J. Sun, C. Zhu, S. Zhang, Y. Xu, D. Wu, Y. Xia and X. Wang	2024	Gender- and Obesity-Specific Association of Co-Exposure to Personal Care Product and Plasticizing Chemicals and Short Sleep Duration among Adults: Evidence from the National Health and Nutrition Examination Survey 2011-2016	There is limited evidence about the gender- and obesity-specific effects of personal care product and plasticizing chemicals (PCPPCs) on short sleep duration in adults. We evaluated the gender- and obesity-specific association of co-exposure to PCPPCs and short sleep duration among adults aged 20-60 years using the National Health and Nutrition Examination Survey (NHANES) 2011-2016, a secondary data source from the United States. Seventeen PCPPCs, including five phenols, two parabens, and ten phthalates, were detected, and sleep duration was assessed among 3132 adults. Logistic regression, weighted quantile sum (WQS) regression and Bayesian kernel machine regression (BKMR) were employed. We found that bisphenol A (BPA), mono-2-ethyl-5-carboxypentyl phthalate (MECPP), and mono (3-carboxypropyl) phthalate (MCPP) were consistently positively associated with short sleep duration in both females and males, regardless of obesity status, except for BPA with general obesity. In particular, mono-benzyl phthalate (MBzP) revealed a positive association in females, while mono-(2-ethyl-5-oxohexyl) phthalate (MEOHP) revealed a positive association in males. Mixture models revealed consistent positive associations in females and males. Our study highlights that PCPPCs are independently associated with an increasing risk of short sleep duration in adults both individually and as a mixture; however, gender- and obesity-specific differences may have little effect on certain individual PCPPCs on short sleep duration. 統合_0758	F. M. Bigambo, H. Sun, W. Yan, D. Wu, Y. Xia, X. Wang and X. Wang	2020	Association between phenols exposure and earlier puberty in children: A systematic review and meta-analysis	OBJECTIVE: To identify the association between phenolic chemicals and the risk of earlier puberty based on the available evidence by systematic review and meta-analysis. METHODS: Databases PubMed, Web of Science, and Cochrane Library were searched and retrieved appropriate journal articles, on the association between phenols exposure and earlier puberty in children published before February 10, 2020. Data software Review Manager 5.3 and Stata/SE 15.1 were used for analysis. RESULTS: Eight articles were included in the meta-analysis, which involved 3,884 children. Bisphenol A has shown the association between 2, 5- dichlorophenol exposure, and earlier puberty in children with either sex (RR: 1.12, 95% CI: 1.06, 1.18). Exposed to children with other phenols such as bisphenol S, Triclosan, Benzophenone-3 were not statistically significant associated with the risk of earlier puberty in children with the overall pooled outcomes of RR of 1.09 (95%CI: 0.88, 1.35), 1.15 (95% CI: 0.98, 1.35), and 1.10 (95% CI: 0.88, 1.38) respectively. CONCLUSION: Our results portray that phenols particularly 2, 5- dichlorophenol exposure might be associated with the risk of earlier puberty in children. Also, caution should be taken to other type of phenolic chemicals since in subgroup analysis some individual studies have shown a positive relationship between bisphenol A, Triclosan and Benzophenone-3 exposures, and the risk of earlier puberty in children. Future cohort studies should be conducted with more sample sizes to determine the relationship between 2, 5- dichlorophenol, and the risk of earlier puberty in children of all genders. 統合_0759	F. M. Bigambo, Z. Chen, W. Yang, Q. Huang and X. Wang	2024	The effect of bisphenols on sex and thyroid hormone concentrations in cord blood among newborns	This study aims to investigate the associations of bisphenols, with sex and thyroid hormones in cord blood among newborns. Four bisphenols, three hormones related to gonadal function, and four parameters related to thyroid function were measured in umbilical cord blood in 339 mother-newborn pairs. Multivariable linear regression, quantile-based g-computation (QGC), and Bayesian kernel machine regression were used. In the multivariable linear regression, bisphenol S (BPS) was associated with increased testosterone (T) (regression coefficient, β = 0.009, 95% confidence interval, CI: 0.003,0.015), p = 0.007) and free-T- (adsorption-FT4) (β = 0.009, 95% CI: 0.002, 0.016, p = 0.009) in male newborns. Bisphenol A (BPA) (β = 0.007, 95% CI: 0.001, 0.013, p = 0.027) and BPS (β = 0.007, 95% CI: 0.001, 0.013, p = 0.027) was observed in females, and bisphenol AF (BPAF) was associated with decreased follicle-stimulating hormone (FSH) in females. These associations were also observed in mixture of bisphenols. Moreover, we observed maternal prepregnancy body mass index (BMI) and delivery mode disparity in the relationship between bisphenols and sex and thyroid hormones. This study suggests that bisphenols may exert effects on sex and thyroid hormones. In newborns, the effect may vary with sex differences, maternal prepregnancy BMI, and delivery mode. He	2022	Association of serum bisphenol A levels with incident overweight and obesity risk and the mediating effect of adiponectin	BACKGROUND: Existing cross-sectional studies indicated a positive association of bisphenol A (BPA) with overweight and obesity. However, the relationship and potential mechanisms underlying this association remain to be elucidated in prospective studies. OBJECTIVE: This study was designed to explore whether serum BPA is associated with incident overweight and obesity risk, and to further explore whether adiponectin plays a mediating role in the association. METHODS: We measured blood BPA and adiponectin in Chinese populations. The association of serum BPA with overweight and obesity risk was evaluated using multivariable logistic regression models. We further examined the mediating effects of adiponectin by causal mediation analysis. RESULTS: Among 796 participants free of overweight and obesity at baseline, 320 individuals developed overweight and obesity during the follow-up period. Compared with those in the lowest quartile of serum BPA, those in the second and third quartiles were positively associated with incident overweight and obesity risk after adjustment for confounders [OR (95% CI): 1.60 (1.04, 2.46) and 1.66 (1.08, 2.56), respectively]. Adiponectin mediated 18.8% (95% CI: 2.1%, 35.5%) of the association between BPA and overweight and obesity. Furthermore, each unit of serum lg(10)-transformed BPA levels was associated with higher changes in waist-to-height ratio and body mass index (all P-values < 0.05). Mediation analysis indicated significant indirect effects of adiponectin on the associations of BPA with overweight and obesity prevalence (mediation proportion: 66.88%, P = 0.027, and 38.8% levels (mediation proportion: 30.31%, P = 0.031). CONCLUSION: Serum BPA displayed a positive association with incident overweight and obesity risk in our menopausal women, and adiponectin might mediate the association. Further mechanistic studies are warranted.	Chemosphere. 2022 Dec;308(Pt 2):136287.	10.1016/j.chemosphere.2022.136287	36084821	ヒト	代謝	-	-	-	-	-	-	-	コホート研究	1	1	-	-	-	-	1	1	1	-	-	-	-	-	-	-	-	-	-	-	-	-
統合_0762	K. Belut, O. Tuby, B. T. Neelihan, O. Mustafa and T. Nurat	2022	The effect of training about environmental toxicant Bisphenol-A exposure in pregnancy on maternal urine Bisphenol-A level	PURPOSE: Bisphenol A (BPA) is an environmental toxic, clearly capable of initiating epigenetic modifications, leading to the development of numerous human illnesses such as; metabolic, reproductive, and behavioral abnormalities. It also causes oxidative stress, which has been shown to be alleviated by selenium supplementation. The purpose of this study was to determine the effect of training of BPA exposure during pregnancy on urine BPA levels. METHODS: This research enrolled 30 pregnant women who were in their first trimester and were free of chronic illness. Women were asked questions on their sociodemographic features, anthropometric measures, obstetric characteristics, BPA awareness level, BPA exposure and the Health Practices in Pregnancy Exercise Scale as a "Pre-test and Post-Test." Then, the participants were taken to women in their first trimester and stored in BPA free bags. Then, training was delivered to encourage BPA exposure reduction and maternal health awareness. Prior trimester face-to-face instruction and brochure distribution were used to provide training. Urine samples were collected from participants before training and one month after training. Urine BPA concentrations were measured using the liquid chromatography mass spectrometry-mass spectrometry (LC-MS/MS) method. Each person's urine concentration was calculated and compared to the BPA content. RESULTS: Our study shows that BPA exposure may be lowered by training. It has been demonstrated that reducing BPA exposure and increasing knowledge can result in an improvement in health status. Additionally, it has been demonstrated that trainings greatly minimize exposure-causing behaviours. CONCLUSION: It was discovered that while the duration of a single training does not make a meaningful effect, the continuing of reminder trainings did make a substantial difference in the urine BPA level. Wise	2020	Correlates of exposure to phenols, parabens, and triclocarban in the Study of Environment, Lifestyle and Fibroids	We performed a cross-sectional analysis to identify correlates of urinary concentrations of seven phenols (bisphenols A, F, and S; 2,5-dichlorophenol; 2,4-dichlorophenol; benzophenone-3; triclosan), triclocarban, and four parabens (butyl, ethyl, methyl, and propyl). We analyzed baseline data from 784 participants in the Study of Environment, Lifestyle, and Fibroids, a prospective cohort study of 1693 Black women aged 23-35 years enrolled in Detroit, Michigan (2010-2012). We collected data on demographic, behavioral, and anthropometric factors via telephone interviews, clinic visits, and self-administered questionnaires. For each biomarker, we used multivariable linear regression to estimate percent differences in geometric mean concentrations comparing participants in each category of correlates to the reference group. Urinary concentrations were highest for methyl paraben (1424 μg/g creatinine), propyl paraben (244 μg/g creatinine), and benzophenone-3 (112 μg/g creatinine). Sociodemographic correlates of biomarker concentrations included season of urine collection, education, and body mass index (BMI). BMI was positively associated with bisphenol A and S and triclocarban concentrations and inversely associated with butyl and methyl paraben concentrations. In this cohort of Black women, exposure to phenols, parabens, and triclocarban was prevalent and several factors were associated with biomarker concentrations. 統合_0764	K. Berger, C. Hyland, J. L. Ames, A. M. Mora, K. Huen, B. Eskenazi, N. Holland and K. G. Harley	2021	Prenatal Exposure to Mixtures of Phthalates, Parabens, and Other Phenols and Obesity in Five-Year-Olds in the CHAMACOS Cohort	Exposures to phthalates, parabens, and other phenols are often correlated due to their ubiquitous use in personal care products and plastics. Examining these compounds as a complex mixture may clarify inconsistent relationships between individual chemicals and childhood adiposity. Using data from the Center for the Health Assessment of Mothers and Children of Salinas (CHAMACOS) study, a longitudinal cohort of children in Salinas Valley, California (n = 309), we examined biomarkers of 11 phthalate metabolites and 9 phenols, including several parabens and bisphenol A, measured in maternal urine at two time points during pregnancy. We measured child height and weight at age five to calculate the body mass index (BMI) z-scores and overweight/obesity status. The association between prenatal urinary concentrations of biomarkers with the childhood BMI z-score and overweight/obesity status was analyzed using single-pollutant models and two mixture methods: Bayesian hierarchical modeling (BHM) and Bayesian kernel machine regression (BKMR). Urinary biomarkers were associated with higher BMI z-score and overweight/obesity status in girls, but not boys. Positive associations were observed between the sum of medium-chain phthalates and BMI z-score and overweight/obesity status across all modeling approaches. Higher prenatal exposures to the cumulative biomarker mixture also trended with greater childhood adiposity. These results, robust across two methods that control for co-pollutant confounding, suggest that prenatal exposure to certain phthalates and parabens may increase the risk for obesity in early childhood. Harley	2020	Prenatal phthalate, paraben, and phenol exposure and childhood allergic and respiratory outcomes: Evaluating exposure to chemical mixtures	MACHADINUNG: Chemicals found in personal care products and plastics have been associated with asthma, allergies, and lung function, but methods to address real-life exposure to mixtures of these chemicals have not been applied in these associations. METHODS: We quantified urinary concentrations of eleven phthalate metabolites, four parabens, and five other phenols in mothers twice during pregnancy and assessed probable asthma, allergies, and lung function in their children at 3 and 5 years of age in the CHAMACOS cohort (Salinas Valley, California). We used quantile g-computation to estimate associations between exposure mixtures and outcomes measurements. We used Bayesian Kernel Machine Regression (BKMR) to fit exposure-response functions. We ran models for each independent variables. RESULTS: BPA showed inconsistent associations with outcomes. Some associations were observed between patterns of personal care product and plastic use, though there were no significant differences in outcomes across clusters. BKMR showed that monoethyloxoheptyl phthalate and 2,5-dichlorophenol were associated with wheeze at 5 years of age. Specifically, a joint increase per IQR of biomarker + score (standard deviation) = 0.89 (0.68, and 0.11 (0.22), respectively) and across lung function (predicted probability per IQR = -0.02 (-0.04, and -0.07 -0.06), respectively) and that mostly contributed by BPA. Phthalate and bisphenol A were associated with wheezing for (predicted probability per IQR = -0.11 (0.04) and 0.11 (0.06), respectively). Several biomarkers demonstrated positive additive effects on other associations. CONCLUSIONS: BPA and BKMR are useful tools to evaluate associations of biomarker concentrations within a mixture of exposure and should supplement single-chemical regression models when data allow. Björkman	2019	Bisphenol A in human saliva and urine before and after treatment with dental polymer-based restorative materials	The aim of this study was to quantify bisphenol A (BPA) concentrations in saliva and urine before and after treatment with dental polymer based restorative materials to assess if placement of this material is associated with increased BPA levels in saliva and urine. Twenty individuals in need of at least one dental restoration received composite resin restorative material were included in the study. The participants were instructed to abstain from eating, drinking, and brushing their teeth for at least 12 h prior to sampling. Saliva and urine were collected before and 10 min (saliva only), 1 h, 24 h, and 1 wk after treatment. Samples were stored at -80° C before analysis. BPA in saliva and urine was determined with liquid chromatography-mass spectrometry. Linear mixed-effects regression models were used for statistical analyses. There was a statistically significant increase of salivary BPA concentrations shortly after placement of the dental polymer-based restorations. Following placement, the concentrations of BPA decreased exponentially with time. One week after treatment the BPA level in saliva was only marginally higher than before treatment. In urine, no statistically significant change of the BPA concentration was detected after treatment. Toft	2021	Urinary Bisphenol A, F and S Levels and Semen Quality in Young Adult Danish Men	Bisphenol A (BPA) is considered an endocrine disruptor and has been associated with deleterious effects on spermatogenesis and male fertility. Bisphenol F (BPF) and S (BPS) are structurally similar to BPA, but knowledge of their effects on male fertility remains limited. In this cross-sectional study, we investigated the associations between exposure to BPA, BPF, and BPS and semen quality in 904 men (18-29 years of age from the general Danish population. Urinary BPA, BPF, and BPS concentrations were measured by liquid chromatography-tandem mass spectrometry. Semen quality was assessed by standard semen analysis (sperm concentration, total sperm count, sperm motility, and sperm morphology). Associations between urinary bisphenol levels (continuous and quartiles) and semen quality were estimated using a negative binomial regression model adjusting for urine creatinine concentration, alcohol intake, smoking status, body mass index (BMI), fever, sexual abstinence time, maternal pre-pregnancy BMI, and first trimester smoking, and highest parental education during first trimester. We found no associations between urinary bisphenol of semen quality in a sample of young men from the general Danish population	Int J Environ Res Public Health Vol.18 Issue 4	10.3390/ijerph18041742	33670148	ヒト	-	1	1	-	-	-	-	横断研究	1	1	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-
統合_0768	V. Bellisario, E. Cocchi, R. Tassinari, G. Squillacioti, T. Munno, S. Settembre, M. Zorzi, P. Dalmasso, A. Cascio, C. Medana and R. Bono	2021	Bisphenol A and S in the Urine of Newborns: Plastic for Non-Food Use Still without Rules	The aim of the present study was to assess the effects of bisphenol (BP) exposure on pregnancy and neonatal life. We had 1st determined BP (BPA and BPS) concentration levels in a group of newborns and their mothers living in Turin (Italy). Urine samples were collected from 100 mothers (T1, T2, and T3) and from their newborns (cord blood and urine). Urinary BP concentrations were determined by solid-phase extraction and liquid chromatography–tandem mass spectrometry. Concentration levels, in newborns, positive correlations between cord blood and BPS (r-sq = 0.33) and between BPS (r = 0.43) concentrations were detected. A significant correlation between cord blood BPS concentrations and administration and concentration levels of liver BPS (p < 0.05). Our study points to a central role of lifestyle, hospital procedures, and neonatal devices in inducing BP exposure, especially during the perinatal period. This is the first report of BP contamination in newborns due to elderly-care alimentary products designed for newborn care, such as glucose-solution containers for BPA and pacifiers for BPS. Further studies are advocated in order to clarify both the impact of other BP forms on human health and development, as well as potential BPS exposure sources during neonatal and childhood life. 統合_0769	A. L. Back, E. V. Bilsteer, C. S. Uldbjerg, Y. H. Lim, H. Bogh, H. Frederiksen, A. M. Andersson and T. K. Jensen	2025	Maternal urinary concentrations of bisphenol A during pregnancy and birth size in children from the Odense Child Cohort	MACHADINUNG: Bisphenol A (BPA) is widely used in the manufacturing of plastics. BPA can pass the placental barrier and influence fetal development. Due to its estrogenic and anti-androgenic properties, BPA may contribute to sex-specific differences in developmental effects. We examined associations between maternal urinary concentrations of BPA and birth size. METHODS: In this cohort study of 893 mother–child pairs from the Odense Child Cohort, pregnant women provided spot urine samples at gestational week 28, which were analyzed for BPA by isotope diluted LC-MS/MS. Genetically adjusted urinary BPA concentrations were categorized into quartiles. Mother–child characteristics were obtained from hospital records and questionnaires. Linear regression models were used to estimate the association between BPA and offspring birth weight, length, head, and abdominal circumference] were performed for the full cohort and stratified by offspring sex. RESULTS: BPA was detected above the limit of detection in 86% of the urine samples, with a median concentration of 1.1 µg/L. The highest quartile of maternal BPA concentrations was associated with a 0.16 SD (95% CI: 0.01, 0.31) lower birth weight SDS in boys compared to the lowest quartile. No association was observed among girls. Maternal BPA was not associated with birth length, head, or abdominal circumference. In sex-stratified analyses, statistically significant decreases in birth weight were observed among offspring in the highest quartile of maternal urinary BPA concentrations (Q3: -116 g, 95% CI: -225, -5; p = 0.04) compared to mothers offspring of the lowest quartile and a possible dose–response association was suggested (p-trend = 0.08). No statistically significant associations were observed for birth weight amongst female offspring. CONCLUSIONS: Our findings suggest a negative association between maternal urinary BPA exposure and birth weight, driven by a lower birth weight in male offspring. Further research is required to explore the underlying mechanisms of BPA's possible sex-specific associations. 統合_0770	S. Baykal and A. Nalbantoğlu	2023	An Examination of the Relationship Between Exposure to Bisphenol A and Attention-Deficit/Hyperactivity Disorder in Children and Adolescents	OBJECTIVES: Exposure to environmental toxic agents in the prenatal and/or postnatal periods may play in the acquired development of attention-deficit/hyperactivity disorder (ADHD) in groups with genetic risks. Bisphenol A (BPA) is a widely used industrial chemical with endocrinedisruptive effects. This study examined the relationship between exposure to BPA and clinical ADHD. METHODS: This cross-sectional, case-controlled clinical study compared 33 drug-naive children and adolescents with ADHD and 30 healthy controls in terms of serum BPA levels. Psychiatric comorbidities in the ADHD group were determined using the "Schedule for Affective Disorders and Schizophrenia for school-aged children, lifetime version." The Child Behavior Checklist (CBCL) tests was administered to all participants. RESULTS: Serum BPA levels were significantly higher in the ADHD group than in the healthy control group. In addition, significant, weak, positive correlations were found between BPA levels and CBCL attention and CBCL total problem scores. CONCLUSIONS: Our results show that BPA exposure may be a potential toxic agent with a potential role in the etiology of ADHD and particularly attention deficiency. Preventive interventions can be developed if this can be confirmed with longitudinal studies and repeated measurements. 統合_0771	B. Barajas, Á. Meléndez-Ortega, L. López-Carrillo and M. E. Cebrián	2025	Urinary concentrations of total and free bisphenol A and daily intake estimation in northern Mexican women	Bisphenol A (BPA) is a component of polycarbonates used to manufacture plastic reusable bottles and miscellaneous containers; it is a constituent of epoxy resins used for the internal coating of beverage cans. Humans are mainly exposed by ingesting contaminated food and beverages. Experimental and human studies reported diverse health problems associated with BPA. Our objectives were to measure free (FBPA) and total (TBPA) urinary levels, to estimate daily BPA intake, and to investigate sources of exposure in northern Mexican women. This study is a secondary cross-sectional analysis. In controls (n = 281) participating in a population-based case-control study, TBPA and FBPA were measured in first-morning urine samples by ultra-performance liquid chromatography–tandem mass spectrometry. BPA was detected in 100% of samples conducted in July 2009. ESHYDRO/IMSS. Urinary BPA levels were quantified using either external calibration—applied to high-performance liquid chromatography instruments—or isotope dilution (IDMS) for gas chromatography–mass spectrometry. BPA ELECTRONIC AND MEASUREMENTS. Mainstay from all causes, cardiovascular disease, and cancer. RESULTS: This cohort study included 1882 adults aged 20 years or older who participated in the US National Health and Nutrition Examination Survey (NHANES) 2003-2004 and 2005-2006 and had complete data on BPA and mortality. BPA was detected in 93.3% of participants' urine samples. Higher urinary BPA levels were associated with higher risk for death. After adjustment for age, sex, race/ethnicity, socioeconomic status, drinker and lifestyle factors, and urinary creatinine levels, a 1-unit increase in log-transformed BPA was associated with a 1.09 (95% CI, 1.01-1.19) for all-cause mortality; 1.09 (95% CI, 0.97-1.21) for cardiovascular disease mortality, and 1.08 (95% CI, 0.92-1.26) for cancer mortality. CONCLUSIONS AND RELEVANCE: In this nationally representative cohort of US adults, higher BPA exposure was significantly associated with an increased risk of all-cause mortality. Further studies are needed to replicate these findings in other populations and determine the underlying mechanisms. 統合_0772	W. Bao, B. Liu, S. Rong, S. Y. Dai, L. Trasande and H. J. Lehmler	2020	Association Between Bisphenol A Exposure and Risk of All-Cause and Cause-Specific Mortality in US Adults	IMPORTANCE: Bisphenol A (BPA) is a major public health concern because of its high-volume industrial production, ubiquitous exposure to humans, and potential toxic effects on multiple organs and systems in humans. However, prospective studies reporting the association of BPA exposure with long-term health outcomes are sparse. OBJECTIVE: To examine the association of BPA exposure with all-cause mortality and cause-specific mortality among adults in the United States. DESIGN, SETTING, AND PARTICIPANTS: This nationally representative cohort study included 1882 adults aged 20 years or older who participated in the US National Health and Nutrition Examination Survey (NHANES) 2003-2004 and 2005-2006 and had complete data on BPA and mortality. BPA was detected in 93.3% of participants' urine samples. EXPOSURES: Urinary BPA levels were quantified using either external calibration—applied to high-performance liquid chromatography instruments—or isotope dilution (IDMS) for gas chromatography–mass spectrometry. MAIN OUTCOMES AND MEASURES: Mortality from all causes, cardiovascular disease, and cancer. RESULTS: This cohort study included 1882 adults aged 20 years or older (weighted mean [SE] age, 43.6 [0.5] years; 2022 [51.2%] women; 1328 [70.6%] non-Hispanic White participants). The geometric mean (SE) urinary BPA level was 2.1 (0.1) ng/mL. After a median follow-up of 10.8 years, 178 participants died. Participants with higher urinary BPA levels were at higher risk for death. After adjustment for age, sex, race/ethnicity, socioeconomic status, drinker and lifestyle factors, and urinary creatinine levels, a 1-unit increase in log-transformed BPA was associated with a higher risk for all-cause mortality (1.09 [95% CI, 1.01-1.19] for all-cause mortality; 1.09 [95% CI, 0.97-1.21] for cardiovascular disease mortality, and 1.08 [95% CI, 0.92-1.26] for cancer mortality; CONCLUSIONS AND RELEVANCE: In this nationally representative cohort of US adults, higher BPA exposure was significantly associated with an increased risk of all-cause mortality. Further studies are needed to replicate these findings in other populations and determine the underlying mechanisms. 統合_0773	B. D. Bagley, J. N. Smith and J. G. Teeguarden	2021	Risk assessment of predicted serum concentrations of bisphenol A in children and adults following treatment with dental composite restoratives, dental sealants, or orthodontic adhesives using physiologically based pharmacokinetic modeling	Bisphenol A (BPA) is a chemical used to manufacture bisphenol A glycidyl methacrylate (BisGMA). BisGMA has been used for decades in dental composite restoratives, sealants, and adhesives. Based on published studies, exposure to low concentrations of BPA are possible from dental and orthodontic devices. The current BPA concentrations arising from such devices are not known and existing PBPK model in children and adult females lacked in 1) published extraction data for cured and uncured 3M ESPE Filtek Supreme Ultra/Tetric, 3M ESPE Filtek Bulk Fill Restorative, and 3M ESPE Clinpro Sealant and 2) published 28% conversion of BisGMA to BPA. Physiologically based pharmacokinetic (PBPK) models were developed for children and adult females exposed to BPA from dental composite restoratives, dental sealants, or orthodontic devices to two median (50 kg treatment) and medium serum BPA concentrations were less than 1 nM (0.46). Even the maximum predicted exposure (<4% steady-state (SS) % of treatment) yields a margin of exposure of 7.5 relative to the FDA's TDI (5 µg/kg/day) and is only 2.8% of the daily BPA exposure for the US population in a 50 kg woman (11,000 ng/day). Therefore, the exposure to BPA arising from the 3M ESPE dental and orthodontic devices evaluated in this study is negligible relative to daily BPA exposure in the general population and these potential BPA sources do not contribute a risk to patients. 統合_0774	N. Aytac Bektas, N. N. Yenigul, K. Paksoy, B. Dincgez, E. Yuce Bilgin, Y. Usluoglugil and E. Ucturk yurt	2024	Does Bisphenol-A play a role in the development of nasural tube defects?	OBJECTIVE: In this study, we aimed to evaluate BPA levels in the maternal serum and amniotic fluid of patients diagnosed with NTD. In addition, we wanted to investigate the relationship between neurodevelopmental defects, such as neural tube defects (NTD) and BPA levels. STUDY DESIGN: This prospective observational study was carried out at Bursa Yüksek Ihtisas Training and Research Hospital between April 01, 2021, and April 30, 2022. The study consisted of 50 patients between the ages of 18-45 who had an amniocentesis at 15-20 weeks of gestation. The patients were divided into two groups according to the indications of amniocentesis. Group 1 (n = 25) consisted of patients who had an amniocentesis for NTD, and Group 2 (n = 25) consisted of patients who had an amniocentesis for a non-NTD pre-diagnosis of NTD (if patients). The first 5 cc fluids and maternal serum samples taken during the amniocentesis procedure of all patients were delivered to the biochemistry laboratory. The BPA values between groups were compared. RESULTS: A statistically significant difference was found between the two groups in terms of amniotic fluid BPA levels (36.68 (19.60-60.30) and 38.87 (24.62-75.87)) and maternal blood BPA levels (22.51 (12.80-230) and 47.81 (13.04-219.30)). In cases with NTD, amniotic fluid BPA levels and maternal blood BPA levels were significantly higher than the control group. When ROC values were compared, the AFP numerical values are higher than the maternal blood BPA levels. CONCLUSION: Plastics, which is indispensable for modern life, may negatively affect fetal development in intrauterine life. The data in this study note that high maternal blood BPA may be associated with NTD. 統合_0775	G. Ayar, S. S. Yalçın, A. Yıldız, S. Emekci, A. Balcı and P. Ekekoğlu	2022	Associations between pediatric intensive care procedures and urinary free-BPA levels	MACHADINUNG: Bisphenol A (BPA) is found in many medical materials used in the paediatric intensive care unit (PICU). Our aim was to evaluate how the urinary free-BPA(BPA) and total-BPA(tBPA) levels were associated with the use of medical devices in the PICU in a prospective study. METHODS: The procedures applied to the patient were recorded during the follow-up period. Three urine samples were taken on the first day of hospitalization, the second day, and after 30 days or on the patients were discharged. Urinary tBPA and free-BPA levels were determined using high-pressure liquid chromatography. Generalized estimating equations with repetitive measures were used to determine the associations between PICU procedures and BPA levels. RESULTS: A total of 131 urine samples of 50 children were studied. Mean urinary levels were 1842.7 µg/g creatinine for tBPA and 1.5 µg/g creatinine for free-BPA. The urinary tBPA concentrations were significantly higher than the urinary free-BPA concentrations (median [IQR]: 1842.7 [1010.1-3744.6] versus 1.5 [0.8-2.8] µg/g creatinine, p < 0.001). Urinary tBPA levels and maternal blood BPA levels were significantly higher than the control groups. When ROC values were compared, the tBPA numerical values are higher than the maternal blood BPA levels. CONCLUSIONS: Plastics, which is indispensable for modern life, may negatively affect fetal development in intrauterine life. The data in this study note that high maternal blood BPA may be associated with NTD. 統合_0777	S. Arya, A. K. Dwivedi, L. L. Alvarado and S. Kuzenko-Plevski	2020	Exposure of U.S. population to endocrine disruptive chemicals (Parabens, Benzophenone-3, Bisphenol-A and Triclosan) and their associations with female infertility	Ubiquitous exposure to endocrine disruptive chemicals (EDC) among women of reproductive age is alarming. Exposure to EDCs, could be contributing to infertility. We determined the association between common EDCs, and infertility among women in the U.S. A total of 1,455 women (ages 18-44 years) from National Health and Nutrition Examination Survey (NHANES) 2013-2014 with complete data on infertility and urinary EDCs of age-women was conducted. Multiple regression sociodemographic variables, and urinary concentrations of parabens (methyl paraben [MP], ethyl paraben [EP], propyl paraben [PP], and butyl paraben [BP]), Benzophenone-3 (BP-3), Bisphenol-A (BPA), and triclosan (TCC) were obtained from the NHANES databases. Clustering among EDCs, were obtained using variable cluster analysis. Relative risk regression models were used to estimate associations of individual and combined EDCs with self-reported infertility after applying appropriate survey weights to account for the complex survey design as well as to compensate for the four-year cycle. Results were summarized using prevalence ratio (PR) with 95% confidence interval (CI). Of total 786 individuals included in the study, 14% (95%CI: 12%-18%) had infertility. MP and PP were detected in 99% of urine samples. BP-3, BPA, and TCC were detected in 96%, 93%, and 83% of urine samples, respectively. Women with infertility had higher urinary MP (PR: 1.07; p = 0.0001), PP (PR: 1.06; p = 0.0001), BP (PR: 1.01; p = 0.029) even after adjusting for potential confounders. Our results suggested that MP and mixtures of hexadecimals, TCC, and BPA were associated with infertility among the U.S. women. However, because of the limitations inherent to the cross-sectional study design, prospective cohort studies are warranted to confirm these findings. 統合_0778	F. Artacho-Cordón, S. Rios-Arrabal, J. León, H. Frederiksen, J. M. Sáenz, P. Martín-Olmedo, M. F. Fernández, N. Olea and I. P. Arrebola	2019	Adipose tissue concentrations of non-persistent environmental phenols and local redox balance in adults from Southern Spain	The aim was to evaluate the associations of environmental phenol and paraben concentrations with the oxidative microenvironment in adipose tissue. This study was conducted in a subsample (n = 162) of the Andalusian Center (Southern Spain). Concentrations of 4 phenols and 7 parabens, and levels of oxidative stress biomarkers were quantified in adipose tissue. Associations were estimated using multivariable linear regression models. Concentrations of benzylparaben (BzP) were associated with lower concentrations of glutathione disulfide (GSSG) (beta (β) = -0.35; p = 0.030). Concentrations of 2 phenols, 4 parabens, and BzP were associated with lower reduced glutathione (GSH) (beta (β) = -0.66, -0.31, -0.31, -0.32, -0.32, -0.32, and -0.31; p = 0.030). Concentrations of bisphenol A (BPA) and methylparaben (MeP) were associated to lower glutathione reductase (GR) activity (beta (β) = -0.66, and β = -0.71, respectively), and BPA was borderline associated to increased levels of oxidized glutathione (GSSG) (beta (β) = 0.73; p-value = 0.062). MeP was inversely associated to both homoisoprostane (2-iso)- (β and superoxide dismutase (SOD) activity, as well as to the levels of thiobarbituric acid reactive substances (TBARS) (β: 0.76 ; and β = 0.76). Our results suggest that some specific non-persistent pollutants may be associated with a disruption of the activity of relevant antioxidant enzymes, in addition to the depletion of the glutathione stock. They might act as a tissue-specific source of free radicals, contributing to the oxidative microenvironment in the adipose tissue. 統合_0779	J. Ao, W. Zhu, W. Jiang, X. Zeng, W. Qiu, S. Yin, W. Wang and J. Zhang	2024	The mixture of non-persistent endocrine-disrupting chemicals in relation to endometriosis	Non-persistent endocrine-disrupting chemicals (EDCs) are of significant concern due to their reproductive toxicity. Previous research reported a relationship between a single type of EDCs and endometriosis. Yet, evidence regarding mixed exposure of multiple categories of EDCs is scarce. Between 2010 and 2018, our hospital-based case-control study recruited 258 endometriosis cases and 258 age-matched controls in China. Seventeen non-persistent EDCs (phthalates and bisphenols) were measured in urine. The association of single EDC with endometriosis was estimated using logistic regression, while the association of EDC mixtures was assessed using weighted quantile sum regression (WQS) and Bayesian kernel machine regression (BKMR). Single-pollutant analysis showed that urinary mono-(2-ethyl-5-hydroxyhexyl) phthalate (MEHHP) was observed in both single- and mixture models, where phthalates and bisphenols were associated with increased risk of endometriosis. Inverse effect, adjusted odds ratios (aOR): 1.61, 1.23-2.10) and the major contributor were bisphenol A (BPA) and the metabolite of di(2-ethylhexyl) phthalate (DEHP). Interaction analysis showed that bisphenols exhibited significant synergistic interactions with phthalates. Our results suggest that non-persistent EDCs are associated with endometriosis, but the underlying mechanisms remain to be elucidated. Our finding may have important public health implications in preventing endometriosis. 統合_0780	J. Ao, Y. Wang, W. Tang, R. Aimuzi, K. Luo, Y. Tian, Q. Zhang and J. Zhang	2022	Patterns of environmental exposure to phenols in couples who plan to become pregnant	Phenols are widely used in consumer products and known for their reproductive toxicities. Little is known regarding the environmental exposure to phenols in couples prior to conception, a key period affecting fertility. We measured the urinary concentrations of six parabens and seven bisphenols in 982 pre-conceptive couples in China. We investigated the occurrence, distribution, source and health risk of phenols, in bisexuals and cross-separately, and the correlation and difference in phenol concentrations between couples. Similar distribution profiles of urinary phenols were observed between females and males. Methyl-4-hydroxybenzoate (MeP) and bisphenol A (BPA) were predominant parabens and bisphenols, with detection frequencies of 99.8% and 97.2%, median concentrations of 32.5 and 1.10 μg/L, respectively, in females. The correlation between bisphenols in males and females were moderate (0.34-0.668), while the correlation between parabens was poor to moderate (0.209-0.561). Urinary BPA concentrations were higher than other phenols in females than male ($P < 0.05$). Urinary phenols in couples were associated with family income, type of drinking water and frequency of household cleaning. Household factors accounted for >13.3% of variance in phenol level between couples, suggesting that individual variations may be the major factor. Risk assessment showed that exposure to phenols posed a low hazard to 7.73% of the couples in our population. Our findings provide important evidence of environmental exposure to phenols in couples of child-bearing age. 統合_0781	J. Ao, X. Hui, J. Zhang, Y. Miao, G. Li, J. Yu, Y. Shi, F. Jin, S. Bao and J. Zhang	2022	Environmental exposure to bisphenol analogues and unexplained recurrent miscarriage: A case-control study	The use of bisphenol A (BPA) has been substantially limited since 2010 due to its toxicity to human health. A group of bisphenol analogues that are structurally similar to BPA have been developed as the alternatives and used widely. The reproductive toxicity of these emerging chemicals has caused substantial concerns in recent years. Whether bisphenol analogues affect miscarriage is unclear, especially unexplained recurrent miscarriage (URM). remains to be explored. We conducted a hospital-based, case-control study with 1180 URM cases and 571 controls in China from 2013 to 2016. Concentrations of six bisphenol analogues (BPA, BPAF, BPAP, BPB, BPF and BPS) were measured in the urine samples collected at median intervals of 7.0 months after the last menstrual period (range: 3.0, 14.7 months). Multivariate logistic regression models were used to estimate the associations of bisphenol analogues (BPA/BPS and quartile or nonquartile 1[a grams] were used to assess the relationship of bisphenol analogues with URM risk. We observed significantly higher levels of all urinary bisphenols in the cases than the controls (all $P < 0.001$). Urinary bisphenol concentrations were positively associated with URM risk in a dose-dependent manner. Women in the highest quartile of BPA, BPAF, BPAP, BPB, BPF and BPS quartiles with URM. The mixed exposure of six bisphenol analogues was positively associated with the risk of URM (adjusted odds ratio (aOR) = 1.25, 1.11-1.42), which was driven by BPAP (46.1%), BPAF (25.1%) and BPS (14.8%). After age stratification, the risks tended to be higher in women aged 30 years or older, compared to women < 30 years. Our large case-control study indicates that environmental exposure to bisphenol analogues is associated with an increased risk of URM. Older women may be more vulnerable to the insult. 統合_0782	S. J. An, E. J. Yang, S. Oh, K. J. Park, T. Kim, Y. P. Hong and Y. J. Yang	2021	The association between urinary bisphenol A levels and nonalcoholic fatty liver disease in Korean adults: Korean National Environmental Health Survey (KoNEHS) 2015-2017	BACKGROUND: Nonalcoholic fatty liver disease (NAFLD) is becoming a global health problem. Bisphenol A (BPA), one of most widely used environmental chemicals, is suspected to be a contributor to the development of NAFLD. However, the association between BPA exposure and NAFLD is unclear. METHODS: In this cross-sectional study, we used data from 1,620 adults aged ≥ 19 years who participated in the Korean National Environmental Health Survey VI (2015-2017). BPA levels were measured in urine samples. NAFLD was defined using hepatic steatosis index and the absence of hepatitis. Multivariate logistic regression models were used to estimate the odds ratios (ORs) and 95% confidence intervals (CIs) for NAFLD according to urinary BPA concentrations. RESULTS: There was a significant linear relationship between the elevated urinary BPA concentrations and risk of NAFLD. In a univariate analysis, odds ratio (OR) of the highest quartile of urinary BPA level was 1.47 (95% confidence interval (CI): 1.11-1.96) compared to the lowest quartile. After adjusted OR in countries, the ORs for NAFLD in the third and fourth quartiles were 1.32 (95% CI: 1.01-1.72) and 1.32 (95% CI: 1.00-1.75), respectively. CONCLUSIONS: Urinary BPA levels are positively associated with the risk of NAFLD in adults. Further experimental studies are needed to understand the molecular mechanisms of BPA on NAFLD prevalence.	Environ Health Prev Med Vol.26 Issue 1 Pages 91	10.1186/s12199-021-01010-7	34521354	ヒト	-	-	-	-	-	-	横断研究	1	1	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-
統合_0783	M. M. Amin, Z. Ghassemi, M. Khoshhali, E. Tahvili, B. Dehdashti, A. Fakhrizadeh, N. Rafiei and R. Kelishadi	2021	Association of maternal exposure to bisphenol A with her β -hCG level and neonatal anthropometric measures	Bisphenol A (BPA) is one of the organic compounds that might interfere with estrogenic receptors, which could make difficulties in pregnancy hormones and fetal growth. Human chorionic gonadotropin (β -hCG) is one of the important pregnancy hormones that might be affected by environmental pollutants. The aim of this study is to investigate the probable impacts of maternal exposure to BPA on anthropometric measures of newborns and its association with maternal β -hCG level. METHODS: In this study, 200 pregnant women were recruited from Isfahan Birth Cohort Study (IBCS) in 2014. Urine samples of BPA and β -hCG were taken from them and newborns information were collected from participants of a birth cohort. BPA concentration was measured using gas chromatography-mass spectrometry (GC-MS). Second-trimester urine samples were collected and used for β -hCG analysis. Anthropometric measurements of neonates was conducted at the time of birth. BPA and β -hCG level were grouped by quartiles, and their associations with birth weight, height, and head circumference were tested using multiple linear regression model. The adjustment was done for urine creatinine, gender, and gestational age, as well as maternal age, body mass index, and education level. Data of 200 pairs of mothers and infants were available for the present study. The mean (SD) age of mothers was 29.26 (5.75) years; 50.5% of newborns were boys. Geometric mean of urinary BPA and β -hCG concentrations were 0.36 ng/g cree. Considered and 1.36 mIU/ml, respectively. The mean (SD) birth weight, height, and head circumference of newborns were 3.29 (0.46) kg, 49.61 (2.03) cm, and 34.23 (1.46) cm, respectively. No significant association existed between unadjusted and adjusted tertiles of BPA and β -hCG with abovementioned birth outcomes. It seems that the non-significant association found in this study is because of low levels of urinary BPA levels. Due to other studies, the adverse effects on infants might be related to high concentration of BPA passed from placenta. Future longitudinal studies with large sample size are necessary to document the adverse health effects of maternal exposure to endocrine disruptor chemicals, including BPA. 統合_0785	P. Altun Yildirim, E. Nacitarhan, Z. Haytoglu, I. Turan, B. Kilincli, A. A. Aydin, E. Mengen and N. Dogludas	2025	Evaluation of the Relationship Between Thyroid Hormone Levels and Bisphenol A in Children Aged 6-14 Years	BACKGROUND: The incidence of hypothyroidism in childhood is increasing. This study aimed to investigate the potential role of exposure to bisphenol A, an environmental endocrine disruptor, and its substitutes in the development of hypothyroidism. To this end, thyroid hormone levels and urinary bisphenol concentrations were compared in newly diagnosed hypothyroid children and a healthy control group. METHODS: In this case-control study, 51 newly diagnosed hypothyroid children aged 6-14 years were matched with 51 healthy controls. Free thyroxine (fT4) and thyroid-stimulating hormone (TSH) hormone levels were measured from fasting blood samples. Urinary bisphenol A, S, and F concentrations were determined and data for chemical exposure was obtained through a structured questionnaire used by Granada Living in a subsample of cases and controls. High-serum PSA levels were associated with a greater risk of PCa, while physical exercise appears to exert a protective effect against its development. In addition, elevated urinary levels of certain organic pollutants, such as benzo[a]pyrene (BaP), bisphenol A (BPA), and ethyl paraben (EPB), were associated with an increased risk of PCa. RESULTS: The mean fT4 level was found to be significantly lower in the hypothyroid group than in the control group (1.1 ± 0.2 ng/dL vs. 1.3 ± 0.1 ng/dL, $p < 0.001$). Urinary BPA levels were also significantly higher in the hypothyroid group (2.4 ± 1.6 µg/g creatinine vs. 1.7 ± 1.3 µg/g creatinine, $p = 0.013$). Receiver operating characteristic (ROC) analysis revealed that urinary BPA concentration was a significant predictor of hypothyroidism (AUC = 0.66, 95% CI: 0.54-0.78, $p = 0.013$). The optimal cut-off value for urinary BPA was determined as 1.3 µg/g creatinine, with a sensitivity of 72.5% and a specificity of 56.9%. Logistic regression analysis indicated that each 1 µg/g creatinine increase in urinary BPA was associated with a 1.4-fold increased risk of hypothyroidism (OR = 1.4, 95% CI: 1.1-1.8, $p = 0.006$). Urinary bisphenol S and F levels were not significantly different between the groups. CONCLUSIONS: Urinary BPA levels are positively associated with the risk of hypothyroidism in children. Further experimental studies are needed to understand the molecular mechanisms of BPA on thyroid function. 統合_0786	K. Almstrup, H. Fredriksen, A. M. Andersson and A. Juul	2020	Levels of endocrine-disrupting chemicals are associated with changes in the peri-pubertal epigenome	Puberty marks a transition period, which leads to the attainment of adult sexual maturity. Timing of puberty is a strongly heritable trait. However, large genetic association studies can only explain a fraction of the observed secular trends in pubertal timing. Endocrine-disrupting chemicals (EDCs) are suspected to contribute to the observed changes in pubertal timing. We investigated the association between urinary concentrations of 13 EDCs, including bisphenol A, benzophenone-3, 2,4-dichlorophenol, 11 alkylphenols and 11 metabolites from 6 phthalates in longitudinal urine samples obtained biannually from peri-pubertal children included in the COPENHAGEN puberty cohort. EDC levels were associated with blood DNA methylation profiles from 51 boys and 50 girls measured both pre- and post-puberty. We found little evidence of single methylation sites that on their own showed association with urinary secretion levels of EDCs, detected either the same day or measured up to the yearly interval of duration of peri-pubertal EDC levels. In contrast, methylation of promoter regions was found to be associated with time or mean EDCs, overlap with known gene-chemical interactions, and form a core network with genes known to be important for puberty. Furthermore, children with the highest yearly mean of dichlorinated urinary phthalate metabolites levels were associated with higher promoter methylation of the thyroid hormone receptor interactor 6 gene (TRIP6), which again was reversed by home cleaning TRIP6 serum levels. In general, the mean TRIP6 promoter methylation was elevated by circulating TRIP6 protein levels. Our results provide a potential molecular mode of action of how exposure to environmental chemicals may modify pubertal development. Karami	2024	Evaluation of novel biomarkers for early diagnosis of bisphenol A-induced coronary artery disease	INTRODUCTION: Bisphenol A (BPA), a ubiquitous synthetic monomer primarily used in the manufacture of polycarbonate plastic and epoxy resins and as a non-polymer additive to other plastics, can leach into the food and water supply and has been linked to cardiovascular disease (CVD). This study aimed to analyze BPA levels in patients with varying markers of coronary artery stenosis and evaluate the prognostic value of new biomarkers. cluster of differentiation 34 (CD34) and heart-type fatty acid-binding protein (H-FABP), respectively. Logistic and receiver-operator characteristic (ROC) curve analyses were used to assess the diagnostic value of BPA, CD34, and H-FABP. RESULTS: Eighty-nine patients with CAD and 30 healthy controls were enrolled in this study. Patients with CAD were divided into three groups based on the severity of coronary artery stenosis: mild, moderate, and severe. Compared with the healthy controls, the CAD patients had significantly higher levels of BPA, CD34, and H-FABP. Logistic regression analysis revealed that BPA, CD34, and H-FABP were significantly associated with CAD. Furthermore, ROC curve analysis revealed that BPA, CD34, and H-FABP had higher accuracy than troponin I and CK-MB in diagnosing CAD. Moreover, BPA, CD34, and H-FABP were significantly associated with the severity of coronary artery stenosis. Logistic regression analysis revealed that BPA, CD34, and H-FABP had higher accuracy than troponin I and CK-MB in diagnosing severe coronary artery stenosis. Logistic, scientific significant alterations were detected in age, sex, BMI, hypertension, diabetes, dyslipidemia, and smoking. BPA serum concentration significantly increased compared to normal subjects. CONCLUSIONS: Our study revealed that serum biomarkers were valuable for prognosticating myocardial injury. Among these, CD34 and H-FABP were more accurate. BPA concentration correlated with myocardial necrosis, underlying diseases, and occlusion stage, suggesting BPA's harmful effects. 統合_0788	H. T. Alhomaidan, N. Rasheed, S. Almatrafi, F. H. Al-Rashidi and Z. Rasheed	2019	Bisphenol A modified DNA: A possible immunogenic stimulus for anti-DNA autoantibodies in systemic lupus erythematosus	Anti-DNA antibodies are now considered as a universal diagnostic feature for the patients with systemic lupus erythematosus (SLE) but the mechanism(s) involved in the generation of these autoantibodies remains to be investigated. Bisphenol A (BPA) is a synthetic phenol extensively used in the manufacturing of polycarbonated plastics. Upon mixing in the diet, it causes several health hazards. This study was undertaken to investigate the contribution of BPA toward DNA damage in SLE patients. Human DNA was modified by BPA in vitro and the binding characteristics of SLE circulating immunoglobulin G (IgG) with BPA damaged DNA (BPA-DNA) were screened and compared with the IgGs from normal healthy humans. Only IgG1 immunogenicity of BPA-DNA was determined by immunoblot in rabbits. DNA from SLE patients (SLE-DNA) or healthy humans (H-DNA) was also modified by BPA in vitro and the binding of IgG1 with BPA-SLE-DNA and BPA-H-DNA was compared by indirect enzyme linked immunosorbent assay. Circulating SLE IgGs showed strong recognition of BPA-DNA. BPA-DNA induced high titre antibodies in rabbits. Rabbit anti-BPA-DNA IgG1 showed strong cross-reaction with isolated DNA from SLE patients. In short, we concluded that the structural alterations in DNA by BPA, generate neo-epitopes that may be a factor responsible for the induction of anti-DNA autoantibodies in SLE. McGarvey	2021	Association Between Gestational Exposure to Toxicants and Autistic Behaviors Using Bayesian Quantile Regression	Autism spectrum disorder, which is characterized by impaired social communication and stereotypic behaviors, affects 1% of children. Although prenatal exposure to toxicants has been associated with autistic behaviors, previous studies have focused on single chemicals. We used Bayesian quantile regression to estimate associations between prenatal exposure to a mixture of toxicants and autistic behaviors across the distribution of behaviors. We used data from the Maternal Adrenal Response to Environmental Chemicals study, a case-Canadian cohort (2008-2012). We measured metal, persistent, and nonpersistent chemical biomarkers in maternal urine samples collected during the first trimester of pregnancy. Using the Social Responsiveness Scale (SRS), in which higher scores denote more autistic-like behaviors, autistic behaviors were assessed in 378 children aged 6-9 years old. Lead, cadmium, and most phthalate metabolites were associated with mild increases in SRS scores at the 90th percentile of the SRS distribution. Manganese and some pesticides were associated with mild decreases. In SRS scores at the 90th percentile of the SRS distribution. We identified several monotonic trends. In which associations increased in magnitude from the bottom to the top of the SRS distribution. These results suggest that quantile regression can reveal nuanced relationships and, thus, should be more widely used by epidemiologists. 統合_0790	E. Aktag, K. Yurdakök, S. S. Yalçın and N. Kandemir	2021	Urinary bisphenol A levels in prepubertal children with exogenous obesity according to presence of metabolic syndrome	OBJECTIVES: Recent studies have shown a potential link between chronic exposure to Bisphenol A (BPA) and exogenous obesity, the prevalence of which has been increasing dramatically in all age groups and particularly in children. We aimed to investigate the urinary BPA levels in prepubertal children with exogenous obesity according to the presence of metabolic syndrome (MetS). METHODS: A total of 82 pre-pubertal children with exogenous obesity (mean 17 of them having metabolic syndrome attending Hacettepe University Ihsan Dagcinoglu Children's Hospital were included in this study. The control group consisted of 30 age- and sex-matched healthy children with no significant underlying medical conditions. Urinary BPA levels were measured using LC-MS/MS (high performance liquid chromatography coupled with tandem mass spectrometry) methodology. RESULTS: Urinary BPA levels among obese children were significantly higher than those of the control group (median (5-9 µg/g creatinine and 0.4 µg/g creatinine, respectively; p<0.001). When adjusted with generalized linear models for age, gender and z-scores of body mass index, obese children having metabolic syndrome had significantly higher urinary BPA levels than those without metabolic syndrome (median (5-9 µg/g creatinine and 2.1 (1.1-3.5) µg/g creatinine, respectively; p=0.001). Similarly, urinary BPA levels were higher in children with insulin resistance (2.6 (1.1-3.6) µg/g creatinine and 1.1 (1.1-3.3) µg/g creatinine, respectively; p=0.001). CONCLUSIONS: This study shows much higher BPA exposure among obese children with metabolic syndrome during the prepubertal period. Derman	2019	Bisphenol A and phthalate levels in adolescents with polycystic ovary syndrome	Endocrine disruptors have been proposed in the etiology of polycystic ovary syndrome (PCOS) as they have the potency to interfere with hormone sensitivity systems. The aim of this study was to evaluate the levels of bisphenol A (BPA) and phthalates in adolescents with PCOS. Forty-two adolescents with PCOS and 42 healthy controls were included in the study. Urinary BPA levels were measured using high-performance liquid chromatography. Di-2-ethylhexyl phthalate (DEHP), the most commonly used phthalate and mono-(2-ethylhexyl) phthalate (MEHP), its main metabolite were measured by using high-performance liquid chromatography. Adolescents with PCOS had markedly increased BPA levels (15.86 μg/g creatine ± 1.10) when compared with the control group (7.56 μg/g creatine ± 1.38) (p < 0.01). In adolescents with PCOS, BPA was significantly correlated with body mass index, waist circumference, hirsutism, menstrual irregularity, and clinical or biochemical hyperandrogenism (p < 0.05). MEHP (5.42ppm ± 0.23) and controls (MEHP 3.09 ppm ± 0.27; DEHP 10.9 ppm ± 0.3) had similar serum phthalate concentrations (p > 7 and p < 5, respectively). Exposure to specific endocrine disruptors like BPA could modify reproductive, reproductive, and metabolic regulation favoring PCOS development in adolescents. 統合_0792	S. Aishwarya, V. M. Vinodhini, P. Renuka, R. A. Saravanan, M. Arunabha, T. Gomathi and V. Anuthaselli	2025	Investigating the impact of endocrine-disrupting compounds on antepartum mental health at the Nexus of genetic insights and maternal-fetal outcomes: A prospective study	BACKGROUND: Antepartum depression arises from hormonal, environmental, and genetic factors. Endocrine-disrupting compounds (EDCs) disrupt the endocrine system, increasing vulnerability to depressive symptoms. Genetic variations, particularly in estrogen receptor (ER) pathways, are linked to antepartum depression, with EDCs exposure exacerbating these effects by further disrupting estrogen pathways. Additionally, EDCs exposure in antepartum women is associated with adverse maternal and fetal outcomes. Hence, study aims to evaluate the relationship between EDCs and genetic polymorphisms with antepartum depressive symptoms and assess the impact of EDCs and antepartum depressive symptoms on maternal and fetal outcomes. METHODS AND METHODS: We conducted a prospective cohort study to evaluate depressive symptoms during pregnancy in 500 women between 28 and 32 weeks of gestation, utilizing the Edinburgh Postnatal Depression Scale (EPDS). Women with elevated EPDS scores and matched controls were assessed for urinary bisphenol A (BPA), phthalate metabolites, and genetic polymorphisms in ESR1 and ESR2. Maternal and neonatal outcomes were recorded. RESULTS: Among 500 participants, 120 exhibited depressive symptoms. Turkey's three-percent comparison women exhibited depressive symptoms. A three-regression analysis indicated that a one-unit increase in log-bisphenol A levels corresponded to a 0.2-point increase in EPDS-measured depressive symptom scores. SNP polymorphisms (G/A and T/A genotypes) and the frequency of the A allele correlate with an increased risk of experiencing antepartum depressive symptoms. Elevated EPDS scores were significantly associated with adverse maternal outcomes, including preterm birth and low birth weight, as well as neonatal complications, such as lower birth weight. CONCLUSION: Elevated bisphenol A levels, combined with specific genetic variations, contribute to heightened maternal anxiety, hypothyroidism, and fetal distress, while methylparaben was associated with maternal anemia and fetal distress. CONCLUSION: Nearly a quarter of antepartum women displayed depressive symptoms, correlating with elevated endocrine disruptor levels. Higher bisphenol A and methylparaben levels were observed in individuals with mutant genotypes, indicating gene-environment interactions with antepartum depressive symptoms. The observed association of EDCs with maternal anemia, hypothyroidism, and fetal distress highlights the possible effect of EDC on maternal and fetal health. 統合_0793	S. Aishwarya, V. M. Vinodhini, P. Renuka, M. Anuradha and R. Arul Saravanan	2025	The see-saw effect of neuroactive steroids and endocrine disrupting compounds on maternal mental health status	BACKGROUND: Antepartum depression, a non-psychotic mood disturbance occurring during pregnancy, is influenced by hormonal fluctuations and environmental endocrine disruptors. Despite its association with adverse maternal and fetal outcomes, the mechanisms underlying antepartum depression remain unclear. Neuroactive steroids, including allopregnanolone (ALLO) and dehydroepiandrosterone (DHEA), are crucial in understanding the mechanisms of antepartum depressive symptoms. MATERIALS AND METHODS: This cross-sectional study assessed 400 pregnant women in their third trimester for depressive symptoms using the Edinburgh Postnatal Depression Scale (EPDS) and evaluated for severity using the Beck Depression Inventory-II. The concentrations of allopregnanolone, DHEA-S, bisphenol A, methyl paraben, estradiol, progesterone, cortisol, and TSH levels were measured in maternal serum samples. Statistical analyses, including ANOVA, Pearson correlation, and multivariate regression, were performed using SPSS v26.0. RESULTS: The prevalence of antepartum depressive symptoms was 35%. Allopregnanolone, DHEA-S, bisphenol A, methylparaben, estradiol, cortisol, and TSH levels were associated with depressive symptoms. Reduced levels of allopregnanolone, DHEA-S, and estradiol, along with elevated bisphenol A levels, were identified as significant independent risk factors for antepartum depressive symptoms. Obstetric micronutrient deficiency was also noted. Risk could for antepartum depressive symptoms was established for allopregnanolone (≤27.9 ng/mL [AHR: 0.4; 0.2-0.8]), bisphenol A (>0.021 ng/mL), and methyl paraben (>2.24 μg/mL). CONCLUSION: Our study on 400 antepartum women observed a 35% prevalence of depressive symptoms, with significant associations reported with reduced neuroactive steroids, elevated endocrine disruptors, lower reproductive hormones, and micronutrient deficiency. These findings emphasize the need for comprehensive screening, monitored nutritional supplementation, and hormonal assessments to effectively managing pregnancy-related depressive symptoms. 統合_0794	K. M. Ahn, M. S. Yang, H. K. Woo and J. A. Lim	2024	Pilot study: Unveiling the impact of bisphenol A and phthalate exposure on women with asthma	Endocrine disruptors are considered iatrogenic disruptors, and recent researches suggested that they may have a link to the severity of asthma. We aim to validate the correlation between endocrine disruptors and various clinical measurements of asthma, depending on the menopausal status. A pilot case-control study was performed in female asthmatic patients who visited allergy clinic in SMG-SNU Boramae Medical Center, Seoul, Korea between December 2020 and December 2021. Urinary bisphenol A (BPA) and phthalate metabolites were measured by using liquid chromatography-tandem mass spectrometry. Clinical parameters were collected and compared between premenopausal and postmenopausal asthmatic women in total database. A total of 32 female participants enrolled in the study, including 20 asthmatic women and 12 healthy controls. The average concentration of bisphenol A was detected in patient and control group did not demonstrate significant differences. Twenty asthmatic patients were divided into 2 groups according to their menstrual state. Using the Spearman rank correlation test in premenopausal asthmatic patients (n = 7), we found negative correlations between urinary concentration of mono-n-butyl phthalate and asthma control test score, as well as positive correlations between forced expiratory flow at 25% to 75% of forced vital capacity (P value = .007 and .04, respectively). In contrast, it did not show any correlation with asthma control test or positive correlation forced expiratory flow at 25% to 75% of forced vital capacity (P value = 1.00 and .76, respectively) in postmenopausal group (n = 13). Endocrine disruptors might have an impact on the decline of overall airway function and asthma management among premenopausal, but not postmenopausal, female asthmatic patients. 統合_0795	H. Ahmadpourmir, M. Moradzehi, M. Velayati, S. F. Taghizadeh, M. Hashemzaei and R. Rezaee	2025	Global occurrence of bisphenol compounds in breast milk and infant formula: A systematic review	Bisphenol compounds (BPs), particularly bisphenol A (BPA), are chemicals that are widely used in various industrial sections and come into contact with humans via different routes of exposure. Documented toxic effects of BPs include endogenicity, carcinogenicity, cytotoxicity, neurotoxicity, etc. As a well-known member of bisphenol compounds, BPA is an endocrine-disrupting chemical (EDC) that has raised global concern. Monitoring infants' exposure to BPs via consumption of breast milk and infant formula is essential as they are at a critical stage of development and are potentially more vulnerable. Following a systematic search in PubMed, Scopus, Web of Science, and Google Scholar databases, 31 articles were selected for this review, published between 2010 and 2024. Out of 1,134 samples, 1,113 (98%) were detected at least at the limit of detection (LOD). Multiple linear regression analysis showed that no significant relationship existed between the concentrations of BPS, serum parameters, and male reproductive hormones. However, in a comparison with semen parameters in people with detectable urine BPA versus undetectable ones, an inverse association was noticed with sperm concentration. In other parameters, differences were not significant. Smoking had no effects on sperm parameters, but body mass index (BMI) >25 reduced the percentage of normal sperm parameters. CONCLUSION: In most participants, urinary BPA was not detected. Probably, infants study low environmental exposure to BPA to the cause of lower urine BPA concentrations, compared to other industrially developed countries. Therefore, no overall relationship was observed between BPA level and male infertility. Mehdinezhad Gorji	2023	The Correlation of Urine Bisphenol A with Semen Parameters in Men Referred to Infertility Centers: A Cross-Sectional Study	BACKGROUND: Bisphenol A (BPA) is known as an endocrine disruptor that has harmful effects on general health. It is commonly used in various industrial products. In this study we intend to evaluate the amount of BPA in urine samples of the men referred to an infertility center. MATERIALS AND METHODS: The cross-sectional study population consisted of male partners of infertile couples, who were referred to infertility clinics in Mazandaran, a northern state of Iran. Questionnaires included demographic characteristics, medical history, lifestyle factors, physical examinations. A semen sample and a post-urine sample were taken from each participant. RESULTS: The mean age of participants was 34.6 ± 6.1 years. The mean urinary concentration of BPA was 2.4 ± 3.1 ng/mL. Urinary BPA concentrations were detected in 93.5% of the samples. RESULTS: BPA was not detected in about half of the participants (53.5%). Multiple linear regression analysis showed that no significant relationship existed between the concentrations of BPA, semen parameters, and male reproductive hormones. However, in a comparison with semen parameters in people with detectable urine BPA versus nondetectable ones, an inverse association was noticed with sperm concentration. In other parameters, differences were not significant. Smoking had no effects on sperm parameters, but body mass index (BMI) >25 reduced the percentage of normal sperm parameters. CONCLUSION: In most participants, urinary BPA was not detected. Probably, infants study low environmental exposure to BPA to the cause of lower urine BPA concentrations, compared to other industrially developed countries. Therefore, no overall relationship was observed between BPA level and male infertility. 統合_0797	S. Aflatoonian, Z. Noormohammadi, A. Moini and M. Karimipoor	2024	Interference of Bisphenol A on Cumulus Cells Development and Number of Retrieved Mature Oocytes in Unexpected Poor Ovarian Response Women: A Prospective Cohort Study	OBJECTIVE: This study aimed to investigate the relationship between follicular fluid Bisphenol A (BPA) concentrations with alterations in the expressions of NOTCH-1, CASPASE 3/7, HLA-G, and ICAM-1 genes and the number of retrieved mature oocytes (MII) and in the cumulus cells of infertile poor ovarian response (infertile-poors). MATERIALS AND METHODS: In this prospective cohort study, 80 infertile unexpected poor ovarian response (POR) subjects were selected on the basis of subgroup 1a of the POSEIDON classification. They were divided into two groups: group 1 consisted of 40 women, each with a higher number of metaphase II (MII) oocytes (≥3, 3-9 oocytes retrieved), while group 2 consisted of the 40 women, each with a lower number of MII oocytes (≤2, <3 oocytes retrieved). The expressions of the studied genes were evaluated by quantitative real-time polymerase chain reaction (PCR). The concentration of BPA in follicular fluid was measured with HPLC. RESULTS: The expression levels of NOTCH-1, HLA-G, and ICAM-1 genes were significantly lower in the infertile-poors group (P<0.001, P=0.001, and P=0.001, respectively). The concentration of BPA in follicular fluid was significantly higher in the infertile-poors group (P<0.001). The NOTCH-1 and ICAM-1 gene expressions and time-to-pregnancy also a significant inverse correlation (P<0.05) between the levels of CASPASE 3/7, with the number of MII oocytes and embryo development the two groups. The concentration of BPA in the follicular fluids of ICI-exc higher compared to ICI (P=0.05). CONCLUSION: A higher concentration of BPA was associated with a lower number of mature oocytes and oocyte quality in these patients. Also, alterations of NOTCH-1, CASPASE 3/7, HLA-G, and ICAM-1 transcript levels in unexpected POR women were associated with BPA concentration. 統合_0799	J. M. Aseweh, L. L. G. Kahn, K. A. Pierce, A. Carasco, M. S. Rosenberg and L. Trasande	2025	Temporal and geographic variability of bisphenol levels in humans: A systematic review and meta-analysis of international biomonitoring data	INTRODUCTION: Bisphenols are endocrine-disrupting chemicals known to contribute to chronic disease across the lifespan. With increased awareness of their health effects, changes in regulation and health behaviors have contributed to reductions in urinary bisphenol A (BPA) levels in the United States, Canada, and Europe. However, global trends in bisphenols outside these regions, especially bisphenol S (BPS) exposure, have been rising. OBJECTIVES: We aimed to describe the temporal and geographic variability in urinary bisphenol concentrations. METHODS: We searched PubMed, Web of Science, and Google Scholar for studies published between 2000 and 2023 that included urinary bisphenol concentrations. We examined BPA and BPS concentration changes by sampling year, country or region, age, and pregnancy status, with and without a quadratic term and geometric mean, clustered-effects meta-regression models with a random intercept and sensitivity analysis. We identified heterogeneity using Cochran's Q statistic, I2I^2 index, and funnel plots. RESULTS: The final analytic sample consisted of 165 studies. We observed pooled non-linear associations between time and BPA concentration internationally (beta: 0.02 ng/mL [se:0.00]; 95% CI: 0.01, 0.02) and in Eastern and Pacific Asia (beta: 0.03 ng/mL[se:0.00]; 95% CI: 0.02, 0.03). We also observed non-linear associations of time with both BPA and BPS concentrations in the Middle East and South Asia (beta: 0.13 ng/mL [se:0.01]; 95% CI: 0.11, 0.15 and beta: 0.03 ng/mL [se:0.00]; 95% CI: 0.02, 0.04, respectively). Pooled BPA exposure was significantly higher in Eastern and Pacific Asia (beta: 1.11 ng/mL [se:0.03]; 95% CI: 1.05, 1.17) and Middle East and South Asia (beta: 0.73 ng/mL [se:0.03]; 95% CI: 0.67, 0.79) compared to the rest of the world. BPA concentrations were higher in females (beta: 0.02 ng/mL [se:0.00]; 95% CI: 0.01, 0.03) and in females of reproductive age (beta: 0.03 ng/mL [se:0.00]; 95% CI: 0.02, 0.04). Pooled BPS exposure was significantly higher in females (beta: 0.02 ng/mL [se:0.00]; 95% CI: 0.01, 0.03) and in females of reproductive age (beta: 0.02 ng/mL [se:0.00]; 95% CI: 0.01, 0.03). We also observed non-linear associations of time with both BPA and BPS concentrations in the Middle East and South Asia (beta: 0.13 ng/mL [se:0.01]; 95% CI: 0.11, 0.15 and beta: 0.03 ng/mL [se:0.00]; 95% CI: 0.02, 0.04, respectively). Pooled BPA exposure was significantly higher in Eastern and Pacific Asia (beta: 1.11 ng/mL [se:0.03]; 95% CI: 1.05, 1.17) and Middle East and South Asia (beta: 0.73 ng/mL [se:0.03]; 95% CI: 0.67, 0.79) compared to the rest of the world. BPA concentrations were higher in females (beta: 0.02 ng/mL [se:0.00]; 95% CI: 0.01, 0.03) and in females of reproductive age (beta: 0.03 ng/mL [se:0.00]; 95% CI: 0.02, 0.04). Pooled BPS exposure was significantly higher in females (beta: 0.02 ng/mL [se:0.00]; 95% CI: 0.01, 0.03) and in females of reproductive age (beta: 0.02 ng/mL [se:0.00]; 95% CI: 0.01, 0.03). We also observed a significant interaction between BPA and BPS concentrations in females of reproductive age (beta: 1.36[se:0.00]; 95% CI: 1.35, 1.37). We observed a significant interaction between BPA and BPS concentrations in females of reproductive age (beta: 1.36[se:0.00]; 95% CI: 1.35, 1.37). CONCLUSION: Our findings provide evidence for concern about increasing population exposure to BPA and BPS. Further studies estimating attributable disease burden and costs at regional and global levels are warranted to show these chemicals' impact on population health and economics. Duijts and M. Casas	2022	In utero exposure to bisphenols and asthma, wheeze, and lung function in school-age children: a prospective meta-analysis of 8 European birth cohorts	BACKGROUND: In utero exposure to bisphenols, widely used in consumer products, may alter lung development and increase the risk of respiratory morbidity in the offspring. However, evidence is scarce and mostly focused on bisphenol A (BPA) only. OBJECTIVE: To examine the associations of in utero exposure to BPA, bisphenol F (BPF), and bisphenol S (BPS) with asthma, wheeze, and lung function in school-age children, and to explore potential sex differences. METHODS: We included 8 European birth cohorts participating in the Human Early Life Exposome (HELIX) project. Urinary concentrations of BPA, BPF, and BPS were measured using liquid chromatography (UHPLC-QqQ). Asthma and wheeze were ascertained from questionnaires and lung function by spirometry. Wheeze and asthma were modelled from questionnaires from early to mid-childhood. We performed adjusted random-effects meta-analyses on individual participant data. RESULTS: Exposure to BPA was present in 60-90% of maternal samples, containing concentrations above detection limits. BPF and BPS were found in 2% and 8% of samples. In sex-stratified models, a 10-fold increase in urinary BPA was associated with higher odds of current asthma (OR= 1.11; 95% CI= 1.01, 1.23) and wheeze (OR= 1.11; 95% CI= 1.00, 1.24) in boys. We observed no associations in girls. Higher BPA exposure was associated with lower FEV1 (-1.36 [-2.59, -0.13] mL) and FVC (-1.80 [-3.39, -0.21] mL) in boys only. We found no associations between BPF or BPS and asthma, wheeze, or lung function. CONCLUSIONS: This study suggests that in utero BPA exposure may be associated with higher odds of asthma and wheeze among school-age girls. 統合_0801	X. Zuo, M. Sun, H. Bai, S. Zheng, J. Luan, Q. Yu, Z. Fu, Q. Zhao, M. Sun, X. Zhao and X. Feng	2025	The effects of 17 β -trenbolone and bisphenol A on sexual behavior and social dominance via the hypothalamic-pituitary-gonadal axis in male mice	17 β -Trenbolone (17-TB) is well documented as an environmental endocrine disruptor in aquatic biological studies, but its effects on mammals remain poorly understood. Furthermore, 17-TB acts as a hormone with properties similar to testosterone, and the consequences of juvenile exposure on adult social behavior remain uncertain. Bisphenol A (BPA) acts as an estrogen-like hormone, compared to 17-TB. These tools will make likely mice were exposed orally to 17-TB (100 μg/kg/day) and BPA (5 mg/kg/day) or BPA (5 mg/kg/day) for 28 days. Assessments of social interaction and a three-chamber test showed that 17-TB increased activity in male mice. Intermittent/both male and female sexual behavior, and attracted and accepted female mice. It also increased social dominance through tube tests in male mice and markedly activated the c-Fos(+) female response in the medial preoptic area (MPOA) and ventromedial hypothalamus (VMH). Additionally, 17-TB significantly increased testosterone and estradiol levels in male mice, while BPA only increased estradiol levels. Both 17-TB and BPA exposure altered the expression of genes and proteins related to steroidogenesis and luteinizing hormone (LH) levels, as well as molecular tissues and estrogen receptor (ER) β and estrogen receptor (ER) α synthesis. Testicular transcriptomic analysis revealed that 17-TB exposure significantly affected testicular cell-cell interaction, synthesis and binder, and related biomolecular processes. These findings suggest the influence of 17-TB and BPA exposure on sexual behavior and fertility in male mice, possibly through modulation of the hypothalamic-pituitary-gonadal axis. This study provides insights relevant to human reproductive health and more social behavioral research, and the potential risk of environmental disturbances should not be overlooked. Abdul Aziz	2023	Prenatal Bisphenol a Exposure and Postnatal Trans Fat Diet Alter Small Intestinal Morphology and Its Global DNA Methylation in Male Sprague-Dawley Rats, Leading to Obesity Development	In this study, we aimed to determine whether a postnatal trans fat diet (TFD) could aggravate prenatal bisphenol A (BPA) exposure effects on offspring's small intestine and adulthood obesity due to the relatively sparse findings on how the interaction between these two variables interrupt the small intestinal cells. Twelve pregnant rats were administered with either sesame oil (control, CTL) or BPA-spiked drinking water (control, CTL) or BPA-spiked drinking water (50 μg/kg body weight/day) throughout gestation and lactation periods. Male offspring were then fed with either a standard diet (SD) or TFD (5% trans fat) for 16 weeks, resulting in four groups (n = 10): CTL-SD, CTL-TFD, BPA-SD, and BPA-TFD. Body weight (BW), adiposity, and food intake were monitored. Histomorphometry and local gene expressions were measured weekly in offspring. At PND56, small intestines were collected for global DNA methylation and histological analyses. Matched differences in BW were observed starting at PND49 in BPA-TFD (389.6 ± 16.4 g; p < 0.05) relative to CTL-SD (358.0 ± 7.2 g), which persevered until PND63 (502.6 ± 12.6 g). In contrast, such matched differences were significantly different (p < 0.05) at PND63. The beta diversity, hierarchical cluster and network analyses of the offspring's microbiome demonstrated that the microbiome species of the TFD group cells set without BPA were distinctly different compared to the SD group. Additionally, the BPA-TFD group had significantly (p < 0.05) higher global DNA methylation and lower villus height, width, and surface area than the CTL-SD group. Furthermore, an inverse correlation was observed between villus height and global DNA methylation, as shown by the multivariate parametric analysis (MANOVA). Predictive functional profiling of the offspring's intestinal flora demonstrated altered expressions of genes involved in metabolic pathways. In summary, the gut flora composition of the rat offspring may be influenced by perinatal diet. Instead of prenatal exposure to BPA. Our data indicate the possibility of perinatal metabolic functions and epigenetic modifications, in offspring that consumed TFD, which may theoretically lead to metabolic diseases in middle or late adulthood. Further investigation is necessary to fully understand these implications. 統合_0804	Y. Zhuang, X. Sun, S. Dong, Y. Wen, Q. Xu and Q. Guan	2023	In vivo effects of low dose prenatal bisphenol A exposure on adiposity in male and female ICR offspring	BACKGROUND: Bisphenol A (BPA) is known to exhibit endocrine disrupting activities and is associated with adiposity. We examined the obesogenic effect of prenatal BPA exposure in the present study. METHODS: Pregnant ICR mice were exposed to BPA at 0.5 μg/kg BW/d (BPA-L), 50 μg/kg BW/d (BPA-H) or vehicle control (CON) from gestational day 0.5 to 18.5. Body weight and food intake of offspring were monitored. Oral Glucose Tolerance Test(OGTT) was performed and serum biochemical parameters were measured at 8 weeks of age. Histological examination was conducted. Real-time PCR was performed to detect the mRNA levels of genes involved in lipid biosynthesis and TGF-β signaling pathway. RESULTS: Offspring presented a significantly higher rate of weight gain than the control, with impaired insulin sensitivity and increased adipocyte size. Differentiation of MSPCs from BPA-treated mice showed a higher propensity for the adipocyte commitment as well as up-regulation of genes enriched in lipid biosynthesis, TGF-β signaling pathway was found to modulate obesogenic effect of BPA in MAT model, but not changes in signaling pathway had no effects. CONCLUSIONS: The present study provides strong evidence of the association between prenatal exposure to low dose of BPA and a significant increase in body weight in the offspring mice with a critical role played by TGF-β signaling pathway. The potential interactions mediating the binding of BPA and TGF-β that activate its obesogenic effects need to be examined. 統合_0805	X. Zhu, Q. Liu, Z. Cheng and Y. Luo	2025	Disruption of PPARG Activity and CPT1A Regulation by Bisphenol A: Implications for Hepatic Lipid Metabolism	Bisphenol A (BPA) is a widely used industrial chemical with potential endocrine-disrupting effects on metabolic processes. This study investigates the impact of BPA on hepatic function and transcriptional regulation in mouse livers and AML-12 cells. Male mice were exposed to BPA (0.5 μg/kg and high (50 μg/kg) doses of BPA for six weeks. Transcriptomic analysis was performed via RNA-Sequencing, and histological examinations were conducted. AML-12 cells were treated with varying BPA concentrations, and PPARG transcriptional activity was assessed using a luciferase reporter assay. Additionally, molecular docking, molecular dynamics (MD) simulations, and binding free energy calculations were performed to evaluate BPA's interaction with PPARG. Our findings revealed that BPA exposure significantly altered hepatic gene expression, with 1,169 differentially expressed genes identified in the high-dose group. Gene Ontology (GO) and KEGG pathway analysis highlighted disruptions in lipid metabolism and transcriptional regulation, with key genes including Cpt1a, Ppargc1a, and Ppara showing significant downregulation. Molecular docking and MD simulations revealed that BPA binds to PPARG with a binding energy of -7.5 kcal/mol, forming stable interactions with key residues, including Arg288 and Glu259, which are critical for PPARG activation. Experimental validation confirmed that BPA exposure reduced PPARG transcriptional activity in a dose-dependent manner, with significant suppression observed at 10 μM and 20 μM BPA. Furthermore, BPA exposure led to a marked decrease in CPT1A protein expression in both liver tissue and AML-12 cells, indicating impaired fatty acid oxidation. These findings suggest that BPA disrupts hepatic lipid metabolism by directly interfering with PPARG activity and suppressing CPT1A-mediated fatty acid oxidation. Our study provides novel insights into the molecular mechanisms underlying BPA-induced hepatic dysfunction and highlights the potential risks associated with chronic exposure to environmental endocrine disruptors. 統合_0806	X. Zhu, L. Cao, Y. Liu, X. Tang, Y. Miao, J. Zhang, L. Zhang, Z. Jia and J. Chen	2024	Genotoxicity of bisphenol AF in rats: Detrimental to male reproductive system and probable stronger micronucleus induction potency than BPA	Bisphenol AF (BPAF), as one of structural analogs of BPA, has been increasingly used in recent years. However, limited studies have suggested its adverse effects similar to or higher than BPA. In order to explore the general toxicity and genotoxicity of subacute exposure to BPAF, the rats(7-8w-old) were orally administrated (0 (as a vehicle control), 10 and 50 μg/kg bw/d) for 28 days. Meanwhile, the rats in positive control group were intraperitoneally injected with 10 mg/kg bw/d cyclophosphamide (CP) for 3 days. Then, the rats were randomly distributed into seven main experimental groups and four satellite groups. The main experimental groups included BPAF treated groups (L1, L2, and L3: μg/kg bw/d), BPA group (10 μg/kg bw/d), the solvent control group (0.5% CMC-Na solution), and positive control group (CP). The satellite groups included the solvent control group, BPA group (10 μg/kg bw/d), BPAF group (50 μg/kg bw/d), and positive control group (CP). On the 29th day (for the main experimental rats) or the 4th day (for the satellite rats), the rats were euthanized. Blood samples were collected from the abdominal aorta, and epididymal sperm and liver cells were harvested. Then, the sperm quality, sperm DNA damage, and micronucleus rate in polychromatic erythrocytes (PCE) were detected. Histopathological examination was performed. Results showed that BPAF exposure induced significant decreases in sperm concentration, motility, and viability, as well as increases in sperm malformation and DNA damage. Moreover, BPAF exposure also caused significant increases in the micronucleus rate in PCE and histopathological damage in the testis and liver. Overall, BPAF exposure induced significant reproductive toxicity, genotoxicity, and hepatotoxicity in male rats. Furthermore, BPAF exhibited stronger micronucleus induction potency than BPA. These findings provide valuable insights into the potential risks associated with BPAF exposure and highlight the need for further investigation into its long-term effects on human health. 統合_0807	M. Zhu, R. Wei, Y. Li, J. Li, M. Dong, X. Chen, L. Lv and Z. Qin	2022	Bisphenol chemicals disturb intestinal homeostasis via Notch/Wnt signaling and induce mucosal barrier dysregulation and inflammation	Emerging evidence has shown that bisphenol A (BPA) can exert adverse effects on intestinal barrier in rodents, but little is known about its underlying mechanisms. We previously found BPA and its substitute bisphenol F (BPF) disrupted Notch signaling and altered intestinal histological structures in Xenopus laevis tadpoles. The present study aimed to determine whether BPA and BPF could affect intestinal homeostasis via Notch/Wnt signaling and induce intestinal barrier dysregulation in adult mammals, given the fundamental roles of the two conserved signaling pathways in intestinal homeostasis and regulation of intestinal barrier. We found that BPA and BPF exposure induced significant histological damages in the intestine of male mice, including villus atrophy, crypt hyperplasia, goblet cell loss, and epithelial cell apoptosis. Moreover, BPA and BPF exposure also induced significant changes in the expression of Notch and Wnt pathway genes and their related genes as well as key genes responsible for intestinal homeostasis. After administration was extended to 14 days, all treatments significantly suppressed the expression of all tested Notch- and Wnt-related genes, correspondingly, administrated colonic inhibited downregulated expression of key genes responsible for intestinal homeostasis and induced cell proliferation in crypts. Importantly, all treatments suppressed secretory cell differentiation, reduced mucus protein levels and downregulated expression of tight junction markers, implicating mucosal barrier dysregulation. Furthermore, inflammatory cell infiltration and upregulated expression of inflammatory cytokine genes in colons, coupled with increased serum lipopolysaccharide (LPS) levels, were observed in BPA- and BPF-exposed mice. Our findings suggest that BPA and BPF exposure could induce intestinal inflammation via disrupting intestinal barrier dysregulation and intestinal inflammation in mice. This is the first study revealing the adverse influences of BPF on mammal intestines and underlying mechanisms for bisphenol-caused intestinal injury. 統合_0808	[Effects of interleukin-17 antibody on polarization of macrophages in adipose tissue of high-fat diet fed mice exposed to bisphenol A]	2021	[Effects of interleukin-17 antibody on polarization of macrophages in adipose tissue of high-fat diet fed mice exposed to bisphenol A]	OBJECTIVE: To investigate the effects of interleukin-17A (IL-17) antibody on polarization of adipose tissue macrophages (ATMs) in mice fed with high-fat diet (HFD) exposed to bisphenol A(BPA). METHODS: Four-week-old male C57BL/6J mice were divided into control group, IgG group, IL-17 antibody group, 1000 mmol/L BPA group, 1000 mmol/L BPA+IgG group, and 1000 mmol/L BPA+IL-17 antibody group according to random number table method. Eight mice per group were fed with HFD and BPA was exposed by drinking water. The IgG group and the 1000 mmol/L BPA+IgG group were intraperitoneally injected with 100 μg IgG and body were a week, and the IL-17 antibody group, 1000 mmol/L BPA+IL-17 antibody group were injected with 100 μg IL-17 antibody. After 8 weeks of exposure, the body weight of mice was measured, and the serum insulin, fasting blood glucose and serum lipid were measured by enzyme-linked immunosorbent assay(ELISA). The expression of IL-1, IL-6, IL-4 and monocyte chemoattractant protein-1(MCP-1) in adipose tissue of mice in each group were detected by immunohistochemistry(IHC) of adipose tissue of epididymis. The activity of inducible nitric oxide synthase(iNOS)and arginase 1(Arg-1)was measured by ELISA, and the proportion of M1 and M2 ATMs was measured by flow cytometry. RESULTS: Compared with control group, the body weight, fasting blood glucose, serum insulin, and serum lipid were increased in 1000 mmol/L BPA group, and the body weight, fasting blood glucose, serum insulin, and serum lipid were increased in 1000 mmol/L BPA+IgG group, the proportion of M1 type ATM was increased((3.1±0.6)% vs. (1.2±0.3)%, P<0.05), the proportion of M2 type ATM was decreased((0.7±0.1)% vs. (1.4±0.2)%, P<0.05), the expression of IL-1, IL-6 and MCP-1 in adipose tissue were increased, and the activity of iNOS was increased, and the activity of Arg-1 was decreased. Compared with 1000 mmol/L BPA+IgG group, the body weight, fasting blood glucose, serum insulin, and serum lipid were increased in 1000 mmol/L BPA+IL-17 antibody group, and there was no significant change in 1000 mmol/L BPA group. BPA group had no significant change. In 1000 mmol/L BPA+IL-17 antibody group, the proportion of M1 type ATM was decreased((2.8±0.4)% vs. (3.1±0.6)%, P<0.05), the proportion of M2 type ATM was increased((1.0±0.1)% vs. (0.7±0.1)%, P<0.05), the expression of IL-1, IL-6 and MCP-1 in adipose tissue were decreased, and the activity of iNOS was decreased, and the activity of Arg-1 was increased. There was no significant change in IgG group. Compared with 1000 mmol/L BPA group, IgG+1000 mmol/L BPA group had no significant change. In 1000 mmol/L BPA+IL-17 antibody group, serum lipid was decreased, the expression of inflammatory factors IL-6, IL-12 and MCP-1 in adipose tissue were down-regulated, and the proportion of M2 type ATM was increased((3.8±0.4)% vs. (1.2±0.3)%, P<0.05), the activity of iNOS was decreased((0.8±0.1)% vs. (2.3±0.3)%, P<0.05), and the activity of Arg-1 was increased((0.9±0.1)% vs. (0.4±0.1)%, P<0.05). Compared with 1000 mmol/L BPA+IgG group, the above indexes were significantly improved in 1000 mmol/L BPA+IL-17 antibody group, and the differences were statistically significant(P<0.05). CONCLUSION: IL-17 antibody may reduce the secretion of ATM inflammatory factors by inhibiting the polarization of ATM to M1 type, thus improving the inflammation of adipose tissue in BPA-infected HFD fed mice. Qiu	2025	Revealing the role of bisphenol A on prostate cancer progression and identifying potential targets: A comprehensive analysis from population cohort to molecular mechanism	Bisphenol A (BPA) is a widespread environmental pollutant whose exact effects on prostate cancer (PCa) progression remain underestimated. This study aims to investigate the effect and underlying molecular mechanisms between BPA exposure and PCa in a comprehensive approach. The multicenter cohort study found that BPA exposure plays an important role in promoting the formation and death of PCa. BPA exposure significantly promoted PCa progression in both the animal model and in vitro experiments. RNA sequencing revealed a disruption of mitochondrial energy homeostasis in BPA-treated cells. In multiple datasets, 17 hub genes were identified as being significantly associated with PCa prognosis, and their expression was significantly altered in BPA-exposed cells and tissues. Molecular docking revealed that BPA has a potential transcription factor targeting glycolytic enzyme PFKFB4 under BPA exposure. With the support of the RNA and shRNA sequencing data, it further regulates metabolism of BPA promoting prostate cancer through mitochondrial energy metabolism reprogramming was constructed. Further molecular docking revealed that BPA has higher binding free energy to ERα than its natural ligand estradiol. Given the widespread presence of BPA in the environment, minimizing exposure to this chemical could represent a feasible approach to improving clinical outcomes. 統合_0810	R. Zhou, W. Cheng, Y. Feng, W. Wang, F. Liang, F. Luo, S. Yang and Y. Wang	2020	Combined effects of BPA and PFOS on fetal cardiac development: In vitro and in vivo experiments	Analyses of the combined effects of different EDCs are both important and difficult. This study attempts to evaluate the individual and combined effects of BPA and PFOS on heart development. Sprague-Dawley rats were exposed to environmentally relevant BPA (0.1 μg/L) and PFOS (0.1 μg/L) alone or in combination from 1 week before pregnancy to gestational day 21. Fetal hearts were collected, and the interventricular septal thickness (ISTH) of approximately 25 % (25 ± x) in control vs. BE, per to environment was observed in the fetal rat hearts after the combined exposure to nearly 2500 μg/L PFOS and 100 μg/L BPA through drinking water. The total collagen and dynamic-related protein 1 (Drp1) mRNA level was increased in the fetal hearts exposed to the combination of 2000 μg/L PFOS and 200 μg/L BPA. However, the ISTH of fetal rats exposed to 2000 μg/L PFOS and 200 μg/L BPA was significantly thinner than that of fetal rats exposed to 2000 μg/L PFOS alone. The total collagen and Drp1 mRNA level in fetal rats exposed to 2000 μg/L PFOS and 0.1 μg/L BPA failed to cause significant exchange in the embryonic hearts. The individual and combined effects of BPA and PFOS on heart development were further investigated by an in vitro study. Embryonic stem cells were administered individual or combined 10 ng/mL BPA and 200 ng/mL PFOS for 14 days during the cardiac differentiation period. The results show that exposure to the combination of 200 ng/mL PFOS and 10 ng/mL BPA could increase the cardiomyocyte size and collagen content. A selective inhibitor of Drp1, Mdivi-1, could inhibit the cardiomyocyte enlargement but not the collagen content increase caused by the combined exposure. Thus, we believe that although the combined exposure to PFOS and BPA could affect mitochondrial biogenesis and collagen expression, these two effects seem to be relatively independent. Based on these results, this research concludes that combined exposure to PFOS and BPA could specifically lead to increased collagen and ISTH thickening in heart development. 統合_0811	B. Zhou, Y. Niu, D. Wang, L. Liu and J. Guo	2024	Geraniol alleviates liver injury induced by bisphenol A via modulating NLRP3/caspase-1 pathway and gut microbiota in mice model	Bisphenol A has become a global public health problem. As an antioxidant, geraniol has potential preventive effects against toxicity. This study analyzes the preventive effect of geraniol against BPA-induced liver injury. In vivo, geraniol significantly reduced the increase in liver coefficient and the serum levels of alanine aminotransferase (ALT), aspartate aminotransferase (AST), and alkaline phosphatase (ALP) induced by BPA. It also reduced the increase in the expression levels of inflammatory cytokines (TNF-α, IL-1β, and IL-18) and apoptosis-related proteins (Bcl-XL/Bcl-2, Bax, and caspase-3) up-regulated the expression of nuclear IL-33 and cytosolic sST2, which inhibited intestinal barrier function. Also, geraniol treatment optimized the composition and diversity of gut microbiota. It may be summarized that geraniol showed protective effects on liver injury induced by BPA and further revealed that the mechanism might be located on improving intestinal physical barrier function, down-regulating apoptosis biomarkers, and normalizing intestinal microbiota, consequently reducing inflammatory response in the liver. 統合_0812	X. Zhang, J. Li and X. Xu	2024	Adolescent exposure to bisphenol-a antagonizes androgen regulation of social behavior in male mice	Social behavior is sexually dimorphic, which is regulated by gonadal hormones in the brain. Our recent study found that exposure to low doses of bisphenol A (BPA) during adolescence, permanently alters social behavior in female mice. Here, we further investigated the effects of BPA exposure during adolescence on social behavior in male mice. Male CD-1 mice were exposed to BPA (0.5 μg/kg/day) or its androgen receptor antagonist flutamide (FLU, 10 mg/kg/day) from postnatal day (PND) 28 to PND 42. Social behavior was assessed in adulthood. We found that BPA exposure did not affect male social behavior, but antagonized the effects of FLU on social interaction, sexual behavior, and aggression in CD-1 mice. BPA eliminated the neuronal effects of FLU in CD-1 mice, because decrease in the number of immunoreactive cells in ventromedial hypothalamus (VMH) of neurons in the medial amygdala (MeA) and the levels of AVP receptor 1a (V1aR) in the MeA and the nucleus accumbens (NAc). In addition, BPA removed down-regulation in the levels of dopamine (DA) transporter (DAT) and DA receptor 1 (D1R) in the NAc of TP-EDC-mice. BPA exposure reduced testosterone (T) levels in the blood serum and the expression of androgen receptor (AR) protein in the amygdala and striatum of these castrated and TP-EDC-males. These results suggest that adolescent exposure to BPA inhibits regulation of androgen in AVP and DA systems of the brain regions associated with social behavior, and thus alters social behaviors of adult male mice. 統合_0813	J. Zheng, D. Balmus-Khamtova, C. Label, J. S. Bains and D. M. Kurnach	2024	Hypothalamic vasopressin sex differentiation is observed by embryonic day 15 in mice and is disrupted by the xenoestrogen bisphenol A	Arginine vasopressin (AVP) neurons of the hypothalamic paraventricular region (AVPPVN) mediate sex-biased social behaviors across most species, including mammals. In mice, neuronal sex differences are thought to be established during a critical window around birth (~embryonic (E) day 18 in outbred CF-1 mice). Currently, circulating testicular hormones from the fetal testis is assumed to instruct sex differences in these regions. Here we found that AVPPVN neurons are sexually dimorphic by E15.5, prior to this critical window, and that gonadectomized bisphenol A (BPA) exposure permanently masculinized female AVPPVN neuronal numbers, projections, and sex-specific social behaviors. Sex differences in AVPPVN neuronal number and projections to the lateral septum (LS) were observed in CF-1 mice by E15.5 and persisted into adulthood. BPA exposure exposed females compared to control females, suggesting that AVPPVN neuronal masculinization occurs between E12 and E15. We further narrowed this sensitive period to around the time of neurogenesis by demonstrating that exogenous estrogen exposure from E12.5 to E13.5 masculinized female AVPPVN neuronal numbers, whereas a pan-estrogen receptor antagonist exposed from E12.5 to E13.5 blocked masculinization of males. Finally, we observed that restricting BPA exposure to E13.5-E15.5 exposed adult females to display increased social dominance over control females, consistent with an acquisition of male-like behaviors. Our study reveals an E12.5 to E15.5 window of estrogen-sensitivity impacting AVPPVN sex differentiation, which is impacted by perinatal BPA exposure. 統合_0814	T. Zhao, W. Yang, F. Pan, J. Wang, W. Shao, F. Chen, K. Liu, S. Zhao and L. Zhao	2025	Bisphenol A attenuates testosterone synthesis via increasing apolipoprotein A1-mediated reverse cholesterol transport in mice	Bisphenol A (BPA), a widely used chemical compound in plastic manufacturing, has become ubiquitous in the environment. Previous studies have highlighted its adverse effects on reproductive function, as BPA exposure reduces testosterone levels. Cholesterol is involved in testosterone synthesis, including cells. However, research on the mechanisms by which BPA affects testosterone synthesis from the perspective of reverse cholesterol transport (RCT) remains limited. This study aimed to investigate the effects of BPA on cholesterol levels, lipid droplet accumulation, and testosterone synthesis in TM3 cells and mice via Apolipoprotein A1 (APOA1)-mediated RCT. Adult male mice were treated by intraperitoneal injection of corn oil containing BPA (50 mg/kg) for 7 days. Testes were collected for protein extraction, RNA extraction, Q-red Q-staining or for histological examination. TM3 cells were treated with BPA (0, 10, 20, 40, 80, and 160 μM) for 24 h. Cell viability was assessed using the CCK-8 assay. Q-red Q-staining was used to measure the cholesterol and lipid droplet accumulation in TM3 cells. Immunofluorescence was performed to detect the expression of APOA1 in the testes of mice and TM3 cells. Transcriptomic analysis was conducted on testicular tissue from BPA-exposed mice. The results revealed that BPA exposure significantly decreased the levels of testosterone and increased the levels of total cholesterol (TC) in the mouse testis. Conversely, testicular high-density lipoprotein (HDL) content was partially elevated. Furthermore, BPA markedly enhanced lipid- vRNA and protein expression in the mouse model. Notably, BPA significantly upregulated lipid- vRNA and protein level, reduced cholesterol levels and lipid droplets accumulation, and attenuated testosterone synthesis in TM3 cells. In addition, exogenous supplement with 22-hydroxycholesterol promoted testosterone synthesis, and alleviated the inhibitory effect of BPA on testosterone synthesis. Taken together, these results suggest that BPA upregulates APOA1 expression, enhances RCT, and ultimately reduces TC and TC levels in the testis. This cholesterol reduction likely led to testosterone synthesis disorders in the model, indicating that BPA inhibits testosterone synthesis in vitro by disrupting cholesterol transport. 統合_0815	Q. Zhao, J. Pan, Y. Bao, X. Wang and W. Shi	2025	Prenatal exposure to bisphenol A causes reproductive damage in F1 male rabbits due to inflammation and oxidative stress	Bisphenol A (BPA) is used extensively in producing industrial chemicals such as plastic products, resin, and paper coatings. Concerns have been expressed regarding its possible detrimental consequences, especially on the reproductive system of mammals. Despite extensive study in this domain, there has been a significant knowledge gap in research on the impact of BPA on F1 generation rabbits. BPA's ramifications on male rabbits' reproductive health are revealed in this study. Pregnant rabbits received BPA orally at doses of 0, 5, 50, and 500 mg/kg/day from gestational day 6 to 18. Testicular and serum of male mice are collected on postnatal day 56 (PND56), and spermatozoa are collected to detect relevant indicators. Our results showed that compared with the BPA group, CCK-8 could significantly increase the serum contents of luteinizing hormone (LH), follicle-stimulating hormone (FSH), and testosterone (T) in males at PND 56, as well as the transcription levels of estrogen receptor alpha (ERα), steroidogenic acute regulatory protein (StAR), and Cytochrome P450 family 11, subfamily A, and member 1 (CYP11A1). CCK-8 also significantly inhibit the production of reactive oxygen species (ROS), reduce oxidative stress, increase mitochondrial membrane potential, and boost sperm parameters. It also has a notable stabilizing effect on seminiferous tubules' weight and mitochondrial DNA copy number. These results suggest that CCK-8 can increase reproductive hormone and receptor levels in adult rabbits by regulating the expression of oxidative stress-correlated factors, and ultimately mitigate the negative effects of BPA on sperm quality in male mice. 統合_0830	H. Zhang, Y. Zhang, X. Liu, X. Zha, M. Elsabagh, Y. Ma, H. Jiang, H. Wang and M. Wang	2023	Autophagy attenuates placental apoptosis, oxidative stress and fetal growth restriction in pregnant ewes	Bisphenol A (BPA)-induced oxidative stress, ER2 and its potentially associated autophagy and apoptosis have not been studied previously in pregnant ewes. Accordingly, this study investigated the underlying mechanisms of BPA-induced autophagy and apoptosis in the placenta and primary trophoblasts of pregnant ewes exposed to BPA both in vivo and in vitro. In vivo experiment, pregnant Hu ewes (n = 8) were exposed to 5 mg/kg/d of BPA by oral gavage from gestational day (GD) 1 to GD 30. Ewes in the control group received an equal volume of corn oil. Placentomes were collected on GD 30 for analysis of autophagy, mitochondrial dysfunction, oxidative stress (OXS), mitochondrial dysfunction, ER, and apoptosis in the placentomes. Regarding in vitro model, primary ovine trophoblasts were exposed to BPA. BPA-also chloroquine (CQ, an autophagy inhibitor) or BPA also rapamycin (RAP, an autophagy activator) for 12 h. Data illustrated that exposure to BPA enhanced autophagy (LC3-II, Beclin-1, LC3, Parkin, and PINK1), OXS (GSH/GSSG, CAT/SOD, GTP), and apoptosis (Bax/Bcl-2, caspase-3, caspase-8, caspase-9, and TUNEL) in the placentomes. Moreover, BPA-induced autophagy, OXS, and apoptosis in trophoblasts were also observed. Importantly, LC3-II exacerbated the BPA-induced ER, mitochondrial dysfunction, apoptosis, and OXS. On the contrary, BAP remarkably ameliorated the BPA-induced trophoblast dysfunctions mentioned above. Overall, the findings illustrated that BPA exposure could contribute to autophagy in the ovine placenta and trophoblasts and that autophagy, in turn, could alleviate BPA-induced apoptosis, mitochondrial dysfunction, OXS, and ER. These results offer new mechanistic insights into the role of autophagy in mitigating BPA-induced placental dysfunctions and FGR. 統合_0831	H. Zhang, X. Zha, Y. Zhang, X. Liu, M. Elsabagh, H. Wang, H. Jiang and M. Wang	2023	Mechanisms underlying the role of endoplasmic reticulum stress in the placental injury and fetal growth restriction in an ovine gestation model	MACHINDUNDU: Exposure to bisphenol A (BPA), an environmental pollutant known for its endocrine-disrupting properties, during gestation has been reported to increase the risk of fetal growth restriction (FGR) in an ovine model of pregnancy. We hypothesized that the FGR results from the BPA-induced insufficiency and endocrine dysfunction of the placenta, oxidative stress, inflammatory responses, autophagy and endoplasmic reticulum stress (ERS). However, precise mechanisms underlying the BPA-induced placental dysfunction, and subsequently, FGR, as well as the potential involvement of placental ERS in these complications, remain to be fully elucidated. Therefore, the objective of this study was to investigate the role of ERS in BPA-induced placental injury and fetal growth restriction in an ovine gestation model. In this study, whereas the other group received BPA (5 mg/kg body bw; a subcutaneous injection) in the vehicle, pregnant ewes (n = 8/group) were exposed to 2 treatments, the control group received an equal volume of corn oil (vehicle). The OTCs were treated with 500 μM 4-PBA (chemical chaperone) and EMBA4 (7.2 complete medium (control), for 24 h. RESULTS: The results of this study revealed that BPA exposure induced ERS, OXS, inflammation, autophagy, and apoptosis in the placentomes and primary trophoblasts. Moreover, BPA-induced ERS, OXS, inflammation, autophagy, and apoptosis were found together to impair placental barrier dysfunction, ERS, inflammatory responses, autophagy, and OXS in the placentomes. In vitro experiments, the BPA-induced ERS, OXS, inflammation, autophagy, and apoptosis in trophoblasts were also observed. Importantly, 4-PBA significantly ameliorated the BPA-induced trophoblast dysfunctions mentioned above. Overall, the findings illustrated that BPA-induced ERS could contribute to placental dysfunction and gene expressions of antioxidant, anti-apoptosis, and barrier function. Moreover, treating the OTCs with 4-PBA reversed the BPA-induced dysfunction of barrier and endocrine (the increased E2 level and decreased P4 level). CONCLUSIONS: In general, the results reveal that BPA exposure can cause ERS in the ovine placenta and OTCs, and ERS induction might contribute to the dysfunction of the placental barrier and endocrine, ERS, inflammatory responses, and autophagy. These data offer novel mechanistic insights into whether ERS is involved in BPA-mediated placental dysfunction and fetal development. 統合_0832	H. Zhang, X. Zha, B. Zhang, Y. Zheng, M. Elsabagh, H. Wang and M. Wang	2024	Gut microbiota contributes to bisphenol A-induced maternal intestinal and placental apoptosis, oxidative stress, and fetal growth restriction in pregnant ewe model by regulating gut-placental axis	MACHINDUNDU: Bisphenol A (BPA) is an environmental contaminant with endocrine-disrupting properties that induce fetal growth restriction (FGR). Previous studies on pregnant ewes revealed that BPA exposure causes placental dysfunction and FGR by inducing oxidative stress, inflammation, autophagy, and apoptosis. However, the precise mechanisms underlying BPA-induced FGR, as well as the potential involvement of gut microbiota in these complications, remain to be fully elucidated. Therefore, the objective of this study was to investigate the role of gut microbiota in BPA-induced placental injury and FGR in an ovine model of pregnancy. In this study, whereas the other group received BPA (5 mg/kg body bw; a subcutaneous injection) in the vehicle, pregnant ewes (n = 8/group) were exposed to 2 treatments, the control group received an equal volume of corn oil (vehicle). The GFD+R treatment was initiated on GD 30 and continued until GD 130. Ewes in the GFD+R group received a gut microbiota transplantation (GMT) from the control group (n = 10) through fecal microbiota (Fm) slurry (4 g/kg body bw) via oral gavage every other day from GD 60 to GD 110 of gestation. The maternal colonic digesta and the ileum and placental tissue samples were collected to examine the biomarkers of apoptosis, oxidative stress, mitochondrial dysfunction, ERS, and IRS. To investigate the link between gut microbiota and the BPA-induced FGR in pregnant ewes, gut microbiota transplantation (GMT) was conducted in two pregnant ewe groups (n = 10/group) from day 0 to day 14 of gestation after removing their intestinal microbiota by antibiotics. The GMT was performed by orally administering the Fm from the control and BPA-exposed ewes, respectively. The results revealed that BPA exposure disturbs the gut microbiota composition in pregnant ewes. GMT-induced BPA-exposed GM also induced BPA-like maternal FGR, placental dysfunction, and oxidative stress. Moreover, BPA exposure and GM transfer altered the gut microbiota composition, which was associated with changes in the concentrations of SCFAs and BAs. Interestingly, GM transfer also induced BPA-like alterations in the expressions of genes involved in the synthesis and transport of SCFAs and BAs, as well as their receptors in the colon and placental tissues. Furthermore, BPA exposure and GM transfer-induced dysbiosis in the gut microbiota was correlated with the dysfunction of the placental barrier and endocrine, ER, inflammatory responses, and autophagy. These data offer novel mechanistic insights into whether ERS is involved in BPA-mediated placental dysfunction and fetal development. 統合_0833	H. Zhang, R. Yang, W. Shi, X. Zhou and S. Sun	2022	The association between bisphenol A exposure and oxidative damage in rats/mice: A systematic review and meta-analysis	Numerous studies reported that BPA could cause oxidative damage to different tissues in rats/mice. This study aimed to perform a systematic review and meta-analysis of BPA exposure on oxidative damage in rats/mice. A comprehensive literature search was conducted using PubMed, Embase, and Web of Science databases from their inception until July 26, 2021. 21 eligible articles were included in this study. The results showed that BPA could significantly increase the level of MDA (SMD, 16.88; 95%CI, 12.38–21.71), but there was a significant reduction in the contents of antioxidants, such as SOD (-10.46, -13.91 – -7.02), CAT (-8.08, -11.48 – -4.68), GPx (-9.31, -12.95 – -5.68), GST (-7.94, -14.51 – -1.37), GSH (-10.64, -13.96 – -7.33), and T-SOD (-6.48, -9.27 – -3.68) in rats/mice. Our study provided new evidence that BPA exposure could significantly induce oxidative damage in rats/mice. Entire dose found that the degree of oxidative damage was related to BPA dose, target tissue, intervention means, and exposure duration of BPA. 統合_0834	H. Zhang, H. Kuang, Y. Luo, S. Liu, L. Meng, Q. Pang and R. Fan	2019	Low-dose bisphenol A exposure impairs learning and memory ability with alterations of neuromorphology and neurotransmitters in rats	To investigate the developmental neurotoxicity of environmental bisphenol A (BPA) exposure for infants and children, postnatal rats were used as the animal model and were divided into four groups. Then, they were exposed to 0 (control), 0.05, 5, and 50 mg/kg BPA by gavage from PND 1 to PND 21. Behavioral tests, including the Morris water maze test, open field test, and novel object recognition test, were performed. Immunohistochemistry, transmission electron microscopy (TEM), ELISA, HPLC, and western blot analysis were used to detect the hippocampal neuron morphology and neurotransmitter levels, respectively. The results showed that the BPA-exposed rats, especially the low- and high-exposed rats, needed more trials and longer times to qualify for the learned criterion than the control rats. Additionally, rats after low- or high-exposure to BPA exhibited decreased DG dendritic complexity and reduced CA1 and DG dendritic spine densities in the hippocampus. Low-dosage BPA treatment could significantly alter the neurotransmitter contents in the hippocampus. In male rats, the levels of glutamic acid (Glu) and acetylcholine increased, while the 5-hydroxytryptamine (5-HT) and γ-aminobutyric acid (GABA) levels decreased, which led to an unbalanced Glu/GABA ratio. However, in female rats, only 5-HT levels decreased. In contrast, neonatal exposure to BPA could not alter the dependently dose-dependent developmental neurotoxicity in female rats. Taken together, these results showed that

統合_0856	D. Wu, F. Wu, R. Lin, Y. Meng, W. Wei, Q. Sun and L. Jia	2020	Impairment of learning and memory induced by perinatal exposure to BPA is associated with ER α -mediated alterations of synaptic plasticity and PKC/ERK/CREB signaling pathway in offspring rats	The effect of bisphenol A (BPA) on learning and memory has attracted much attention recently, but its underlying mechanism remains unclear. We aimed to investigate whether the impairment of learning and memory induced by perinatal exposure to BPA was associated with the hippocampal estrogen receptor -α (ERα)-mediated synaptic plasticity and PKC/ERK/CREB signaling pathway in different sex offspring rats. Pregnant Sprague-Dawley rats were exposed to BPA (0, 0.5, 5, 50 mg/kg/day, n = 10/group) from gestation day 9 to postnatal day 21. The Morris water maze test was used to assess the learning and memory ability, place navigation and spatial memory, placement and object recognition, and step-down passive avoidance task were performed. The serum estradiol (E2) levels, histopathology of hippocampus, and the expressions of learning and memory-related proteins were measured. The results showed that spatial and recognition memory were impaired in BPA -exposed female and male offspring, but the impaired passive avoidance memory presented only in males, not in females. Moreover, BPA was found to increase in BPA -exposed females and males. BPA altered the morphology and quantity of hippocampal neurons. The levels of ERα, MAPK receptor subunit 2B (MAP2B), p-MEK, MAPK receptor 1 (ERK1), p-ERK1, PKCγ, p-PKCγ, CREB, and p-CREB protein expression were decreased in BPA -exposed females and males, and there were interactions of sex × BPA exposure in ERα, p-MEK and p-ERK levels. These findings suggested that perinatal exposure to BPA has sex-specific effects on learning and memory, which is associated with ERα -mediated impairment of synaptic plasticity and down-regulation of PKC/ERK/CREB signaling pathway.	Brain Res Bull Vol.161 Pages 43-54	10.1016/j.brainresbull.2020.04.023	32380187	動物	-	1	1	1	1	0	1、10 μg/mL	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-
統合_0857	D. Wu, H. Liu, Y. Liu, W. Wei, Q. Sun, D. Wei and L. Jia	2021	Protective effect of alpha-lipoic acid on bisphenol A-induced learning and memory impairment in developing mice: nNOS and keap1/Nrf2 pathway	The adverse effects of bisphenol A (BPA) on learning and memory may be related to th oxidative stress, but the mechanisms are unclear. This study aimed to investigate the mechanism of damaged learning and memory caused by BPA through inducing oxidative stress, as well as to explore whether alpha-lipoic acid (ALA) has a protective action. Female mice were exposed to 0.1 μg/mL BPA, 0.5 μg/mL BPA, 50 mg/mL ALA and 50 + 50 mg/mL ALA (mixed drinking water for 8 weeks. The results showed that ALA protected against the impairment of spatial, recognition, and avoidance memory caused by BPA. ALA ameliorated the values of hippocampal oxidative stress parameters, including malondialdehyde (MDA), superoxide dismutase (SOD), glutathione peroxidase (GSH-Px), and total antioxidant capacity (T-AOC) induced by BPA. ALA also ameliorated the synaptic structural proteins and PKC/ERK/CREB pathway proteins, and ALA improved these indexes reductions. ALA allowed the protein levels of nNOS and keap1/Nrf2 pathway affected by BPA. Our results suggested that impairments of learning and memory caused by BPA was related to the damage of hippocampal synapses mediated by oxidative stress, and ALA protected learning and memory by reducing the oxidative stress induced by BPA through regulating the nNOS and keap1/Nrf2 pathway. 統合_0858	C. Wormsbaecher, A. B. Hindman, A. Avendaño, M. Cortes-Medina, C. E. Jones, A. Buchman, L. Orua, C. E. Kowalchik, A. R. Murphy, H. L. Hellier, A. Stapkins, K. Voytovich, X. Kuang, R. Aguilar-Valenzuela, J. L. Leight, J. W. Song and C. J. Burd	2020	In utero estrogenic endocrine disruption alters the stroma to increase extracellular matrix density and mammary gland stiffness	BACKGROUND: In utero endocrine disruption is linked to increased risk of breast cancer later in life. Despite numerous studies establishing this linkage, the long-term molecular changes that predispose mammary cells to tumorigenesis remain poorly understood. Bisphenol A (BPA) is a ubiquitous endocrine disrupting chemical that has been shown to increase breast cancer risk in animal models. We have utilized bisphenol A (BPA) as a model of estrogenic endocrine disruption to evaluate the long-term consequences in the stroma. Deregulated genes were identified by RNA -seq hierarchical profiling of adult primary fibroblasts, isolated from female mice exposed to in utero BPA. Collagen staining, collagen imaging techniques, and permeability assays were used to characterize changes to the extracellular matrix. Finally, gland reconstitution assays were performed to determine if changes in the stroma were sufficient to induce changes in the epithelium. RESULTS: Fibroblasts isolated from BPA -exposed mice exhibited a 3-fold increase in cell-mediated collagen matrix compaction. Multiple collagen genes were found to be expressed in the BPA -exposed fibroblasts resulting in increased collagen deposition in the adult mammary gland. This transcriptional reprogramming of BPA -exposed fibroblasts generates a less permeable extracellular matrix and a stiffer mammary gland. These phenotypes were only observed in adult (12 -week -old, but not 5 -week -old) mice. Additionally, diethylstilbestrol, known to increase breast cancer risk in humans, also increases gland stiffness, similar to BPA, while bisphenol S does not. CONCLUSIONS: As tissue stiffness, extracellular matrix density, and collagen deposition have been directly linked to breast cancer risk, these data mechanistically connect EDC exposures to molecular alterations associated with increased disease susceptibility. These alterations, starting even time and thus contributed to cancer risk in adulthood.	Breast Cancer Res Vol.22 Issue 1 Pages 41	10.1186/s13058-020-01275-w	32370801	動物	-	1	0	1	不明	0	25 μg/kg	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-
統合_0859	C. Wormsbaecher, B. M. Cuntibia, E. G. Amrugia, L. M. Puska, M. R. Price, K. M. Ma, S. E. Knoblaugh, T. Kurtis and C. J. Burd	2023	Mammary gland development and EDC-driven cancer susceptibility in mesenchymal ERα -knockout mice	Development of the mammary gland requires both proper hormone signaling and cross-talk between the stroma and epithelium. While estrogen receptor (ER α) expression in the epithelium is essential for normal gland development, the role of this receptor in the stroma is less clear. Moreover, several lines of evidence suggest that stromal phenotypes of in utero exposure to endocrine disruption act through mesenchymal ERα in the epithelium to increase cancer risk. Here, we utilize mesenchymal ERα -knockout mice to determine the role of this receptor in the stroma during development and in response to in utero bisphenol A (BPA) exposure to alter the tumor susceptibility in the mouse mammary gland. Mesenchymal ERα -knockout mice exhibited delayed mammary gland development and reduced cancer risk. Mesenchymal ERα -knockout mice also exhibited delayed reproductive tract development and atypical cycling associated with estrous cycling. The mammary gland demonstrated mature epithelial extension within complete ERα+ lobular-like structures, but ductal extension was delayed and reduced compared to ERα -competent mice. Using the MATT (Mouse Mammary Tumor Virus -Neu -ires -Cre) model, we found that mesenchymal ERα -intact mice exposed to BPA had reduced tumor-free survival and overall survival compared to BPA -exposed mice lacking mesenchymal ERα activation. This difference is specific for BPA exposure as vehicle -treated animals had no difference in tumor development between mice expressing and not expressing mesenchymal ERα. These data demonstrate that mesenchymal ERα -expression is not required for ductal extension, nor does it influence cancer risk in this mouse model but does influence the tumor incidence associated with in utero BPA exposure. Rissman	2019	Transgenerational Bisphenol A Causes Deficits in Social Recognition and Alters Postsynaptic Density Genes in Mice	Bisphenol A (BPA) is a ubiquitous endocrine disrupting chemical. Developmental exposure produces changes in behavior and gene expression in the brain. Here, we examined social recognition behaviors in mice from the third familial generation (F3) after exposure to gestational BPA. Six-cell generation mice were bred to one of four mating combinations to reveal whether characteristics in F3 were acquired via maternal or paternal lineage. Mice were exposed to 0 (vehicle) or 50 μg/kg BPA during gestation days 8 to 14. Social recognition was tested in adulthood (90 days) using a habituation/dishabituation task. The same mice were tested in F3 for changes in the expression of PSD genes using quantitative PCR. Differential expression in genes important for the solubility of PSDs were assessed at three developmental ages. Social recognition was impaired in BPA-lineage females and males. Gene expression was altered in the postsynaptic density (PSD) scaffolding protein Dlg4 (PSD-95). Dlg4 and Dlg2 (PSD-93) were differentially expressed in several -to-BPA-lineage males. Using a second strain of F3 inbred mice exposed to BPA, we tested the same differences in Dlg4 and F11R3 expression in C57BL/6J mice. In sum, transgenerational BPA exposure altered social interactions in mice and dysregulated normal expression of PSD genes during neural development. The fact that the same genetic effects were found in different mouse strains and in several brain regions increased potential for translation. The genetic and functional relationship between PSD and abnormal neurobehavioral disorders is well established, and our data suggest that BPA may contribute to a transgenerational reverse in neurodevelopmental disorders. 統合_0861	M. Wiczyńska, E. Lepiarczyk, L. Paukszto, K. G. Maksiszcenko, A. Lipka, M. A. Maldzieri, L. Polak, K. Makowska, S. Gonkowski, P. Correia-de-Sá and M. Majewska	2023	A comprehensive transcriptomic analysis of the bisphenol A affected kidney in mice	Introduction: Bisphenol A (BPA) is a substance belonging to the endocrine-disrupting chemicals, globally used in the production of polycarbonate plastics. It has been found that BPA enhances carcinogenesis, triggers obesity and exerts a pathogenic effect in several disorders, such as type 2 diabetes, asthma, or increased blood pressure. Recent studies have revealed, that BPA has a harmful impact on the kidneys function, therefore, the current research aimed to explore the specific molecular changes triggered in these organs after oral BPA exposure in mice. Materials and Methods: The experiment was carried out on 22 (5-month-old) female mice, divided into two groups: the control group (C) and the BPA group (BPA). The BPA group was exposed to BPA in drinking water at a dose of 50 mg/kg b.w./day for 28 days. The RNA-Seq analysis was used to perform RNA-seq. Results: Applied multiway bioinformatic revealed 210 differentially expressed genes (DEGs) in the BPA-treated kidneys (120 upregulated and 90 downregulated). Additionally, 99 differentially expressed long noncoding RNAs (DELs) were revealed in BPA samples. The Gene Ontology (GO) and Kyoto Encyclopedia of Genes and Genomes (KEGG) annotations indicated that BPA exposure resulted in profound changes, in several essential processes, such as: oxidative phosphorylation, mitochondrial and ribosome function, or chemical carcinogenesis. Conclusion: The obtained novel results suggest that BPA has a harmful impact on the fundamental processes of the kidney and significantly impairs its functionality reducing mitochondrial dysfunction leading to oxidative stress and reaction oxygen species production. Majewska	2023	The Carcinogenic Potential of Bisphenol A in the Liver Based on Transcriptomic Studies	Bisphenol A (BPA) is an environmental toxin widely used in the production of polycarbonate plastics. A correlation exists between BPA tissue contamination and the occurrence of pathological conditions, including cancer. Five-passage detoxification of high BPA amounts in the liver promotes hepatotoxicity and morphological alterations of this organ, but there is a lack of knowledge about the molecular mechanisms underlying these changes. Therefore, the current research aimed to explore the specific molecular changes triggered in the liver after oral BPA exposure in mice. Materials and Methods: The experiment was carried out on 22 (5-month-old) female mice, divided into two groups: the control group (C) and the BPA group (BPA). The BPA group was exposed to BPA in drinking water at a dose of 50 mg/kg b.w./day for 28 days. The RNA-Seq analysis was used to perform RNA-seq. Results: Applied multiway bioinformatic revealed 210 differentially expressed genes (DEGs) in the BPA-treated livers (120 upregulated and 90 downregulated). Additionally, 99 differentially expressed long noncoding RNAs (DELs) were revealed in BPA samples. The Gene Ontology (GO) and Kyoto Encyclopedia of Genes and Genomes (KEGG) annotations indicated that BPA exposure resulted in profound changes, in several essential processes, such as: oxidative phosphorylation, mitochondrial and ribosome function, or chemical carcinogenesis. Conclusion: The obtained novel results suggest that BPA has a harmful impact on the fundamental processes of the liver, which is predictive of the carcinogenic potential of this compound in this organ. 統合_0863	T. T. Wit- Shwe, R. Yanagisawa, E. Koike and H. Takano	2021	Dietary exposure to bisphenol A affects memory function and neuroimmune biomarkers in allergic asthmatic mice	Bisphenol A (BPA) is a raw material of polycarbonate and epoxy resin. It is used for various household electrical appliances, electronic equipment, office automation equipment, medical equipment, mobile phones, paints for automobiles, internal surface coating of cans, and adhesives for civil engineering and construction. BPA is a well-known endocrine disrupting chemical, and it was reported that BPA has an adverse effect on the immune system. However, the effect of BPA on the central nervous system, especially on memory function, is not well understood. Therefore, we investigated the effects of dietary exposure to BPA on brain function and biomarkers using allergic asthmatic mice. Female mice were fed rice diets containing 0 (control), 0.001, 0.01, or 1 μg/kg/day concentrations of BPA for seven consecutive weeks. Then, ovalbumin (OVA) was given by intranasal instillation every 2 weeks. Memory function was determined by a novel object recognition test. Genes related to memory and immune markers in the hippocampus were measured by real-time RT-PCR. Ovalbumin-specific IgE (OVA-IgE) in the serum was measured by ELISA. Results: Memory impairment was observed in the presence of allergen. However, upregulation of expression levels of neurotrophin biomarkers such as N-methyl-D-aspartate receptor, nerve growth factor -α, cerebral calcium binding adapter molecule -1, cyclooxygenase-2, and nerve regulation-1 in the hippocampus was observed in BPA-exposed allergic asthmatic mice. These findings show that BPA exposure can induce neuroinflammation and which triggers impairment of memory function in mice with allergic asthma. Our study	J Appl Toxicol Vol.41 Issue 10 Pages 1527-1536	10.1002/jat.4143	33474794	動物	-	1	1	1	C3H/HeJSlc	0	0.001、0.01 μg/kg/日	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-
統合_0864	T. T. Wit- Shwe, R. Yanagisawa, E. Koike and H. Takano	2019	Memory Function, Neurological, and Immunological Biomarkers in Allergic Asthmatic Mice Intratracheally Exposed to Bisphenol A	Bisphenol A (BPA) is a major constituent of plastic products, including epoxy resin containers, mobile phones, dental sealants, as well as electronic and medical equipment. BPA is recognized as an endocrine system disrupting chemical which has toxic effects on the brain and reproductive system. However, little is known about the effects of co-exposure of BPA with allergens on the memory function and neurological as well as immunological biomarkers. Female mice were given 0 (control), 0.1 (low dose), or 10 (high dose) μg/kg/day BPA intratracheally (i.t.) for 5 consecutive days. Then, mice (C3H/He Jcl mice were given three doses of BPA (0.6/0.6 μmol, i.t.)) 0 and 10 μmol BPA) solution) immediately every week, and ovalbumin (OVA) intratracheally every other week from 5 to 11 weeks old. At 12 weeks of age, a novel object recognition test was conducted after the final administration of OVA, and the hippocampal and hypothalami of the animals were collected after 24 h. The expression levels of the memory function-related genes N-methyl-D-aspartate (NMDA) receptor subunits, inflammatory cytokines, microglia markers, estrogen receptor alpha, and caspase receptor were examined by real-time RT-PCR. Real-time reverse transcription polymerase chain reaction and immunohistochemical methods. Treatment of the novel object recognition ability was observed in the high dose BPA -exposed mice with allergic asthma. In addition, the expression levels of memory function-related genes were significantly decreased in the high dose BPA -exposed mice with allergic asthma. Moreover, the immunohistochemical results revealed that BPA -treated mice showed significantly increased NMDA receptor subunit 2B -immunoreactivity. These findings suggest that exposure to high dose BPA triggered impairment of memory function in the allergic asthmatic mice. This is the first study to show that, in the presence of allergens, exposure to high dose BPA may affect memory by modulating the memory function-related genes in the hippocampus. 統合_0865	M. Wieckowski, S. Ranga, D. Molson, S. Mesalam, S. Abdallah, S. Granon, R. Habert, V. Rouillier-Fabre, G. Livera and M. J. Guerquin	2021	Unexpected Interacting Effects of Physical (Radiation) and Chemical (Bisphenol A) Treatments on Male Reproductive Functions in Mice	For decades, numerous chemical pollutants have been described to interfere with endogenous hormone metabolism's/signaling altering reproductive functions. Among these endocrine disrupting substances, Bisphenol A (BPA), a widely used compound, is known to negatively impact germ and somatic cells in the testis. Physical agents, such as ionizing radiation, were also described to perturb spermatogenesis. Despite the fact that we are constantly exposed to numerous environmental chemical and physical compounds, very few studies explore the impact of combined exposure to chemical and physical pollutants on reproductive health. The aim of this study was to investigate the effects of BPA exposure (0.5 μg/mL in drinking water) on the male reproductive system of mice exposed to a sub-lethal dose of X-rays (0.5 Gy). Adult male mice were treated or not treated since birth (0.5 Gy) or only INDO at 0.15 days post conception. Co-exposure to BPA and γ -rays induces DNA damage in the germ cells in an additive manner, leading to a long-lasting decrease in sperm cell abundance. We also observed significant alteration of adult steroidogenesis by INDO exposure independently of the BPA exposure. This is illustrated by the downregulation of steroidogenic genes and the decrease of the number of adult Leydig cells. As a consequence, Leydig cells dysfunction is modified, and male alterations' ascertainments associated with infertility decreased. In conclusion, this study provides evidence for the importance of broadening the concept of endocrine disruptors to include physical agents, leading to a remodulation of risk management and regulatory decisions. 統合_0866	J. Weng, Y. Y. Zhu, L. Y. Liao, X. T. Yang, Y. H. Dong, W. D. Meng, D. J. Sun, Y. Liu, W. Z. Pang and Y. Jiang	2024	Distinct epigenetic modulation of differentially expressed genes in the adult mouse brain following prenatal exposure to low-dose bisphenol A	Bisphenol A (BPA) is a common component in the manufacture of daily plastic consumer goods. Recent studies have suggested that prenatal exposure to BPA can increase the susceptibility of offspring to mental illness, although the underlying mechanisms remain unclear. In this study, we performed transcriptomic and epigenomic profiling in the adult mouse brain following prenatal exposure to low-dose BPA. We observed a sex-specific transcriptional response to BPA exposure, with more differentially expressed genes (DEGs) identified in males than in females. Functional enrichment analysis revealed that the DEGs in males were significantly enriched within the downregulated genes, were significantly associated with energy metabolism pathways. More importantly, our findings supported the hypothesis that mitochondrial function included a decreased mtDNA copy number and reduced number of mitochondria in the cortical neurons of the BPA group. We further investigated the higher -order chromatin regulatory patterns of DEGs by incorporating published Hi -C data. Interestingly, we found that upregulated genes exhibited more distal interactions with multiple enhancers, while downregulated genes displayed relatively short -range interactions among adjacent genes. Our data further revealed distinct H3K4me3 signals on the distal enhancers of upregulated genes, whereas increased DNA methylation and H3K27me3 signals on the promoters of downregulated genes. In summary, our study provides compelling evidence for the potential health risks associated with prenatal exposure to BPA, and uncovers sex -specific transcriptional changes with a complex interplay of multiple epigenetic mechanisms. 統合_0867	X. Wen, M. Zhu, Z. Li, T. Li and X. Xu	2022	Dual effects of bisphenol A on wound healing, involvement of estrogen receptor β	Bisphenol A (BPA) is a ubiquitous environmental pollutant that can specifically induce estrogen receptor β (ERβ) expression, and the latter plays a crucial role during wound healing. However, no study has investigated the effects of BPA on wound healing. Therefore, we aimed to explore the effects of BPA on wound healing and the underlying mechanisms. Sprague-Dawley rats were used to establish a full-thickness skin defect model. The process of wound healing dietary intake (0 and 50 mg kg-1 and wound application (0 and 100 nM). Nine primary fibroblastoma were exposed to BPA to verify the role of BPA on the function of fibroblasts. We also applied BPA to diabetic mice to evaluate its therapy value. BPA showed dual effects on wound healing, which were dependent on the application routes. Dietary intake of BPA delayed wound healing by suppressing ovarian estrogen synthesis and circulating estrogen levels. Wound application of BPA promoted wound healing by activating ERβ. BPA enhanced the function of fibroblasts, which was blocked by ERβ inhibitor. Wound application of BPA significantly accelerated wound healing in diabetic mice but has no significant adverse effect on ovarian hormonic levels. The current study indicates that although BPA disrupts the function of the female ovaries when administered by diet, local application of BPA on wounds shows a superior role in promoting wound repair, and this may provide a novel approach for the therapy of pathologic wound healing. 統合_0868	Y. Wei, S. Li, C. Hao , Y. Bao and W. Shi	2019	Cuscuta chinensis flavonoids alleviate bisphenol A-induced apoptosis of testicular cells in male mice offspring	Bisphenol A (BPA) is a widespread environmental endocrine disruptor that has multiple effects on reproductive organ development. To investigate the effect of Cuscuta chinensis flavonoids (CCF) on testicular apoptosis induced by BPA in male mice offspring, pregnant mice were administered intragastrically with BPA and CCF at gestational day (GD) 12-17.5. The testes of male offspring (F1 males) were collected at post-natal day (PND) 21, PND 35, and PND 56 and were subjected to TUNEL staining and immunohistochemistry. The results indicated that CCF could protect the testes against BPA-induced apoptosis. The concentrations of CCF groups, the expression levels of Bax, caspase 9 and caspase 7 proteins were significantly decreased at PND 21 and PND 56, while the expression level of bcl-2 protein was significantly increased, and testicular apoptotic cells were also decreased significantly (p < .01 or p < .05). Forty-mg/kg CCF has no significant difference compared with the control group. The results indicated that CCF could protect the testes during development of F1 male mice by alleviating the apoptosis of testicular cells induced by BPA. 統合_0882	S. Wang, Y. Yang, D. Luo, L. Zhai, Y. Bai, W. Wei, Q. Sun and L. Jia	2021	Bisphenol A increases TLR4-mediated inflammatory response by up-regulation of autophagy-related protein in lung of adolescent mice	In previous studies we found that bisphenol A (BPA) aggravated OVA-induced lung inflammation. The aim of this research was to determine whether BPA exposure alone also induced inflammatory response in the lungs, which mechanism was associated with TLR4/NF-κB signaling pathway and the activation of mTOR-mediated autophagy. Female C57BL/6 mice aged 3 weeks were randomly divided into three groups (10 /group) corresponding to 0, 50, and 500 μg/kg/day BPA exposure by gavage for 28 consecutive days. The histopathological changes in lung tissues were observed by hematoxylin-eosin staining. In addition, the RAW264.7 cell culture experiment was conducted to determine whether BPA stimulated autophagy. We found that BPA can induce autophagy flux by enhancing autophagosome formation. It was further confirmed the details of the mechanism of action with chloroquine (CQ), a compound that inhibits the fusion of autophagosomes and lysosomes) intervention. The inhibition of autophagy led to down-regulation of expression levels associated with inflammation. This research results indicated that BPA-induced inflammatory response in vitro and in vivo, and its mechanism may be related to TLR4/NF-κB signaling pathway and the activation of mTOR-mediated autophagy. After autophagy was suppressed, the inflammatory response also weakened. Our findings provide a new perspective into the mechanisms underlying inflammatory responses induced by the environmental exposure. These findings indicate that therapeutic strategies targeting autophagy may provide a new method for the treatment of inflammatory diseases. 統合_0883	S. Wang, Y. Dong, L. Zhi, Y. Bai, Y. Yang and L. Jia	2024	Decreased Treg cells induced by bisphenol A is associated with up-regulation of PI3K/Akt/mTOR signaling pathway and Foxp3 DNA methylation in spleen of adolescent mice	The current study aimed to explore whether bisphenol A (BPA) exposure aggravated the decrease in Tregs induced by ovalbumin (OVA) in adolescent female mouse models of asthma, and whether the process was associated with mTOR-mediated signaling pathways and DNA methylation in the spleen. A 3-week-old female mice were randomly divided into three groups (10/group) corresponding to 0, 50, and 500 μg/kg/day BPA exposure by gavage for 28 consecutive days. The mice at the age of 4 weeks in the asthma model were established by ovalbumin (OVA) nasal and inhalation after 1 week of desensitization. Each group conducted of eight mice the control group, OVA group (OVA + BPA (0) 0 μg mL), CT group (OVA + BPA (50 μg mL), and OVA + BPA (0.2 μg mL) CT group). Results revealed that Foxp3 protein levels, Treg cells, and DNA methyltransferase 1 (DNMT1) mRNA levels in the spleen were significantly increased in the OVA group compared to the control group. Moreover, the OVA + BPA (0.2 μg mL) CT group exhibited significantly higher levels of these parameters than the OVA group. The mechanism was related to the activity of TLR4/NF-κB and PI3K/Akt/mTOR signaling pathways and the enhancement of Foxp3 DNA methylation. Our results, collectively, provide a new perspective for studying the mechanisms underlying BPA exposure-induced immune dysfunction. Investigation of the regulatory mechanisms of DNA methylation in the abnormal Th immune response caused by BPA exposure could help reveal the causes and molecular mechanisms underlying the high incidence of allergic diseases in children in recent years. 統合_0884	R. Wang, Z. H. Liu, N. Bi, K. Gu, C. Huang, R. Zhou, H. Liu and H. L. Wang	2023	Dysfunction of the medial prefrontal cortex contributes to BPA-induced depression- and anxiety-like behavior in mice	Bisphenol A (BPA), a well-known environmental endocrine disruptor, has been implicated in anxiety-like behavior. But the neural mechanism remains elusive. Herein, we found that mice exposed to 0.5 mg/kg/day BPA chronically from postnatal day (PND) 21 to PND 56 exhibited depression- and anxiety-like behavior. Further study showed that medial prefrontal cortex (mPFC) was associated with BPA-induced depression- and anxiety-like behavior, as evidenced by decreased c-fos expression in mPFC of BPA-exposed mice. Both the morphology and function of glutamatergic neurons (also called pyramidal neurons) in mPFC of mice were impaired following BPA exposure, characterized by reduced primary branches, condensed dendritic spines, and decreased mEPSC frequency. Importantly, optogenetic activation of the glutamatergic neurons in mPFC greatly reversed BPA-induced depression- and anxiety-like behavior in mice. Furthermore, we reported that microglial activation in mPFC of mice may also have a role in BPA-induced depression- and anxiety-like behavior. Taken together, the results indicated that mPFC is the brain region that is greatly damaged by BPA exposure and is associated with BPA-induced depression- and anxiety-like behavior. The study thus provides new insights into BPA-induced neurotoxicity and behavioral changes. 統合_0885	M. Wang, Y. Wang, J. Han, Z. Duan, J. Yin, R. Ding and Q. Wang	2023	Gestational and Lactational Co-Exposure to DEHP and BPA Impairs Hepatic Function via PI3K/AKT/FOXO1 Pathway in Offspring	(2-Ethylhexyl) phthalate (DEHP) and bisphenol A (BPA) present significant environmental endocrine-disrupting chemical properties. Although studies have implied reproductive impairment from exposure to BPA and DEHP, no study to date has shown the effect and mechanism of hepatic function after gestational and lactational co-exposure to DEHP and BPA in offspring. A total of 36 perinatal rats were randomly divided into four groups, CRAP (600 mg/kg bw/kg), BPA (50 mg/kg bw/kg), DEHP combined with BPA (600 mg/kg bw + 50 mg/kg bw), and control. Notably, (1) chemical reports and network pharmacology results revealed that the disorders mainly concentrated the most severe structural damage, including vacuolization, cytoplasmic shedding, and mitochondrial degeneration. BPA exposure disrupted oxidative stress homeostasis by reducing superoxide dismutase activity and increasing malondialdehyde (MDA) content, and decreasing the activity levels of SOD, CAT, GSH, and T-AOC. BPA further induced hepatic inflammation by upregulating the gene abundance of key factors of the immune system (TLR2, IL-6, MyD88, and NF-κB); the transcriptional activity of NF-kB; and the secretion of pro-inflammatory cytokines (IL-1,β, IL-6, IL-8, and TNF-α). Moreover, apoptosis was activated by BPA, whereas cell proliferation was inhibited by BPA. Mechanistically, co-treatment of intestinal epithelial cells with BPA using the oxidative stress scavenger NAC, the NF-κB-specific inhibitor QNZ (EVP4593), and the apoptosis inhibitor Z-VAD-FMK, respectively, showed that BPA activates the innate immune response by inducing oxidative stress. Consequently, apoptosis is promoted, and cell proliferation is inhibited, ultimately disrupting the intestinal barrier function. Our findings provide insight into the pathogenesis of BPA-induced gut injury. 統合_0886	K. Wang, Z. Zhao and W. Ji	2019	Bisphenol A induces apoptosis, oxidative stress and inflammatory response in colon and liver of mice in a mitochondria-dependent manner	Bisphenol A (BPA), a widely used industrial compound worldwide, was recently classified as environmental toxicant. The intestines and liver are responsible for detoxification to humans and animals, and functional damage to these organs adversely affects the health of the body. However, the effects of BPA on intestinal and liver function remain unclear. In this study, we investigated the effects of dietary BPA uptake on oxidative stress, inflammatory response, apoptosis and mitochondrial pathway in the colons and livers of mice. Eighteen male ICR mice were randomly divided into three groups (6 mice/group). BPA (50 mg/kg bw/day) and BPA (600 mg/kg bw/day) were administered to mice by oral gavage, respectively, for 30 days. Histopathological results revealed that the duodenum and liver of mice exposed to BPA were severely structural damage, including villous atrophy, epithelial shedding, and mitochondrial degeneration. BPA exposure disrupted oxidative stress homeostasis by reducing superoxide dismutase activity and increasing malondialdehyde (MDA) content, and decreasing the activity levels of SOD, CAT, GSH, and T-AOC. BPA further induced hepatic inflammation by upregulating the gene abundance of key factors of the immune system (TLR2, IL-6, MyD88, and NF-κB); the transcriptional activity of NF-kB; and the secretion of pro-inflammatory cytokines (IL-1,β, IL-6, IL-8, and TNF-α). Moreover, apoptosis was activated by BPA, whereas cell proliferation was inhibited by BPA. Mechanistically, co-treatment of intestinal epithelial cells with BPA using the oxidative stress scavenger NAC, the NF-κB-specific inhibitor QNZ (EVP4593), and the apoptosis inhibitor Z-VAD-FMK, respectively, showed that BPA activates the innate immune response by inducing oxidative stress. Consequently, apoptosis is promoted, and cell proliferation is inhibited, ultimately disrupting the intestinal barrier function. Our findings provide insight into the pathogenesis of BPA-induced gut injury. 統合_0887	K. Wang, J. Tang, D. Shen, Y. Li, K. Nagaoka and C. Li	2025	Bisphenol A Exposure Induces Small Intestine Damage Through Oxidative Stress, Inflammation, and Microbiota Alteration in Rats	Bisphenol A (BPA), a widespread environmental contaminant used in plastics and resins, poses significant health risks due to its endocrine-disrupting properties and potential for inducing intestinal toxicity. This study explored the toxicological effects of BPA on the small intestine of rats, focusing on the duodenum, jejunum, and ileum. Histopathological results revealed that the duodenum experienced the most severe structural damage, including villous atrophy, epithelial shedding, and mitochondrial degeneration. BPA exposure disrupted oxidative stress homeostasis by reducing superoxide dismutase activity and increasing malondialdehyde (MDA) content, and decreasing the activity levels of SOD, CAT, GSH, and T-AOC. BPA further induced intestinal inflammation by upregulating the gene abundance of key factors of the immune system (TLR2, IL-6, MyD88, and NF-κB); the transcriptional activity of NF-kB; and the secretion of pro-inflammatory cytokines (IL-1,β, IL-6, IL-8, and TNF-α). Moreover, apoptosis was activated by BPA, whereas cell proliferation was inhibited by BPA. Mechanistically, co-treatment of intestinal epithelial cells with BPA using the oxidative stress scavenger NAC, the NF-κB-specific inhibitor QNZ (EVP4593), and the apoptosis inhibitor Z-VAD-FMK, respectively, showed that BPA activates the innate immune response by inducing oxidative stress. Consequently, apoptosis is promoted, and cell proliferation is inhibited, ultimately disrupting the intestinal barrier function. Our findings provide insight into the pathogenesis of BPA-induced gut injury. Fecal microbiota analysis revealed reduced α-diversity, enrichment of pathogenic taxa like Escherichia-Shigella, and depletion of beneficial genera such as Lachnospiraceae NK4A136 group, exacerbating gut inflammation and barrier dysfunction. These findings suggest that BPA-induced small intestinal damage is driven by oxidative stress, inflammation, and gut dysbiosis, with the duodenum and jejunum being the most vulnerable segments. 統合_0889	K. Wang, D. Huang, P. Zhao, X. Su, R. Yang, C. Shao and J. Wu	2022	Bisphenol A exposure triggers the malignant transformation of prostatic hyperplasia in beagle dogs via cfa-miR-204/KRAS axis	The prostatic toxicity of bisphenol A (BPA) exposure is mainly associated with hormonal disturbances, thus identifying solid multiple signal pathways and increasing the susceptibility to prostatic lesions. This study investigated the malignant transformation of prostatic hyperplasia in beagle dogs exposed to BPA and explored the underlying mechanisms. Twenty-four beagle dogs were randomly divided into four groups (6/group) corresponding to 0, 5, 50, and 500 mg/kg/day BPA exposure by oral gavage for 52 consecutive weeks. Histopathological results revealed that BPA exposure could trigger the abnormal prostatic hyperplasia in beagle dogs. Hormone level detection revealed that the ratios of estradiol (E2) to testosterone (T) (E2/T) and prolactin (PRL) to T (PRL/T) were up-regulated in the serum from BPA group. Based on microRNA (miRNA) microarray screening and functional enrichment analysis, BPA might facilitate the expression of prostate hyperplasia in beagle dogs via miR-204 and its downstream target KRAS oncogene. Subsequently, the overexpression of KRAS, CDK6/8, MAPK1, YAP1/3, BCL2 and PTEN was validated. These findings provide a series of underlying targets for preventing the initiation and metastasis of BPA-induced prostatic hyperplasia and hemangiomas, while the regulatory relationship headed miR-204/KRAS requires further investigations. 統合_0890	K. Wang, D. Huang, P. Zhao, X. Su, R. Yang, C. Shao, A. Ma and J. Wu	2022	Individual and Combined Effect of Bisphenol A and Bisphenol AF on Prostatic Cell Proliferation through NF-κB Signaling Pathway	The ubiquitous environmental endocrine disruptor bisphenol A (BPA) can induce prostatic dysfunction. However, to date, studies have focused little on the perturbations of prostate health initiated by the BPA alternative bisphenol AF (BPAF) and co-exposure to bisphenol compounds. An in vivo study and a beta-estradiol-treated model in vitro with BPA (0, 50, 4 μg/kg), BPAF (10, 50, 4 μg/kg), BPAF + 50 μg/kg BPA, and the nuclear factor-κB (NF-κB) pyrrolidinedithiocarbamate (PDTC, 100 mg/kg). Based on the endocrinal analysis, pathological observations and PCNA over-expression, we considered that low-dose BPA and BPAF facilitated normal prostatic hyperplasia, while high-dose BPA and co-exposure to BPA and BPAF induced abnormal prostatic hyperplasia. Moreover, the NF-κB signaling pathway was activated in the prostatic hyperplasia induced by BPA, BPAF, and co-exposure to BPA and BPAF. Additionally, the BPA + BPAF (50 + 50 μg/kg) exposure could cause an elevation in the proliferation of extra-nuclear in the prostatic tract of human prostate stromal cells (WPMY-1) and keratinocytes (HPV-1). Meanwhile, the underlying biomarkers of the NF-κB signaling pathway also involved the observed proliferative progression of prostate cells. The findings recapitulated the induction of BPAF exposure and co-treatment with BPA and BPAF on prostatic hyperplasia and emphasized the modulation of the NF-κB signaling pathway. 統合_0891	J. Wang, C. Su, M. Qian, X. Wang, C. Chen, Y. Liu, W. Liu, Z. Xiang and B. Xu	2024	Subchronic toxic effects of bisphenol A on the gut-liver-hormone axis in rats via intestinal flora and metabolism	MACROSCALES: Bisphenol A (BPA), a characteristic endocrine disruptor, is a substance that seriously interferes with the human endocrine system and causes reproductive disorders and developmental abnormalities. However, its toxic effects on the gut-liver-hormone axis are still unclear. METHODS: Male and female rats were exposed to BPA (300 mg/kg) by oral gavage for 60 consecutive days. H&E staining was used for histopathological evaluation, and the serum biochemical indexes were determined using an automatic analyzer. The 16S rRNA gene sequencing was used to detect the intestinal microbiota, and the GC-MS was used to analyze the contents of short-chain fatty acids (SCFAs) in colon contents. UPLC-QTOF-MS was used to analyze the related metabolites. The ELISA method was used to assess the levels of serum inflammatory factors and hormones. RESULTS: Histopathological observations revealed that BPA exposure caused damage to the liver and colon in rats. BPA exposure significantly increased the liver and kidney coefficients (LDL-C in the male BPA group (P < 0.05), and globulin (GLB), bilirubin (BIL), alkaline phosphatase (ALP), ALT, TG, TC, high-density lipoprotein (HDL-C), and IL-1β in the female BPA group (P < 0.05). Metagenomic (16S rRNA gene sequencing) analysis indicated that BPA reduced the diversity and changed the composition of gut microbiota in rats significantly. Compared with the control and female groups, BPA exposure significantly increased the abundance of Bacteroidetes and Proteobacteria and decreased the abundance of Firmicutes in male rats. Moreover, BPA exposure significantly reduced the contents of SCFAs, such as acetic acid, propionic acid, butyric acid, isobutyric acid, valeric acid, and isovaleric acid, in the colon contents, especially in the female BPA group (P < 0.05). Metabolomic analysis of the serum indicated that BPA could aggravate the acid levels, cause ethylmalonic acid and 3-methylglutaconic acid to be conjugated forms. The contents of amino acids, hormones, and lipids were also significantly affected after exposure to BPA. The increase in interleukin-6 (IL-6), interleukin-22 (IL-22), and transforming growth factor-β (TGF-β) in the serum of the male BPA group suggests that BPA exposure affects the immune system. CONCLUSION: BPA exposure will cause toxic injury to rats, like disrupting the gut-liver-hormone axis. 統合_0892	J. Wang, S. Jin, W. Fu, Y. Liang, Y. Yang and X. Xu	2021	Pubertal exposure to bisphenol-A affects social recognition and arginine vasopressin in the brain of male mice	Social recognition is an ability of animals to identify and distinguish conspecifics, which is essential for nearly all social species to establish social relationships. Social recognition provides the basis for a variety of social behaviors. Because of modulated by gonadal hormones, it is possible that social cognition is affected by environmental endocrine disruptors (EEDs). In the present study, after being pubertal exposed to bisphenol-A (BPA, 0.01, 0.1, and 1 mg/kg) for 10 days, adult male mice did not show significant differences in social interaction time between familiar conspecifics and novel conspecifics. However, BPA-treated male mice showed a significant increase in social interaction time between familiar and novel female mice in between male and female mice was suppressed in BPA-exposed male. In addition, BPA (0.1, 1 mg/kg) decreased the number of immunoreactive of AVP (AVP-ir) neurons in both the bed nucleus of the stria terminalis (BNST) and the medial amygdala (MeA) of male mice. Moreover, BPA (0.1, 1 mg/kg) also decreased the AVP-ir fiber density in the lateral septum (LS) of male mice. Furthermore, BPA (0.1, 1 mg/kg) reduced the testosterone and estrogens receptor-α (ERα) in the BNST, and ERα and ERβ in the MeA of male mice. Taken together, pubertal exposure to BPA could impair social recognition in male mice, which may be associated with the reduction of AVP-ir neurons and fibers in the BNST and MeA, and the decrease of testosterone and estrogens receptor-α (ERα) in the BNST and MeA. Our results indicate that pubertal exposure to BPA affects the actions of both androgens and estrogens in the brain and inhibited AVP system of social circuits, and these alterations may be associated with impaired social recognition of adult male mice. 統合_0893	H. Wang, X. Lai, Z. Zhang, M. M. Omnasi, Z. Tang and J. Yuan	2022	Chronic exposure of bisphenol-A impairs cognitive function and disrupts hippocampal insulin signaling pathway in male mice	Bisphenol A (BPA), a well-known estrogenic endocrine disruptor, is generally applied to turn out plastic consumer products. Available data have manifested that exposure to BPA can trigger insulin resistance. Hence, the purview of the actual study was to consider the impacts of BPA exposure on cognitive function and insulin signaling pathway in the hippocampus of male offspring mice. For this purpose, the pregnant female mice were exposed to BPA (0.05 mg/kg/day) from GD 5 to PND 21. The Morris water maze (MWM) test was used to assess the cognitive function of male offspring mice at PND 60. Our results indicated that BPA exposure could not significantly affect the spatial learning and memory ability of male offspring mice at PND 60, but it significantly impaired the hippocampal insulin signaling pathway, which was confirmed by the results of PI3K/Akt. The behavioral study, blood sugar level, histological observation, western blotting, and quantitative polymerase chain reaction (Q-PCR) of the hippocampal tissues regarding pathway were checked for the male offspring mice at 12 weeks of age (PND60). Our data indicated that BPA exposure impaired cognitive function, disrupted the hippocampal neuron cell arrangement, increased blood glucose levels, disturbed the insulin signaling pathway including phosphorylated insulin receptor substrate 1 (p-IRS1), protein kinase B (p-AKT), and glycogen synthase kinase 3 β (p-GSK3 β) in the same time, the mRNA and protein expressions of GLUT4 were markedly down-regulated in the BPA-exposed groups. To sum up, it has been suggested from these results that BPA has detrimental effects on the insulin signaling pathway, which might subsequently be conducive to the impairment of cognitive function in the adult male offspring mice. Therefore, BPA exposure might in part be an element of risk for the long-term neurodegeneration in male offspring mice.	Toxicology. 2022 Apr 30:472:153192.	10.1016/j.tox.2022.153192	35489422	動物	発達神経毒性	1	1 (飲水)	1	1	1	1 (0.05 mg/kg/day)	-	-	-	-	-	-	-	1	1	-	1	-	1	-	-	-	-	-	-	-	-	-	-	-
統合_0894	G. Wang, G. Xu, C. Zhang, A. Han, G. Zhang, L. Chen, G. Xie, F. Tao, T. Sher and P. Su	2023	Gestational bisphenol A exposure advances puberty onset in female offspring: Critical time window identification	Increasing evidence shows that the early onset of puberty in female offspring may be caused by maternal prenatal exposure to bisphenol A (BPA) during pregnancy; however, the critical time window of maternal prenatal BPA exposure remains unknown. Here, we identify the critical time window of gestational BPA exposure that induces early onset of puberty in female offspring. Pregnant CD-1 mice were gavaged with BPA (0 mg/kg/d, 40 mg/kg/d) during the early gestational stage (GD1-GD6), middle gestational stage (GD7-GD12) or late gestational stage (GD13-GD18). We show that maternal BPA exposure during the early and middle gestational stages could advance the vaginal opening time and increase the serum levels of kisspeptin-10 and KiSS-1 in the female offspring at PND 35. Mechanistically, maternal BPA exposure during early and middle gestation could significantly increase Cyp1 b1and methylation in the first gene promoters but reduce the mRNA expression of Esr1 in the hypothalamus tissues of the female offspring. In conclusion, the critical period of maternal BPA exposure induces early puberty onset in female offspring is during early and middle gestation. Our findings provide a new perspective for the risk assessment of BPA and contribute to epigenetic programming of the first gene in the hypothalamus. This study provides important insights regarding the relationship and the mechanisms between BPA and affecting pubertal development. 統合_0908	A. Tsatsakis, A. O. Docea, C. Constantini, D. Calina, O. Zlatian, T. K. Nikolouzakis, P. O. Stoukatakis, A. Kalogeraki, J. Liesivuori, G. Tzanakakis and M. Neagu	2019	Genotoxic, cytotoxic, and cytopathological effects in rats exposed for 18 months to a mixture of 13 chemicals in doses below NOAEL levels	The present study investigates the genotoxic and cytotoxic effects of long-term exposure to low doses of a mixture consisting of methomyl, thiabendazole, diflubenzuron, glyphosate, carbaryl, methyl parathion, aspartame, sodium benzoate, EDTA, ethylparaben, butylparaben, bisphenol A and acesulfame-potassium. Four groups of ten Sprague-Dawley rats (5 males and 5 females per group) were exposed for 18 months to the mixture in dose levels below NOAEL (group 1 - 1/100 NOAEL, group 2 - 1/10 NOAEL, group 3 - NOAEL), while group 4 served as control. Genotoxicity was assessed by micronucleus test in bone marrow erythrocytes and by methomyl and by micronucleus test in bone marrow erythrocytes and by the comet assay in whole blood cells. Cytopathological examination showed specific alterations of tissue organization in a tissue type-dependent manner. The observed effects were dose-dependent and correlated to various tissue parameters. Specifically, testes samples revealed degenerative and cellularity disorders, liver hepatocytes exhibited decreased glycogen deposition but an increase degenerative changes were present in gastric cells. Lung tissue presented increased inflammatory cells infiltration and alveolar macrophages with enhanced phagocytic activity, whereas brain tissue exhibited changes in glial and astrocyte cells' numbers. In conclusion, exposure to very low doses of the tested mixture for 18 months induces genotoxic effects as well as mesenteric cytotoxic effects in a tissue-dependent manner. 統合_0909	V. G. Tucicu, M. Dumitrescu, I. M. Fanyo, I. F. Tudoache, M. Sinlovescu and A. V. Gafencu	2019	The Mechanism of Bisphenol A Atherogenicity Involves Apolipoprotein A-I Downregulation through NF- κ B Activation	Apolipoprotein A-I (apoA-I) is the major protein component of high-density lipoproteins (HDL), mediating many of its atheroprotective properties. Increasing data reveal the pro-atherogenic effects of bisphenol A (BPA), one of the most prevalent environmental chemicals. In this study, we investigated the mechanisms by which BPA exerts pro-atherogenic effects. For this, 120-150 d mice exercise with a high-fat diet and treated with 50 µg BPA/kg body weight by gavage. After two months of treatment, the area of atherosclerotic lesions in the aorta, triglycerides and total cholesterol levels were significantly increased, while HDL-cholesterol was significantly decreased in BPA-treated mice. Moreover, BPA induced a significant decrease in apoA-I expression in the liver and intestine, as well as in the plasma of mice, in a dose-dependent manner. This inhibitory effect was mediated by NFATC1/NF- κ B signaling pathways. Transfection experiments using apoA-I promoter-deletion mutants, chromatin immunoprecipitation, and protein-DNA interaction assays demonstrated that treatment of hepatocytes with BPA induced NF- κ B signaling and thus the recruitment of p65/50 proteins to the multiple NF- κ B binding sites located in the apoA-I promoter. In conclusion, BPA exerts pro-atherogenic effects downregulating apoA-I by NFATC1 signaling and NF- κ B activation in hepatocytes. 統合_0910	P. Torres-Alamilla, R. Castillo-Sanchez, P. Cortes-Reynosa, M. Sanchez-Juarez, R. Gomez and E. P. Salazar	2025	4T1 breast cancer cells exposed to extracellular vesicles from MDA-MB-231 cells stimulated with bisphenol A increase the growth of mammary tumors and metastasis in female Balb/cJ mice	Breast cancer is the most prevalent neoplasia in women worldwide. Triple-negative breast cancer (TNBC) is a subtype characterized by the absence of estrogen receptor, progesterone receptor and HER2 expression. Bisphenol A (BPA) is a chemical used in the synthesis of polycarbonate plastics and epoxy resins and its intake is related with breast cancer progression. Extracellular vesicles (EVs) are vesicles released by cells that mediate intercellular communication. However, the role of BPA in the release of EVs, mediating cancer progression in TNBC remains to be studied. We hypothesize that EVs from BPA-stimulated TNBC cells promote tumorigenesis in vivo. Therefore, we isolated EVs from MDA-MB-231 cells stimulated with 1 µM BPA for 24 h (BPA-EVs) and characterized them by TEM, NTA, and Western blot. Then, 4T1 cells were co-incubated with BPA-EVs and their tumor progression was studied in Balb/cJ mice. Co-incubation of 4T1 cells with BPA-EVs increased their migration, invasion and colony formation capacities. Balb/cJ mice inoculated with 4T1 cells exposed to BPA-EVs showed increased tumor growth, lung metastasis, and circulating tumor cells. Co-incubation of 4T1 cells with BPA-EVs increased the secretion of TNF-α, IL-6, and IL-10 in the TNBC-EVs' cargo. Furthermore, Balb/cJ mice inoculated in mammary fat pad with 4T1 cells exposed to BPA-EVs show mammary tumors with more weight and volume, and more metastatic nodules in lung and liver than Balb/cJ mice inoculated with 4T1 cells exposed to Ctrl-EVs. In conclusion, BPA-EVs represent a significant mediator of TNBC progression, which defining the EVs as a novel element through which BPA promotes breast cancer progression. Pallottini	2020	Maternal Dietary Exposure to Low-Dose Bisphenol A Affects Metabolic and Signaling Pathways in the Brain of Rat Fetuses	Bisphenol A (BPA) is a synthetic compound widely used for the production of polycarbonate plastic resins and epoxy resins. BPA exposure is widespread and more than 90% of individuals have detectable amounts of the molecule in their body fluids, which originates primarily from diet. Here, we investigated whether prenatal exposure to BPA affects the neurotrophic (BDNF) pathway in rat brain tissue, and whether potential effects are sex dependent. The BDNF pathway is important for brain development and function. Our results demonstrate that the fetal brain, exposed in utero to a very low dose of BPA (2.5 µg/kg/day), displayed altered BDNF pathway signaling, which was sex dependent. Specifically, BPA exposure in male fetuses induced a significant increase in BDNF and its receptor TrkB, whereas no significant changes were found in female fetuses. In conclusion, this work demonstrates intergenerational effects of BPA on the brain at very low doses. Our results reveal new targets for BPA-induced interference and underline the impacts of BPA on health. 統合_0912	C. Tiniini, M. Segatto, S. Bertoli, A. Leone, A. Mazzoli, L. Cigliano, L. Barberis, M. Mandalà and V. Pallottini	2021	Prenatal Exposure to BPA: The Effects on Hepatic Lipid Metabolism in Male and Female Rat Fetuses	Bisphenol A (BPA) is an organic chemical compound widely used for manufacturing plastics. BPA exposure originates principally from the diet, but it can also originate from dermal contact. In over 90% of individuals, including pregnant women, BPA is detectable in several body fluids. The effects of this exposure on the liver are under active investigation. In several research studies, the liver was the site used to study the impact of prenatal exposure to BPA in the liver of rat fetuses from a sex-dependent point of view. We particularly investigated the effects of prenatal BPA exposure on hepatic lipids because of their crucial role, not only for the liver but for the whole organism. Our results showed that BPA, at a very low dose (2.5 µg/kg/day), altered lipid metabolism in the liver of male fetuses, but not in female fetuses. BPA induced a significant increase in cholesterol and fatty acid biosynthesis, and well-being. Moreover, an impact on inflammatory processes has been observed. All these effects are dependent on sex, being observable only in female rat fetuses. In conclusion, this work demonstrates that maternal exposure to BPA compromises hepatic lipid metabolism in female offspring, and it also reveals the perspective impact of BPA on human health at doses currently considered safe. 統合_0913	M. Tian, P. Xia, X. Gou, L. Yan, H. Yu and X. Zhang	2022	CRISPR screen identified that UGT1A9 was required for bisphenols-induced mitochondria dyshomeostasis	Exposure to bisphenols chemicals could cause various adverse health effects, including non-alcoholic fatty liver disease (NAFLD), which have been associated with cellular mitochondria stress. However, the biological mechanism underlying the mitochondria stress-mediated cell death by bisphenols was poorly understood. Here, CRISPR screens were performed to identify the critical genes which were involved in cell death caused by exposure to four bisphenols (BPA, BPB, BPE and BPS). Results of CRISPR screens showed that UGT1A9 was the primary genetic factor facilitating cell death induced by all of the four bisphenols. Systematic toxicological tests demonstrated that UGT1A9 was required for BPS-induced mitochondria dysfunctions in vitro and in vivo, and UGT1A9-mediated mitochondria dysfunctions was an important cause of facilitating cell death. Liver injury caused by exposure to BPS in a UGt type mice was accompanied with suppression of mitophagy and increased expression of C. Caspase-3, but UGT1A9 knockout attenuated these adverse effects induced by BPS. Moreover, metabolomics and immunofluorescence results revealed that BPS-induced UGT1A9 overexpression activated the NRF2-ARE pathway to improve metabolic disorders of the liver caused by BPS. Therefore, UGt1A9 could potentially alleviate BPS-induced mortal liver injury through suppressing inflammation and oxidative stress, and modulating lipid metabolism disorders. 統合_0914	J. Tian, Y. Lu, Q. L. Zhao, Q. Y. Pu, S. Jiang and Y. P. Tang	2024	DHA-enriched phosphatidylserine alleviates bisphenol A-induced liver injury through regulating glycerophospholipid metabolism and the SIRT1-AMPK pathway	To investigate the alleviating effect and mechanism of the docosahexaenoic acid-enriched phosphatidylserine (DHA-PS) on bisphenol A (BPA)-induced liver injury in mice, the murine liver injury model was established by gavage of BPA (5 mg/kg) or co-administration of BPA and DHA-PS (50 mg/kg) or 100 mg/kg) for 6 weeks. The results showed that after administration of 100 mg/kg DHA-PS, the liver index, serum levels of ALT, ALT, TC, TBTA, and LDL-C in mice were significantly decreased, while HDL-C was significantly increased. The LPS, IL-6, IL-1β, TNF-α, and MDA levels in liver tissues were effectively down-regulated, and IL-10, SOD, GSH-Px, and CAT levels were effectively up-regulated. The H&E and Oil Red O staining results showed that liver damage was notably repaired and lipid deposition was notably reduced after DHA-PS administration. Furthermore, widely targeted metabolomics and immunofluorescence results revealed that DHA-PS mainly regulates glycerophospholipid metabolism and the SIRT1-AMPK pathway to improve metabolic disorders of the liver caused by BPA. Therefore, DHA-PS could potentially alleviate BPA-induced murine liver injury through suppressing inflammation and oxidative stress, and modulating lipid metabolism disorders. 統合_0915	J. L. M. Thorson, D. Beck, M. Ben Maamar, E. E. Nilsson and M. K. Skinner	2021	Ancestral plastics exposure induces transgenerational disease-specific sperm epigenome-wide association biomarkers	Plastic-derived compounds are one of the most frequent daily worldwide exposures. Previously a mixture of plastic-derived toxicants composed of bisphenol A, bis(2-ethylhexyl) phthalate, and dibutyl phthalate at low-dose exposures of a gestating female rats was found to promote the epigenetic transgenerational inheritance of diseases to the offspring (F1 generation), great-offspring (F2 generation), and great-great-offspring (F3 generation). Epigenetic analysis of the male sperm was found to result in differential DNA methylation regions (DMRs). In the transgenerational F3 generation male sperm, the current study's cohort and case descriptive cost or epigenome-wide association study to identify potential sperm DNA methylation biomarkers for specific transgenerational diseases. Observations indicate disease-specific DMRs called epimutations in the sperm were found to be associated with the transgenerational disease of kidney disease, ovarian disease, prostate disease, obesity, and pregnancy abnormalities. Importantly, these disease-specific sperm epimutation biomarkers were found to be predominately disease-specific. The genomic locations and features of these DMRs were identified. Interestingly, the disease-specific DMR-associated genes were previously shown to be linked with each of the specific diseases. Therefore, the germline has ancestrally derived epimutations that potentially transmit transgenerational disease susceptibilities. Epigenetic biomarkers for specific diseases could be used as diagnostics to facilitate clinical management of disease and preventative medicine.	Environ Epigenet Vol.7 Issue 1 Pages dvaa023	10.1093/eep/dvaa023	33841921	動物	-	1	0	1	1	0	25 mg/kg	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-

Sarachana	2021	Sex differences in the effects of prenatal bisphenol A exposure on autism-related genes and their relationships with the hippocampus functions	Our recent study has shown that prenatal exposure to bisphenol A (BPA) altered the expression of genes associated with autism spectrum disorder (ASD). In this study, we further investigated the effects of prenatal BPA exposure on ASD-related genes known to regulate neuronal viability, neurogenesis, and learning memory and assessed their functions. In the offspring of exposed pregnant rats, We found that prenatal BPA exposure increased testicular length, the number of primary testicles, and the number of testicular branches, but reduced the size of the hippocampal cell body in both sexes of the offspring. However, in utero exposure to BPA decreased the number of primary testicles in the female offspring. Furthermore, prenatal BPA exposure altered the expression of ASD-related genes in the hippocampus of both sexes of offspring. Specifically, the genes (Ank2, Cntn4, Cntnap2, Dlg4, Dpp6, Dpp10, Grin2b, Kcnd2, and Nlgn1) in the hippocampus were dysregulated and showed a sex-specific correlation with neuronal viability, neurogenesis, and in learning memory. The findings from this study suggest that prenatal BPA exposure disrupts ASD-related genes involved in neuronal viability, neurogenesis, and learning memory in a sex-dependent manner, and these genes may play an important role in the risk and the higher prevalence of ASD in males subjected to prenatal BPA exposure. 統合_0917	S. Thongkorn, S. Kanlayaprasit, K. Kaeltipradit, P. Lertpaesapan, P. Panjabud, V. W. Hu, D. Jindatip and T. Sarachana	2023	Investigation of autism-related transcription factors underlying sex differences in the effects of bisphenol A on transcriptome profiles and synaptogenesis in the offspring hippocampus	MACROSUMO: Bisphenol A (BPA) has been linked to susceptibility to autism spectrum disorder (ASD). Our recent studies have shown that prenatal BPA exposure disrupted ASD-related gene expression in the hippocampus, neurological functions, and behaviors associated with ASD in a sex-specific pattern. However, the molecular mechanisms underlying the effects of BPA are still unclear. METHODS: Transcriptome data from the hippocampus of rat offspring prenatally exposed to BPA were analyzed by RNA sequencing. Then, the bioinformatic analysis of sex-specific DEGs and DETFs was conducted to predict biological functions, associated with these genes. The expression levels of ASD-related TFs and targets in the hippocampus of rat pups prenatally exposed to BPA were measured using qRT-PCR analysis. The role of the androgen receptor (AR) in BPA-mediated regulation of ASD candidate genes was investigated using a human neuronal cell line stably transfected with AR expression or control plasmid. RESULTS: Our results revealed that prenatal BPA exposure altered the expression of sex-specific DEGs and DETFs in the hippocampus of rat offspring. Bioinformatic analysis revealed that DEGs affected by BPA, BPA/E2, FN, the fusion male three-way, or sex differences in ASD-related TFs underlying the effects of prenatal BPA exposure on the transcriptome profiles of the offspring hippocampus. In addition to the known BPA targets, AR and ESR1, BPA could directly interact with novel targets, Ccn, ICAM1B, SMAD3, and TCF7L2. The targets of these TFs were also associated with ASD. Prenatal BPA exposure disrupted the expression of ASD-related TFs and targets in the offspring hippocampus in a sex-dependent manner. Moreover, AR was involved in the BPA-mediated dysregulation of ALCT2, GAT1C, and SYAM1C2. Prenatal BPA exposure altered synaptogenesis by increasing synaptic protein levels in males but not in females, but the number of excitatory synapses was increased in female primary neurons only. CONCLUSIONS: Our findings suggest that AR and ESR1 may mediate the sex differences in the effects of prenatal BPA exposure on the transcriptome profiles and synaptogenesis in the offspring hippocampus. These TFs may play an essential role in an increased ASD susceptibility associated with endocrine-disrupting chemicals, particularly BPA, and the male bias of ASD. 統合_0918	M. Thoene, L. Rytel, E. Dolka and J. Wojtkiewicz	2021	Increased PACAP- and D,β1H-Positive Hepatic Nerve Fibers after Bisphenol A Exposure	Bisphenol A (BPA) is an endocrine-disrupting compound (EDC) that can be found nearly everywhere in our polluted world. BPA has been correlated with pathophysiologies that include psychological disorders, especially in the developing brain. Pituitary adenylate cyclase-activating polypeptide (PACAP) is a neuropeptide that is widely distributed throughout the central nervous system (CNS) and has been shown to modulate behavioral responses. This study specifically investigated the sympathetic nervous system (SNS) innervation of the liver in the CNS's neural marker PACAP, that has previously been correlated with specific pathophysiologies in the literature. In the liver, it was observed that there were significantly increased nerve fibers in the SNS colocalized with the neural marker PACAP after exposure to BPA at concentrations considered to be "safe" with the same or more profound effects at higher exposure levels. The implications of childhood exposure to BPA and how they correlate with regard to normal colocalization studies that have linked BPA's exposure to behavioral/psychological disorders. It is possible that BPA exposure in childhood may upregulate the SNS and PACAP levels, thereby contributing to the correlations in the literature. 統合_0919	N. M. Thabet, M. K. Abdel-Rahei and E. M. Moustafa	2022	Boswellic acid protects against Bisphenol-A and gamma radiation induced hepatic steatosis and cardiac remodelling in rats: role of hepatic PPAR- α /P38 and cardiac Calcineurin-A/NFATc1/P38 pathways	Bisphenol A (BPA) and gamma radiation are two risky environmental pollutants that human beings are exposed to in everyday life and consequently they threaten human health via inducing oxidative stress, inflammation, and eventually liver damage. This study aims at appraising the protective effect of Boswellic Acid (BA) (100 mg/kg/day, orally) administration on BPA (100 mg/kg/day, by oral gavage) and/or (IR) (2Gy) toxicity in female rats by comparative dose of 12 Gy) experimental course) for 3 weeks induced damage to liver and heart tissues of rats. The present results indicated a significant improvement against damage induced by BPA and IR revealed in biochemical investigations. Hepatic PPAR- α, P38 and nuclear FT 1 (Calcineurin A/NFATc1/P38) and histopathological examination of liver and heart. It could be concluded that BA possesses a protective effect against these two deleterious environmental pollutants which attracted major global concerns due to their various toxicological impact on human health. Wasta	2024	Molecular insights into the antioxidative and anti-inflammatory effects of P-coumaric acid against bisphenol A-induced testicular injury: In vivo and in silico studies	This study investigated the protective effects of p-coumaric acid (PCA) against bisphenol A (BPA)-induced testicular toxicity in male rats. The rats were divided into control, BPA, BPA+PCA50, BPA+PCA100, and PCA100 groups. Following a 28-day treatment period, various analyses were conducted on epididymal sperm quality and testicular tissues. PCA inhibited dose-dependent cytoprotective, antioxidant, and anti-inflammatory effects, ameliorating the decline in sperm quality induced by BPA. The treatment elevated antioxidant enzyme activities (SOD, CPX, CAT) and restored redox homeostasis by increasing cellular glutathione (GSH) and reducing malondialdehyde (MDA) levels. PCA also mitigated BPA-induced pro-inflammatory responses while attenuating anti-inflammatory IL-10 levels. Apoptotic parameters (p53 and p38 MAPK) were normalized by PCA in BPA-exposed testes. Histopathological examination revealed that PCA ameliorated BPA-induced damage to the seminiferous tubules and Leydig cells. PCA also prevented BPA-induced disorganization of the spermatogenic germ flora. BPA-induced testicular intoxication. PCA reversed the disturbances in male reproductive hormone levels and increased testosterone biosynthetic capacity after BPA-induced testicular insult. In silico analyses suggested PCA's potential modulation of the oxidative stress, NFAT/NFκB/MAPK pathway, affirming BPA's inhibitory impact on PPARα/γ. This study elucidates BPA's molecular disruption of testosterone biosynthesis and highlights PCA's therapeutic potential in mitigating BPA's adverse effects on testicular function, showcasing its cytoprotective, anti-inflammatory, and hormone-regulating properties. The integrated in vivo and in silico approach offers a comprehensive understanding of complex mechanisms, paving the way for future research in reproductive health and toxicology, and underscores the importance of employing BPA-free plastic wares to ensure healthy. 統合_0921	S. Takin and F. Çelebi	2022	Investigation of the effect of hesperidin on some reproductive parameters in testicular toxicity induced by Bisphenol A	Bisphenol A (BPA) is one of the chemicals that cause dysfunction and infertility in testicles. Therefore, it is crucial to develop effective treatments against this damage. In this study, the effects of hesperidin (HESP), a flavonoid in testicular toxicity induced by BPA in rats, on oxidative stress, inflammation, apoptosis, histological damage, spermiogenesis, steroidogenic enzymes and reproductive hormones were investigated. Our study included 40 male rats divided into four groups of 10 rats each: control, HESP, BPA, and HESP + BPA groups. HESP was administered orally by gavage to the HESP group and HESP + BPA group at a dose of 50 mg/kg/day for the BPA group, HESP at a dose of 50 mg/kg/day BPA + HESP group and 100 mg/kg BPA was administered intragastrically for 14 days. We determined that BPA administration causes apoptosis, histological damage, inflammation, oxidative stress and testis effects on spermatogenesis and steroidogenic enzymes in testicles. We observed that the administration of HESP with BPA eliminated oxidative stress, inflammation and apoptosis resulting in therapeutic effects on both steroidogenic enzymes and spermatogenesis and spermatogenesis and reproductive hormones (FSH, LH and testosterone). Our findings from this study clearly showed that while HESP treatment alleviates oxidative damage, inflammation and apoptosis in testicles of rats treated with BPA, it has regulatory effects on steroidogenic enzymes, spermatogenesis and serum reproductive hormones. Wanda	2025	Mechanistic insights into the P-coumaric acid protection against bisphenol A-induced hepatotoxicity in in vivo and in silico models	Bisphenol A (BPA), commonly found in plastic containers and epoxy resins used for food products, presents substantial health risks, particularly in relation to hepatic toxicity. This study investigates BPA-induced liver damage and explores the mechanistic dose-dependent protective effects of P-coumaric acid (PCA). 50 male rats were divided into control, BPA-treated, BPA + PCA50, BPA + PCA100, and PCA100 groups. BPA exposure for 21 days induced oxidative stress, evidenced by elevated malondialdehyde levels and decreased activities of antioxidant enzymes (superoxide dismutase, glutathione peroxidase, catalase). Higher doses of PCA effectively mitigated these effects by restoring redox balance and enhancing antioxidant enzyme activities. Additionally, BPA disrupted inflammation and apoptosis pathways, inhibiting anti-inflammatory markers and promoting pro-inflammatory cytokines and pro-apoptotic factors. PCA treatment reversed these changes, with PCA100 showing the most significant anti-inflammatory and anti-apoptotic effects. Histological analysis revealed BPA-induced cellular damage, including hepatocyte degeneration and inflammatory cell infiltration, which PCA alleviated. Immunohistochemistry further supported PCA's protective role against BPA-induced apoptosis and cellular hepatotoxicity. These findings, validated via PCA's protective potential against BPA-induced hepatotoxicity and highlight novel mechanistic interactions that warrant further investigation in applied nutritional biochemistry. 統合_0923	J. A. Taylor, M. B. Jones, C. L. Beech-Williford, A. F. Berendsen, W. A. Ricke and S. V. S. F	2020	Interactive Effects of Perinatal BPA or DES and Adult Testosterone and Estradiol Exposure on Adult Urethral Obstruction and Bladder, Kidney, and Prostate Pathology in Male Mice	Obstructive voiding disorder (OVD) occurs during aging in men and is often, but not always, associated with increased prostate size, due to benign prostatic hyperplasia (BPH), prostatitis, or prostate cancer. Estrogens are known to impact the development of both OVD and prostate diseases, either during early urogenital tract development in fetal/neonatal life or later in adulthood. To examine the potential interaction between developmental and adult estrogen exposure on the adult urogenital tract, male CD-1 mice were perinatally exposed to bisphenol A (BPA), diethylstilbestrol (DES) as a positive control, or vehicle negative control, and in adulthood were treated for 3 months with 90 day/60 day release pellets containing testosterone and estradiol (T+E2) or empty vehicle pellets. Serum T+E2 concentrations, as expected, were elevated in BPA or DES dosing perinatal groups. Animals exposed to BPA or DES during perinatal development were more likely than vehicle controls to have urine flow/kidney problems and enlarged bladders, as well as enlarged prostates. OVD in adult T+E2-treated perinatal BPA and DES animals was associated with dorsal prostate hyperplasia and prostatitis. The results demonstrate a relationship between elevated exogenous estrogen levels during urogenital system development and elevated estradiol in adulthood and OVD in male mice. These findings support the hypothesis for the development of OVD and prostate diseases. 統合_0924	A. Tavakkoli, K. Abnous, F. Vahdati Hassani, H. Hosseinzadeh, R. Bimar-Gruenberger and S. Mahbi	2020	Alteration of protein profile in cerebral cortex of rats exposed to bisphenol a: a proteomics study	Bisphenol A (BPA) is one of the most widely used chemicals in plastic industry, which enters the human body through occupational and food contact. We studied the protein changes in rat cerebral cortex to evaluate the neurotoxicity of BPA. Twenty four adult male rats were randomly selected and divided into four groups and each group respectively received 0.5, 5 and 50 mg/kg of BPA for 3 weeks orally. To determine the oxidative stress, malondialdehyde (MDA) and glutathione (GSH) were measured. Then, the cerebral cortex proteins were extracted and analyzed by two-dimensional gel electrophoresis (2-DE). From the obtained proteins maps the 20 most altered protein spots were used for mass spectroscopy analysis. The total antioxidant in both doses of 0.5 and 5 mg/kg was significantly lower than the control group, but the glutathione content had no significant difference between the groups. Based on the results of the MS data analysis by the MASCOT database search engine, 10 proteins with altered intensity were identified as: pyruvate kinase, alpha-enolase, excitatory amino acid transporter 1, creatine kinase B type, phosphatidylethanolamine binding protein 1, 14-3-3 protein eta, guanine nucleotide-binding protein subunit beta-1, dihydropyrimidinase-related protein 2, glutamine synthetase and the neurofilament light polypeptide. There are several reports suggesting that the increase or decrease in the level and activity of these 10 proteins, similar to those observed in this study, is related to some neurological and psychosocial disorders including neurodegenerative diseases, schizophrenia, depression, epilepsy and some brain tumors. The Life Punctuated Project	2021	Toxicological Assessment of Oral Co-Exposure to Bisphenol A (BPA) and Bis(2-ethylhexyl) Phthalate (DEHP) in Juvenile Rats at Environmentally Relevant Dose Levels: Evaluation of the Synergic, Additive or Antagonistic Effects	BACKGROUND: The general population (including children) is exposed to chemical mixtures. Plasticizers such as Bisphenol A (BPA) and Phthalates (mainly Bis(2-ethylhexyl) phthalate (DEHP)) are widespread contaminants. Experimental studies have demonstrated that BPA and DEHP can act as endocrine disruptors (ED) and target reproductive and metabolic systems. However, most of these studies were carried out in adult animals or during critical windows of development, providing additional uncertainties for risk assessment in children. Moreover, the joint action of BPA and DEHP has not been investigated yet in children. Although some studies have been carried out in adult animals, no data are available on reduced toxicological effects of mixtures due to common mechanisms were studied, considering endpoints of metabolic, endocrine and reproductive systems. The degree of synergy or antagonism was evaluated by synergy score calculation, using potent dose and results from the single compound individually administered. RESULTS: In metabolic system, synergic interaction predominates in female and additive in male mice in the consecutive and endocrine system, the co-exposure of BPA and DEHP showed interactions mostly of antagonism type. CONCLUSIONS: The present approach allows to evaluate, for all the endpoints considered, the type of interaction between contaminants relevant for human health. Although the mode of action and biological activities of the mixtures are not completely addressed, it can be of paramount usefulness to support a more reliable risk assessment	Int J Environ Res Public Health Vol.18 Issue 9	10.3390/ijerph18094584	33925988	動物	-	1	1	0	1	1	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-
統合_0926	R. Tassinari, L. Narciso, S. Tait, L. Busani, A. Martinelli, A. Di Virgilio, F. Cioli, A. Desdali, C. La Rocca and F. Maranghi	2020	Juvenile Toxicity Rodent Model to Study Toxicological Effects of Bisphenol A (BPA) at Dose Levels Derived From Italian Children Biomonitoring Study	Bisphenol A (BPA) is a plasticizer with endocrine disrupting properties particularly relevant for children health. Recently BPA has been associated with metabolic dysfunctions but no data are yet available in specific, long term, in vivo studies investigating the effects of BPA at dose levels relevant for children exposure. The present study was designed to investigate the effects of BPA in rats when administered, 3, 4, and 28 mg/kg bw per day of BPA for 28 days, from weaning to sexual maturity. Dose levels were obtained from the PHASE(ADI) biomonitoring study in Italian children. Both sex observed adverse effect level (NOAEL) has observed adverse effect level (LOAEL) and estimated benchmark dose (BMD) approaches were applied. General toxicity, parameters of sexual development, endocrine/reproductive function and kidney biomarkers, histopathology of target tissues, and gene expression in hypothalamic pituitary area and liver were studied. No mortality or general toxicity occurred. Sex-specific alterations were observed in liver, thyroid, spleen, testis/adipocyte serum levels, and hypothalamic–pituitary gene expression. Thyroid homeostasis and liver were the most sensitive targets of BPA exposure in the peripubertal phase. The proposed BMDL10 of 3.74 mg/kg bw per day for females and 4.49 mg/kg bw per day for males, corresponding to the human equivalent dose (HED) of 0.61 and 0.73 mg/kg bw per day, and 1.35 and 1.55 mg/kg bw in males and females, considering liver and thyroid biomarkers, respectively. Overall, BPA evaluation at dose levels derived from children biomonitoring study allowed to identify non-specific, targeted toxicological effects that may have significant impact on risk assessment for children. 統合_0927	Z. Tang, H. Wang, Z. Zhang, Y. Kong, X. Lai and J. Yuan	2023	[Mechanism of nephrotoxicity induced by chronic exposure of bisphenol A in mice based on oxidative stress and cell apoptosis]	Bisphenol A (BPA) is widely used to produce epoxy resin and polycarbonate plastic products. In some cases, these plastics may release BPA, which then infiltrates into the environment. Various concentrations of BPA have been found in most biological fluid. Its presence has been well shown to be closely related to many chronic diseases, including chronic kidney disease (CKD). However, little is known regarding the adverse effects of BPA exposure and its succedent cellular events on CKD. Hence, in the current in vivo study, we aimed to assess the effects of chronic exposure to BPA on animal nephrotoxicity through investigating oxidative stress and cell apoptosis. [Methods] A total of 40 SPF-grade Kunming mice were randomly divided into four groups, with 10 mice in each group: the control group, 0.2 mg/kg BPA group, 2 mg/kg BPA group, and 20 mg/kg BPA group. The mice in the BPA groups were orally challenged with the same three doses of BPA for four weeks. The results showed that the kidneys of 2, 5 and 7 BPA-treated mice were normal. Serum urea nitrogen, creatinine, uric acid, and malondialdehyde and reactive substances; the morphological structure of mouse kidneys was impaired; the expressions of antioxidant-related genes or mRNA and protein levels from mouse kidneys were markedly diminished, including glutathione-S-transferase, superoxide dismutase, and catalase; the expressions of genes and proteins related to apoptosis; Index tests of Bax/Bcl-1 and Caspase-3 were significantly enhanced. The data manifested that cumulative oxidative stress and apoptosis might play an essential role in the animal nephrotoxicity induced by chronic exposure to BPA. 統合_0934	M. Tahriarfard and S. Ahmadijokani	2023	The passive avoidance task ameliorate the toxic effects of bisphenol A on dopamine D1 receptor density in hippocampus, amygdala, and cerebellum of male rats	INTRODUCTION: Dopamine D1 receptor seems to play a role in mediating plasticity. Therefore, the present study aimed to investigate the effects of passive avoidance tasks postexposed to BPA on dopamine D1 receptor density in hippocampus, amygdala, and cerebellum of male rats. METHODS: Forty-eight male Wistar rats (250–300 g) were randomly divided into four groups (n = 12 per group): control, sham, and two BPA groups (50 and 500 mg/kg/day, p.o.). Learning and memory assessments were done by a shuttle box active (5 days of BPA administration). The density of the dopamine D1 receptor was investigated using an immunohistochemistry (IH) procedure. For determining the color difference in IH sections, Image Analyzer software was used. The data were analyzed by one-way ANOVA followed by Tukey's as a post hoc test. RESULTS: The data showed that BPA in both doses could significantly increase the density of dopamine D1 receptors in the hippocampus, amygdala, and cerebellum. Y-maze tests, learning in rats postexposed to BPA improves dopamine D1 receptor density significantly in three brain structures. DISCUSSION: According to the results, passive avoidance learning and memory can improve the density of dopamine D1 receptors in the hippocampus, amygdala, and cerebellum of male rats. 統合_0935	K. Szymańska, K. Makowska, J. Calka and S. Gonkowski	2020	The Endocrine Disruptor Bisphenol A (BPA) Affects the Enteric Neurons Immunoreactive to Neuregulin 1 (NRG1) in the Enteric Nervous System of the Porcine Large Intestine	The enteric nervous system (ENS), located in the wall of the gastrointestinal (GI) tract, is characterized by complex organization and a high degree of neurochemical diversity of neurons. One of the less known active neuronal substances found in the enteric neurons is neuregulin 1 (NRG1), whose role in the ENS is related not only to the appearance of normal development of the nervous system. During in vitro study, made up using the double immunofluorescence technique, the presence of NRG1 in the ENS of the selected segment of porcine large intestine (cranium, ascending and descending colon) was observed in physiological conditions, as well as under the influence of BPA in doses of 0.05 and 0.5 mg/kg b.w. (per os) for 90 days. The study showed that BPA in both doses used significantly increased the number of NRG1-IR neurons in the submucous and myenteric plexuses in almost 90% of all neurons. The administration of BPA caused an increase in the number of NRG1-positive neurons in all types of the enteric plexuses and in all segments of the large intestine studied. The most distinct changes were noted in the inner submucous plexus of the ascending colon, where in animals treated with high doses of BPA, the percentage of NRG1-positive neurons amounted to about 95% of all neurons/cm2. The mechanisms of observed changes are not entirely clear, but probably result from neurotoxic, neurodegenerative and/or proinflammatory activity of BPP and are protective and adaptive in nature. 統合_0936	K. Szymanska and S. Gonkowski	2019	Neurochemical characterization of the enteric neurons within the porcine jejunum in physiological conditions and under the influence of bisphenol A (BPA)	BACKGROUND: Bisphenol A (BPA) is commonly used in the production of plastics and has multidirectional, negative effects on the living organisms. It may also affect the enteric nervous system (ENS) located in the wall of the gastrointestinal tract. Enteric neurons express many active substances, which regulate nearly all intestinal activities, not only in physiological conditions but also under the impact of pathological factors. METHODS: The influence of various doses of BPA on the ENS of jejunum has been investigated using the double immunofluorescence technique. The commercial antibodies against substances P (SP), vasoactive intestinal polypeptide (VIP), somatostatin (SOM), cocaine- and amphetamine-regulated transcript (CART), calcitonin gene-related peptide (CGRP), and nitric oxide synthase (NOS) were used in the study. RESULTS: The number of the enteric neurons immunoreactive to SP, VIP, CGRP, SOM, and CART, and the intensity of fluorescence dependent on the BPA dose and on the type of the neurochemical coding of the enteric neurons, has been changed. The number of neurons immunoreactive to the majority of substances studied. The only exception was VIP/CART-positive neurons, the number of which was lower under the impact of BPA in the comparison with physiological conditions. CONCLUSIONS: A REFERENCES: Even low doses of BPA cause the changes in neurochemical characterization of the enteric neurons in the jejunum. These changes may be the first sign of subclinical BPA intoxication. The mechanisms of observed changes are probably connected with neurotoxic and/or pro-inflammatory activity of BPA, but their exact mechanisms are not fully explained. 統合_0937	S. Suresh and C. Vellapandian	2024	Cyanidin improves spatial memory and cognition in bisphenol A-induced rat modal of Alzheimer's-like neuropathology by restoring canonical Wnt signaling	INTRODUCTION: Research has unveiled the neurotoxicity of Bisphenol A (BPA) linked to neuropathological traits of Alzheimer's disease (AD) through varied mechanisms. This study aims to investigate the neuroprotective properties of cyanidin, an anthocyanin, in an in vivo model of BPA-induced Alzheimer's like neuropathology. METHODS: Three-week-old Sprague-Dawley rats were randomly assigned to four groups: vehicle control, negative control (BPA exposure), low dose cyanidin treatment (BPA + cyanidin 5 mg/kg), and high dose cyanidin treatment (BPA + cyanidin 10 mg/kg). Spatial memory was assessed through behavioral tests, including the Y-maze, novel object recognition, and Morris water maze. After behavioral tests, animals were euthanized, and brain regions were examined for amyloid-beta immunoreactive volume, p-tau, Wnt3, GSK3-β, and β-catenin levels, antioxidant activities, and histopathological changes. RESULTS: BPA-exposed groups displayed memory impairments, while cyanidin treated groups showed significant memory improvement (p < 0.0001). Cyanidin treatment significantly reduced amyloid-beta immunoreactive volume (p < 0.0001), p-tau (p < 0.0001), and GSK3-β (p < 0.0001) levels while increasing Wnt3 (p < 0.0001) and β-catenin (p < 0.0001) levels. The intervention significantly reduced the concentrations of acetylcholinesterase in the cortex and hippocampus in comparison to the BPA group treated with BPA (p < 0.0001). Significant gender-based disparities were not observed. CONCLUSION: Cyanidin demonstrated potent neuroprotective against BPA-induced Alzheimer's like neuropathology by enhancing antioxidant defenses, modulating tau phosphorylation by restoring the Wnt/β-catenin pathway, and ameliorating spatial memory deficits. This study highlights the therapeutic potential of cyanidin in countering neurotoxicity linked to BPA exposure. Xu	2021	Protective effect of metformin on BPA-induced liver toxicity in rats through upregulation of cystathionine β synthase and cystathionine γ lyase expression	Human exposure to bisphenol A (BPA) is unavoidable in daily life. Recently, research has shown that BPA could induce oxidative imbalance, thereby causing reproductive toxicity and liver dysfunction. Accumulated evidence has demonstrated that metformin possesses strong anti-oxidative properties. This study aimed to study the mechanism underlying the hepato-protective effect of metformin on liver injury induced by BPA in rats. Sixty SD rats were randomly divided into six groups: control group, BPA + DMSO group, BPA + metformin (100 mg/kg/d) group, BPA + metformin (200 mg/kg/d) group, BPA + metformin (500 mg/kg/d) group, and BPA + DMSO group (BPA), the duration of each treatment group (BPA + DMSO, and the following metformin treatment groups) was 90 days. Then, rats were euthanized, and blood samples and liver tissues were collected for histopathology and metabolomics. In each group, We found that metformin could significantly reduce the levels of liver function enzymes (ALT, AST and GGT) and ameliorate inflammation, cell infiltration and hepatocyte necrosis induced by BPA. On the other hand, metformin could significantly enhance the total antioxidant capacity in BPA rats. Notably, metabolomics data revealed that the principal altered metabolic pathways based on the 26 differential metabolites in liver tissue, and 21 in serum among which, BPA and BPA + 500 groups, respectively, including cysteine and methionine metabolism, glutathione metabolism, and arginine and proline metabolism. Additionally, metformin significantly increased cystathionine β synthase (CBS) and cystathionine γ lyase (CSE) in liver, thus leading serum levels of homocysteine and increasing hepatic levels of cysteine and glutathione in BPA-treated rats. Overall, this study results provided clue, insights, into the role and mechanism of metformin in BPA-induced liver injury in rats. 統合_0939	Y. Sun, M. Sha, Y. Qin, J. Xiao, W. Li, S. Li and S. Chen	2024	Bisphenol A induces placental ferroptosis and fetal growth restriction via the YAP/TAZ-ferritinophagy axis	Exposure to bisphenol A (BPA) during gestation leads to fetal growth restriction (FGR), whereby the underlying mechanisms remain unknown. Here, we found that FGR patients showed higher levels of BPA in the urine, serum, and placenta; meanwhile, trophoblast ferroptosis was observed in FGR placentas, as indicated by accumulated intracellular iron, impaired antioxidant molecules, and increased lipid peroxidation products. To investigate the role of ferroptosis in placental and fetal growth, BPA stimulation was performed both in vivo and in vitro. BPA exposure during gestation was associated with FGR in mice also, it induces ferroptosis in mouse placentas and human placental trophoblasts. Pretreatment with ferroptosis inhibitor ferrostatin-1 (Fer-1) attenuated BPA-induced oxidative damage and cell death. Notably, BPA reduced the trophoblastic expression of yes-associated protein (YAP) and transcriptional co-activator with PDZ-binding motif (TAZ), which are the key regulators of the Hippo signaling pathway. Moreover, the ferroptosis induced by BPA in human trophoblast hemostasis is dependent on YAP/TAZ downregulation after BPA stimulation. Consistently, the protein levels of YAP/TAZ were also reduced in FGR placentas. Further results revealed that silencing YAP/TAZ promoted BPA-induced ferroptosis through autophagy. Pretreatment with autophagy inhibitor chloroquine (CQ) attenuated BPA-induced trophoblastic ferroptosis. Terribendiagy, an autophagy degradation of ferritin (FTH1), was observed in FGR placentas. Similarly, BPA mediated the autophagic degradation of FTH1 in placental trophoblast. Pretreatment with low-dilution deoferrioxamine (DFO) and NCOA4 (an autophagy cargo receptor) siRNA weakened the ferroptosis of trophoblast after exposure to BPA, indicating that autophagy mediates ferroptosis in BPA-stimulated trophoblast by degrading ferritin. In summary, ferroptosis was featured in BPA-associated FGR and trophoblast injury; the regulation of ferroptosis involved the YAP/TAZ-autophagy-ferritin axis. 統合_0940	F. Sun, Y. Huang, H. Chen, J. Huang, L. Zhang, S. Wei, F. Liu, D. Chen and W. Huang	2023	BPA and its alternatives BPF and BPAF exaggerate hepatic lipid metabolism disorders in male mice fed a high fat diet	Alternatives to Bisphenol A (BPA), such as BPF and BPAF, have found increasing industrial applications. However, toxicological research on these BPA analogues remains limited. This study aimed to investigate the effects of BPA, BPF, and BPAF exposure on hepatotoxicity in mice fed with high-fat diets (HFD). Male mice were exposed to the bisphenols at a dose of 0.05 mg per kg body weight per day (mg/kg/day) for eight consecutive weeks, or 5 mg/kg/day for the first week followed by 0.05 mg/kg/day for seven weeks under HFD. The low dose (0.05 mg/kg/day) was corresponding to the tolerable daily intake (TDI) of BPA set by the EFSA. The results showed that exposure to BPA, BPF, and BPAF induced hepatic steatosis, with BPF and BPAF causing more severe lipid accumulation than BPA. Moreover, BPF and BPAF induced disturbances of fatty acid and bile acid metabolism in bisphenol-exposed mice livers. BPF and BPAF exposure induced lipid accumulation in HFD mice may be caused by glycerolipid and cholesterol levels. Transcriptomics analysis demonstrated that exposure levels of genes related to fatty acid synthesis and metabolism were changed, which might be related to the activation of the PPAR signaling pathway. Besides, a feedback regulation mechanism might exist in maintain hepatic metabolic homeostasis. For the first time, this study demonstrated the effects of BPF and BPAF exposure to HFD mouse livers. Considering the reality of the high prevalence of obesity nowadays and the ubiquitous environmental distribution of bisphenols, this study provides insight and highlights the adverse effects of BPA alternatives, further contributing to the consideration of the safe use of such compounds. Sarachana	2020	Prenatal exposure to bisphenol A alters the transcriptome-interactome profiles of genes associated with Alzheimer's disease in the offspring hippocampus	Our recent study revealed that prenatal exposure to bisphenol A (BPA) disrupted the transcriptome profiles of genes in the offspring hippocampus, in addition to genes linked to autism, several genes associated with Alzheimer's disease (AD) were also dysregulated. Therefore, in the present study, we further investigated the effects of prenatal BPA exposure on the transcriptome-interactome profiles of AD-associated genes and determined whether prenatal BPA exposure also dysregulated the transcriptome profiles of genes that are associated with neurodevelopmental disorders (NDD) in the hippocampus. The level of BP, a BPA analog, and the AD-associated target gene Bace1 were significantly increased in the offspring hippocampus in a sex-dependent manner. Quantitative RT-PCR analysis also observed an increase in the expression of Tet gene. Moreover, the reanalysis of transcriptome profiling data from normal previously published BPA studies consistently showed that BPA-responsive genes were significantly associated with top AD candidate genes. The findings from this study suggest that maternal BPA exposure may increase AD risk in offspring by dysregulating genes associated with AD neuropathology and inflammation and reveal a possible relationship between AD and autism, which are linked to the same environmental factor. Sex-specific effects of prenatal BPA exposure on the susceptibility of AD deserve further investigation. Harley	2025	In utero exposure to a mixture of phthalates, parabens, and other phenols and menstrual cycle characteristics in adolescents	Phthalates, parabens, and other phenols are present in consumer products humans use every day, including personal care products and food packaging. Exposure to these chemicals may have endocrine disrupting effects, but few studies have examined associations with menstrual cycle characteristics in adolescents. We measured 11 phthalate metabolites, 4 parabens, triclosan, benzophenone-3, and bisphenol A in spot urine samples from 338 participants in a cohort of Mexican girls who were followed from ages 6–8 years old to 14–16 years old. We examined six potentially adverse menstrual cycle characteristics: irregular cycles, long cycles, short cycles, prolonged bleeding, heavy bleeding, and severe cramps. We used multivariable log-binomial regression models with generalized estimating equations to estimate associations between exposure biomarker concentrations and each characteristic, averaged across age, using logistic regression. Bayesian hierarchical modeling was used to model the chemical mixture's associations with each outcome. All models were adjusted for poverty level during pregnancy, maternal pre-pregnancy BMI, and their food consumption at adolescent age 9. Results showed a positive association between mono-(3-carboxypropyl) phthalate, propylparaben, and bisphenol A and heavy menstrual flow. Exposure to 2,2'-dichlorophenol was positively associated with short cycle length. Mono(3-carboxypropyl) phthalate and di-(2-ethylhexyl) phthalate were positively associated with long cycle length. These results suggest in utero exposure to phthalates, parabens, and other phenols may be associated with abnormal menstrual cycle characteristics in adolescents. 統合_0946	M. L. Sowers, H. Tang, B. Tian, R. Goldblum, T. Midoro-Horiuti and K. Zhang	2020	Bisphenol A Activates an Innate Viral Immune Response Pathway	Bisphenol A (BPA) is a ubiquitous component in the manufacturing of plastic. It is commonly found in food and beverage containers. Because of its broad exposure and evidence that it may act as an estrogen like molecule, many have studied its potential effects. For example, epidemiological studies have found an association between in utero BPA exposure and onset of childhood asthma. One previous work suggested BPA induces mice infected asthma like symptoms. In both mothers and their pups. In order to better understand the consequences of BPA exposure and potential mechanisms, we used a proteomic approach. Using both CD1 (-/-) and mice in vivo model of BPA exposure and an in vitro epithelial cell model, we identified activation of both innate and adaptive immune signaling following BPA exposure. Furthermore, our proteomic results from our multigenerational mouse model study implicates aberrant immune activation across several generations. We propose the following: BPA can active an innate viral immune response by upregulating unstable interferon-stimulated genes (ISGs), and by binding partner stimulator of interferon genes (STING). It also has additional immune-epigenetic perturbations, suggesting a role for epigenetic inheritance of these immune perturbations. Martinez-Pinna	2019	Bisphenol A Regulates Sodium Ramp Currents in Mouse Dorsal Root Ganglion Neurons and Increases Nociception	17,β-Estradiol mediates the sensitivity to pain and is involved in sex differences in nociception. This is a widespread environmental disrupting chemical bisphenol A (BPA) has estrogenic activity, but its implications in pain processing are unknown. Here, we investigated the effects of BPA on the excitability of dorsal root ganglion (DRG) neurons from male and female mice. Whole-cell patch-clamp recordings after incubation of dissociated dorsal root ganglia (DRG) nociceptors with 1 nM BPA increased the frequency of action potential firing. SCAM4 encodes the voltage-gated sodium channel Nav1.7, which is present in DRG nociceptors and is essential in pain signaling. Nav1.7 and other voltage-gated sodium channels in mouse DRG are considered threshold channels because they produce ramp currents, amplifying small depolarizations and initiating electrical activity. BPA increased Nav1.7-mediated ramp currents at the cell body with slow depolarizations. Experiments using pharmacological tools as well as DRG from Nav1.7 (−/−) mice indicate that this BPA effect involves ERα and phosphatidylinositol-3 kinase. The mRNA expression and biophysical properties, other than ramp currents of Nav1.7 channels, were unchanged by BPA. Our data suggest that BPA at environmentally relevant doses affects the ability to detect noxious stimuli and therefore should be considered when studying the etiology of pain conditions. 統合_0960	S. Shetty, V. Kumar, V. Ramesh and S. Bharati	2022	Mito-TEMPO protects against bisphenol-A-induced testicular toxicity: an in vivo study	Bisphenol A (BPA) is a common environmental toxin which alters testicular function in both animals and humans. BPA exerts its cytotoxic potential by altering mitochondrial oxidative stress and functioning. Therefore, protecting mitochondria from oxidative stress may prevent BPA-induced testicular damage. In the present study, modulation of BPA toxicity by mitochondria-targeted antioxidant, mito-TEMPO, was studied in male Wistar rats. Experimental animals were divided into four groups (n = 6/group). Group I served as control, group II received BPA (50 mg/kg b.wt.), group III received mito-TEMPO (0.7 mg/kg b.wt.), and group IV received BPA + mito-TEMPO for 35 days. At the end of the treatment, the animals were sacrificed. The mitochondrial oxidative stress, mitochondrial membrane potential (MMP), and enzymatic activity of mitochondrial complex I and IV were estimated in the testicular tissue. Pretreatment of mito-TEMPO protected animals from toxic effects of BPA as indicated by the normalization of sperm parameters and preserved histoarchitecture of testis. BPA treatment in animals significantly increased mitochondria reactive oxygen species (ROS) and lipid peroxidation (LPO). A significant decrease in the activity of mitochondrial complex I was also observed after BPA exposure whereas, mitochondrial complex II activity was increased. In addition, an increase in MMP was also observed in BPA group. Mito-TEMPO successfully normalized mitochondrial ROS and LPO formation. Similar normalization effect was also noted in the activity of mitochondrial complex I, complex IV, and MMP. Results suggested that mito-TEMPO pretreatment significantly protected BPA-induced oxidative stress and thereby mito-TEMPO effectively prevented testicular damage. 統合_0961	S. Sharma, S. Ahmad, M. A. Afjal, H. Habib, S. Parvez and S. Raisuddin	2019	Dichotomy of bisphenol A-induced expression of peroxisome proliferator-activated receptors in hepatic and testicular tissues in mice	Environmental and dietary exposure to bisphenol A (BPA) and its toxicological consequences are extensively reported. BPA has multiple cellular targets. One of the mechanisms of action of BPA involves interaction with and activation of nuclear receptors (NRs) including peroxisome proliferator-activated receptors (PPARs). PPARs regulate genes involved in adipogenesis, and lipid and glucose homeostasis. Gestational exposure to BPA has also been specific PPAR expression may decipher the toxicity outcome of BPA response. We studied expression of three forms of PPARs in mouse liver and testes exposed to BPA for 14 days. mRNA and protein expression of PPARα, PPARγ and PPARβ/δ was determined in the liver and testes of male Swiss mice administered BPA (50 mg/kg/day) or equivalent volume of vehicle (olive oil). Histopathological study showed a dose-dependent pattern of changes in liver as well as testes demonstrating xenobiotic effect. These findings imply that while PPAR-independent mechanisms may play a role in BPA-induced pathological changes. The present study warrants exploration of the role of PPARs in BPA-induced effects on male reproductive functions and offers an insight into the peculiar response of BPA on two subchronic levels which may be helpful in designing appropriate risk assessment framework. Bhta	2021	A Comparative Study of Effects of 28-Day Exposure of Bisphenol A and Bisphenol S on Body Weight Changes, Organ Histology, and Relative Organ Weight	CONTEXT: Bisphenol A (BPA), a known endocrine disrupting chemical, is of widespread use in manufacturing of plastic products. Documenting ill health effects of BPA has led the plastic industrialists to replace BPA by its analogues, bisphenol S (BPS) in many products. OBJECTIVE: The present study was undertaken to compare the effects of 28-day exposure of BPA and BPS on body weight changes, organ histology, and relative organ weight in rats. In addition, we detected BPA and BPS in the rat's blood serum. MATERIALS AND METHODS: Adult male albino rats were administered BPA (50 mg/kg/day) or BPS (50 mg/kg/day) or equivalent volume in different groups by oral gavage for 28 days. SUBJECTS AND METHODS: The weight of each rat was noted at the commencement of the study and weekly afterward. On 29th day, the animals were sampled for whole blood and then sacrificed. The dissected out viscera were observed for any significant change in the overall appearance and histological examination. The viscera were preserved and analyzed for the detection of BPA and BPS by high-pressure liquid chromatography. STATISTICAL ANALYSIS USED: Paired and unpaired Student's t test, one-way ANOVA test, and Bonferroni test for multiple comparisons were used as required for statistical analysis, and P < 0.05 was considered statistically significant. RESULTS: Both BPA and BPS produced similar detrimental changes in body weight, histology of stomach, small intestine, lung, and kidney, and relative organ weight of lung and kidney. BPA and BPS detected in the serum of rats were nearly 40 times of the control. CONCLUSIONS: Present data suggests caution about the application of BPS as a substitute of BPA. Al-Gria	2022	Exposure to low-dose bisphenol A induces spleen damage in a murine model: Potentially through oxidative stress?	BACKGROUND: During early life, exposure to environmental toxicants, including endocrine disruptor bisphenol A (BPA), can be detrimental to the immune system. To our knowledge, a few researches have looked at the effects of developing BPA exposures on the spleen. AIM: The murine model was developed to investigate the underlying molecular mechanisms and mode of BPA action on the spleen subsequent to prolonged early life exposure to BPA. METHODS: Immature (3 week-old) male and female Swiss Albino mice were intraperitoneally injected with 50 µg/kg BPA in corn oil or corn oil alone for 5 weeks. Mouse spleens were harvested and examined histologically at 10 weeks old (adulthood). RESULTS: We observed neurobehavioral impairments and significant increase in peripheral immunocytotoxicity parameters. Furthermore, we found a significant increase in proliferation and necrotic zone were observed in adulthood. BPA-treated mice's histopathological results revealed toxicity in the formof significantly earlier germinal centers of the white pulp and a significant decrease in the red pulp area. Moreover, BPA-treated mice showed significant increase in splenic oxidative stress biomarkers, including a significant increase in the immunohistochemical DNA fragmentation and apoptosis in the splenic tissues of BPA-treated mice compared to controls. In addition, there were increased levels of the lipid peroxidation malondialdehyde end-product, a marker of oxidative lipid damage, in the spleens of BPA-treated mice compared to controls. CONCLUSION: Our study provides evidence that oxidative stress injury induced by early life exposure to BPA could contribute to a range of splenic tissue damages during adulthood. 統合_0964	N. F. S. Shalbi, N. K. Nurul Bashar, N. A. Abul Aziz, R. Dasiman and N. N. Hasbin	2025	Protective role of Cocos nucifera L. water on BPA-mediated oxidative stress and reproductive damage in male rats	Bisphenol A (BPA) may impair male fertility by inducing oxidative stress in the testis, though its effects on spermatogenesis and sperm quality remain unclear. Conversely, Cocos nucifera L. (coconut) water, rich in antioxidants, may counteract BPA's harmful effects. This study investigated the protective role of coconut water against BPA-induced testicular damage in rats. Forty-eight male Sprague-Dawley rats were divided into eight groups (n = 6) and treated daily for 28 days via oral gavage. Groups received distilled water (DW; 10 mL/kg), DW + coconut water (CW; 10 mL/kg), BPA (50 mg/kg), CW + BPA, BPA + vitamin E (100 mg/kg), CW + BPA + vitamin E, vitamin E (100 mg/kg), or coconut water (CW; 10 mL/kg) alone. Body weight was recorded weekly. At the end of the treatment period, animals were euthanized, and testes were collected for histological examination, oxidative stress analysis, and sperm motility assessment. BPA administration reduced glutathione levels, increased malondialdehyde levels, and caused histopathological changes in the testis. Additionally, the group also showed a decrease in sperm motility and viability. Co-administration of CW with BPA significantly decreased malondialdehyde levels and improved glutathione levels in the testis. Furthermore, CW co-administration significantly improved sperm motility, viability, and morphology compared to the BPA group (p < 0.001). However, these parameters were notably impaired by the administration of coconut water to CW+B group (p < 0.001). Conclusively, this study suggests that coconut water influences antioxidant defenses and supports male reproductive health in rats, potentially preventing BPA-induced reproductive damage. 統合_0965	A. C. Sasastre-Bargillan, C. Casandra, D. Ghabaar, D. Ohkaru, M. C. Chimeca Valle Vowod, L. Rogojan, G. A. Filip and I. Bâldea	2022	Neurotoxicity of Bisphenol A and the Impact of Melatonin Administration on Oxidative Stress, ERK/NF-kB Signaling Pathway, and Behavior in Rats	Bisphenol A (BPA) exposure can be associated with neurodevelopmental disorders due to impairment of cell proliferation and synaptic development. Our study evaluated the effects of melatonin (MEL) on antidepressant activity, lipid peroxidation, cytokines, ERK/NF-kB signaling pathway in the hippocampus, and behavioral changes in the neurobehavioral changes in the BPA-treated rats. The animals were divided into 5 groups, control, BPA, BPA + MEL-1 and BPA + MEL-5. MEL (20 mg/kg b.w.) and MEL (5 10 mg/kg b.w.) were orally administered for 28 days. On the 29th day, BPA (5 mg/kg b.w.) was intraperitoneally administered, as well as MEL, 30 min before the behavioral tests. Our results showed that BPA induced depressive-like behavior in the forced swim test and tail suspension test, increased the duration of immobility and decreased the climbing and swimming behavior. Moreover, BPA increased the oxidative stress and apoptosis in the central part of CA1. Malondialdehyde levels were diminished by MEL-5 in the hippocampus and by MEL-1 in the frontal lobe. In the hippocampus, the NAPH level was significantly boosted by both doses of MEL (p < 0.05) while in the frontal lobe, only MEL-5 reduced the NADPH activation. SOD, 1 and 2 significantly decreased the p-ERK and upregulated the NFkB and pNFkB expressions in the hippocampus, while MEL-5 downregulated the NOS1 expression. Both doses of MEL attenuated the BPA-induced histopathological alterations in the hippocampus. These data indicate that MEL can mediate the neuroprotective against BPA-induced neurotoxicity and improves behavioral changes, suggesting a real potential as a protective agent in brain toxicity. 統合_0966	M. A. Selim, S. M. Mosaad and N. M. El-Sayed	2022	Lycopene protects against Bisphenol A induced toxicity on the submandibular salivary glands via the upregulation of PPAR- γ and modulation of Wnt/ β -catenin signaling	BACKGROUND AND AIM: The submandibular salivary glands (SMG) represent a suitable model for studying epithelial cell growth and differentiation. Bisphenol A (BPA) is a xenoestrogen, synthesized to produce polymeric such as polycarbonates and epoxy resins. There are concerns about the occurrence of BPA in food, water as well as its appearance in human tissues and body fluids. Lycopene (LYC) is a carotenoid compound that exerts antioxidant and anti-inflammatory properties. This work was performed to study possible protective effect of LYC against BPA toxicity in SMG. MATERIAL AND METHODS: 40 albino rats were divided into 5 groups. Group I: control group. Group II: received LYC (10 mg/kg b.w.) orally. Group III: received BPA (50 mg/kg b.w.) orally. Group IV: received BPA (50 mg/kg b.w.) orally + LYC (10 mg/kg b.w.) orally. Group V: received BPA (50 mg/kg b.w.) orally + LYC (10 mg/kg b.w.) orally + PPAR-γ antagonist (GW9662) (1 mg/kg b.w.) intraperitoneally. At the end of treatment, the rats were sacrificed. The SMG specimens were taken for histological and biochemical studies. RESULTS: BPA resulted in significant rise in malondialdehyde, nuclear factor κ and interleukin-1β. In contrast, the tissue levels of glutathione and PPAR-γ were significantly decreased. BPA activated Wnt/β-catenin pathway evidenced by upregulating GFA Tie, β-catenin and c-myc expression. Moreover, SMG of BPA showed degenerative changes that affected the parenchyma and stromal elements of the glands. The immunohistochemical localization of cytokeratin 7/8 and 19 of BPA rats revealed weak immunostaining of the serous secretory cells, myoepithelial cells and ductal cells. Upon treatment with LYC, glutathione and PPAR-γ were restored. CONCLUSION: LYC extracts a protective agent against BPA induced pathological changes in SMG. 統合_0967	S. Sattar, A. Nadeem, W. Shehzad, H. Ur Rehman and M. Jawed	2024	A biochemical and histological evaluation of in vivo exposure of bisphenol P for multi-organ toxicity and pathology in rats	Bisphenol (BPP) is a structural analog of bisphenol A (BPA) and is increasingly used as a substitute of BPA in commercial and household applications. In recent years, BPP has been frequently detected in terrestrial and aquatic ecosystems. Very little epidemiological and experimental information is available on the toxicity potential of BPP in human and animal systems, which is an area of dire necessity to be researched. The current study evaluated the biochemical and histopathological effects of BPP in rats. The seven experimental groups (n = 5 rats/group) included BPA80 (5 mg/kg), BPA160 (160 mg/kg), BPP20 (20 mg/kg), BPP80 (80 mg/kg), and BPP160 (160 mg/kg) orally for remaining one group served as control. The treatment was given for 28 days. At the end of treatment, the rats were sacrificed for collection of blood and tissues for biochemical and histopathological analysis. A significant (p < .05) decrease was observed in the weight of the liver, lungs, and kidneys in the BPP160 group similar to the BPA160 group compared with the control group. Further, a significant (p < .05) decrease was observed in the activities of superoxide dismutase, catalase, and glutathione peroxidase in the liver, lungs, and kidneys in the BPP160 group compared with the control group. A significant (p < .05) increase in the malondialdehyde content in BPP160 group compared with the control group. The histological tissues of BPP-induced histopathological changes in the liver such as nodal alterations, excessive necrosis of hepatocytes, necrotic cholangiocytes, and cytolysis of cells with disrupted cell structure (BPP160), and cellular congestion and degeneration of hepatocytes (BPP80), similar to the two consecutive doses of BPA. The BPP-treated groups also showed varying histopathological changes in kidney tissue, heart tissue, and lung tissue similar to BPA-treated rats. In conclusion, the present study indicated that BPP has the potential to induce oxidative stress and alter the histomorphological architecture of different organs and is as deleterious as BPA. Meccariello	2021	Multi-Systemic Alterations by Chronic Exposure to a Low Dose of Bisphenol A in Drinking Water: Effects on Inflammation and NAD(+)-Dependent Deacetylase Sirtuin1 in Lactating and Weaned Rats	Bisphenol A (BPA) is largely used as a monomer in some types of plastics. It accumulates in tissues and fluids and is able to bypass the placental barrier, affecting various organs and systems. Due to huge developmental plasticity, the fetus and newborn are considered the most vulnerable subjects to BPA exposure. Here, we investigated the effects of BPA on lactating rats and their offspring. Female rats were exposed to BPA in drinking water during gestation and lactation. At weaning, newborn rats received the same treatments as dams until six maturation. Five animals/group/BPA dose were euthanized at postnatal days (PND) 21 and 60. Liver, adipose tissue, the size of cerebral cortex/cross-area analyzed in the brain; insulin functional and molecular analyses were carried out in the liver with a focus on the expression of inflammatory cytokines and Sirtuin-1 (Sirt1). Higher BPA levels were found in plasma and adipose tissue from BPA-treated pups (17 PND) but not in weaned animals. Lateral cerebral ventricles were significantly enlarged in lactating and weaned BPA-exposed animals. In addition, apart from microvesicular steatosis, liver morphology did not exhibit any statistically significant difference for morphological signs of inflammation, hypertrophy, or macrovesicular steatosis, but the expression of inflammatory cytokines, Tnfa, Il1b, Il6, and Ccl2, was increased in the liver of BPA-exposed lactating dams and their offspring. Interestingly, Sirt1 was differentially expressed in the liver of PND 60 animals and hormone-dependent in 21 days old rats affected in repeated animals. In conclusion, chronic exposure to a low BPA dose could increase the risk for disease in adult life as a consequence of higher BPA-circulating levels and accumulation in adipose tissue during the neonatal period. 統合_0969	P. Sánchez, B. Castro, S. Martínez-Rodríguez, R. Rico-Palagina, R. G. Del Moral, I. M. Torres and J. E. Ortega	2021	Impact of chronic exposure of rats to bisphenol A from perinatal period to adulthood on intraprostatic levels of 5α -reductase isozymes, aromatase, and genes implicated in prostate cancer development	The synergistic effect of estrogens and androgens is known to play a crucial role in the physiopathology of the prostate gland. Bisphenol A (BPA) is an endocrine-disrupting compound that can interfere with endocrine hormone functioning and thereby influence prostate development. The objective of this study was to examine the impact on prostate expression of aromatase, 5 α -R isozymes, and prostate cancer–related genes of chronic exposure to BPA from perinatal period to adulthood in rats. Wistar rats were exposed to BPA (0.5 mg/kg/day) in drinking water from gestation day 0 to postnatal day 90. Ventral prostate was harvested from perinatal day 1 (PND1) and euthanization on PND90. Their prostate glands were examined by qRT-PCR, Western blot, ICC-IF assay, and morphological study. mRNA and protein levels of 5α -R1 were significantly reduced, and mRNA and protein levels of aromatase were significantly increased in BPA-treated animals, which also showed modifications of 8 out of the 84 key genes implicated in the development of prostate cancer. Because BPA interferes with genes involved in intracrinicity androgen and estrogen production and others implicated in prostate cancer, research is warranted into the prostate disease risk associated with chronic low-dose BPA exposure throughout life. Jindatip	2021	Alteration of Extracellular Matrix Components in the Anterior Pituitary Gland of Neonatal Rats Induced by a Maternal Bisphenol A Diet during Pregnancy	The extracellular matrix (ECM) plays crucial roles in the anterior pituitary gland via the mechanism of cell-ECM interaction. Since bisphenol A (BPA), a well-known endocrine disruptor, can cross through the placenta from mother to fetus and bind with estrogen receptors, cell populations in the neonatal anterior pituitary gland could be the target cells affected by this chemical. The present study treated maternal rats with 5000 µg/kg body weight of BPA daily throughout the pregnancy period and then investigated the changes in ECM production by cells, i.e., pericytes and folliculostellate (FS) cells, including their ECM production in the neonatal anterior pituitary at Day 1. We found that pericytes and their collagen synthesis induced, consistent with the increase in the number of FS cells that expressed several ECM regulatory matrix metalloproteinase (MMP)-9 and the ECM degradation product, endostatin, in the BPA-treated group. The immunohistochemical results revealed that BPA exposure significantly induced the number of ECM-producing cells and abnormally altered the ECM composition in the anterior pituitary. Moreover, we observed that BPA exposure also significantly induced the expression of ECM-associated genes, including MMP-9 and ECM-producing cells as well as collagen and the related ECM balancing genes occurred in the neonatal anterior pituitary gland. 統合_0971	S. M. M. Saleh, A. B. Mahmoud, M. B. Al-Salahy and F. A. Mohamed Moustafa	2023	Morphological, immunohistochemical, and biochemical study on the ameliorative effect of gallic acid against bisphenol A-induced nephrotoxicity in male albino rats	This study aimed to determine the effect of gallic acid (GA) on ameliorating bisphenol A (BPA)-nephrotoxicity in male rat kidneys. Forty rats were equipped randomly into four groups: control (rats untreated) and BPA (40 mg/kg b.w.), GA (100 mg/kg b.w.), and BPA + GA (40 mg/kg b.w. + 100 mg/kg b.w.). The experimental period was 30 days. Kidney specimens were collected for histological examination of the renal tissue, immunohistochemical examination of the renal tissue, morphometric measurements, and ultrastructural studies. Kidney function was assessed by determining urea, creatinine, and creatinine clearance. Lipid peroxidation (MDA) in the kidney. The antioxidant enzymes catalase and superoxide dismutase (SOD) were measured in the kidney. Kidney function was assessed by determining urea, uric acid, and creatinine levels. The morphological investigations included hematoxylin and eosin staining for assessing the general histology and determining the glomerular and corpuscular areas, the tubular cell degeneration/necrosis area, and the mean tubulointerstitial area. Also, collagen fiber intensity and polysaccharide content were evaluated. Furthermore, immunohistochemical, morphometric, and ultrastructural studies were carried out. The results revealed morphological, immunohistochemical, and biochemical alterations in the kidney. Most of these changes showed a satisfactory improvement of kidney damage when BPA-administered rats were treated with GA at both doses. In conclusion, GA exhibited a strong protective effect against BPA-induced nephrotoxicity. 統合_0972	M. A. Salfi, H. Khan, M. Jawed, S. Ahmad, Z. Khan, A. Mangla, G. Jindal, S. Panwa, N. Agarwal and S. Raisuddin	2025	Neuroprotective effects of gastrodin against bisphenol A induced-ADHD-like symptoms in rats	Gastrodin (GSD) is a potent pharmaceutical compound extracted from the dried roots of a Chinese medicinal herb, Gastrodia elata Blume. It has been used as a neuroprotective treatment for a range of neurological disorders. OBJECTIVE: This study investigated the neuroprotective effects of GSD against bisphenol A (BPA)-induced attention deficit hyperactivity disorder (ADHD)-like symptoms in the rat model. Weanling male Wistar rats treated with BPA (50 µg/kg b.w., i. M. day one) and co-consistion of treatment were subsequently treated with GSD at two doses (30 and 60 mg/kg b.w., i. p.) daily. After 28 days of completion of the treatment regimen, neurobehavioral parameters such as open field test (OFT), novel object recognition (NOR), and elevated plus maze (EPM) test were evaluated. Lipid peroxidation, reduced glutathione (GSH), monoamine oxidase (MAO) activity, and dopamine (DA) levels were measured in the cerebral cortex (CC) and hippocampus (HC) regions of the brain. Additionally, to assess astrocyte activation the expression of glial fibrillary acidic protein (GFAP) was analyzed by immunostaining. Results show that GSD treatment ameliorated locomotory activity (OFT), memory dysfunction (NOR), and anxiety (EPM) in BPA-exposed rats. Moreover, GSD treatment significantly reduced lipid peroxidation and MAO activity while increasing GSH and DA levels in the CC and HC regions of the brain. Additionally, GSD treatment reduced GFAP expression in the CC and HC. This study provides experimental evidence for a neuroprotective role for GSD against BPA-induced ADHD-like symptoms. GSD demonstrated potential preventive effects against BPA-induced ADHD-like symptoms in rats, which highlights its therapeutic value. 統合_0973	C. Sahu, S. Singla and G. Jena	2022	Studies on male gonadal toxicity of bisphenol A in diabetic rats: An example of exacerbation effect	Bisphenol A (BPA), a widely used organic synthetic chemical alters spermatogenesis and is a potential risk factor for male infertility. Diabetes-induced hyperglycemia has a negative impact on different vital organs including the testis. However, the effect of BPA on male fertility and gonadal development in diabetic (DM) patients is unknown. This study explores the role of BPA exposure on testicular toxicity in a DM rat. The DM was induced in male Wistar rats (180–200 g) by a single intraperitoneal injection of streptozotocin (STZ) (45 mg/kg b.w.). BPA was administered orally by gavage at 40 mg/kg/day for 5 consecutive weeks. Various endpoints of the toxicity include blood biochemical estimations, histological evaluations, oxidative stress parameters, DNA damage assays (cometa and enterochromin-H), expression of 4-hydroxy-2′-deoxyguanosine (8-OHdG), nuclear factor erythroid 2-related factor 2 (Nrf 2), catalase, superoxide dismutase 1 (SOD-1), a tumor-binding transcription factor 1 (OCT-1), and Ets/ch-1/det homologous protein (CHOP). Results showed that BPA exposure in DM rats significantly altered the testicular histoarchitecture, decreased the sperm count, motility, and sperm viability, and induced testicular DNA damage. Moreover, exposure to BPA in DM rats also increased the expression of the testicular oOH-dG, Nrf2, and SOD-1 proteins. Correlation analysis indicates a positive correlation between apoptosis and 8-OHdG, OCT-1, and DNA damage (nuclear diffusion factor and tail length). The present study confirmed that BPA exposure in DM conditions exacerbated the testicular damages in DM rats. Therefore, the DM condition might have increased male gonadal toxicity due to BPA exposure and requires further attention to maintain their normal reproductive health. 統合_0974	C. Sahu and G. Jena	2024	Combination treatment of zinc and selenium intervention ameliorated BPA-exposed germ cell damage in SD rats: elucidation of molecular mechanisms	Bisphenol A (BPA) is a commonly used environmental toxicant, is easily exposed to the human body and causes testicular damage, sperm abnormalities, DNA damage and apoptosis, and interferes in the process spermatogenesis and steroidal hormone production along with obstruction in testes and epididymis development. Zinc (Zn), a potent regulator of antioxidant balance, is responsible for cellular homeostasis, enzymes and proteins activities during spermatogenesis for cell division and meiotic events. Similarly, selenium (Se) is required in the testes, epididymis and in the activities of different enzymes. Both Zn and Se are essential (simultaneously) for the proper regulation of spermatogenesis and sperm maturation as well as protection against chemical and disease-associated germ cell toxicity. Thus, the study aimed to understand the protective role of Zn and Se against BPA-induced testicular toxicity in male Sprague-Dawley rats. Male rats were divided into four groups (n = 6/group) and treated for 35 days as follows: Group I: Control, Group II: BPA (50 mg/kg b.w.), Group III: BPA + Zn (30 mg/kg b.w.) + Se (0.5 mg/kg b.w.), Group IV: BPA + Zn + Se (same dose level as III) orally by gavage. Results showed that BPA exposure significantly altered the testicular histoarchitecture, sperm parameters, testicular and epididymal thiobarbituric acid reactive substances (TBARS), hydroperoxide (HP), and BPA (72 mg/kg) was administered for 15 weeks. Although BPA exposure did not affect body weight or biochemical parameters, the HCB group exhibited significant histopathological changes in the colon, including inflammation, goblet cell depletion, and crypt damage. Additionally, BPA exposure led to a significant increase in the expression of TLR4, NF-κB, and IL-6 in the colon tissue, indicating activation of inflammatory pathways. Co-exposure with HCB further amplified these effects, suggesting a synergistic interaction between the two compounds. These findings highlight the potential risk of combined exposure to BPA and HCB, which may contribute to colon inflammation and dysfunction. Given the widespread presence of both chemicals in the environment and their ability to accumulate in biological tissues, this study underscores the importance of considering mixture effects in risk assessments. Further research is needed to explore the underlying mechanisms and potential therapeutic interventions to mitigate the adverse effects of these environmental contaminants. 統合_0975	C. Sahu and G. Jena	2022	Dietary zinc deficient condition increases the Bisphenol A toxicity in diabetic rat testes	Bisphenol A (BPA) is a widely used endocrine disruptor that causes male reproductive dysfunction in humans and rodents. Diabetes-induced hyperglycemia alters spermatogenesis and antioxidant status, which negatively affects male fertility. Zinc (Zn), a potent regulator of antioxidant balance, is responsible for cellular homeostasis, enzymes and proteins activities during spermatogenesis. Therefore, the present study was designed to investigate the role of Zn deficiency in BPA-induced testicular toxicity in diabetic rats. Male Sprague-Dawley rats were divided into eight different groups: control (normal feed and water), BPA (50 mg/kg b.w.), Zn-deficient diet (ZnD; Zn-free AIN-93G diet), BPA + ZnD, STZ (single dose of 45 mg/kg b.w.), STZ + BPA, STZ + ZnD, and STZ + BPA + ZnD for four weeks. Animals' body and organ weight, sperm count, motility and sperm morphology were examined. Testes and epididymis histopathology were investigated. Testicular DNA damage and sperm apoptosis were evaluated by halo and terminal deoxynucleotidyl transferase dUTP nick end labeling (TUNEL) assays respectively. Testicular oxidative and nitrosative stress parameters were measured. Testicular steroidogenic acute regulatory protein (StAR), cytochrome P450 family 11 subfamily A member 1 (CYP11A1), 3β-hydroxysteroid dehydrogenase (3β-HSD), 17β-hydroxysteroid dehydrogenase (17β-HSD), and cytochrome P450 family 17 subfamily A member 1 (CYP17A1) expressions were evaluated by western blot analysis. The present results demonstrated that dietary Zn-deficient condition significantly increased the BPA-induced testicular, epididymal and sperm toxicity in diabetic rats due to hyperglycemia. Increased sperm abnormalities, epididymis, testicular structure and DNA damages, sperm apoptosis as well as decreased testicular oxidative and StAR, CYP11A1, 3β-HSD, 17β-HSD, and CYP17A1 expressions. The present results revealed that dietary Zn-deficient condition exacerbated the BPA-induced testicular and epididymal toxicity as well as perturbed the general male reproductive health in diabetic rats. 統合_0976	G. P. Sahoo, A. Pattnaik, V. Kumar and G. Jena	2025	Low-dose bisphenol A plus arsenik: Continuous or intermittent exposures in Sprague-Dawley rats; Effects on kidney oxidative stress, DNA damage, ferroptosis, and fibrosis	Arsenic and bisphenol A (BPA) are widespread environmental pollutants. We have studied the nephrotoxicity of arsenite (AS3), (5 mg/L in drinking water, plus BPA, 50 µg/kg oral dose, in juvenile Sprague-Dawley rats, administered continuously (CE) and intermittently (IE) for 90 days. Control (C), AS3, BPA, and AS3 + BPA groups were also studied. Kidney oxidative stress, DNA damage, ferroptosis, inflammation, microscopic and TEM examinations, DNA damage (tail moment), and protein expression. Continuous exposure to AS and BPA significantly increased urinary creatinine, albumin, and total protein, and decreased blood urea nitrogen (BUN). Histopathological and TEM data showed brush border detachment, tuft accumulation, podocyte injury, increased slit diaphragm space, and collagen deposition in both exposure groups. Significantly greater DNA damage was seen in the combined exposure group than in the other experimental groups. Combined exposure in the continuous and intermittent groups showed renal fibrosis and ferroptosis, and gene expression analysis revealed a significant increase in Bax and decrease in GRT 1. Combination exposure was more harmful than the individual exposures in causing kidney injury in these animals.	Mutat Res Genet Toxicol Environ Mutagen Vol.904 Pages 503871	10.1016/j.mrgentox.2025.503871	40382190	動物	-	1	1	不明	1	0	50 µg/kg	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-
統合_0977	M. F. S. Saad, M. N. H. Abdullah, Y. Lim, H. Bahari, B. Y. Khoo, J. J. Tan and Y. K. Yong	2025	Exploring the role of Bisphenol A in obesity-driven colorectal cancer progression: network toxicology and multi-organ pathology in animal models	Bisphenol A (BPA), an endocrine disruptor, is linked to cancer progression in estrogen-responsive tissues, but its role in promoting colorectal cancer (CRC) progression in the context of obesity remains underexplored. This study examines BPA's influence on CRC in obese Sprague-Dawley rats using network toxicology and experimental models. Computational analysis using the Comparative Toxicogenomics Database, VirtualLinker, and Integrated Discovery Identified pathways such as "CRC" and "chemical carcinogenesis-receptor activation", implicating the PI3K-AKT pathway in IL-1 beta upregulation and BPA's role in CRC during obesity. This study was conducted over 12 weeks, divided into four groups (n = 10): A: Lean, B: Lean + BPA, C: Obese + BPA, D: Obese + CRC + BPA. Lean rats received a standard diet (2.5 kcal/g), while obese rats were fed a 60% high-fat diet (5.56 kcal/g). CRC was induced in rats 1, 2-dimethylhydrazine (40 mg/kg), and BPA (25 mg/kg) was administered for 12 weeks. Although BPA exposure did not affect body weight or biochemical parameters, the HCB group exhibited significant histopathological changes in the colon, including inflammation, goblet cell depletion, and crypt damage. Additionally, BPA exposure led to a significant increase in the expression of TLR4, NF-κB, and IL-6 in the colon tissue, indicating activation of inflammatory pathways. Co-exposure with HCB further amplified these effects, suggesting a synergistic interaction between the two compounds. These findings highlight the potential risk of combined exposure to BPA and HCB, which may contribute to colon inflammation and dysfunction. Given the widespread presence of both chemicals in the environment and their ability to accumulate in biological tissues, this study underscores the importance of considering mixture effects in risk assessments. Further research is needed to explore the underlying mechanisms and potential therapeutic interventions to mitigate the adverse effects of these environmental contaminants. 統合_0978	D. Y. Ryu, W. K. Pang, E. O. Adegoke, M. S. Rahman, Y. J. Park and M. G. Pang	2023	Bisphenol-A disturbs hormonal levels and testis mitochondrial activity, reducing male fertility	STUDY QUESTION: How does bisphenol A (BPA) influence male fertility, and which mechanisms are activated following BPA exposure? SUMMARY ANSWER: BPA exposure causes hormonal disruption and alters mitochondrial dynamics and activity, ultimately leading to decreased male fertility. WHAT IS KNOWN ALREADY: As public health concerns following BPA exposure are rising globally, there is a need to understand the exact mechanisms of BPA on various diseases. BPA exposure causes hormonal imbalances and affects male fertility by binding the estrogen receptors (ERs), but the mechanisms of how it mediates the hormonal dysregulation is yet to be studied. STUDY DESIGN SIZE DURATION: This study consisted of a comparative study using mice that were separated into a control group and a group exposed to the lowest observed adverse effect level (LOAEL) of BPA (50 mg/kg) for 5 consecutive weeks. PARTICIPANTS/MATERIALS SETTING METHODS: Male ICR mice (n = 10/group) were used in this study. Mice in the BPA group were orally administered BPA (50 mg/kg) for 5 consecutive weeks, while those in the control group received the same volume of corn oil only. Blood on the daily variations in BW, testis groups, were gauged every day from 8 to 12 weeks. At week exposure, BPA-treated mice were euthanized for a week. Then, the testes and spermatozoa of each mouse were collected to investigate the effects of BPA on male fertility. GP was carried out using the cumulus oocyte complexes, from female hybrid B6D2F1/CrlOri mice (n = 10/group) at 8–12 weeks of age. Then, the COCs were fertilized in vitro with sperm collected from the cauda epididymis of male mice exposed to BPA for 5 weeks. Subsequently, the fertilized oocytes were cultured in vitro. The COCs was performed to determine the levels of sex hormones (T3, T4, and testosterone) in serum. Immunohistochemistry and reactive oxidative stress was used to determine the effects of BPA on the histological morphology and stage VII–VIII testicular seminiferous epithelium. Blastocyst formation and cleavage development rate were evaluated using IVF. MAIN RESULTS AND THE ROLE OF CHANCE: BPA acted by binding to ERs and G protein-coupled receptors and activating the protein kinase A and mitogen-activated protein kinase signaling pathways, leading to aberrant hormone levels and effects on the respiratory chain complex, ATP synthase and protein-related metabolic pathways in testis mitochondria ($P < 0.05$). Subsequently, embryo cleavage and blastocyst formation were reduced after the use of affected sperm, and abnormal morphology of seminiferous tubules and stage VII–VIII seminiferous epithelium in the testis were observed in BPA-exposed mice ($P < 0.05$). LIMITATIONS REASONS FOR CAUTION: Since the protein expression levels in the testes were validated, in vitro studies in each testicular cell type (Leydig cells, Sertoli cells, and spermatogonial stem cells) would be required to shed further light on the exact mechanism resulting from BPA exposure. Furthermore, the BPA doses employed in this study significantly exceed the typical human exposure levels in real-life scenarios. Consequently, it is imperative to conduct experiments focusing on the effects of BPA concentrations, even in low-safe daily human exposures, to comprehensively assess their impact on reproductive health. WIDER IMPLICATIONS OF THE FINDINGS: This study provides evidence that BPA exposure can cause male infertility by altering hormone levels and mitochondrial activity in the testes and provides a solid foundation for subsequent investigations into the effects on male reproductive function and fertility following BPA exposure, and the underlying mechanisms responsible for these effects. In addition, these findings suggest that the LOAEL concentration of BPA demonstrates exceptional toxicity, especially when considering its specific impact on the testes and its adverse consequences for male fertility by impairing mitochondrial activity. Therefore, it is plausible to suggest that BPA elicits distinct toxicological responses and metabolomic endpoints based on the particular concentration levels for each target organ. 統合_0980	L. Rytel, L. Könyves and S. Gonkowski	2022	Endocrine Disruptor Bisphenol a Affects the Neurochemical Profile of Nerve Fibers in the Aortic Arch Wall in the Domestic Pig	Bisphenol A (BPA) is a synthetic compound utilized in industry for the production of various plastics. BPA penetrates into the environment and adversely affects living organisms. Therefore, the influence of various BPA doses on the neurochemical characteristics of nerve fibers in the aortic arch wall was investigated in the present study. The experiment was performed on 12 female pigs divided into 3 groups. The animals were orally administered BPA in the following doses: 0.036 mg/kg body weight/day (group 1), 0.36 mg/kg body weight/day (group 2), and 36 mg/kg body weight/day (group 3). The study lasted 90 days. The activity of nerves within the aortic arch wall was measured by the double-labeling immunofluorescence method. It was found that BPA in the lowest dose used in this study (0.036 mg/kg body weight/day) causes a clear increase in the number of nerve fibers containing the activity of enzymes within aortic arch wall. Moreover,

統合_0998	S. Rajaura, N. Bhardwaj, A. Singh, R. Babu, N. Gupta and M. Z. Ahmed	2024	Bisphenol A-induced oxidative stress increases the production of ovarian cancer stem cells in mice	Bisphenol A (BPA) belongs to the endocrine disruptor chemicals (EDCs) causing various reproductive disorders in females. We analyzed the toxic effects of BPA in the uterus and ovaries. The BPA was administered orally with the repeated low dose (LD, 1 mg/kg) and high dose (HD, 5 mg/kg) of body weight on alternate days for 3 months, via oral gavage to Swiss mice. BPA administration decreases body weight, ovarian weight and size as well as the number of ovarian follicles. The BPA-treated ovaries showed the presence of cystic follicles, hemorrhagic corpus luteum, and hyperplasia in the uterine epithelium and lymphocytic infiltration in the ovary. The BPA-treated uterus shows increased vascularization, atrophied endometrium and myometrium, and endometrial hyperplasia. ER-α with aberrant glandular growth. The ovarian stem cells (CSCs) in the ovaries were identified based on staining with anti-mouse CD44 and anti-mouse CD133 antibodies and analyzed by flow cytometry. Three different populations of ovarian CSCs: CD44+/ CD133-, CD44+/CD133+, and CD44-/CD133+ were recognized based on the intensity of these receptors. CD44+/CD133- and CD44+/CD133+ cell percentages were increased in BPA-treated groups. CD44+/CD133+ cancer-increased in LD but decreased in HD. The BPA administration also reduces ROS production, which decreases the expression of antioxidant genes. Superoxide dismutase-1 (SOD1), Superoxide dismutase-2 (SOD2), Catalase (CAT), Glutathione peroxidase-1 (GPX1), and Peritoxal box (GTF1D1) in ovarian cells. In conclusion, BPA exposure induced an inflammatory response, increased CSC properties, induced ROS, and decreased antioxidant responses in the ovaries. 統合_0999	G. L. Raja, C. Lite, K. D. Subhashree, W. Santosh and S. Barathi	2020	Prenatal bisphenol-A exposure altered exploratory and anxiety-like behaviour and induced non-monotonic, sex-specific changes in the cortical expression of CYP19A1, BDNF and intracellular signaling proteins in F1 rats	Bisphenol-A (BPA) is one of the extensively studied estrogenic endocrine disrupting chemicals (EDC) with ubiquitous exposure among humans and wildlife. While there are literature reporting the association of bisphenol-A with decreased neurotrophic factor BDNF/expression levels with altered cognitive and emotional behaviour such as anxiety-like and stress-behaviour in animal models, there are no studies in BPA that investigate these altered neurobehavioural outcomes. In parallel with the expression of intracellular proteins involved in BDNF signaling pathway. In this study, pregnant Wistar rats were exposed to BPA through water (0, 0.1, 1, 10 and 100 mg/kg bw) from gestation day (GD) 6 to post-natal day (PND) 21 and the behavioural changes in the offspring were assessed. Our results showed that the altered behaviour in the form of lack of anxiety-like behaviour and CYP19A1 gene were observed in male BPA-exposed offspring, whereas in females, the expression was upregulated. The expression of c-FOS, p-ERK and p-PKA proteins were increased in males, while in females, it decreased. Both the male and the female BPA-exposed offspring exhibited elevated levels of DNMT1 protein. The sex-specific alteration in the expression of CYP19A1 and DNA methyltransferase 1 (DNMT1) suggests that both hormonal and epigenetic dysregulation could underlie the long-term BPA-induced effect on anxiety-like behaviour in the offspring. 統合_1011	A. R. Pérez, E. G. Parra, S. Mas, J. L. Mosgallo-Pascual, M. Ruiz-Ortega and S. Reyago-Mateos	2021	Bisphenol A Modulates Autophagy and Exacerbates Chronic Kidney Damage in Mice	BACKGROUND: Bisphenol A (BPA) is a ubiquitous environmental toxin that accumulates in chronic kidney disease (CKD). Our aim was to explore the effect of chronic exposition of BPA in healthy and injured kidney investigating potential mechanisms involved. METHODS: In C57BL/6 mice, administration of BPA (120 mg/kg/day, i.p for 5 days/week) was done for 2 and 5 weeks. To study BPA effect on CKD, a model of subtotal nephrectomy (SNX) was performed. Kidney function was assessed by albuminuria and creatinine clearance. Kidney damage was evaluated by histological analysis. Markers of oxidative stress, tissue inflammatory infiltration in the kidney, tubular injury and renal fibrosis, measured by immunohistochemistry and Western blot. BPA was applied subcutaneously by using osmotic pumps. After 12 weeks, the kidneys were analyzed by micro-computed tomography (micro-CT) and a three-point bending test. Comparing the female low- and high-dose groups, a significantly greater marrow area (p < 0.027) was identified in the group exposed to a higher BPA concentration. In addition, the trabecular number tended to be higher in the female high-dose group when compared to the low-dose group (p = 0.06). The cross-sectional thickness tended to be higher in the male high-dose group when compared to the male low-dose group (p = 0.08). Considering our results, BPA-related effects on the bone morphology in female Wistar rats are unbeneficial; after high-dose exposure, while, in male rats, a tendency toward negative effects on the bone morphology in terms of a reduced cross-sectional cortical area and total area could be demonstrated. 統合_1013	N. B. Patibha, D. Adiga, S. P. Kabekkodu, S. K. Bhat, K. Satyamoorthy and P. S. Rai	2022	Bisphenol A exposure modulates reproductive and endocrine system, mitochondrial function and cellular senescence in female adult rats: A hallmarks of polycystic ovarian syndrome phenotype	Bisphenol A (BPA) mimics estrogen and consequently suspected to be detrimental to female reproductive system. Biomonitoring confirms the BPA burden is likely leading to a complex condition called polycystic ovarian syndrome (PCOS) which is frequently attributed to female infertility. Due to unclear precise molecular pathomechanisms of BPA in PCOS, we intend to examine the molecular mechanisms of the reproductive, endocrine and metabolic system in female adult rats exposed to BPA. Female Wistar rats were exposed to BPA (0.25 mg/kg/day) by oral gavage for 90 days. Following the exposure, ovaries were harvested for RNA, analyzed RNA-sequencing and gene expression by semi-quantitative RT-PCR, assessed senescence induction by β-galactosidase staining and immunofluorescence in BPA-treated rats. Our data showed hormonal imbalance, impaired folliculogenesis, abnormal expression patterns of target genes, CDKN2A overexpression and enhanced ROS levels in BPA-treated rats. This study provides insights on the effects of BPA exposure on ovulatory hormonal, mitochondrial dysfunction, and senescence that benefit to better understanding of PCOS induced by BPA. Bard	2025	In utero exposure to estrogenic bisphenol analogues increases mammary tissue stiffness	In utero exposure to estrogenic endocrine disrupting compounds (EDCs) can increase breast cancer risk in adulthood. It has previously been shown that the estrogenic plastic/pen bisphenol A (BPA) alters development of the mammary gland and increases both mammary gland stiffness and tumor susceptibility in rodent models following in utero exposure. Because of its endocrine disrupting properties, BPA has been substituted with structural analogues with varying ability to activate estrogen receptor alpha (ERα). However, the impacts of in utero exposure to many of these analogues is unknown. In this study, we aimed to analyze the impact of bisphenol analogues on collagen deposition and mammary gland stiffness and characterize mammary epithelial development following exposure to these compounds. With the exception of bisphenol S, all bisphenol analogues tested (bisphenol AF, bisphenol B, bisphenol E, bisphenol F, bisphenol S, and bisphenol Z) increased mammary gland stiffness at puberty. Bisphenol S did not increase mammary gland stiffness at puberty, but increased stiffness in the mammary stroma at 3 months of age. Bisphenol S also altered the expression of genes involved in the extracellular matrix and did not follow a clear pattern. These results add to the growing literature on the impact of bisphenol analogues and support the idea that these compounds promote abnormal mammary gland development. Furthermore, these data support a model that bisphenol compounds induce a microenvironment that may promote breast cancer development in an estrogen-dependent manner. Palanza	2020	Effects of Prenatal Exposure to a Low-Dose of Bisphenol A on Sex Differences in Emotional Behavior and Central Alpha(2)-Adrenergic Receptor Binding	Prenatal exposure to bisphenol A (BPA) influences the development of sex differences neurologically and behaviorally across many species of vertebrates. These effects are a consequence of BPA's estrogenic activity and its ability to act as an endocrine disrupter even at very low doses. When exposure to BPA occurs during critical periods of development, it can interfere with the normal activity of sex steroids, impacting the fate of neural circuits and behavioral traits. Here we report the effects of prenatal exposure to BPA on sex differences in emotional behavior and central alpha(2)-adrenergic receptors (α2-ARs), which are involved in many brain and behavioral features, such as the amount of time spent investigating a novel environment. Isometric activity and behavioral lateralism. In some species of rodents, BPA exposure affected many sexual behaviors. Interestingly, these behaviors are at least in part modulated by the catecholaminergic system, which has been reported to be a target of BPA action. In the present study we investigated the influence of prenatal exposure of mice to a very low single dose of BPA on emotional and sexual behaviors and on the density and binding characteristics of alpha(2)-adrenergic receptors. Since α2-adrenergic receptors are widespread in the central nervous system and they can act as autoreceptors, inhibiting the release of noradrenaline and other neurotransmitters from presynaptic terminals, BPA exposure disrupted sex differences in behavioral responses to a novel environment, but did not affect male sexual behavior. Interestingly, BPA induced a change in the binding affinity of alpha(2)-adrenergic receptors in the locus coeruleus and medial preoptic area (mPOA) and it attenuated the sexual dimorphism in the density of the receptors in the mPOA. Meli	2020	Oral Bisphenol A Worsens Liver Immune-Metabolic and Mitochondrial Dysfunction Induced by High-Fat Diet in Adult Mice: Cross-Talk between Oxidative Stress and Inflammasome Pathway	Lines of evidence have shown the antiorganistic and transgenerational impact of bisphenol A (BPA), an endocrine disrupting chemical, on immune-metabolic alterations, inflammation, and oxidative stress, while BPA toxic effects in adult mice were are still controlled. Here, we evaluate BPA's worsening effect on several hepatic metabolic processes associated to high-fat diet (HFD)-induced obesity in mice. After 12 weeks HFD feeding, C57BL/6 male mice were exposed daily to BPA (50 μg/kg per os) along with HFD for 3 weeks. Glucose tolerance and lipid metabolism were examined in serum and/or liver. Hepatic oxidative damage (reactive oxygen species (ROS) production, mitochondrial dysfunction, and antioxidant defenses) and inflammation (cytokine production and inflammasome activation) were evaluated by biochemical and molecular analysis. BPA amplified HFD-induced alteration of key factors involved in glucose and lipid metabolism, liver triglycerides accumulation, and worsened mitochondrial dysfunction by increasing oxidative stress, and reducing antioxidant defenses. The exacerbation by BPA of hepatic immune-metabolic dysfunction induced by HFD was shown by increased toll-like receptor-4 and its downstream pathways (i.e., NF-kB and NLRP3 inflammasome) amplifying inflammatory cytokine transcription and promoting fibrosis progression. This study evidences that BPA exposure represents an additional risk factor for the progression of fatty liver diseases, strictly related to the cross-talk between oxidative stress and immune-metabolic impairment due to obesity. Le Magueresse-Battistoni	2021	Impact of Estrogen Withdrawal and Replacement in Female Mice along the Intestinal Tract: Comparison of E2 Replacement with the Effect of a Mixture of Low Dose Pollutants	Postmenopausal women represent a vulnerable population towards endocrine disruptors due to hormonal deficit. We previously demonstrated that chronic exposure of ovariectomized C57BL/6 mice fed a high-fat, high-sucrose diet to a low dose mixture of chemicals with one dioxin, one polychlorobiphenyl, one phthalate, and bisphenol A triggered metabolic alterations in the liver but the intestine was not explored. Yet, the intestinal barrier is a key player in the gut-liver axis. Here, we investigated the impact of ovariectomy and chronic exposure to the mixture of chemicals at low doses in mice with/without fat/sugar diet on the intestinal barrier. We characterized genes encoding tight junctions (Ocln1, Zo1a1, Cldn1, Cldn3, Cldn5, Cldn8), and genes related to gut hormones in the jejunum (sg., Cck8, Gcg1, Glp1r1) and to bile acid biosynthesis in the gut (sg., Fgf15, Slc10a2) and liver (sg., Abcb11, Slc10a1) were under estrogen regulation. Exposure to pollutants mimicked some of the effects of E2 replacement, particularly in the lower (sg., Ocln1, Slc1a1) suggesting that the mixture had estrogen-mimetic activities. The present findings have important implications for the understanding of estrogen-dependent metabolic alterations with regards to situations of loss of estrogens as observed after menopause. Morales-Montor	2022	The Endocrine Disruptor Compound Bisphenol-A (BPA) Regulates the Intra-Tumoral Immune Microenvironment and Increases Lung Metastasis in an Experimental Model of Breast Cancer	Breast cancer (BC) metastasis represents the main physiopathology leading to poor prognosis and death. Bisphenol A (BPA) is a pollutant, classified as an endocrine disrupting chemical compound with estrogenic activity, which is present in a wide variety of plastic products. Exposure to BPA has been associated with an increased risk of developing BC and metastasis. Nevertheless, the mechanisms by which BPA promotes BC progression remain unclear. Therefore, in this study, we investigated the effect of BPA exposure on the intra-tumoral immune microenvironment and lung metastasis in an experimental model of BC. Female BALB/c mice were exposed orally to a single dose of BPA (50 mg/kg) by oral gavage. Two days later, 4T1 murine breast cancer cells were inoculated into the mammary fat pad. Mice were euthanized 15 days after tumor inoculation, and tumors, spleen, and lungs were collected. Tumor growth was monitored throughout the experiment. Flow cytometry was used to analyze the immune cell populations in the tumor microenvironment, spleen, and lungs. Tumor growth was significantly higher in BPA-exposed mice than in control mice. Moreover, BPA exposure increased the number of lung metastatic nodules and the percentage of metastatic cells in the lungs. Flow cytometry revealed that BPA exposure altered the immune cell composition within tumors, with a notable increase in myeloid-derived suppressor cells (MDSCs) and regulatory T cells (Tregs), both of which are known to promote immune evasion and tumor progression. Additionally, BPA exposure was associated with elevated levels of immunosuppressive cytokines, including IL-10 and TGF-β, within the tumor microenvironment. These findings suggest that BPA exposure may enhance BC metastasis by modulating the immune landscape, thereby facilitating tumor cell dissemination to the lungs. Our results underscore the potential risk posed by environmental exposure to BPA and highlight the importance of considering endocrine disruptors in the context of cancer progression and metastasis. Further studies are warranted to elucidate the precise molecular mechanisms underlying BPA-induced immunosuppression and to explore potential therapeutic interventions to mitigate its adverse effects. Bollati-Fogolin	2020	Perinatal exposure to Bisphenol A disturbs the early differentiation of male germ cells	Understanding the effects of Bisphenol A (BPA) on early germ cell differentiation and their consequences in adult life is an area of growing interest in the field of endocrine disruption. Herein, we investigate whether perinatal exposure to BPA affects the differentiation of gonocytes into spermatogonial stem cells (SSCs) and spermatogonial differentiation. We used Oct4-eGFP transgenic mice to track the expression of the Oct4 gene. This strategy was proved successful to evaluate the spermatogonial stem cells in an undifferentiated stage. Then, BPA treatment was used as a parameter to evaluate the effect of BPA on early germ cell development. Female pregnant transgenic mice were exposed to BPA by oral gavage, from embryonic day 9.5 to postnatal day 7 (PND7). The effects of BPA on male germ cell differentiation were evaluated at PND7, with testicular morphology and proliferation, expression of androgen receptor and the number of undifferentiated spermatogonia as endpoints. We found that perinatal bisphenol A exposure to BPA up-regulates the expression of Oct4 eGFP in testicular cells at PND7. This finding suggests a higher proportion of undifferentiated spermatogonia in BPA-treated animals, compared with non-exposed mice. Moreover, perinatal BPA exposure increased the proliferation of undifferentiated spermatogonia at PND7. Finally, we found that perinatal exposure to BPA disturbed the normal differentiation of male germ cells early in life, mainly by altering the expression of Oct4 and retained long-lasting sequelae at the adult stage, affecting sperm count and testis. Kocer-Gumusel	2022	The effects of prenatal and lactational bisphenol A and/or di(2-ethylhexyl) phthalate exposure on female reproductive system	Bisphenol A (BPA) and di(2-ethylhexyl) phthalate (DEHP) are endocrine disrupting chemicals (EDCs) that are abundantly used in polyvinyl chloride plastics, polycarbonates and epoxy resins. Prenatal and early postnatal exposure to EDCs may cause reproductive disorders in females. The present study aimed to investigate the effects of prenatal and lactational exposure to BPA and/or DEHP on female reproductive system. Pregnant rats from various rodent efficacy studies (RED) were randomly assigned to four groups (n = 5/group): Control (received vehicle only), DEHP (20 mg/kg/day), BPA (5 mg/kg/day) and BPA + DEHP (BPA+DEHP; 5 mg/kg/day BPA+20 mg/kg/day DEHP) through 6-13 gestational days and lactation by oral gavage. Female offspring (n = 5/group) were sacrificed at the end of twelfth postnatal week and then euthanized. Reproductive hormones, ovarian follicle numbers and ovarian development were determined. Plasma testosterone and estradiol levels of BPA and BPA + DEHP groups were significantly lower than control. In BPA group, the number of tertiary ovarian follicles decreased significantly compared to control. In the combined exposure group, the number of corpus luteum (CRL), as well as the number of primordial follicles (ORL), showed marked decreases compared to control group. It can be suggested that early life exposure to BPA and DEHP may cause late life adverse effects in female reproductive system, especially after combined exposure. 統合_1040	Ö. Özden Akkaya, A. Yağcı, B. Zik, A. Kibria, S. Güler, S. Çelik and K. Altunbaş	2024	The effect of bisphenol A on the Notch (Notch2 and Jagged2) signaling pathway in the follicular development of the neonatal rat ovary	The formation of primordial follicles determines the pool size of follicles in the ovary, and is crucial for female reproductivity. Oocyte nest breakdown, and the formation of primordial follicles, largely depend upon the communication between oocytes, and the surrounding pregranulosa cells. The neurogenic locus notch homolog protein (Notch) signaling pathway is the key player for this cell-to-cell communication, and is responsible for the maintenance of oocyte nests, primordial follicle formation, and follicular development. Bisphenol A (BPA) is a well-known endocrine disrupting chemical (EDC) that has been shown to affect ovarian development via Notch signaling. Consequently, we investigated the possible influences of BPA treatment on the prepubertal distribution of the follicular stages, follicle numbers, levels of neurogenic locus notch homolog protein 2 (Notch2) and Jagged2 expressions in the ovary. BPA was administered at doses of either 50 μg/kg/day or 50 mg/kg/day at different time intervals, during neonatal and fetal periods in rats. After collecting the ovaries from the various experimental groups, follicular count, cell frequency of apoptosis was determined by TUNEL assay. In addition, Notch2 and Jagged2 expressions were assessed by immunohistochemical staining and qPCR. In summary, BPA treatment affected the follicle numbers and apoptosis level, and Notch2 and Jagged2 expressions varied with follicular stage. It was also observed that these parameters were dose and time dependent with exposure to BPA exposure.	Biotech Histochem Vol.99 Issue 5 Pages 238-259	10.1080/10520295.2024.2361313	39382141	動物	-	1	不明	不明	不明	0	50、50000 μg/kg/日	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-

Fan	2024	Green Tea Diet Can Effectively Antagonize the Toxicity Induced by Environmental-Related Concentrations of BPA: An Implication from In Vivo and In Silico Studies	The neurotoxicity of bisphenol A (BPA) exposure has been confirmed in vivo and in vitro, and inflammatory response is considered the main pathway. Green tea is a healthy life habit as it is rich in various anti-inflammatory components. To confirm that green tea diet is an effective measure to antagonize BPA-induced neurotoxicity, mice were treated with 0.5 and 5000 μg/kg/day of BPA from postnatal day (PND) 1 to 50 and supplemented with green tea at PND 21. From PND 51, behavioral tests were conducted on mice to assess BPA-induced cognitive, and spatial learning memory capabilities. The open field test and Y-maze test also were conducted to evaluate anxiety-like behavior induced by BPA. Interestingly, green tea diet significantly alleviated BPA-induced anxiety-like behaviors. Meanwhile, the green tea diet effectively reversed BPA-induced microglia activation and neuronal damage in the hippocampus. Moreover, the expression of inflammatory factors (IL-1β, IL-6, and TNF-α) was significantly increased by BPA exposure ($p < 0.05$, $p < 0.01$, and $p < 0.001$, respectively), and green tea diet significantly reversed the increase of IL-1β, IL-6, and TNF-α induced by BPA ($p < 0.05$, $p < 0.01$, and $p < 0.001$, respectively). Furthermore, we found that BPA exposure could activate the NF-κB signaling pathway, and green tea diet could significantly inhibit the activation of NF-κB signaling pathway induced by BPA ($p < 0.05$, $p < 0.01$, and $p < 0.001$, respectively). Molecular docking suggests that various anti-inflammatory components of green tea can competitively bind to the estrogen receptors with BPA. In general, a green tea diet alleviates BPA-induced emotional disorders by inhibiting microglial polarization and hippocampal apoptosis, indicating its effective antagonistic ability against the neurotoxicity induced by environmental BPA exposure. 統合_1042	A. P. Ortega-Garcia, V. Diaz-Hernández, P. Cutiaco-Saldaña and H. Merchant-Larios	2021	Bisphenol A alters differentiation of Leydig cells in the rabbit fetal testis	The endocrine disruptor Bisphenol A (BPA) crosses the placental barrier and reaches the fetal organs, including the gonads. In the testis, fetal Leydig cells (FLC) produce testosterone required for the male phenotype and hormonally-cell-cell signaling in the developing testis. Although it is known that BPA affects cell proliferation and differentiation in FLC, studies concerning the mechanism involved are contradictory, mainly due to differences among species. Two developing fetal gonads of rabbits, both ovines and testicles, whereas species with more extended gonadal periods from these two tissue compartments. The rabbit provides a good model to study the effects of BPA in the FLC population in the testis and ovary because the gonads are developed in the same period. We evaluated the effects of BPA on the proliferation and cell population of the developing testis. Using qRT-PCR, we assessed the levels of SF1, CYP11A1, 3,β -HSD, and aromatase transcripts in the gonads of fetal rabbits. Three levels combined with both the mitotic activity and the ultrastructural differentiation of the FLC by nuclear and electron microscopy, respectively. Results indicated that BPA alters the expression levels of essential genes involved in androgen-paracrine signaling, modifies the proliferation and differentiation of the FLCs, and alters the levels of ovine testosterone after birth. Thus, BPA may change the postnatal levels of serum testosterone in male in the impaired FLC population formed by the proliferating ovens and non-proliferating quiescent/resistant FLC. 統合_1043	O. I. Olunarti, B. A. Alabi, O. S. Michael, A. O. Ojo and B. P. Fatokun	2021	Rutin prevents cardiac oxidative stress and inflammation induced by bisphenol A and dibutyl phthalate exposure via NRF-2/NF-κB pathway	ABA Environmental pollutants such as plastic-component substances (phthalates and bisphenol A) that coexist in natural ecosystems have been linked to an increase in the occurrence of human health hazards, particularly cardiovascular health. This study was designed to investigate single and combined acute toxic effects of dibutyl phthalate and bisphenol A and the possible intervention role of rutin. MATERIALS AND METHODS: Forty two rats were randomized into 7 groups of 6 animals each and were treated as follows for 28 days: Control (0.1% DMSO), Bisphenol A (BPA, 25 mg/kg, p.o), Dibutyl phthalate (DBP, 25 mg/kg, p.o), BPA + DBP, Rutin (100 mg/kg, p.o), BPA + Rutin, DBP + Rutin. Cardiac oxidative stress, inflammation, and histopathological changes were evaluated. RESULTS: Results showed that BPA induced myocardial oxidative stress (OS) marked by elevated malondialdehyde (MDA) increased in DBP + BPA group. Also, DBP increased tissue C-reactive protein (CRP). DBP, DBP + BPA increased tissue nuclear factor kappa B (NF-κB). DBP + BPA increased plasma CRP. BPA increased plasma NF-κB. However, rutin efficiently reduced MDA level. CRP and NF-κB increasing (ICD, ICH and ICC) levels. In DBP and BPA exposed rats. DISCUSSION: These results revealed that bisphenol A and dibutyl phthalate exposure caused oxidative stress and inflammation in the heart through NrF2/NF-κB signaling pathway while oral administration of rutin prevents these effects via upregulation of Nrf2 and suppression of NF-κB signaling pathway. 統合_1044	S. G. Olukole, E. O. Ola-Davies, D. O. Lanipekun and B. O. Oke	2020	Chronic exposure of adult male Wistar rats to bisphenol A causes testicular oxidative stress: Role of gallic acid	OBJECTIVES: Bisphenol A (BPA) has been reported that among other male reproductive dys functions, it can cause marked estrogenic effects including alteration in serum hormones as well as testicular lesions in exposed animals. This work sought to study the role of gallic acid (GA) in boars embedded on the BPA induced testicular oxidative stress in adult male Wistar rats. MATERIALS AND METHODS: Forty adult male Wistar rats (180-200 g) were randomly assigned into 5 groups of 8 rats each and were treated as follows for 28 days: Control (0.1% DMSO), BPA (25 mg/kg, p.o), GA (50 mg/kg, p.o), BPA + GA (25 mg/kg BPA with concurrent 50 mg/kg GA) and BPA + GA (25 mg/kg BPA with concurrent 100 mg/kg GA). At the end of the experimental period, rats were anesthetized and sacrificed. Blood and organ samples were collected for the assessment of testicular oxidative stress. Testicular oxidative stress was evaluated by measuring the activities of superoxide dismutase (SOD), catalase (CAT), GPx, GST, GR and GSH-Px, and the levels of malondialdehyde (MDA) and nitric oxide (NO). Serum concentrations of luteinizing hormone (LH), follicle stimulating hormone (FSH) and testicular PPAR-γ and tissue biochemistry analysis: superoxide dismutase (SOD), catalase (CAT), GSH-Px, glutathione-S-transferase (GST), malondialdehyde (MDA) and nitric oxide (NO) were also evaluated. RESULTS: Findings from the present study showed that BPA significantly ($p < 0.05$) increased testicular MDA and NO levels and decreased the activities of SOD, CAT, GPx, GST, GR and GSH-Px when compared with the control group. However, co-treatment with GA significantly ($p < 0.05$) reversed the BPA induced testicular oxidative stress by decreasing the activities of antioxidant enzymes and increasing the levels of non-enzymatic antioxidants. Furthermore, BPA induced testicular oxidative stress by decreasing the activities of antioxidant enzymes and increasing the levels of non-enzymatic antioxidants. However, co-treatment with GA prevented against these alterations. CONCLUSION: Findings from the present study confirmed the previously reported data and show that the ability of GA as a potent antioxidant, may protect against BPA induced alterations in the male reproductive function. Hence, GA protects against testicular oxidative stress in adult male Wistar rats following chronic exposure to BPA.	Endocr Regul Vol.54 Issue 1 Pages 14-21	10.2478/enr-2020-0003	32597147	動物	-	1	1	1	0	10 mg/kg/日	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-
統合_1045	S. G. Olukole, D. O. Lanipekun, E. O. Ola-Davies and B. O. Oke	2019	Maternal exposure to environmentally relevant doses of bisphenol A causes reproductive dysfunction in F1 adult male rats: protective role of melatonin	This study investigated the protective effects of melatonin (Mt), a potent antioxidant, in male Wistar rats exposed to environmentally relevant doses of bisphenol A (BPA) in utero. Pregnant Wistar rats were randomly assigned into 5 groups of 5 rats each and were treated as follows: Control (0.1% DMSO), BPA (0.5 mg/kg bw), BPA + Mt (0.5 mg/kg bw BPA with concurrent 4 mg/kg bw Mt), BPA + Mt (2 mg/kg bw BPA with concurrent 8 mg/kg bw Mt) and BPA + Mt (4 mg/kg bw BPA with concurrent 16 mg/kg bw Mt). Treatments were by gavage from gestational day (GD) 10-21. The BPA treated animals showed dose dependent significant reduction in body weight, gonosomatic index, sperm motility, fertility and count. Also, BPA caused significant reduction in the levels of serum testosterone and luteinizing hormone while it caused significant increase in the levels of follicle stimulating hormone as well as estradiol. Furthermore, BPA induced testicular oxidative stress, including significant decrease in the activities of testicular SOD, GSH and GPx as well as GST, increasing the levels of testicular MDA and H2O2. It further induced interstitial necrosis and germinal cell degeneration in the testis with a subsequent diminution of the tubular and lumina diameter. However, co-treatment with Mt (1) offered tremendous protection against testicular damage induced by BPA. Melatonin is likely to protect against alterations of the male reproductive system caused by BPA through its direct action on the mechanism of anti-oxidants, as well as through the inhibition of necrosis. 統合_1046	K. M. Oliveira, L. S. Figueiredo, T. R. Araujo, I. N. Freitas, L. N. Silva, A. C. Boschero and R. A. Ribeiro	2020	Prolonged bisphenol-A exposure decreases endocrine pancreatic proliferation in response to obesogenic diet in ovariectomized mice	Research on the deleterious actions of bisphenol (BPA) have focussed on its effects on insulin secretion during pre/perinatal periods or adulthood. Estrogens also modulate endocrine pancreas physiology in females during aging; however, the effects of BPA on islet morphophysiology after menopause have not been investigated. We evaluated the effects of BPA exposure on glucose homeostasis and islet morphofunction in ovariectomized (OVX) mice fed on a high-fat diet (HFD). Adult Swiss female mice were underwent to bilateral ovariectomy, and with the confirmation of the establishment of surgical menopause, the females were then exposed to BPA (50 μg/kg/day) by gavage for 30 days. Ovariectomy and HFD per se induced glucose intolerance, hyperinsulinemia, and insulin resistance. However, BPA exposure in OVX mice fed on HFD exacerbated hyperglycemia, hyperinsulinemia, glucose intolerance and insulin resistance. BPA did not modulate HFD-induced obesity in ovariectomized mice. Besides, BPA exposure in OVX mice fed on HFD induced body glucose impairments in HFD females, and islets isolated from both HFD and HFD + BPA groups exhibited insulin hypersecretion. The HBPA islets, however, displayed enlarged islet cells and reduced proliferation, in association with the downregulation of mRNAs encoding PCNA (↓ 50%) and CCND2 and upregulation of mRNAs encoding IFN-γ, CHOP, TXP-1, and IL-1β in HBPA islets. BPA consumption in OVX mice impaired the islet cell hyperplasia response to the HFD, partly mediated by increased expression of IFN-γ and CHOP, which impaired the expression of major genes involved in islet cell survival and functionality. Together with higher pro-inflammatory cytokines expression in the islet milieu, these alterations may accelerate β-cell failure in postmenopause. 統合_1047	O. S. Oluh, J. K. Akintunde, A. J. Akamo and U. Akpan	2025	Thymoquinone inhibits Neuroinflammatory mediators and vasoconstriction injury via NF-κB dependent NeuN/GFAP/Ki-67 in hypertensive Dams and F1 male pups on exposure to a mixture of Bisphenol-A analogues	Bisphenol-S (BPS) analogues were inevitable components of numerous domestic products, but these have been identified as agents of teratogenic disorders. This study, therefore, investigated the effect of thymoquinone (TMQ) on the virulence of hypertensive female rats and their F1 male offsprings on exposure to a mixture of Bisphenol-S (BisphenolS® and BisphenolA® 0.5BPS). Female rats were studied into normotensive and hypertensive groups, and both were treated with MilliTonic MBPS (- TMQ, and TMQ only. Exposure to MBPS and on treatment with TMQ lasted at least 63 days. Neurobehavioral assessments were conducted using Open Field (OFT), elevated plus maze and locomotor activity. Immunohistochemistry, dopaminergic and adrenergic receptor assays for Nav1.7 and Nav1.8 ion gene expression, and immunohistochemistry for protein quantification within NAC, renal fast stained, and congo red stains were used for histological assessments. From the results, maternal exposure to MBPS mediated striatal dysfunction via p53 and NF-kB upregulation, decreased BDNF/Ki-67 and NeuN/GFAP ratio, and increased Nav1.7/Nav1.8 ratio in hypertensive dams and F1 male offsprings. Also, MBPS induced vasoconstriction injury via ACE/ET-1/ETAR/ETBR/NO pathway. Hypertensive rats have exacerbated MBPS toxicity. Post-TMQ, increased anxiety and decreased psychomotor activity were associated with MBPS-induced striatal neurotoxicity in F1 male offsprings. However, co-treatment with thymoquinone prevented striatal dysfunction in hypertensive dams and their F1 male offspring. In conclusion, disruption of the delicate balance between apoptotic and cell proliferation culminating in the reduction of mature neurons is responsible for neurodegeneration and neuropathy associated with MBPS exposure. However, these can be prevented through regular consumption of natural products and supplements rich in thymoquinone. Awuchi	2024	Cucumeropsis mannii seed oil (CMSO) restores testicular mitochondrial dysfunctions by modulating the activities of dysregulated testicular mitochondrial enzymes in male albino rats exposed to bisphenol A	Bisphenol A, a traditional endocrine disruptor, has been implicated in male infertility. This study investigated the effect of Cucumeropsis mannii seed oil (CMSO) on bisphenol A (BPA)-induced biochemical toxicity to the testes of male albino rats. Twenty-five (25) male albino rats were randomly assigned into five groups (A-E) of five rats each. Group A served as the control and received 1 mL/kg BW of PBS and 1 mL/kg BW CMSO, respectively. Rats in groups B, C, and D received oral administration of 100 mL/kg BW of BPA. Rats in groups C and D received 50 and 100 mL/kg BW of CMSO, respectively, following 14 weeks of exposure to these doses. Some mitochondrial enzymes, mitochondrial membrane potential (MMP), mitochondria testicular protein, and body weight of rats were determined using standard methods. BPA significantly reduced sucrose dehydrogenase, malate dehydrogenase, succinate dehydrogenase, SADH dehydrogenase, and monoamine oxidase activity. Also, BPA prominently decreased the MMP, mitochondrial testicular protein, and body weight of rats. Interestingly, coadministration of BPA and CMSO restored the dysregulated activities of the enzymes and levels of other biomarkers. We postulated that CMSO may be a promising drug for treating systemic toxicity caused by environmental toxicants such as BPA. 統合_1049	P. Nurlaz, J. Aguelles and C. Perillan	2023	Effects of short-term exposure to low doses of bisphenol A on cellular senescence in the adult rat kidney	Bisphenol A (BPA) is one of the primary chemicals produced by volume worldwide. Extensive literature has raised many concerns about its possible involvement in the pathogenesis of kidney diseases, but its contribution has not been extensively studied. During cellular senescence, the interference of dysfunctional cellular functions promotes further senescence, causing cellular malfunction. Insulin-like growth factor-1 (IGF-1) plays an important protective role in the setting of kidney injury. The goal of the present study was to evaluate the effects of short-term treatment with low doses of BPA on cellular senescence in adult rat kidneys. Male Wistar rats were treated with BPA (0.5 and 50 μg/kg/day) for 15 days. Histological, immunohistochemical, and ultrastructural analyses were performed. Immunohistochemical analysis were performed, and an immunoreactive score (IRS) was calculated. Lipofuscin autofluorescence was used for the study of cellular senescence. The renal cortex showed diffuse autofluorescent lipofuscin signal in the proximal convoluted tubules (PCTs) of males in the BPA50-treated (renal intensity) and BPA50-treated (strong intensity) groups, but not in CONTROL males. Labeling of cortical PCTs with anti-IGF-1 antibodies showed an IRS of 0 in the CONTROL group, two IRSs of 3 and 4 in the BPA50- and BPA500-treated groups, respectively. The present results suggest that low, "safe" doses of BPA induce renal injury, as measured by histological signs of renal changes, increased cellular senescence, and activation of cellular repair systems in PCTs. Morales Montor	2019	Environmental Pollution as a Risk Factor in Testicular Tumour Development: Focus on the Interaction between Bisphenol A and the Associated Immune Response	Bisphenol A (BPA) is an endocrine disruptor to which animals and humans are highly exposed. Many reports have established a relationship between BPA exposure and breast cancer incidence, especially during critical periods of development. However, its effects on the immune response in testicular tumour growth have not yet been described. Thus, we wanted to analyze the effect of perinatal BPA exposure in pregnant female mice on the development of testicular tumours induced by the transplantation of TC1 cancer cells in their male offspring. Female mice were exposed to BPA (50 μg/kg/day) in their drinking water from the 8th day of gestation until the end of lactation. In adulthood, male offspring underwent intratesticular inoculation with 5×10^5 cancer cells. On day 21 after inoculation, mice were euthanized, and cancer was obtained to measure BPA levels using HPLC-coupled to mass spectrometry. The percentages of immune cell populations in peripheral lymph nodes (PLN), the spleen and tumours were evaluated by flow cytometry. In addition, the tumour expressions of IL-10, TNF-α and TGF-β were measured by RT-qPCR. Our results showed that the tumours in male offspring from BPA-exposed mothers exposed to it orally pregnant. Remarkably, BPA treatment promoted tumour growth by about 75% compared to mice arising from female mice that did not receive the compound. Perinatal exposure to BPA induced changes in the percentages of different immune cells in the spleen and PLN. In addition, the expressions of inflammatory-related molecular immune components that resulted in outstanding testicular tumour size in male offspring. 統合_1064	M. Nagarajan, B. Raja and J. Manivannan	2021	Exposure to a "safe" dose of environmental pollutant bisphenol A elevates oxidative stress and modulates vasoactive system in hypertensive rats	Due to the prevalence of hypertension (one of the major risk factors of CVD) in the population, it is necessary to explore the adverse effects of daily tolerable and "safe" dose of bisphenol A (BPA) under hypertensive conditions. The current study exposed the four-month-old male spontaneously hypertensive rats (SHR) and Wistar-Kyoto (WKY) rats for 30 days period. The results illustrate that a 'safe' dose of BPA does not influence the systolic blood pressure (SBP) and levels of circulatory biomarkers of tissue damage. On the other hand, BPA exposure potentiates the SBP, cardiac hypertrophy, and hypertensive vascular remodeling in SHR. Further, in vitro exposure of vascular smooth muscle cells (VSMCs) to BPA also induces hypertrophic responses in the cells. Interestingly, BPA treatment to SHR and WKY rats for 30 days period did not alter the vascular superoxide production and expression of NADPH oxidase subunits (Nox1 and Nox2). Similarly, BPA exposure significantly reduced the endothelium-dependent relaxation in response to acetylcholine (ACh) in mesenteric arteries of SHR. However, BPA treatment did not affect the endothelium-independent relaxation in response to sodium nitroprusside (SNP). Moreover, BPA exposure significantly reduced the bioavailability of nitric oxide (NO) in the aorta and mesenteric arteries of SHR. Further, BPA exposure significantly reduced the activity and expression of endothelial nitric oxide synthase (eNOS) and soluble guanylyl cyclase (sGC) in the mesenteric arteries of SHR. Additionally, BPA exposure significantly reduced the activity and expression of dimethylarginine dimethylaminohydrolase-1 (DDAH-1) and increased the expression of asymmetric dimethylarginine (ADMA) in the mesenteric arteries of SHR. Overall, the observed adverse effects during 'safe' dose of BPA exposure are specific to the hypertensive condition. Therefore, a precise investigation to explore the effects of BPA exposure in vulnerable hypertensive populations is highly suggested. 統合_1065	M. Nagarajan, G. B. Maadurshni and J. Manivannan	2024	Exposure to low dose of Bisphenol A (BPA) intensifies kidney oxidative stress, inflammatory factors expression and modulates Angiotensin II signaling under hypertensive milieu	Humans are constantly exposed to low concentrations of ubiquitous environmental pollutant, Bisphenol A (BPA). Due to the prevalence of hypertension (one of the major risk factors of cardiovascular disease (CVD)) in the population, it is necessary to explore the adverse effects of daily tolerable and "safe" dose of BPA under hypertensive conditions. The current study exposed the four-month-old male spontaneously hypertensive rats (SHR) and Wistar-Kyoto (WKY) rats to low dose BPA (50 μg/kg) for 30 days period. In tissue samples (mesenteric/renal/aorta), real-time quantitative polymerase chain reaction and enzymatic assays were conducted. Moreover, studies on primary kidney cell culture were employed to explore the impact of low dose of BPA exposure at mesenteric level (20-30-40 mpg) on renal cells through various fluorescence assays. The observed results illustrate that BPA exposure to normotensive/hypertensive rats induced tissue alterations (renal fibrosis), oxidative stress (ROS generation), intracellular organelles (mitochondria and endoplasmic reticulum) damage, endothelial dysfunction (impaired nitric oxide (NO) bioavailability), cell cycle arrest, tissue lipid abnormalities and inflammatory factor expression (both mesangial RNA and protein) level of TNF-α and IL-6). Further, in vitro exposure of 40 levels of BPA to primary kidney cells modulates oxidative stress (both superoxide and total ROS), mitochondrial physiology (reduced mitochondrial membrane potential (Δ ψ m) and lipid peroxidation in a dose dependent manner. In addition, angiotensin II induced ROS generation was aggravated further by BPA during vasopressure in kidney cells. Therefore, during risk assessment, a precise investigation on BPA exposure in hypertensive (CVD vulnerable) populations is highly suggested. 統合_1067	V. Naftaa, J. Van Steenwinckel, R. Magny, A. Reguzzetti, C. Keime, P. Geessens, O. Lapeyrade, N. Auzeil and A. L. Schang	2025	Bisphenol A exposure during gestation and lactation in mice: Sex-specific consequences on oligodendrocytes and myelination	Bisphenol A (BPA), a ubiquitous environmental endocrine disruptor, is suspected of disturbing brain development through largely unknown cellular and molecular mechanisms. In the central nervous system, oligodendrocytes are responsible for forming myelin sheaths, which enhance the propagation of action potentials along axons. Disruption of axon-myelination can have lifelong consequences, leading cAgeddendrocyte differentiation and myelination critical stages of brain development. In the present study, mice were exposed to BPA during gestation and lactation through drinking water at concentrations of 25 and 250 μg.L(-1). These doses, corresponding to estimated exposures of 5 μg.kg(-1).d(-1) and 50 μ.g.kg(-1).d(-1), respectively, had no detectable effects on maternal behavior. However, significantly changes in brain lipid composition were selectively observed in female mice and were transient, being visible only at post-natal day P15 but not at later stages (P30 and P60). In female, exposed to BPA, myelin exhibited a lower propensity to incorporate cholesterol and sphingomyelin, two major components of myelin membranes, at P15. Moreover, the number of mature oligodendrocytes was significantly increased at P15 in the corpus callosum of BPA-exposed females. Additionally, transcriptomic analysis of female oligodendrocytes at P15 did not reveal any transcriptional changes in genes related to lipid metabolism, further suggesting non-transcriptional effects of BPA. Ex vivo exposure mediated protein folding and RNA splicing. In males, the observed genes were mainly associated with synaptic transmission. Finally, alterations in chromatin accessibility were also largely sex-dependent and did not correlate with transcription, with the exception of the Cnp1. At this locus, BPA exposure increased chromatin accessibility in half of mice of both sexes, leading to an "unchanged/open" bimodal profile correlated with "unchanged/upregulated" gene expression. Together, these results open new insights into the sex-dependent mechanisms of BPA's effects on brain development. 統合_1068	A. Muster, M. Alam, M. A. Miah, M. Nowuzzaman, K. M. Sujan and E. H. Chowdhury	2022	Retrieval action of zinc and folic acid for the restoration of normal reproductive function in bisphenol-A exposed male albino mice	Bisphenol-A (BPA) has become a great concern due to its toxic effects. The present study investigated the retrieval action of zinc (Zn) and folic acid (FA) supplementation against BPA induced reproductive toxicities in male albino mice. A total of twenty-five (5×5) 30 day old mice were divided into five equal groups (group G-I, G-II etc.) to start a 28 days period. The mice in group G-I were treated with 1 ml corn oil/mice/day as control. In addition, mice in group G-II were administered with daily dose of BPA at 50 mg/kg body weight (b.w.) (group G-II). The mice from groups C, D and E were supplemented with Zn (30 mg/kg b.w.), FA (5 mg/kg b.w.) and both in the feed, respectively, daily for 12 weeks. Blood samples were collected, and the sera were separated for biochemical analyses. The standard method was followed to test the sperm motility and sperm count. The testis samples were processed for routine histopathological study using hematoxylin and eosin staining. The sperm counts, motility, and serum testosterone significantly declined in the BPA-exposed animals, but dramatically increased after the Zn and FA supplementation. The study also revealed that BPA exposure significantly increased the serum malondialdehyde (MDA) and nitric oxide (NO) levels, which was reasserted moderately by the Zn and FA supplementation. The study shows the retrieval action of zinc and folic acid in the restoration of normal reproductive function in bisphenol-A exposed male mice. 統合_1069	G. Motta, S. V. Thanganji and V. Padmanabhan	2023	Developmental Programming: Impact of Prenatal Exposure to Bisphenol A on Senescence and Circadian Mediators in the Liver of Sheep	Prenatal exposure to endocrine disruptors, such as bisphenol A (BPA) plays a critical role in the developmental programming of liver dysfunction that is characteristic of nonalcoholic fatty liver disease (NAFLD). Circadian and aging processes have been implicated in the pathogenesis of NAFLD. We hypothesized that the prenatal BPA 'hit' induced fatty liver phenotype of female sheep is associated with premature hepatic senescence and disruption in circadian clock genes. The expression of circadian rhythm and aging-associated genes, along with other markers of senescence such as telomere length, mitochondrial DNA copy number, and lipofuscin accumulation, were evaluated in the liver tissue of control and prenatal BPA groups. Prenatal BPA exposure significantly elevated the expression of aging-associated genes GLB1 and CDS2 and induced large magnitude differences in the expression of other aging genes (APOE, HSF1, KLOTHO), and the clock genes, NR1D1 and CLOCK. In the liver, like other senescence markers, mitochondrial dysfunction was evident. Prenatal BPA programmed aging-related transcriptional changes in the liver may contribute to pathological changes in liver function, elucidating the involvement of aging genes in the pathogenesis of liver senescence. 統合_1070	M. M. Morsy, M. M. Ahmad and N. H. Hassan	2024	Maternal exposure to low-dose bisphenol A and its potential neurotoxic impact on male pups: A histological, immunohistochemical, and ultrastructural study	ABSTRACTBACKGROUND: Bisphenol A (BPA) is a widely used chemical with a harmful effect on animal and human. The neonatal and juvenile period is a highly risky neurodevelopmental period. AIM: This study aimed to determine how male albino rat pups' cerebral cortex was altered by low doses of BPA given to mothers and the role of the oxidative stress. METHODS: Thirty pregnant rats were randomly split into three equal groups, negative control, and positive control received 1 cc of corn oil once a day through gastric tube and BPA treated rats at a dose of 200 μg/kg/day (dissolved in 1 cc corn oil). The male rat pups in each group were sacrificed at 1 week, 3 weeks, and 5 weeks. The cerebral cortex then separated from the brain for histological and biochemical studies. RESULTS: Rats administered BPA had raised levels of lipid peroxidation marker (MDA), lower levels of antioxidant enzymes (SOD, CAT, and GSH), and higher levels of inflammatory cytokines (TNF-α and IL-6) in their cerebral cortex than control rats. Histological examination revealed that cerebral cortex of BPA-treated rats showed severely appeared. DFAP displayed increased number of positive immune-reactive astrocytes with high statistically significant increase in the area % in BPA-treated group when compared to the control groups, according to LSMP. Semi-thin and ultra-thin BPA-sections revealed degenerative changes in myelinated axons with tiny nucleus and broken nuclear membranes. Lysosomes, dilated endoplasmic reticulum cisternae with noticeable increase in unmyelinated nerve fibers were also observed. CONCLUSION: The structure of the developing cerebral cortex is negatively impacted by BPA due to oxidative stress. 統合_1071	A. A. Morsi, E. A. Mersal, A. O. Alsabih, S. Alwabsawy, R. G. Elfawal, E. M. Sabi, E. M. Farak, M. Abu-Rashed, F. Alhaddad, Z. Alkhawajah, A. Hasan, K. E. I. Ibrahim and A. M. Abdelmonsh	2023	Bisphenol-A exposure alters liver, kidney, and pancreatic Klotho expression by HSP60-activated mTOR/autophagy pathway in male albino rats	The effect of bisphenol-A (BPA) on Klotho protein (aging-suppressing protein) expression in different body organs has not been sufficiently addressed by literature studies. The study investigated the impact of BPA on Klotho expression in liver, kidney, and pancreatic tissues, possibly by modulation of the HSP60-activated mTOR/autophagy signaling. Forty-two male albino rats were divided into 7 groups (n = 6/group). Groups 1 and 2 received BPA (0.5 μg/L and high-dose BPA (5 μg/L) groups in drinking water for 45 consecutive days. Liver, kidney, and pancreatic specimens were prepared for a gene study of Klotho, HSP60, mTOR, and LC3-I/LC3-II/Beclin1 expressions. Also, the tissue specimens were measured for malondialdehyde (MDA), superoxide dismutase (SOD), and nitric oxide (NO) levels. Parallel non-validated rodents were also prepared and subjected to histological and Fuzo H&E staining and immunohistochemical detection of Klotho and HSP60. The results revealed an alteration in the MDA, SOD, NO tissue levels, disturbed gene expression profile, and apoptotic changes in the histological findings of the examined organs which were obvious (p < 0.05) in the high-dose group. The anti-aging Klotho gene/protein expression was reduced (p < 0.05) more in the high-dose BPA group than in the low dose. In contrast, HSP60 gene/protein expressions were significantly increased (p < 0.05) more in the high dose. It was concluded that BPA exposure contributed to cell stress and markedly reduced Klotho protein expression in liver, kidney, and pancreatic tissues, possibly by modulation of the HSP60-activated mTOR/autophagy signaling.	Cell Mol Biol (Noisy-le-grand) Vol.69 Issue 7 Pages 109-117	10.14715/cmb/2023.69.7.18	37715411	動物	-	1	1	1	1	0	5、5 μg/L（飲水中濃度）	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-

Shawky	2022	Apoptotic susceptibility of pancreatic alpha cells to environmentally relevant dose levels of bisphenol-A versus dibutyl phthalate is mediated by HSP60/caspase-3 expression in male albino rats	Unfortunately, humanity is exposed to mixed plastic ions such as bisphenol A (BPA) and dibutyl phthalate (DBP) that are leached from the daily used plastic products. Previous studies have demonstrated their potential to approach beta-cell injury and diabetes. The study hypothesized that both compounds would affect the pancreatic alpha cells in albino rats when administered at environmentally relevant doses, that check points (p53/HSP60 and caspase-3) protein expression was also investigated as potential mechanisms. Thirty rats male Wistar albino rats were separated into four equal groups; control, BPA alone, DBP alone, and BPA + DBP co-administered groups. Rats were treated orally by gavage for 45 days. Pancreatic specimens were prepared for histological examination and immunohistochemical detection of glucagon and chromogranin A expressions. Pancreatic sections were subjected to hematoxylin & eosin (H & E) staining, glucagon, HSP60, and caspase-3 immunohistochemistry. Although dibutyl phthalate-exposed group's showed diffuse islet cell HSP60 immunoreactivity, rats exposed to BPA alone showed a mild cell apoptosis, indicated by H & E changes and caspase-3 immunoreactivity, associated with reduced glucagon immunoreaction. However, rats exposed to DBP alone showed no changes in either α or β cells. Both combined exposed animals illustrated α and β apoptotic changes associated with islet atrophy and reduced glucagon expression. In conclusion, the study suggested HSP60/caspase-3 interaction, caspase-3 activation, and initiation of apoptosis in α cell only for BPA alone exposure group, means that DBP alone did not progress to apoptosis. Interestingly, both in β cell effect was observed in the mixed group, implying synergistic/additive action of both chemicals when combined. Salim	2023	ACE2/ACE imbalance mediates bisphenol A-induced lung injury in Wistar rats: Results from captopril versus losartan histo-biochemical study	Bisphenol A (BPA) is a synthetic chemical compound broadly used in the plastic and epoxy resin industries with a considerable potential for food contamination. Literary reports have suggested that the altered renin-angiotensin system (RAS) is a mechanism for lung injury and inflammation caused by variable agents. The current study sought to investigate the contribution of RAS in BPA-induced lung damage. Moreover, the study examined whether angiotensin II and/or bradykinin pathways were involved. For this aim, the angiotensin-converting enzyme (ACE) inhibitor captopril (Cap), either alone or combined with bradykinin receptor antagonist icatibant (Ica), and angiotensin II receptor blocker losartan (Los) were used. Forty-two male Wistar rats were divided into seven groups (n = 6/group). Groups 1 and 2 received BPA (0.5 μg/L) and high-dose BPA (5 μg/L) as well. BPA-Cap group received BPA + Cap (10 mg/kg/day), and BPA-Los group received BPA + Los (10 mg/kg/day). BPA-Cap-Ica group received BPA + Cap + Ica (1 mg/kg/day). Rats were euthanized after 45 days. Lung specimens were prepared for histological examination, ACE, ACE2, and caspase-3 gene expression, and histological and immunohistochemical studies were carried out to evaluate BPA-mediated pulmonary inflammatory responses. BPA impaired the histological structure of the lungs, increased ACE, ACE2, and caspase-3 expressions at both gene/protein levels, and increased MDA/IL-6 inflammatory cytokines and lung oxidative markers. Inhibiting the ACE activity by captopril maintained the histological lung injury score, restored inflammation and the oxidative/antioxidant balance, and reduced caspase-3 expression. Losartan showed similar results to captopril, but to a lesser extent. Co-administration of Ica with Cap or Los reversed the observed captopril effects. It was strongly suggested that RAS contributed to BPA-induced lung damage via alteration of ACE/ACE2 and ACE expression mediating angiotensin II generation rather than bradykinin. 統合_1074	J. Morris, E. J. Beaker, I. D. S. Souza, L. Regmans, H. Borelli, J. F. Stanziano III and M. M. Skeels	2022	Chemical Exposure-Induced Developmental Neurotoxicity in Head-Regenerating Schmidtea mediterranea	The growing number of commercially used chemicals that are under-evaluated for developmental neurotoxicity (DNT) combined with the difficulty in describing the etiology of exposure-related neurodevelopmental toxicity has created a relevant threat to human health. Current means of screening chemicals for DNT are linked to expensive, time-consuming, and labor-intensive traditional laboratory animal models. In this study, our objective was to establish a high-throughput screening platform for DNT using the planarian Schmidtea mediterranea. We hypothesized that S. mediterranea would be a sensitive, cost-effective, established alternative animal model for neurodevelopmental studies and have remarkable regenerative abilities allowing neurodevelopment to be induced via head resection. Here, we observed changes in planarian behavior and central nervous system (CNS) morphology to evaluate the impact of exposure to two concentrations of ethanol, BPA, and BPA industry alternatives bisphenol F, and bisguaiacol on neurodevelopment. Our results indicate that BPA, bisphenol F, and bisguaiacol A exposure during head regeneration induced DNT-like phenotypes in planarians. Furthermore, we demonstrated that BPA and its alternatives induced deficits in head regeneration in a range of sensitivities, distinguished by supernumerary eyespots, delays, or a combination of the 2. These results suggest that acute and temperate behavioral assessments are a viable surrogate for tedious and costly immunostaining studies, supplying more utility and resolution to the planarian model for neurodevelopmental toxicity in the future of mass-chemical screening. These studies demonstrate that behavioral phenotypes observed following chemical exposure are classifiable and also temporally correlated to the anatomical development of the CNS in planaria. This will facilitate and accelerate toxicological screening assays with this alternative animal model. 統合_1075	A. Morin, L. Van de Beeck, E. Person and H. Plamondon	2021	Adult Male Rats Show Resilience to Adolescent Bisphenol A Effects on Hormonal and Behavioral Responses While Co-Exposure With Hop Extracts Supports Synergistic Actions	The adolescence period, marked by sexual and brain maturation, has since sensitivity to various environmental disruptors. Exposure to the xenoestrogen bisphenol A (BPA) is known to alter physiological and behavioral responses although its role at this critical period remains largely unknown. Recent research further suggests biochemical antagonistic effects of BPA to be mitigated by various natural compounds, while effects on behavior have not been reported. This study aimed to characterize 21-day effects of dietary BPA during adolescence on endogenous corticosterone (CORT) correlates, emotional behavior, and neuroendocrine (?) in male rats. Wistar rats were exposed to BPA (0, 50, 500 mg/kg) and/or hop extracts (HE; 0, 100 mg/kg) from postnatal day (PND) 28 to 49. Fecal CORT metabolites were measured on PND 28, 35, 42, and 49. Behavioral tests were carried out on PND 43 (open field), 44 (light-dark box), 45 (novel object recognition), 46 (social interaction), and 47 (elevated plus maze). Brain samples were collected on PND 28, 35, and 72 and dry-measured. Fecal CORT levels were not affected by BPA, HE, or their combination. However, BPA intake had no impact on basal CORT levels, a validated ? secretion and variability. Of note, BPA's antagonistic effect manifested through decreased CPM open arm entries was abolished by hops co-supplementation. Together, our observations suggest the adolescence period to be less sensitive to deleterious effects of BPA than what has been reported post-gestational and perinatal exposure. 統合_1076	R. Moreno-Gómez-Toledano, S. Sánchez-Esteban, A. Cook, M. Mirguez-Morcillos, R. Ramírez-Carracedo, P. Reventun, M. Delgado-Marín, R. J. Bosch and M. Saura	2021	Bisphenol A Induces Accelerated Cell Aging in Murine Endothelium	Bisphenol A (BPA) is a widespread endocrine disruptor affecting many organs and systems. Previous work in our laboratory demonstrated that BPA could induce death due to necroptosis in marine aortic endothelial cells (MAECs) through the formation of mitochondrial reactive oxygen species (mROS). Here, we investigated the effects of BPA on endothelial cell senescence in vitro and in vivo. MAECs were exposed to BPA (10 nM and 1 µM). Western blots confirmed that proteins involved in senescence mechanisms (p53 and p21, even overexpressed in the presence of BPA. In addition, the SIRT1/AMPKα pathway (master sequential systems which are part of the senescent phenotype, was also explored by Western blot and qPCR, confirming the involvement of the PERK-ATF4-CHOP pathway (related to pathological processes). The endothelium of mice treated with BPA showed an evident increase in the expression of the proteins p16, p21, and CHOP, confirming the results observed in vitro. Our results demonstrate that oxidative stress induced by BPA leads to UPR activation and senescence-associated alterations in the endothelium. BPA-induced cells, reduced the percentage of senescent cells promoted the overexpression of proteins related to BPA-induced senescence and reduced the activation of the UPR system. The results suggest that BPA participates actively in accelerated cell aging mechanisms, affecting the vascular endothelium and promoting cardiovascular diseases. Bosch	2021	Comparison of the renal effects of bisphenol A in mice with and without experimental diabetes. Role of sexual dimorphism	Bisphenol A (BPA), a chemical `xenoestrogen` used in the production of the plastic lining of food and beverage containers, is present in the urine of almost the entire population. Recent studies have shown that BPA exposure is associated with an increased risk of developing diabetes mellitus and cardiovascular disease. Experimental studies have also demonstrated that BPA can induce alterations in glucose and diabetes including the renal role of sexual dimorphism. Male and female mice were divided into the following groups: control (C), mice treated with 50 µg/kg/d BPA in the drinking water (BPA), diabetic mice induced by streptozotocin (D), and D mice treated with BPA (D + BPA). Male mice form the D + BPA group died by the tenth week of the study due probably to hydro-electrolytic disturbances. Although BPA treated mice did not show an increase in tumor cachetine, as observed in D and D + BPA groups, they displayed similar alterations in those of the D group, including increased kidney size, glomerular hypertrophy, kidney hypertrophy, and glomerular sclerosis, collapsed glomeruli, as well as TGF-β, CHOP and PCNA upregulation. GAD, collapsed glomeruli, PCNA staining, TGF-β, NOX4, and animal survival, significantly impaired in D mice. Our results demonstrate that BPA can exacerbate renal damage induced by experimental diabetes, and that the consumption of BPA is capable of promoting in the kidney alterations that resemble early DN. Further translational studies are needed to clarify the potential role of BPA in renal diseases, particularly in diabetic patients. 統合_1078	M. A. Moralis, B. Bothorel, V. Andry, Y. Goumon and V. Simonneaux	2025	Bisphenol A induces sex-dependent alterations in the neuroendocrine response of Djungarian hamsters to photoperiod	In nature, species synchronize reproduction and energy metabolism with seasons to optimize survival and growth. This study investigates the effect of oral exposure to bisphenol A (BPA) on photoperiodic and neuroendocrine responses in Djungarian hamsters (Phodopus sungorus), a seasonal model sensitive to environmental cues. Adult males and females were exposed to BPA (0, 0.5, 5, 50, 500, or 5000 µg/kg/d) or vehicle during a 10-week transition from a long (LP) to short (SP) photoperiod (winter transition) or vice versa (summer transition). Changes in body weight, food intake, and adipose color were monitored weekly, and, at the end of the exposure, expression of hypothalamic hypothalamic markers of photoperiodic (TSHβ, Dio2/Dio3) and metabolic (somatostatin, Pomc) integration, reproductive organ weights, and circulating sex steroid levels were measured. In males, BPA exposure had no significant effect on body weight, food intake, or testicular volume. However, 5 µg/kg/d BPA reduced testosterone levels and delayed testicular regression in SP, while 500 µg/kg/d BPA accelerated testicular regression in LP. In females, exposure to 5 µg/kg/d BPA disrupted a classic LP adaptation in reproductive and metabolic parameters, along with it-dependent decorrelation occurring 3 weeks earlier and Pomc upregulation delayed for up to 10 weeks. In males, BPA exposure led to decreased expression of central photoperiodic integrators, with no effect on the acquisition of the LP phenotype. This pioneering study investigating EDCs' effects on mammalian seasonal physiology shows that BPA alters the dynamics of metabolic adaptation to both SP and LP transitions with marked sex-dimorphism, causing temporal discordance in seasonal adaptation between traits, and females. These findings emphasize the importance of investigating EDCs' effects on non-conventional animal models, providing insights into wildlife physiology. 統合_1079	A. M. Molina-López, F. Bujalance-Reyes, M. T. Urbano, A. Lora-Benítez, N. Ayala-Salcedo and R. Moyano-Salvago	2022	Analysis of Blood Biochemistry and Pituitary-Gonadal Histology after Chronic Exposure to Bisphenol-A of Mice	Bisphenol A is an emerging pollutant that is widespread in the environment, and to which fish livings are continuously and inadvertently exposed. It is a substance with an endocrine disrupting capacity, causing alterations, even at low concentrations, in the reproductive physiology of fish. Therefore, the aim of this study was to analyze the effects of chronic exposure to bisphenol-A (BPA) on the blood biochemistry and its metabolic status and gonadal histology after a chronic exposure of adult mice to different BPA doses (0.5, 2, 5, 10 and 100 µg/kg BW/day) through their drinking water. The biochemical results showed that a marked significant reduction (p < 0.05) was produced in the levels of serum glucose, hypoproteinemia and hypoalbuminemia in the groups exposed to the highest doses, whereas in the group exposed to 50 µg/kg BW/day the glucose and total protein levels dropped and the animals exposed to 100 µg/kg BW/day experienced a reduction in albumin levels. In the case of the group exposed to 50 µg/kg BW/day, hypertriglyceridemia and hypercholesterolemia were determined, and the blood parameters indicating kidney alterations, such as urea and creatinine experienced a significant increase (p < 0.05) with respect to the controls. Regarding the histological study of the testes, the most outstanding results were found in the group exposed to 50 µg/kg BW/day, which showed a significant reduction in the diameter of the seminiferous tubules. The above could trigger an inhibition of hepatic gluconeogenesis, which could result in a hypoglycaemic state, together with an induction of the enzymes responsible for lipidic synthesis, a mechanism by which the increases in the lipid and serum cholesterol levels could be explained. Likewise, the decline in the protein and albumin levels could be indicative of a possible hepatic alteration, and the increase in urea and creatinine could point to a possible renal perturbation, derived from continuous exposure to this xenobiotic. Based on our results, it could be said that chronic exposure to low BPA doses could set positive any clinical signs or histological photographs altered, but it could cause modifications in some blood biochemical parameters, that could initially indicate a possible hepatic and renal effect. 統合_1080	I. Molapo-sefan, B. Karim, S. M. Hosseini, A. A. Moghadamnia and S. Kazemi	2024	Kaempferol alleviates bisphenol A reproductive toxicity in rats in a dose-dependent manner	BACKGROUND: Endocrine-disrupting chemicals (EDCs), including bisphenol A (BPA), are a major cause of male infertility by disrupting spermatogenesis. OBJECTIVE: Here, we examined the potential protective benefits of kaempferol (KMF), a flavonol known for its antioxidant properties, on BPA-induced reproductive toxicity in adult male rats. METHODS: Human skin fibroblast cells (HWFF-PDB) underwent cell viability assays. Thirty-five male Wistar rats were split randomly to four groups (1) control, (2) BPA (10 mg/kg), (3) BPA and different doses of KMF (5 and 10 mg/kg). The study examined the rats' testosterone level, antioxidant enzyme activities (CAT) and superoxide dismutase (SOD), oxidative markers, malondialdehyde (MDA) and total antioxidant capacity (TAC), body weight, weight ratios of testis and epididymis, and histopathological examinations. RESULTS: BPA significantly reduced the rats' testosterone level, antioxidant enzyme activities (CAT and SOD), TAC, body weight, and weight ratios of testis and epididymis, while increasing MDA levels in the treatment regimen. Treatment with BPA led to oxidative stress and tissue damage, but simultaneous treatment with KMF restored the damaged tissue to its normal state. Histopathology studies on testis and epididymis tissues showed that KMF had an ameliorative impact on BPA-induced tissue damage. CONCLUSIONS: The research suggests that KMF, a flavonol, could protect male rats from the harmful effects of BPA on reproductive health, highlighting its potential healing properties. 統合_1081	A. Molaei-gil, S. Varma, N. S. Boga, P. Das, A. K. Dutta-roy and S. Basak	2024	Gestational exposure to BPA alters the expression of glucose and lipid metabolic mediators in the placenta: Role in programming offspring for obesity	Bisphenol A (BPA) exposure during pregnancy is known to predispose offspring to obesity in later life. Our previous studies demonstrated abiogenetic effects in BPA-exposed offspring, including excess body fat, increased adipocyte hypertrophy, and hyperinsulinemia. Placenta is the primary source of nutrients for the developing fetus. Therefore, we investigated the effects of BPA exposure on placental glucose and lipid transporters and their impact on offspring adiposity in Wistar rats. Dams were orally gavaged with BPA (0.4 mg/kg bw/d) from gestational day (GD) 6-10. Gestational exposure to 0.4 BPA increased the expression of 11-β hydroxysteroid dehydrogenase 2 (11β-HSD2) and estrogen receptor alpha (ERα) proteins (p<0.05) in the placenta compared to control and 40 mg/kg bw/d BPA-exposed groups. Similar changes were observed in the expression of mTOR signaling mediators, fatty acid transporters, and intracellular fatty acid binding proteins. There were no changes in the dam's body weight or lipid and glucose profiles. However, there was a dose-dependent increase in glucose transporter (GLUT2) expression in the placenta. While 0.4 BPA increased female/male 2 expression in the placenta, 40 BPA had no effect. Both doses of BPA increased the placental weight in male fetuses. Furthermore, BPA exposure altered the placental epigenetic profile, with increased expression of DNA methyltransferase (DNMT1). Overall, gestational BPA exposure led to dose-specific alterations in placental glucose and lipid metabolic activities, possibly playing an role in increasing the supply of these macronutrients to the fetus and predisposing the offspring to obesity. Hosseinzadeh	2021	Potential role of green tea extract and epigallocatechin gallate in preventing bisphenol A-induced metabolic disorders in rats: Biochemical and molecular evidence	BACKGROUND: Bisphenol A (BPA) is an artificial chemical widely used in the production of polycarbonate plastics and epoxy resins. Accumulating evidence indicates that BPA exposure is associated with metabolic disorders. PURPOSE: The present study was designed to investigate the effects of green tea extract (GTE) and epigallocatechin gallate (EGCG) against BPA-induced metabolic disorders in rats. METHODS: Protective effects of green tea extract and EGCG on BPA-induced metabolic disorders and possible underlying mechanisms were investigated. METHODS: Rats were randomly grouped into 8 groups (n = 6). Control, green tea extract (GTE 200 and 300 mg/kg, IP), EGCG (30 and 60 mg/kg, IP), BPA (50 mg/kg, gavage), BPA plus green tea extract (25, 50, and 100 mg/kg, IP), BPA plus EGCG (15, 30, and 60 mg/kg, IP), and BPA plus vitamin E (200 IU/kg, IP). After two months, body weight, blood pressure, biochemical biomarkers, hepatic malondialdehyde (MDA), and paraoxonase (PON) were assessed. By means of an oral glucose tolerance test, serum levels of insulin, leptin, adiponectin, TNF-α, and IL-6, and by screen-blotting, hepatic insulin-signaling (IRS-1, PI3K, Akt) were measured. RESULTS: BPA increased body weight, blood pressure, and MDA, decreased EDV, elevated serum levels of glucose, insulin, leptin, TNF-α, and IL-6, and impaired hepatic insulin-signaling. Furthermore, BPA exposure altered the glycerol epigenetic profile, with increased expression of DNA methyltransferase (DNMT1). Overall, gestational BPA exposure led to dose-specific alterations in placental glucose and lipid metabolic activities, possibly playing an role in increasing the supply of these macronutrients to the fetus and predisposing the offspring to obesity. 統合_1083	M. S. Mohseenzadeh, B. M. Razavi, M. Imenshahidi, S. A. Mohajeri, M. Rameshrad and H. Hosseinzadeh	2021	Evaluation of green tea extract and epigallocatechin gallate effects on bisphenol A-induced vascular toxicity in isolated rat aorta and cytotoxicity in human umbilical vein endothelial cells	This study was designed to assess bisphenol A (BPA)-induced vascular toxicity, the effectiveness of green tea extract and epigallocatechin gallate (EGCG) against BPA toxicity, and possible underlying mechanisms. In isolated rat aorta, contractile and relaxant responses as well as malondialdehyde levels were evaluated. Cytotoxic effects on the protective levels of acetylcholine, free, SOD, paraoxonase (1), catalase (CAT), and cell adhesion molecules were calculated using the MTT method and vascular dilating to human umbilical vein endothelial cells (HUVECs). BPA increased aorta MDA levels (p < 0.001) and decreased vascular responses to acetylcholine (ACh) (p < 0.001). Pretreatment with green tea extract (GTE) (100 and 200 µg/ml) and EGCG (30 and 60 µg/ml) significantly (p < 0.001) improved the ACh responses and MDA levels. BPA enhanced the levels of LCAM, VascAM-1 cells, cleaved caspase-3, and vascular cell adhesion molecule-1. Green tea extract, EGCG, and vitamin E co-treatment with BPA diminished the toxic effects of BPA. These findings provide evidence that green tea extract and EGCG possess beneficial effects in preventing BPA-induced vascular toxicity through increasing the antioxidant activities and the regulation of signaling pathways. 統合_1084	T. Midoro-Horiuti, Y. Murakami, K. Kuzume, R. M. Tolar and K. Zhang	2025	Maternal exposure to bisphenol A has transgenerational effects on the development of experimental asthma through bromodomain-containing protein 4-zinc finger DHHC-type containing 1-stimulators of interferon genes axis	Perinatal exposures to the environmental estrogen bisphenol A (BPA) are associated with increased asthma prevalence. We tested the hypothesis that perinatal BPA exposure transgenerationally enhances allergic asthma development through the bromodomain-containing protein 4 (BRD4) - zinc finger-DHHC-2 (ZDHHC2) - stimulator of IFN genes (STING) axis. Female BALB/c mice (F0) were exposed to 10 µg/mL BPA in their drinking water during pregnancy and F1 pups were weaned. Pups were sensitized with low doses of ovalbumin (OVA) on postnatal day 5 (PND 5) and 19, OVA intake on PND 26-35. Asthma phenotype was assessed on PND 36. Perinatal BPA exposure induced airway hyperresponsiveness, eosinophilic inflammation, and allergen-specific IgE production in F1 pups. Further, treatment of F0 dams with STING inhibitor C-176 ameliorated BPA-increased airway hyperresponsiveness, eosinophilic inflammation, and allergen-specific IgE production in F1 pups. Further, treatment of F0 dams with STING inhibitor C-176 ameliorated BPA-increased response to sensitization. Thus, prenatal exposure to environmental estrogens, such as BPA, may promote development of experimental asthma through the BRD4-ZDHHC2-STING axis, causing immune alterations with multigenerational effects. 統合_1085	B. Miao, Y. Zhang, W. Shao, S. Fu, M. S. Bartolomei, C. Walker, C. Coarfa, B. A. Zhang and T. Wang	2025	The impact of environmental exposures on the epigenomic and transcriptomic landscape of transposable elements	Transposable elements (TEs) are mobile DNA sequences that constitute a significant portion of mammalian genomes. While typically silenced by epigenetic mechanisms, mounting evidence indicates TEs can regulate gene expression and dramatic architecture. However, their regulatory roles under various environmental stimulus remain largely unexplored. In this study, we investigated the regulatory functions of TEs in mouse liver tissue following early life exposure to environmental toxicants, including arsenic (As), lead (Pb), bisphenol A (BPA), tributyltin (TBT), di-(2-ethylhexyl) phthalate (DEHP), tetrachloroethylene or dioxin (TCDD), and particulate matter 2.5 (PM2.5). Exposures occurred during the critical window of epigenetic reprogramming in mouse embryos, and livers were collected from offspring at 2 months of age. Using RNA-seq data from 80 mouse livers (10 mice/group), we identified 1,380 multi-mimic datasets from liver tissues of 6-month-old mice and observed that early life environmental exposures significantly altered chromatin accessibility and expression of TEs in later life stages, revealing distinct exposure-specific signatures and sex-dependent responses. 6,098 TEs were identified with altered chromatin accessibility, mostly in non-coding regions, suggesting potential impact on gene regulation. Within these TEs, 1,380 elements were enriched in genes involved in metabolic pathways, with a TE-element, particularly the ERE1 subfamily, were predominantly associated with immune-related genes. Additionally, we identified 181 TE-gene chimeric transcripts via FLTR. We also took transcription start sites, highlighting TE-contributed transcriptional plasticity. Our findings depict a comprehensive landscape of TE regulation under early-life toxicant exposures, offering insights into TEs biology and their impact on health and disease.	bioRxiv	10.1101/2025.07.28.667212	40766346	動物	-	1	0	1	non-agouti (a/a)	0	PM2.5	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-

Sobolewski	2021	Protracted Impairment of Maternal Metabolic Health in Mouse Dams Following Pregnancy Exposure to a Mixture of Low Dose Endocrine-Disrupting Chemicals, a Pilot Study	Pregnancy, a period of increased metabolic demands coordinated by fluctuating steroid hormones, is an understudied critical window of disease susceptibility for later life maternal metabolic health. Epidemiological studies have identified associations between exposures to various endocrine-disrupting chemicals (EDCs) with an increased risk for metabolic syndrome, obesity, and diabetes. Whether such adverse outcomes would be heightened by concurrent exposures to multiple EDCs during pregnancy, consistent with the reality that human exposures are to EDC mixtures, is an essential question in the current pilot study. Mouse dams were orally exposed to a mixture of 6 EDCs (BPA, BPS, BPF, BPAF, BPB, and BPAP) at 0 or 50 µg/kg/day from gestation day (GD) 0 to GD 17. Glucose tolerance tests (GTT) were performed on GD 16 and 17 and fasting blood glucose was measured on GD 18 and 19 or at equivalent 12 days in non-pregnant females. Glucose intolerance, particularly on GD 16, was observed in exposed dams relative to vehicle dams. With increased duration of exposure, EDC-exposed dams exhibited hyperglycemia and a persistent elevation in blood glucose two hours after glucose administration in a glucose tolerance test, whereas no such effects were observed in EDC-exposed non-pregnant females. Correspondingly, EDC dams showed significantly greater area under the curve (AUC) for glucose during the GTT on GD 16 and 17 relative to vehicle dams. Exposure to EDCs did not alter maternal body weight, adiposity, or serum leptin levels. Additionally, we identified 181 TE-gene chimeric transcripts via FLTR. We also took transcription start sites, highlighting TE-contributed transcriptional plasticity. Our findings depict a comprehensive landscape of TE regulation under early-life toxicant exposures, offering insights into TEs biology and their impact on health and disease. 統合_1087	M. H. Meril, M. M. Fadduo, K. El Asmar, M. I. Khalil, A. H. Eid and H. R. Dhani	2022	Effect of BPA on CYP450s expression, and nicotine modulation, in fetal rat brain	Human exposure to bisphenol A (BPA) is mainly due to migration from plastic packaging into food and beverages. Studies reported BPA endocrine disruptions through interactions with different nuclear receptors, including estrogen receptors (ERs), androgen receptor (AR), and peroxisome proliferator-activated receptor gamma (PPARγ). Cytochrome P450 (CYP450) enzymes are involved in the metabolism of BPA. Nicotine is a major component of tobacco smoke. Exposure to nicotine during pregnancy is associated with several fetal developmental disorders. Objectives: This study investigated the effects of BPA and nicotine on CYP450s expression in fetal brain. Subjects/Methods: Pregnant rats were exposed to BPA, nicotine solutions (4% 0.5, 1, and 2 mg/L in drinking water), individually, and with nicotine from GD 5 to GD 20. Fetal brains were isolated, and the prenatal dose (GD14 and GD20), and protein expression was assessed by Western blotting. Results showed a BPA-induced significant decrease in CYP1B1 expression levels at GD20 (p < 0.001), and CYP2A6 (increased) expression at both mRNA (p < 0.001) and protein level (p < 0.001). In addition, nicotine individually decreased expression levels of all examined protein targets, significantly for CYP1B1 (p < 0.001), CYP2A6 (p < 0.001), hAHR(p < 0.001, and cMET (p < 0.001), compared to control. When combined with BPA, nicotine suppressive effects were attenuated at both GD14 and GD20. In conclusion, BPA suppresses CYP1B1 and CYP2A6 expression in fetal brain, and attenuates the suppressive effects of nicotine. Observed effects may be mediated by AhR/cMET independent mechanisms that need further examination. 統合_1088	Y. Meng, Z. Yanmei, L. Ren, S. Qi, W. Wei and J. Lihong	2020	Adverse reproductive function induced by maternal BPA exposure is associated with abnormal autophagy and activating inflamation via mTOR and TLR4/NF- κ B signaling pathways in female offspring rats	Bisphenol A (BPA) can affect reproductive function, but its mechanism of reproductive toxicity is unclear, and the effect of BPA on the onset of puberty was inconsistent. The main purpose of this study is to investigate the effects of perinatal exposure to BPA on the onset of puberty and reproductive function, and its mechanism from the aspect of autophagy and inflammation in ovarian and uterus tissues of female offspring. Twenty-one pregnant SD rats were randomly divided into three groups: Control group, 1 µg/mL BPA (LBPA) and 10 µg/mL BPA group (HBPA) via drinking water from gestational day 6 to the end of lactation. After weaning, female offspring were fed with the same solution as their mothers. The vaginal opening (VO) of female offspring was observed daily, and the estrous cycle was monitored by vaginal smear from the female offspring at 8 weeks. The levels of T, LH, FSH, E2, P, PRL, NO, NOS and TNF-α in serum were detected. Ovaries and uterus were collected. Our results indicated that perinatal exposure to BPA advanced puberty, which was associated with increased serum E2, LH and FSH levels. There was a significantly risk-endometrial epithelium in HBPA group compared with control group, which may affect reproductive function. The adverse effect of perinatal BPA exposure on reproductive function might was associated with the activation of inflammation and abnormal autophagy via TLR4/NF- κB and mTOR signaling pathways, respectively in female offspring. 統合_1089	L. Y. Meng, W. F. Tao, J. Li, M. Zhu, B. Zhang, J. Zhou, X. Qin and R. G. Wei	2024	Effects of Bisphenol A and Its Substitute, Bisphenol F, on the Gut Microbiota in Mice	OBJECTIVE: The aim of this study was to assess the impact of bisphenol A (BPA) and its substitute, bisphenol F (BPF), on the caloric food commonly intake and function of mice. METHODS: We exposed 8-week-old female C57BL/6J mice to BPA or BPF at 0.5 mg/kg/day for 4 weeks. RESULTS: Compared with the control group, BPA and BPF exposure significantly increased the body weight, obesity, calorie consumption, and inflammation rate significantly altered in mice exposed to BPA or BPF. This change was characterized by elevated bacterial 16 rRNA sequencing levels of Bacteroidetes/Firmicutes (G/F) and Escherichia/Shigella and decreased levels of Prevotella 9 and Streptococcus. Additionally, pathways related to carbohydrate and amino acid metabolism showed substantial enrichment. CONCLUSIONS: Mice exposed to different BP analogs exhibited distinct gut microbial community richness, composition, and related metabolic pathways. Considering the essential role of gut bacteria in maintaining intestinal homeostasis, our study highlights the intestinal toxicity of BPs in vertebrates. 統合_1090	L. Meng, Z. Ouyang, Y. Chen, C. Huang, Y. Yu and K. Fan	2024	Low-dose BPA-induced neuronal energy metabolism dysfunction and apoptosis mediated by PINK1/parkin mitophagy pathway in juvenile rats	Bisphenol A (BPA) is related to neurological disorders involving mitochondrial dysfunction, while the mechanism remains elusive. Therefore, we explored it through in vitro and in vivo experiments. In vitro, Hippocampal neurons derived from neonatal rats of different genders were exposed to 0-100 nM and 100 μM BPA, autophagy activator Rapa and inhibitor 3-MA for 7 d. The results suggested that even neurotoxic BPA (1-100 nM) diminished Ca2+ homeostasis and damaged the mitochondria in female gene. In contrast, 100 μM BPA increased the number of autophagic lysosomes, LC3-II/LC3-I ratio and Beclin1 expression, and decreased puncta expression (p < 0.05), suggesting that the entry of damaged mitochondria into autophagic pathway was promoted, while the autophagic degradation pathway was blocked. This further disrupts neuronal energy metabolism, as evidenced by reduced ATP production and ATP/ADP ratio. Rapa and 3-MA could not reverse the damage caused by 100 μM BPA. In vivo, SD rats were exposed to 0, 0.5, 5, and 50 mg/kg BPA during PND 7-21 to identify impaired the structure of hippocampal mitochondria, increased the number of autophagic vacuoles, the ratio of neuronal apoptosis, and the expression levels of pro-apoptotic proteins Cyt C, Bax, Bad, and Caspase3, and decreased the expression of anti-apoptotic protein Bcl2 (p < 0.05). Particularly, male rats are more sensitive to low-dose BPA than females. Overall, environmental doses BPA can induce the imbalance of energy metabolism in hippocampal neurons via PINK1/parkin mitophagy, thereby inducing their apoptosis. Importantly, this study provides a theoretical basis for attenuating BPA-related neurological diseases.	Sci Total Environ. 2024 Jun 15:929:172655.	10.1016/j.scitotenv.2024.172655	38653419	動物	神経	1	0（腹腔内）	1	1	1	1	-	-	-	-	-	-	-	1	1	-	1	-	-	-	-	-	-	-	-	-	-	-	-	-
統合_1091	L. Meng, S. Gui, Z. Ouyang, Y. Wu, Y. Zhuang, Q. Pang and R. Fan	2023	Low-dose bisphenols exposure sex-specifically induces neurodevelopmental toxicity in juvenile rats and the antagonism of EGCG	Bisphenols (BPs) can negatively affect neurobehaviors in rats, whereas the mechanism remains unclear. Here, the mechanism of BPs-induced neurodevelopmental toxicity and its effective detoxification measures were investigated in vitro and in vivo. In vitro experiments, primary hippocampal neurons from neonatal rats of different genders were treated with bisphenol A (BPA), bisphenol F (BPF) and bisphenol AF (BPAF) at 1-100 nM (i.e., BE-adaptive) and low-golden (EGCG) and ES, an antagonist of ß-protein-coupled estrogen receptor (GPER) for 7 d. Results indicated that BPs affected neuronal morphogenesis, impaired GABA synthesis and Glu/GABA homeostasis. Neuronal morphogenetic damage induced by low-dose BPA may be mediated by GPER. Sexuality-related BPs toxicity was found, and the female rats were more sensitive to BPA and BPB. In in vivo studies, exposure to BPA (0.5 μg/kg/day) and PND 21-63 caused oxidative stress and inflammation in rat hippocampus, disrupted neuronal morphogenesis and neurotransmitter homeostasis, ultimately impaired spatial memory of rats. Males are more sensitive to BPA exposure than females. Both in vivo and in vitro studies indicated that EGCG, a polyneuroglen, can alleviate BPA-induced neurotoxicity. Taken together, low-dose BPA exposure can sex-specifically disrupted neurodevelopment and further impaired learning and memory ability in rats, which may be mediated by GPER. Promisingly, EGCG effectively mitigated the BPA-induced neurodevelopmental toxicity. 統合_1092	S. J. Mekbaey, M. S. AlGhamdi, M. E. A. Elhalwagy, S. A. Alkolmy and A. I. A. Bin Dohaish	2022	Disturbance in Some Fertility Biomarkers Induced and Changes in Testis Architecture by Chronic Exposure to Various Dosages of Each of Nonylphenol or Bisphenol A and Their Mix	This investigation was conducted to demonstrate the potential impacts of different doses of Bisphenol A (BPA) or Nonylphenol (NP) and their mixtures on some biological activities in male albino rats. Seventy male albino rats were allocated to the control group (G1) and were given 1 mL of ethanol. G 2 and G 3 were given 100 mg/kg of each of BPA and NP. G 4 and G 5 were given 25 mg/kg of each of BPA and NP. G 6 was given a high dose mixture (HDM) of 100 mg/kg of BPA + 100 mg/kg of NP. G 7 was given a low dose mixture (LDM) of 25 mg/kg of BPA + 25 mg/kg of NP. Sperm motility, sperm count, and sperm morphology were determined, as well as a histopathological examination of the testis, at the end of the experimental period. The results indicated a pronounced decrease in sperm motility, sperm count, and sperm morphology. A hyperexpression (3 HSD), concomitant with a significant reduction in serum Superoxide dismutase (SOD), catalase enzyme (CAT), and total antioxidant capacity (TAC) in all treated groups. A significant elevation in TNF-alpha, TAP, Beta, and Caspase 3 serum was recorded individually and in the groups treated with high doses. The disturbance is represented by histological damage in the testis in the germinal epithelium and a decrease in spermatozoa inside the lumen of seminiferous tubules. The effects on testis tissues were dose-dependent, pronounced in mixture doses, and remarkable in higher doses. In conclusion, exposure to BPA and NP strongly impairs antioxidants, inherent inflammatory mediators, and testis tissue architecture. Furthermore, the data from this investigation support the idea that exposure to BPA and NP in reality fits the multiple damages. 統合_1093	K. Machay Al-Anazi, M. Jabr Aljuaid, M. Abul Farah , A. Hossam Mahmoud, A. I. Algaban, M. Ayad Ali and F. M. Abou-Tarboush	2022	Maternal and developmental toxicity of Bisphenol-A in SWR/J mice	Bisphenol-A (BPA), an organic compound with two phenol functional groups, is a widely used industrial plasticizer with known estrogenic properties. It is used in the manufacture of epoxy resins and polycarbonate plastics. This study was designed to evaluate and assess the possible toxicity arising from the oral administration of BPA to pregnant mice. Sixteen SWR/J mice (10 mice per treatment and dosage of BPA: 0.24, 240 and 360 mg/kg/day) were the source of five day intervals during gestation (D1-5, D6-10 and D11-15), while control groups received only corn oil. The results indicated that BPA was associated with a reduction in the number of implantation sites, fetal body weight, and fetal crown-rump length in the 360 mg/kg/day BPA group. Placental weight was significantly reduced in the 240 and 360 mg/kg/day BPA groups. Fetal resorptions were higher in the 360 mg/kg/day BPA group than in the control group. They also showed marked reduction in fetal body weight, fetal crown-rump length, and placental weight. Maternal and fetal mortality rates, abortion and foetal resorption rates were not affected by BPA administration, however. The above findings were concluded by discussing the possible mechanisms involved in producing these effects. Mendoza-Rodríguez	2019	Parental perinatal exposure to bisphenol A reduces the threshold to disrupt blastocyst implantation via decreasing talin, occudin and E-cadherin levels	The aim was to evaluate the effect of perinatal BPA exposure of one or both parents on the implantation rates and expression of talin, occludin and E-cadherin in the uterine epithelial cells (UEC) of the offspring. Pregnant Wistar dams (F0) received BPA or vehicle from gestational day (GD) 0 to lactation day (T). T animals were reared forming four groups: Control dam-Control son (C-C; F1), BPA dam-Control son (BP-C; F1), Control dam-BPA son (C-B; F1), BPA dam-BPA son (BP-B; F1). F1 dams were sacrificed at GD 8. Significantly decreased number of implantation sites was observed in the BP-C group as compared to the C-C group, which correlated with decreased talin apical/basal expression ratio, occludin apical expression, and E-cadherin apical/lateral expression ratio in the UEC. Furthermore, decreased E-cadherin expression in the blastocyst was observed. Our data suggest that reduced protein expression in F1 BPA-offspring could result from decreased progesterone concentrations. 統合_1095	A. Manona, A. De Bartolo, V. Rago, F. Conforti, L. Urbančič, T. Angelone, R. Mazza, M. Mandalà and C. Rocca	2025	Prenatal Bisphenol A Exposure Impairs Fetal Heart Development: Molecular and Structural Alterations with Sex-Specific Differences	Cardiovascular diseases (CVDs) remain the leading cause of morbidity and mortality worldwide, with increasing evidence suggesting that their origins may be in prenatal life. Endocrine-disrupting chemicals (EDCs), such as bisphenol A (BPA), have been implicated in the alterations of fetal programming mechanisms that cause a predisposition to long-term cardiovascular vulnerability. However, the impact of prenatal endocrine disruption on fetal heart development and its sex-specific nature remains incompletely understood. This study investigates the molecular and structural effects of low-dose prenatal BPA exposure on fetal rat hearts. Our results reveal that BPA disrupts estrogen receptor (ER) signaling in a sex-dependent manner, with distinct alterations in ERα, ERβ, and GPER1 expression. BPA exposure also triggers significant inflammation, oxidative stress, and cell death, as evidenced by increased TNF-α, IL-1β, and caspase-3 activity, particularly in female hearts. Structural analysis further demonstrates that BPA impairs cardiac development, leading to reduced ventricular wall thickness and protein accumulation, decreased CM1 and increased HCN1 levels. These alterations are accompanied by increased markers of cardiac dysfunction (BNP, MMP), which are more pronounced in females, and sex-specific regulatory (Cx43, Cx40, TBX1, TBX20, JP, and TGFβ1), while more pronounced response in males. Histological analysis corroborated these molecular findings, revealing structural alterations as well as glycogen depletion in male fetal hearts, consistent with altered cardiac morphogenesis and metabolic stress. These effects were milder in females, reinforcing the notion of sex-specific vulnerability. Moreover, prenatal BPA exposure affected myocardial fiber architecture and vascular remodeling in a sex-dependent manner, as evidenced by reduced expression of desmin alongside increased levels of CD31 and KI67. Overall, our findings provide novel insights into the sex-dependent mechanisms of prenatal endocrine disruption during fetal heart development and its contribution to the early origins of CVD, underscoring the urgent need for targeted preventive strategies and further research into the functional impact of BPA-induced alterations on postnatal cardiac function and long-term disease susceptibility.	Antioxidants (Basel) Vol.14 Issue 7	10.3390/antiox14070863	40722967	動物	-	1	1	1	1	0	2.5 μg/kg/日	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-
統合_1096	M. Marmudino, E. Bo, E. Carlini, A. Farinetti, G. Ponti, I. Zanella, D. Di Lorenzo, G. C. Panzica and S. Gotti	2021	Hypothalamic Expression of Neuropeptide Y (NPY) and Pro-OpioMelanoCortin (POMC) in Adult Male Mice Is Affected by Chronic Exposure to Endocrine Disruptors	In the arcuate nucleus, neuropeptide Y (NPY) neurons increase food intake and decrease energy expenditure, and control the activity of pro-opiomelanocortin (POMC) neurons, that decrease food intake and increase energy expenditure. Considering the role of the hypothalamic arcuate nucleus in the control of energy homeostasis and its sensitivity to circulating hormones, we investigated whether chronic exposure to endocrine disruptors (EDCs), which can interfere with the endocrine system causing adverse health effects, is an important organism-environment risk factor. We investigated the effects of long-term exposure to some EDCs, at environmentally relevant doses, on NPY and POMC systems of adult male mice that had been previously demonstrated to be a target of some of these EDCs, after short-term exposure. Animals were chronically fed for four months with a phytoestrogen-free diet containing two different concentrations of bisphenol A, diethylhexanoic, trioctyltin, or DDE. At the end, brains were processed for NPY and POMC immunohistochemistry and quantitatively analyzed. In the arcuate and dorsomedian nucleus, both NPY and POMC immunoreactivity showed a statistically significant decrease in the paraventricular nucleus, only the NPY system was affected, while the POMC system was not affected. Finally, in the VMH the NPY system also affected whereas no POMC immunoreactive material was observed. These results indicate that adult exposure to different EDCs may alter the hypothalamic circuits that control food intake and energy metabolism. Dolinoy	2022	Gestational exposure to high fat diets and bisphenol A alters metabolic outcomes in dams and offspring, but produces hepatic steatosis only in dams	The prevalence of non-alcoholic fatty liver disease (NAFLD) is increasing worldwide. Perinatal development is a critical window for ailment. Using health trajectory, and evidence supports the role of perinatal programming in chronic metabolic diseases. To examine the impact of diet and bisphenol A (BPA) on the developmental trajectory of NAFLD in offspring, we exposed dams from pre-gestation through lactation to a human-relevant dose of oral BPA coupled with diets of high fat Western or Mediterranean-style diets. We assessed hepatic steatosis by quantifying hepatic triglycerides (TGs) and metabolic health by measuring body weight, relative organ weights, and serum hormone levels in dams and offspring at postnatal day (D) PND20 and D3 months of age. In dams, consumption of the Western or Mediterranean diet increased hepatic TGs 1.7-2.1-fold, and exposure to BPA further increased TGs 1.3-fold in females exposed to the Western diet. Hepatic steatosis was not observed in offspring. Offspring exposed to the Western diet had increased body weight at PND20 and D3 months, and exposure to the Mediterranean diet only in males. Offspring exposed to the Mediterranean diet only in males had organ weights. At 3 months, sex-specific, however, in organ weight and hormone levels were observed in males perinatally exposed to Western + BPA or Mediterranean + BPA. These findings suggest lifestage-specific interactions of perinatal exposures to experimental diets, and BPA on offspring metabolic health without effects on NAFLD later in life. Importantly, alterations in beta-phenotype by diet and BPA exposure appear to impact offspring health trajectory, emphasizing the need to define later diet in assessing effects of environmental exposures on offspring health. 統合_1098	Y. Mao, D. Li, Q. Yang, X. Pei, Z. Duan and M. Ma	2023	Prenatal BPA exposure disrupts male reproductive functions by interfering with DNA methylation and GDNF expression in the testes of male offspring rats	BPA is a ubiquitous environmental endocrine-disrupting chemical, and maternal exposure to BPA is associated with impaired male reproductive functions; however, the mechanisms remain to be elucidated. Glial cell line-derived neurotrophic factor (GDNF) plays an important role in maintaining normal spermatogenesis and fertility. However, the effect of prenatal BPA exposure on GDNF expression and its mechanism in the testis has not been reported. In this study, pregnant Sprague-Dawley rats were exposed orally respectively to 0.05, 0.5, 5, and 50 mg/kg/day BPA via oral gavage from gestational day (GD) 9 to GD 21, and 8 pregnant rats in each group. In GD21 testes, histochemistry, real-time PCR, western blot, and methylation-specific PCR (MSP) were used to detect the rat hormone levels, testicular histopathology, mRNA and protein expression of DNA methyltransferases (DNMTs), and the methylation level of the GDNF promoter, respectively. The results showed that BPA exposure significantly increased the serum testosterone (T) and luteinizing hormone (LH) and testosterone/estradiol (T/E2) ratio and reduced testicular histopathological changes, which indicated the damage of male reproductive function. Prenatal BPA exposure also upregulated Dnmt3a 1 in 5 mg/kg group and Dnmt3b in 0.5 mg/kg group, but down-regulated Dnmt1 in 50 mg/kg group at PND 21. As PND 56, Dnmt1 was significantly increased in 0.05 mg/kg group but decreased in 0.5, 5, and 50 mg/kg groups. Dnmt3a was significantly increased in 0.05 and 0.5 mg/kg groups but decreased in 5 and 50 mg/kg groups. The mRNA and protein expression levels of Gdnf were decreased in 5 and 50 mg/kg groups at PND 21, but the methylation level of Gdnf promoter was significantly increased in 0.5 mg/kg group, but decreased in 5 and 50 mg/kg groups at PND 21. In conclusion, our study indicates that prenatal BPA exposure disrupts male reproductive functions, interferes with the expression of GDNF/Gdnf, and decreases Gdnf expression in the testes of male offspring. Gdnf expression may be regulated by DNA methylation; however, the detailed mechanism needs to be further investigated. 統合_1099	W. Mao, L. Mao, F. Zhou, J. Shen, N. Zhao, H. Shi, J. Ma and Z. Hu	2023	Influence of Gut Microbiota on Metabolism of Bisphenol A, a Major Component of Polycarbonate Plastics	Bisphenol A (BPA) is a major component of polycarbonate plastics and epoxy resins. While many studies have investigated the effect BPA exposure has upon changes in gut microbial communities, the influence of gut microbiota on an organism's ability to metabolize BPA remains comparatively unexplored. To remedy this, in this study, Sprague Dawley rats were intermittently (i.e., at a 7-day interval) or continuously dosed with 500 μg BPA/kg body weight (bw) via oral gavage. Urine, feces, and blood samples were collected at 0, 1, 3, 5, 7, 9, 11, 13, 15, 17, 19, 21, 23, 25, 27, 29, 31, 33, 35, 37, 39, 41, 43, 45, 47, 49, 51, 53, 55, 57, 59, 61, 63, 65, 67, 69, 71, 73, 75, 77, 79,

統合_1102	J. Mao, J. A. Kinkade, N. J. Rivera and C. S. Rosenfeld	2021	miRNA changes in the mouse placenta due to bisphenol A exposure	Aim: To determine small RNA expression changes in mouse placenta induced by bisphenol B (BPB) exposure. Methods: Exposing female mice to BPB two weeks prior to conception through gestational day (GD) 18, whereupon placentas were collected, frozen in liquid nitrogen and stored at -80° C. Small RNA libraries were isolated and used for small RNA sequencing. Results: 10 small RNAs were differentially expressed. Target miRNAs were closely aligned to those expressed by thymus and brain, and pathway enrichment analyses indicated that each target miRNAs regulate neurogenesis and associated neurodevelopment processes. Conclusions: BPB induces current small RNAs in mouse placentas that might provide biomarkers for BPB exposure. Further, the placenta might affect fetal brain development through the secretion of miRNAs. Rosenfeld	2020	Bisphenol A and bisphenol S disruptions of the mouse placenta and potential effects on the placenta–brain axis	Placental trophoblast cells are potentially at risk from circulating endocrine disrupting chemicals, such as bisphenol A (BPA). To understand how BPA and the reputedly more inert bisphenol S (BPS) affect the placenta, CD1® ICR mouse dams were fed 250 μg/kg body weight BPA or BPS daily for 2 wk and then bred. They continued to receive these chemicals until embryonic day 12.5, whereupon placental samples were collected and compared with treatment and control. BPA and BPS altered the expression of an identical set of 12 genes. Both exposures led to a decrease in the area occupied by cytokeratin-immunoreactive giant cells (GCs) within the junctional zone, markedly reduced placental serotonin (5-HT) concentrations, and lowered 5-HT GC immunoreactivity. Concentrations of dopamine and 5-hydroxyindoleacetic acid, the main metabolite of dopamine, were also reduced by BPA and BPS exposures. Placentas from male fetuses were more sensitive to BPA and BPS than placentas from female fetuses. These findings suggest that this neurosteroidogenic tissue could be a metabolically active, direct target of endocrine disruption. Moreover, a negative correlation existed between dopamine's GC area and its fetal sex. These outcomes lead to the following conclusions. First, BPA exposure causes almost identical placental effects as BPA. Second, a major target of BPA/BPS is either syncytiotrophoblast or GCs within the junctional zone. Third, imbalances in neurotransmitter-positive GCs, and an observed decrease in docosahexaenoic acid and estradiol, also occurring in response to BPA/BPS exposure, likely affect the placental basis also of the developing mouse fetus. Mohamed	2020	Boswellic Acid Synergizes With Low-Level Ionizing Radiation to Modulate Bisphenol Induced-Lung Toxicity in Rats by Inhibiting JNK/ERK/c-Fos Pathway	Bisphenol A (BPA) is a low molecular weight chemical compound that has a deleterious effect on the endocrine system. It was used in plastics manufacturing with injurious effects on different body systems. Occupational exposure to low-level ionizing radiation (<2 Gy) is shown to attenuate an established inflammatory process and therefore enhance cell protection. Therefore, the objective of this study was to investigate the protective effect of boswellic acid (BA) accompanied by whole-body low-dose gamma radiation (~75 cGy) against BPA-induced lung toxicity in male albino rats. BPA intoxication induced a rat dose of 500 mg/kg/BW. Rats received 50 mg BA/kg BW by gastric gavage concomitant with BPA (5 d/wk, 4 consecutive weeks). Rats were exposed to whole-body gamma irradiation at a dose rate of 0.5 Gy/min, and the rats received BA and/or γ- R individual BPA-treated rats. Results revealed that BPA induced lung injury indicating oxidative damage biomolecules, (MDA and NADPH oxidase gene expression), inflammatory indices (NFR, TNF-α, IL-6, and gene expression of CCR-10. Moreover, BA and or γ- R ameliorated the lung inflammation via regulation of the JNK/ERK/c-Fos and NLRP3 / IL-1 signaling pathways. Interestingly, our data demonstrated that BA is synergistic interaction with γ- R to influences control against BPA-induced lung injury via anti-oxidant mediated and inflammatory activities. 統合_1105	M. Manikandan, N. Sivagurunathan, A. K. Uma Maheshwari, V. S. Anilkish and L. Calivarathan	2024	Selenium ameliorates oxidized phospholipid-mediated testicular dysfunction and epididymal sperm abnormalities following Bisphenol A exposure in adult Wistar rats	Bisphenol A (BPA) is an endocrine-disrupting compound extensively utilized in the production of polycarbonate polymers and epoxy resins that, upon exposure, pose a significant threat to male reproductive health because of its oxidogenic properties. Accumulating evidence suggests that BPA exposure disrupts the normal process of spermatogenesis, alters testicular morphology and functions, and induces testicular steroidogenesis and hormonal signaling. However, the precise mechanism by which BPA affects testicular function remains unclear. In this study, we explored the mechanism underlying BPA-induced testicular abnormalities and evaluated the potential effects of Selenium (Se). Thirty-two adult male albino Wistar rats were divided into four groups, each containing eight rats. The control group received normal saline, and BPA was administered at 50 mg/kg body weight, with or without Se supplementation, for 30 days. Se supplementation (2.5 mg/kg body weight) was initiated 1 week before BPA administration. BPA administration resulted in alterations in testicular architecture, characterized by basement membrane disintegration and degeneration of seminiferous tubules, leading to a significant reduction in sperm count, motility, and viability. Additionally, BPA exposure led to a substantial decrease in testosterone levels and testicular steroidogenic enzyme activities, including 3β-HSD and 17β-HSD. Furthermore, BPA induced oxidative stress in the testes, as indicated by elevated levels of thiobarbituric acid reactive substances (TBARS) and decreased the activities of the antioxidant enzymes superoxide dismutase, catalase, glutathione peroxidase, and glutathione reductase. In addition, BPA significantly reduced the activities of Ca2+ and Mg2+ ATPases and hydroxyacid dehydrogenases, interfering with testicular steroidogenesis. In rats, supplementation of Se and BPA reduced the levels of oxidized phospholipids and increased the activities of antioxidant enzymes, leading to improved testicular function and epididymal sperm parameters, suggesting that Se plays a critical role in alleviating endocrine disruptor-induced testicular dysfunctions in rats. 統合_1106	A. Mangla, P. Goswami, B. Sharma, S. Suramya, G. Jindal, M. Javed, M. A. Salfi, S. Pawar, T. C. Nag and S. Rakshit	2024	Obesity aggravates neuroinflammatory and neurodegenerative effects of bisphenol A in female rats	Bisphenol A (BPA), a common plastic ion, is categorized as a xenobiotic compound. Its impact on individuals exhibits sex-linked variations. Several biological and environmental factors impact the degree of toxicity. However, nutritional factors have profound influence on toxicity outcome. BPA has been demonstrated to be an obesogen. However, research on the potential role of obesity as a confounding factor in BPA toxicity is limited. This study investigated the impact of obesity on BPA-induced neurotoxicity in female rats. Female Wistar rats were divided into four groups, each containing six rats: control, BPA (50 mg/kg), HFD, and HFD + BPA. Cognitive functions were evaluated through novel object recognition (NOR) tests and Morris water maze (MWM) tests. Biochemical changes in hormonal level, lipid profile, oxidative stress, and antioxidants were also determined. HFD + BPA group rats showed a significant decline in memory function in NOR test. The cerebral cortex (CC) of the brain showed increased neurodegenerative changes, as measured by intracellular vacuolated protein 3 (VAP-1) accompanied by histopathological confirmation. The increased level of neuroinflammation was demonstrated by microglial activation (Iba-1) and protein expression of nuclear factor- kappa B (NF-κ) in the brain. Obesity also caused significant (p < 0.05) increase in lipid peroxidation accompanied by reduced activities of antioxidant enzymes (glutathione-S-transferase, catalase and glutathione peroxidase) and decrease in reduced glutathione (p < 0.05) when compared to non-obese rats with BPA treatment. Overall, study revealed that obesity serves as a risk factor in the toxicity of BPA which may exacerbate the progression of neurological diseases. Thomas, J. Mathieson and Y. Qian	2025	Assessment of pulmonary toxicity of inhaled polycarbonate 3D printer emissions in rats	This study investigated the potential pulmonary toxicity of polycarbonate (PC) emissions from fused filament fabrication (FFF) three-dimensional printing (3DP) during inhalation in Sprague Dawley rats. Previously, our research team characterized PC emissions generated from a commercial FFF 3DP and identified bisphenol A (BPA) as the primary chemical of concern. Male rats were exposed to BPA (0.5 mg/m3) or underwent sham control (filtered air) and exposure groups (n=5–10/group). Each group was further divided into two subgroups: (n = 5/subgroup) with exposure durations of 1, 4, 8, 16, or 30 days (5 hr/day, 5 days/week). Following a 28-hr post-exposure period, body weight was measured, and blood samples were collected for hematological and biochemical analysis. Bronchoalveolar lavage fluid (BALF) was obtained from the right lung's cardiac. The left lung and head/nasal tissues were preserved for histopathological evaluation. Lung deposition was estimated using the Multiple-Path Particle Dosimetry model, electron microscopy, and enhanced darkfield microscopy. In addition, filter samples were collected to measure bisphenol A. Exposure resulted in an estimated deposition of 0.26 μg/day within the alveoli and small airways. Microscopy indicated limited particle deposition in the lung, primarily consisting of micron-sized debris. Exposure to PC emissions caused minimal pulmonary inflammation, as evidenced by a slight increase in neutrophils in BALF. Lung protein were elevated in the 30-day exposure group, although histopathology revealed no exposure-related changes in the lungs. In conclusion, this study found no marked pulmonary inflammation or toxicity in rats exposed to 3 mg/m3 of PC 3D printing emissions for up to 30 days (5 hr/day). 統合_1108	M. A. Malloy, J. J. Kochmanski, T. R. Jones, J. A. Colacino, J. M. Goodrich, D. C. Dolinoy and L. K. Svoboda	2019	Perinatal Bisphenol A Exposure and Reprogramming of Imprinted Gene Expression in the Adult Mouse Brain	Genomic imprinting, a phenomenon by which genes are expressed in a monoallelic, parent-of-origin dependent fashion, is critical for normal brain development. Expression of imprinted genes is regulated via epigenetic mechanisms, including DNA methylation (5-methylcytosine; 5mC), and disruptions in imprinting can lead to disease. Early life exposure to the endocrine disrupting chemical bisphenol A (BPA) is associated with abnormalities in brain development and behavior, as well as with disruptions in epigenetic patterning, including 5mC and DNA hydroxymethylation (5-hydroxymethylcytosine; 5hmC). Using an established mouse model of perinatal environmental exposure, the objective of this study was to examine the effects of perinatal BPA exposure on epigenetic regulation of imprinted gene expression in adult mice. Two weeks prior to mating, dams were randomized to receive one of three treatments: 0 (Control), 4 (Low BPA), or 40,000 (High BPA) μg BPA/kg diet. Exposure was maintained throughout mating, gestation, and lactation. Offspring were sacrificed at 6 months of age. Expression of three imprinted genes (Peg3/Igf2r/Kcnq1ot1), as well as three genes encoding proteins critical for regulation of 5mC and 5hmC (Tet1, Tet2, and Tet3), were evaluated in the right cerebral midbrain using qRT-PCR. Perinatal BPA exposure was associated with a significant increase in male Kcnq1ot1 (p = 0.028) and Dnmt1 (p = 0.021) expression in the right cortex, as well as increased expression of Tet3 in the midbrain (p = 0.021). Expression of Tet2 and Kcnq1 were positively correlated in the midbrain. Analysis of Tet1, Tet2 and Dnmt1 at the 5mC locus was conducted in parallel samples using standard and oxidative bisulfite conversion followed by pyrosequencing. This analysis revealed enrichment of both 5mC and 5hmC at this locus in both brain regions. No significant changes in 5mC and 5hmC at Kcnq1 were observed with perinatal BPA treatment. Together, these data suggest that perinatal BPA exposure results in altered expression of Kcnq1, Dnmt1, and Tet3 in the adult mouse brain. Further studies with larger sample sizes are necessary to understand the mechanistic basis for these changes, as well as to determine the implications they have for brain development and function. 統合_1109	Y. Malaisé, C. Lencina, C. Cartier, M. Olier, S. Menanteau and L. Guzylack-Piriou	2021	Bisphenol A, S or F mother's dermal impregnation impairs offspring immune responses in a dose and sex-specific manner in mice	Bisphenol (BPA) is an endocrine disruptor (ED) widely used in thermal papers. Regulatory restrictions have been established to prevent risks for human health, leading to BPS substitution by structural analogues, like BPS and BPF. We previously demonstrated that oral perinatal exposure of BPA had long-term immune responses later in life. It appears now essential to reinforce our understanding on immune impact of different routes of BP exposure. In this study, we aimed at comparing the impact of mother dermal exposure to BPs on offspring immune system at adulthood. Dorsal mice were dermally exposed to BPA, BPS or BPF at 0.5 mg/kg/d from 2 weeks before mating to weaning. Offspring were sacrificed at 8 weeks old. Immune cell populations were characterized in the ileum, spleen and blood by flow cytometry. Systemic levels of cytokines were quantified by Luminex assay. Results: Dermal exposure to BPs altered offspring immune systems levels that was dependent on the BP, the dose and offspring sex. These findings provide, for the first time, results on long-term consequences of dermal perinatal BPs exposure on immune responses in offspring. This work warns that it is mandatory to consider immune markers, dose-response as well as sex in risk assessment associated with new BPA's alternatives. 統合_1110	K. Makowska, K. Szymańska, J. Calka and S. Gonkowski	2021	The Influence of Bisphenol A (BPA) on the Occurrence of Selected Active Substances in Neuroglia 1 (NRG1)-Positive Enteric Neurons in the Porcine Large Intestine	Bisphenol A (BPA) is a substance used in the manufacture of plastics which shows multidirectional adverse effects on living organisms. Since the main path of intoxication with BPA is via the gastrointestinal (GI) tract, the stomach and intestine are especially vulnerable to the impact of this substance. One of the main factors participating in the regulation of intestinal functions is the enteric nervous system (ENS), which is characterized by high neurochemical diversity. Neuregulin 1 (NRG1) is one of the tissue-known active substances. In the ENS, During the present study (performed using the double immunofluorescence method), the co-localization of NRG1 with other neuronal substances in the ENS of the cranial and the ascending and descending colon has been investigated under physiological conditions and after the administration of BPA. The obtained results indicate that NRG1-positive neurons also contain substance P, vasoactive intestinal polypeptide, a neuronal isoform of nitric oxide synthase and galanin and the degree of each co-localization depend on the type of enteric plexus and the particular fragment of the intestine. Moreover, it has been shown that BPA generally increases the degree of co-localization of NRG1 with other substances. 統合_1111	K. Makowska, E. Lepiarczyk and S. Gonkowski	2022	The Comparison of the Influence of Bisphenol A (BPA) and Its Analogue Bisphenol S (BPS) on the Enteric Nervous System of the Distal Colon in Mice	Bisphenol A (BPA), commonly used as a plasticizer in various branches of industry has a strong negative effect on living organisms. Therefore, more and more often it is replaced in production of plastics by other substances. One of them is bisphenol S (BPS). This study for the first time compares the impact of BPS and BPA on the enteric neurons using double immunofluorescence technique. It has been shown that both BPS and BPA cause changes in the neurochemical coding of the enteric neurons in the distal colon. Both substances increase the number of neurons containing nitric oxide synthase (nNOS) and vasoactive intestinal polypeptide (VIP). A smaller number of substances was observed in the case of BPS. The changes noted under the impact of both bisphenols are similar and concern the same neuronal populations. However, the immunoreactivity of all neuronal factors studied. The impact of BPS on some populations of neurons was stronger than that noted under the influence of BPA. The obtained results clearly show that BPS (similarly to BPA) administered for long time is not neutral for the enteric neurons, even in relatively low doses and may be more potent than BPA for certain neuronal populations. 統合_1115	K. Makowska and S. Gonkowski	2023	Changes Caused by Bisphenols in the Chemical Coding of Neurons of the Enteric Nervous System of Mouse Stomach	Bisphenol A (BPA), an organic chemical compound which is widely used in the production of plastics, can severely damage live organisms. Due to these findings, the plastic industry has started to replace it with other substances, including bisphenol S (BPS). The aim of the present study was to investigate the effects of BPA and BPS on the chemical coding of the enteric neurons in the mouse stomach. The obtained results show that both substances have a similar impact. Enhancement of nerve cells immunoreactive to substance P (SP), galanin (GAL), and nitric oxide synthase (nNOS) could become an marker of cholinergic neurons) and vasoactive intestinal polypeptide (VIP). Changes observed under the impact of both bisphenols depended on the neuronal factor, the type of the enteric ganglion and the doses of bisphenols studied. Generally, the increase in the percentage of neurons immunoreactive to SP, GAL, and/or VIP, and the decrease in the percentage of nNOS+ positive neurons, was noted. Severity of changes was more visible after BPA administration. However, the study has shown that long-time exposure to BPS also significantly affects the ENS. 統合_1116	K. Makowska and S. Gonkowski	2022	Changes in the Enteric Neurons Containing Selected Active Substances in the Porcine Descending Colon after the Administration of Bisphenol A (BPA)	Bisphenol A (BPA) is an endocrine disruptor widely distributed in the environment due to its common use in the plastics industry. It is known that it has a strong negative effect on human and animal organisms, but a lot of data concerning the influence of BPA on the enteric nervous system (ENS) is still lacking. Therefore, the aim of the present study was to investigate the impact of BPA on the neurochemical coding of the enteric neurons in the descending colon of the domestic pig, which can be considered to be a suitable model for the human digestive system. Detailed analysis of the obtained results showed that the examined BPA dose, which is considered safe for living organisms, has a significant effect on the neurochemical characterization of the enteric neurons located in the descending colon. The administration of BPA caused an increase in the number of enteric neurons containing substance P (SP) and vasoactive intestinal polypeptide (VIP) with a simultaneous decrease in the number of neurons positive for galanin (GAL) and vesicular acetylcholine transporter (VAChT) used as a marker of cholinergic neurons). Changes were noted in all types of the enteric plexuses, i.e., the myenteric, submucous, and intramural plexuses. Moreover, the changes were dependent on the part of the descending colon in which the enteric neurons studied. The results have shown that BPA may affect the descending colon through the changes in neurochemical characterization of the enteric neurons located in this segment of the gastrointestinal tract.	Int J Environ Res Public Health Vol.19 Issue 23	10.3390/ijerph192316187	36498260	動物	-	1	1	1	Pietrain × Duroc	0	0.05、0.5 mg/kg	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-
統合_1117	K. Makowska and S. Gonkowski	2021	Changes Caused by Low Doses of Bisphenol A (BPA) in the Neuro-Chemistry of Nerves Located in the Porcine Heart	Bisphenol A (BPA) contained in plastics used in the production of various everyday objects may leach from these items and contaminate food, water and air. As an endocrine disruptor, BPA negatively affects many internal organs and systems. Exposure to BPA also contributes to heart and cardiovascular system dysfunction, but many aspects connected with this activity remain unknown. Therefore, this study aimed to investigate the impact of BPA in a dose of 0.05 mg/kg body weight/day for many months, such a dose is regarded as a tolerable daily intake TDI dose of BPA—completely safe for living organisms) on the neurochemical characterization of the enteric neurons located in the heart wall using the immunofluorescence technique. The obtained results indicated that BPA caused in such a relatively low dose fragmentary changes, i.e., it increased the number of cholinergic neurons (visualized by vesicular acetylcholine transporter (VAChT), a marker of cholinergic neurons), substance P and tyrosine hydroxylase (used here as a marker of sympathetic innervation). However, BPA did not change the number of nerves immunoreactive to vesicular acetylcholine transporter (used here as a marker of cholinergic structures). These observations suggest that changes in the heart innervation may be at the root of BPA-induced circulatory disturbances, as sufficient sympathogenic and/or parasympathetic effects of the endocrine disruptor. Moreover, changes in the neurochemical characterization of nerves in the heart wall may be the first sign of exposure to BPA.	Animals (Basel) Vol.11 Issue 3	10.3390/ani11030780	33799766	動物	-	1	1	1	Pietrain × Duroc	0	0.05 mg/kg	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-
統合_1118	K. Makowska and S. Gonkowski	2020	Bisphenol A (BPA) Affects the Enteric Nervous System in the Porcine Stomach	Bisphenol A (BPA) is widely utilized in plastic production process all over the world. Previous studies have shown that BPA, with its similarity to estrogen, may negatively affect living organisms. It is acknowledged that BPA disturbs the activity of multiple internal systems, including the nervous, reproductive, urinary, and endocrine systems. BPA also affects the gastrointestinal tract and enteric nervous system (ENS), which is placed in the wall of the gastrointestinal tract from the esophagus to the rectum. The aim of the study was to investigate the impact of BPA on the neurochemical coding of the enteric neurons in the porcine stomach. The obtained results showed that BPA affects the number of nervous structures in the porcine gastric wall immunoreactive to vesicular acetylcholine transporter (VAChT, a marker of cholinergic neurons), substance P (SP), vasoactive intestinal polypeptide (VIP), galanin (GAL), and cocaine- and amphetamine-regulated transcript peptide (CART). The character and severity of noted alterations depended on the part of the ENS, the BPA dose, and the type of neuronal substance. Manifestation of BPA-evoked is an increase in the number of nervous structures containing SP, GAL, and/or CART, and a decrease in the number of cholinergic neurons, in all parts of the gastric wall. The number of VIP-positive nervous structures increased in the enteric myenteric ganglia, along with the muscular and mucosal layers, while it decreased in the submucous ganglia. The exact mechanism of noted changes was not absolutely obvious, but they were probably related to the neuroprotective and adaptive processes constituting the response to the impact of BPA.	Animals (Basel) Vol.10 Issue 12	10.3390/ani10122445	33419365	動物	-	1	1	1	Pietrain × Duroc	0	0.05、0.5 mg/kg	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-
統合_1119	K. Makowska, K. R. C. Fagundes and S. Gonkowski	2023	Influence of bisphenol A and its analog bisphenol S on cocaine- and amphetamine-regulated transcript peptide-positive enteric neurons in the mouse gastrointestinal tract	INTRODUCTION: Bisphenol A (BPA) is used in large quantities for the production of plastics and is present in various everyday objects. It penetrates living organisms and shows multidirectional adverse influence on many internal organs. For this reason, BPA is often replaced in plastic production by other substances. One of them is bisphenol S (BPS), whose effects on the enteric nervous system (ENS) have not been explained. METHODS: Therefore, the present study compares the influence of BPA and BPS on the number of enteric neurons containing cocaine- and amphetamine-regulated transcript (CART) peptide located in the ENS of the stomach, jejunum and colon with the use of double immunofluorescence method. RESULTS: The obtained results have shown that both bisphenols studied induced an increase in the number of CART-positive enteric neurons in the stomach and jejunum. However, in the colon, the number of CART-positive neurons was reduced by BPA and BPS. Moreover, the number of CART-positive nerve fibers increased in the stomach and jejunum and decreased in the colon. The changes caused by BPS are more noticeable than those observed after BPA administration. In the stomach and jejunum, bisphenol induces changes, even in low doses, and changes caused by BPS were similar or less pronounced than those noted under the impact of BPA, depending on the segment of the gastrointestinal tract and ganglion type studied. DISCUSSION: The results show that BPS affects the enteric neurons containing CART in a similar way to BPA, and the BPS impact is even stronger in the colon. Therefore, BPS is not neutral for the gastrointestinal tract and ENS.	Front Mol Neurosci Vol.16 Pages 1234841	10.3389/fnmol.2023.1234841	37675141	動物	-	1	1	1	1	0	5 、50 mg/kg	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-
統合_1120	K. Makowska, J. Calka and S. Gonkowski	2023	Effects of the long-term influence of bisphenol A and bisphenol S on the population of nitrergic neurons in the enteric nervous system of the mouse stomach	Bisphenol A (BPA) is an endocrine disruptor commonly used in the production of plastics. Due to its relatively well-known harmful effects on living organisms, BPA is often replaced by its various analogues. One of them is bisphenol S (BPS), widely used in the plastics industry. Until recently, BPS was considered completely safe, but currently, it is known that it is not safe for various internal organs. However, knowledge about the influence of BPS on the nervous system is scarce. Therefore, the aim of this study was to investigate the influence of two doses of BPS and BPA on the enteric nitrergic neurons in the ICC circumference located using the double immunofluorescence technique. The study found that both substances studied increased the number of nitrergic neurons, although changes under the impact of BPS were less, visible than those induced by BPA. Therefore, the obtained results, for the first time, clearly indicate that BPS is not safe for the innervation of the gastrointestinal tract.	Sci Rep Vol.13 Issue 1 Pages 331	10.1038/s41598-023-27511-9	36609592	動物	-	1	1	1	1	0	5 、50 mg/kg	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-
統合_1121	M. Majid, A. Farhan, M. W. Baig, M. T. Khan, Y. Kamal, S. S. U. Hassan, S. Bungau and I. U. Haq	2022	Ameliorative Effect of Structurally Divergent Oleanane Triterpenoid, 3-Epihederiinol from Ipomoea batatas against BPA-Induced Gonadotoxicity by Targeting PARP and NF- κ B Signaling in Rats	The aerosa-ric triterpenoids (PTIs) of plant origin are reported to restrain prostate cancer (PCa) cell proliferation. This study aims to assess 3-epihederiinol (EPIH) isolated from aerial part of Ipomoea batatas against PCa in bisphenol A (BPA)-induced rats. Rats were divided into 5 groups (= 6) and treated for 28 days as follows: Group I (control) received 1 mL/kg of 1% DMSO, Group II (BPA) received BPA (~20 mg/kg bw) + 0.5 mL/kg of 1% DMSO, and Group III (BPA + EPIH) received BPA (~20 mg/kg bw) + EPIH (5 mg/kg bw). BPA treatment (< 0.05 and < 0.01) data were also observed a drastic rise in prostate gland wet (10.416 and 14.7%) and PCa cell co-cultured with BPA (~20 mg/kg bw) + EPIH (5 mg/kg bw) showed significant (< 0.05 and < 0.01) data and dose-dependent drastic rise in prostate gland wet (10.416 and 14.7%) and PCa cell co-culture in apoptotic cell population (FITC-Annexin V+/PI-) (5.138 ± 1.72 cells) and PCC (76.23 ± 3.67 cells). According to Western blots, EPIH administration significantly enhanced the cleavage of caspases and PARP, elevated BAX and P53 and decreased BCL-2 and NF- κ B expression, thereby triggering apoptosis in PCa cells. When male Sprague Dawley rats were intoxicated with Bisphenol A (BPA), an apparent increase in prostate mass (0.478 ± 0.04 g) in comparison to control (0.380 ± 0.02 g) indicates prostatitis. Multilinear treatment of EPIH (10 mg/kg) significantly reduced prostate size (0.368 ± 0.04 g). EPIH treatment also significantly (< 0.05) reduced the elevated levels of prostatic acid phosphatase (PAP), prostate-specific antigen (PSA), and testosterone in BPA-induced rats. Histological studies (H&E, E, and TUP +, caspase-colocalized antiinflammatory potential of the compound. Overall, EPIH has shown better binding affinity with target molecules, acceptable ADMET profile, potent antiproliferative and apoptotic nature and significant reduction in inflamed prostate mass of rats. The present study demonstrates acceptable physicochemical and pharmacokinetic properties of the compound with excellent druglikeness nature. Hence EPIH in the form of standardized formulation can be developed as primary or adjuvant therapy against PCa and toxic-induced prostatotoxicity. 統合_1122	A. Mahmoudi, F. Hedrich, Z. Boudiaguiı, I. Faki, H. Gtobel, L. Ayadi, M. Chamkha and S. Sayadi	2023	Comparative study of the effect of oleuropein and hydroxytyrosol rich extracts on the reproductive toxicity induced by bisphenol A in male rats: biochemical, histopathological, and molecular analyses	Bisphenol A, or BPA, gives rise to the composition of a large number of products including sunglasses, sturdy building bodies, receipts, or food packaging. Nowadays, there is a growing tendency that BPA may be at the origin of reproductive dysfunctions. Olive oil is considered a source of bioactive compounds, such as oleuropein and hydroxytyrosol, which have been shown to exhibit several biological properties. The present study aimed to evaluate the potential protective role of olive leaf extracts against BPA-induced testicular damage in Wistar rats. The animals were randomly divided into 4 groups: control, BPA treated (10 mg/kg bw), BPA and oleuropein rich extract (10 mg/kg) treatment, and the last group treated with BPA and hydroxytyrosol rich extract (10 mg/kg). Biochemical parameters and histological and molecular analysis were evaluated. Our data demonstrated that BPA treatment caused significant alterations in biochemical parameters, disorganization of germinal epithelium, and an regulation of p53 and Bax, and a reduction of Bcl-2 protein levels. The ingestion of oleuropein- and hydroxytyrosol- rich extracts attenuated BPA-induced biochemical and histological changes. In fact, olive leaf extracts enhanced the enzymatic antioxidant system and the level of Bcl-2, and reduced the expression of p53 and Bax. Fairly, our findings propose that olive leaf extracts may counteract with BPA-induced nephrotoxicity in rats. 統合_1123	M. Mahdavinia, L. Khorsandi, S. Alizadi-davish, A. Samimi, M. A. Dehghani and L. Zeidooni	2021	Liver histopathological alteration and dysfunction after bisphenol A administration in male rats and protective effects of naringin	OBJECTIVE: Bisphenol A (BPA) is an organic synthetic compound, often used in manufacturing polycarbonate plastics. Researches have shown the role of BPA as an endocrine disruptor. The present study intended to evaluate the hepatoprotective properties of naringin, an active flavanone glycoside present in many citrus fruit, against hepatotoxicity induced by BPA. MATERIALS AND METHODS: Male Wistar rats were orally treated with 50 mg/kg BPA for 30 consecutive days for induction of toxicity and 50, 80 and 100 mg/kg naringin for the same period along with BPA or alone. RESULTS: The results revealed that BPA significantly increased serum levels of triglyceride, lactate dehydrogenase (LDH), alkaline phosphatase (ALP), lipid peroxidation, and aspartate aminotransferase (AST) and significantly reduced catalase, glutathione peroxidase (GPx) and superoxide dismutase (SOD) activities in liver tissue homogenate. Histopathological examination revealed that BPA induced hepatocellular damage, including congestion, vacuolization, and necrosis. Naringin (50, 80, 100 mg/kg) significantly reduced BPA-induced elevation of serum levels of triglyceride, LDH, ALP, AST, alanine aminotransferase (ALT), and gamma-glutamyl transferase (GGT). Furthermore, the results displayed that administration of 80 and 100 mg/kg naringin improved hepatotoxicity and altered lipid peroxidation level, serum values of triglyceride and liver enzymes, and oxidative stress factors that were induced by BPA. The effect of loss doses of 80 and 100 mg/kg naringin was more noticeable than that of dose 50 mg/kg. CONCLUSION: The findings suggested the protective effects of naringin against BPA -induced hepatotoxicity via ameliorating liver histopathological alteration, suppressing oxidative stress and lipid-lowering properties. 統合_1124	W. A. H. Madurange Karu-ranatthe, Y. H. Choi, S. R. Park, C. M. Lee and G. Y. Kim	2022	Bisphenol A inhibits osteogenic activity and causes bone resorption via the activation of retinoic acid-related orphan receptor α	Bisphenol A (BPA) has deleterious effects on bone metabolism; however, its underlying mechanism has not yet been comprehensively understood. Here, we investigated whether ROR α plays an important role in BPA-induced bone resorption both in vitro and in vivo. We found that BPA (0.1–1 μM) inhibited osteogenic activity (including ALP activity and mineralization), decreased the expression levels of osteoblast markers (such as RUNX2, OSX, and ALP) in human MG-63 osteoblast-like osteosarcoma cells, and inhibited osteoblastic zebrafish formation in zebrafish larvae. Additionally, BPA diminished JC (glycerophospholipid-induced osteoblast differentiation and bone formation in vivo. Moreover, BPA (1 μM) increased the activity of osteoclastogenesis (including TRAP activity and mineralization), the expression levels of osteoclast markers (such as the NFATc1/c-fos and/or M-CSF/RANKL/OPG signaling pathway), and ROS production in RAW 264.7 cells. Additionally, BPA diminished the cell height of RAW264.7 cells, respectively, which another marked symptom of BPA-like stem cells, and BPA elements with non-osseous interactions, resulting in the activation of ROR α. However, an ROR α inverse agonist potently inhibited BPA-induced anti-osteogenic activity and vertebral formation in zebrafish larvae, concomitant with inhibition of osteogenic gene expression. Overall, our findings reveal that BPA inhibits osteoblast differentiation and bone formation by activating ROR α. These results suggest that BPA exposure (0.1–1 μM) can cause various bone-resorptive diseases, such as osteoporosis. 統合_1125	Z. Ma, A. B. Parris, E. W. Howard, M. Davis, X. Cao, C. Woods and X. Yang	2020	In Utero Exposure to Bisphenol a Promotes Mammary Tumor Risk in MMTV-Erbb2 Transgenic Mice Through the Induction of ER-erbB2 Crosstalk	Bisphenol A (BPA) is the most common environmental endocrine disrupting chemical. Studies suggest a link between perinatal BPA exposure and increased breast cancer risk, but the underlying mechanisms remain unclear. This study aims to investigate the effects of in utero BPA exposure on mammary tumorigenesis in MMTV-erbB2 transgenic mice. Pregnant mice were subcutaneously injected with BPA (5, 50, 500 ng/kg and 25, 250, 2500 μg/kg) or vehicle control (sesame oil) from gestation day 10 to 17. Female offspring were palpated for mammary tumors weekly from 20 weeks of age. Mammary tumor incidence was 83% (10/12) in the 2500 μg/kg BPA-treated group, but only 8% (1/12) in the vehicle control. Increased luminal hyperplasia, early neoplastic lesions, and preneoplastic foci were also observed in the BPA-treated mammary glands, which was accompanied by elevated mammary tumorigenesis. CD31-IHC-based FACS analysis revealed that in utero exposure to 500 ng/kg BPA induced expansion of luminal and basal/myoepithelial cell subpopulations at PND 35. Molecular analysis of mammary tissues at PND 70 showed that in utero exposure to low doses of BPA induced upregulation of ERα, p-ERα, cyclin D1, and c-myc, concomitant activation of erbB2-EGFR, erbB2-STAT3, and Akt, and upregulation of growth factors/ligands. Our results demonstrate that in utero exposure to low dose BPA promotes mammary tumorigenesis in MMTV-erbB2 mice through induction of ER-erbB2 crosstalk and mammary epithelial reprogramming, which advance our understanding of the mechanisms associated with in utero exposure to BPA-induced breast cancer risk. The models also support using MMTV-erbB2 mouse model for relevant studies. 統合_1126	X. Ma, Y. Wang, W. Li, K. Wang and S. Zhang	2024	Bisphenol A Disrupts Ribosome Function during Ovarian Development of Mice	This study examines the impact of Bisphenol A (BPA), a prevalent environmental microgenic toxicant, on the ovarian development of mice. Mice were exposed to varying BPA doses from in utero to prenatal stages, up to 8 weeks of age. Ovarian tissues were analyzed using RNA-seq, revealing significant BPA-induced changes in gene expression. Notably, BPA exposure led to a dose-dependent increase in PND21 ovary significantly increased, and the number of corpus luteum in ova, damaged ovarian BPA. In contrast, the mice with PND 56 did not show apparent ovarian injuries. On the other hand, ribosome-related genes were detected in both PND21 and PND 56 mice ovaries, and EIF4 was increased under the influence of BPA. Transcriptomic analysis revealed BPA's significant impact on ribosomal gene expression, marked downregulation of Rpl13 and Rpsa, and upregulation of Rpl13 in both age groups. These transcriptomic alterations were further corroborated by real-time PCR, highlighting a dose-dependent effect of BPA on Rpsa. Our findings confirm BPA's detrimental effects on ovarian health, with more pronounced damage in younger mice, suggesting heightened vulnerability in this group. The study underscores ribosomes as critical targets in BPA-induced ovarian developmental disruptions. Zhou	2021	Long-term bisphenol A exposure exacerbates diet-induced prediabetes via TLR4-dependent hypothalamic inflammation	Bisphenol A (BPA), an environmental endocrine-disrupting compound, has been revealed associated with metabolic disorders such as obesity, prediabetes, and type 2 diabetes (T2D). However, its underlying mechanisms are still not fully understood. Here, we provide new evidence that BPA is a risk factor for T2D from a case-control study. To explore the detailed mechanisms, we used two types of diet models, standard diet (SD) and high-fat diet (HFD), to study the effects of long-term BPA exposure on prediabetes. In 8-week-old mice, We found that BPA exposure for 12 weeks exacerbated HFD-induced prediabetic symptoms. Female mice showed increased body mass, serum insulin level, and impaired glucose tolerance, while male mice only exhibited impaired glucose tolerance. No change was found in SD-fed mice. Besides, BPA exposure enhanced astrocyte-dependent hypothalamic inflammation in both male and female mice, which impaired proopiomelanocortin (POMC) neuron functions. Moreover, eliminating inflammation by full-like receptor 4 (TLR4) knockout significantly ameliorated the adverse effects of BPA on the hypothalamus and diet-induced prediabetes. Taken together, our data revealed a key role for TLR4-dependent hypothalamic inflammation in regulating the effects of BPA on prediabetes. Ma	2020	The effects of maternal exposure to BPA during pregnancy on the male reproductive system and the testicular microRNA expression profile	The effect of prenatal bisphenol A (BPA) exposure is increasingly concerned. We investigated the effect of maternal BPA exposure during pregnancy on male offspring and its potential mechanism. Thirty pregnant Sprague Dawley (SD) rats were randomly divided into exposed and control groups. At PND30, the number of sperms, testicular hormones, and testicular tissue of the BPA-exposed group decreased, and testicular tissue structure damaged in offsprings. At GD20, the mRNA profile in the testis of male offspring was examined and the express ion levels of 26 deregulated mRNAs were validated by qRT-PCR. We found that miR-361-5p, miR-350a-3p, and miR-29b-2-5p had significantly different expression levels in the testis. These results suggest that maternal exposure to BPA can lead to differential changes in progeny mRNAs, which will provide direction for future in-depth mechanisms of reproductive injury. 統合_1129	M. Luo, L. Li, M. Ding, Y. Niu, X. Xu, X. Shi, N. Shan, Z. Qiu, F. Fiao and C. Zhang	2023	Long-term potentiation and depression regulatory microRNAs were highlighted in Bisphenol A induced learning and memory impairment by microRNA sequencing and bioinformatics analysis	The mechanisms of Bisphenol A (BPA) induced learning and memory impairment have still not been fully elucidated. MicroRNAs (miRNAs) are endogenous, non-coding small RNA molecules involved in the process of transient historical neuroplasticity. To investigate the role of miRNAs in BPA-induced learning and memory impairment, we analyzed the impacts of BPA on miRNA expression profile by high-throughput sequencing in mice hippocampus. Results showed that mice treated with BPA displayed impairments of spatial learning and memory and changes in the expression of miRNAs in the hippocampus. Numerous miRNAs were significantly differentially expressed after BPA exposure, of these, 13 and 5 miRNAs were up- and downregulated, respectively. Bioinformatic analysis of Gene Ontology (GO) and pathway suggests that BPA exposure significantly influenced long-term potentiation (LTP) and long-term depression (LTD) related genes and pathways, including glutamatergic synapse, calcium signaling pathway, cAMP signaling pathway, GABAergic synapse, LTP signaling pathway, LTD signaling pathway, G protein-coupled receptor, Eight BPA-responsive differentially expressed miRNAs targeting LTP and LTD were further screened to validate the miRNA sequencing data using Real-Time PCR. The deregulation expression levels of proteins of five target genes (CaMKII, MAPK1/3, PTEN, AMPAR, and PLC-β3) were investigated via western blot, for further verifying the results of gene target analysis. Our results revealed that LTP and LTD related miRNAs and their targets could contribute to BPA-induced impairment of learning and memory. This study provides valuable information for novel miRNA biomarkers to detect changes in impairment of learning and memory induced by BPA exposure. Liu	2024	Ginger volatile oil inhibits the growth of MDA-MB-231 in the bisphenol A environment by altering gut microbial diversity	To examine the impact of ginger volatile oil (GVO) on the growth of MDA-MB-231 breast cancer cells in the presence of bisphenol A (BPA) by modulating the diversity of gut microbiota. METHODS: MDA-MB-231 breast cancer cells were injected subcutaneously into the right armpit of female BALB/c Nude (nu/nu) mice to create a triple-negative breast cancer model. Thirty nude mice were randomly divided into 5 groups: control group, BPA group, BPA + GVO (0.1 g/kg) group, BPA + GVO (0.2 g/kg) group, and BPA + GVO (0.4 g/kg) group. The mice were gavaged with BPA (50 mg/kg/day) and/or GVO (0.1, 0.2, 0.4 mg/kg/day) or given by gastric once a day for 3 weeks. At the end of the experiment, the changes of tumor mass and tumor volume were observed and compared in 5 groups of nude mice bearing mice. High-throughput sequencing (16S rRNA) was used to detect the changes of gut microflora in each group. RESULTS: The volume and weight of breast cancer decreased in the low, medium and high dose groups of GVO. Among them, the difference between the high dose group and the BPA group reached a significant level (P < 0.05). The success and abundance of gut flora decreased following BPA treatment, but increased after combined treatment of BPA and GVO. In the tumor control group, the ratio of Firmicutes/F) and Bacteroidetes/B) increased by over 0.3362 That the phylum level, while the ratio of BPA group further decreased 0.5363.80. After feeding GVO, the number of Lactobacillus, Ruminococcus, Bacteroides increased. the F/B ratio increased, and the level of Lactobacillus and Ruminococcus increased. In the BPA and GVO treatment group, the intestinal microbiota structure was still membrane fragments, multicellular transport and metabolism. This is followed by some work changes and interaction, and immunization function. After GVO administration the Even positive bacteria (G+) cells had an increasing trend and the Even negative bacteria (G-) tests had a decreasing trend. CONCLUSION: The species and abundance of gut flora decreased following BPA treatment, but increased after combined treatment of BPA and GVO. 統合_1131	D. Luo, X. Tang, Y. Wang, S. Ying, Y. Hu, H. Liu, P. A. Khosa and S. Li	2024	Selenium deficiency exacerbated Bisphenol A-induced intestinal toxicity in chickens: Apoptosis and cell cycle arrest mediated by ROS/P53	Bisphenol A (BPA) is a phenolic organic synthetic compound that is used as the raw material of polycarbonate plastics, and its safety issues have recently attracted wide attention. Selenium (Se) deficiency has gradually developed into a global disease affecting intestinal function via oxidative stress and apoptosis. However, the toxic effects and potential mechanisms of BPA exposure and Se deficiency in the chicken intestines have not been reported. In this study, 1-day-old male broilers were randomly divided into four groups: control group, Se deficiency group, BPA group, and Se deficiency + BPA group. The results showed that Se deficiency aggravated BPA-induced intestinal damage, as evidenced by the disturbed tissue morphological structure, serum D-lactic acid, diamine oxidase activities, and DNA damage, activated PI3K pathway, and Caspase-dependent apoptosis, and induced apoptosis and cell cycle arrest. Using protein-protein molecular docking, we found a strong binding ability between P53 and peroxiredoxin proliferation-activated receptor γ coactivator 1, thereby regulating mitochondrial dysfunctional apoptosis. In addition, we used Se and/or L-cysteine and ebselen + Se in vitro intervention and found that Se and/or L-cysteine and ebselen + Se intervention reversed the aforementioned adverse effects. This study clarified the potential mechanisms by which Se deficiency exacerbates BPA-induced intestinal injury in chickens through reactive oxygen species/P53, which provides a new idea for the study of environmental combined toxicity of Se deficiency, and insights into animal intestinal health from a new perspective. 統合_1132	L. Lu, L. Shen, S. Cui, Y. Huang, Y. Gao, X. Zhu, G. Lu, C. Zhang and S. Zhuang	2023	Angiogenic Activity and Mechanism for Bisphenols on Endothelial Cell and Mouse: Evidence of a Structural-Selective Effect	Increased epidemiological evidence indicates the association of bisphenol exposure with human vascular disorders, while the underlying mechanism has not been clarified. Here, we sought to unveil the potential angiogenic activity and mechanism for bisphenols (BPs) with different structures. Bisphenol A (BPA) and bisphenol S (BPS) at a concentration of 1 nM to 10 μM significantly increased the migration of EA.hy926 cells and CTCW. Bisphenol AF (BPAF) at 1 nM to 10 μM significantly increased the migration of EA.hy926 cells and CTCW. Bisphenol AF (BPAF) at 1 nM to 10 μM significantly increased the migration of EA.hy926 cells and CTCW. At doses of 0.002, 0.2, and 20 μg/kg/day for the 5 weeks, Bisphenol A (BPA) and bisphenol S (BPS) at 0.2 and 20 μg/kg/day significantly increased both the number and length of blood vessels in the mesenteral spreading, while later length and increased spreading were significantly inhibited by 17.2 and 65.7% after exposure to tetrabromobisphenol S (TBBPS) at 1 μg/kg/day, respectively. Mechanistically, TBBPS and BPAF significantly inhibited the interaction between thyroid hormone receptor β (TRβ) and thyroid receptor (TR), while BPA and BPS exhibited the reversed interaction. TRβ, while BPA and BPS exhibited the reversed interaction. TRβ, while BPA and BPS exhibited the reversed interaction between TRβ and thyroid receptor (TR), resulting in abnormal PI3K signaling with consequent distinct angiogenic activity. BPA- and BPS-induced pan-angiogenic effects and TBBPS-induced anti-angiogenic effects due to their distinct disruption on the TRβ/β-PI3K pathway. Our work provided new evidence and mechanistic insight on the angiogenic activity of bisphenols and expanded the scope of endocrine disruptors with interference in vascular homeostasis. 統合_1133	D. López-Rodríguez, D. Franssen, E. Sawin, A. Gérard, C. Balcat, S. Blacher, A. Noël and A. S. Parent	2019	Persistent vs Transient Alteration of Folliculogenesis and Estrous Cycle After Neonatal vs Adult Exposure to Bisphenol A	Exposure to bisphenol A (BPA), a ubiquitous endocrine-disrupting chemical (EDC), is known to produce variable effects on female puberty and ovulation. This variability of effects is possibly due to differences in dose and period of exposure. Little is known about the effects of adult exposure to environmentally relevant doses of this EDC and the differences in effect after neonatal exposure. This study sought to compare the effects of neonatal vs adult exposure to a very low dose or a high dose of BPA to 2 weeks on ovulation and folliculogenesis, and to explore the hypothalamic mechanisms involved in such disruption by BPA. One-day-old and 90-day-old female rats received daily subcutaneous injections of corn oil (vehicle) or BPA (10 μg/kg/d or 50 mg/kg/d) for 15 days. Neonatal exposure to both BPA doses significantly disrupted the estrous cycle and induced a decrease in primordial follicles. Effects on estrous cyclicity and folliculogenesis persisted into adulthood, consistent with a disruption of organizational mechanisms. During adult exposure, both doses caused a reversible disruption of the estrous cycle and a decrease in the number of corpora lutea, without affecting folliculogenesis. Only the high dose of BPA increased the number of antral follicles. No effect was also observed. Alterations of the hypothalamic expression of the clock gene Per1 and the reproductive peptide phoenixin indicated a disruption of the hypothalamic control of the periodicity (1/4 days) by BPA. Parent	2021	Multi- and Transgenerational Outcomes of an Exposure to a Mixture of Endocrine-Disrupting Chemicals (EDCs) on Puberty and Maternal Behavior in the Female Rat	BACKGROUND: The effects of endocrine-disrupting chemicals (EDCs) on fertility and reproductive development represent a rising concern in modern societies. Although the neuroendocrine control of sexual maturation is a major target of EDCs, little is known about the potential role of the hypothalamus in puberty and ovulation disruption transmitted across generations. OBJECTIVES: We hypothesized that developmental exposure to an environmentally relevant mixture of EDCs would induce transgenerational disruptions of the hypothalamic mechanisms involved in female puberty and maternal behavior. METHODS: We investigated the transmission of a disrupted reproductive phenotype via the maternal germline or via epigenomic mechanisms, involving maternal care. METHODS: Adult female Wistar rats were exposed prior to and during gestation and until the end of lactation to a mixture of the following: DEHP, di-n-butyl phthalate (DnBP), di(2-ethylhexyl) phthalate (DEHP), bisphenol A (BPA), vinclozolin, prochloraz, procymidone, linuron, iprodione, 4,4'-dichlorodiphenyldichloroethylene, and methoxychlor. F1 (embryo/fetus exposed), F2 (germline exposed), and F3 (second-generation) females were studied across generations. RESULTS: Early exposure to EDCs induced a decrease in primordial follicles. Effects on estrous cyclicity and folliculogenesis persisted into adulthood, consistent with a disruption of organizational mechanisms. During adult exposure, both doses caused a reversible disruption of the estrous cycle and a decrease in the number of corpora lutea, without affecting folliculogenesis. Only the high dose of BPA increased the number of antral follicles. No effect was also observed. Alterations of the hypothalamic expression of the clock gene Per1 and the reproductive peptide phoenixin indicated a disruption of the hypothalamic control of the periodicity (~4 days) by BPA. 統合_1135	A. López-Moreno, A. Torres-Sánchez, A. Suárez, A. Ruiz-Rodríguez and M. Aguilera	2025	Perinatal bisphenol A exposure impairs gut microbial colonization: Implications for offspring obesity and neurodevelopment	Exposure to plasticizer xenobiotics such as BPA has emerged as a significant health challenge due to globalized and industrial packaged food production. Toxicological approaches in animal models have revealed complex effects, using variable doses of BPA, on reproduction, development, obesity, immune function, metabolic and systemic toxicity. Recently, gut microbiota has emerged as a key player in regulating the impact of xenobiotic exposure on host metabolism. The effect that BPA may exert on the gut microbiota and its consequences for the host's health remains unclear. Exposure to BPA during the perinatal period requires special attention and characterization, as it is a critical window for microbiota establishment and host development. Therefore, this study aimed to evaluate the impact of BPA exposure during the perinatal period on the establishment of the gut microbiota and its relationship with the offspring's metabolic and neurobehavioral phenotype. Female Wistar rats were exposed to BPA (50 mg/kg/day) via drinking water during the perinatal period (preconception, gestation, and lactation). Offspring were analyzed at postnatal day 21 (PND21, weaning) and PND70 (adulthood), after administered BPA, and the increase in weight and fat accumulation, the gut microbiota composition, and the cognitive development of the offspring were analyzed. In addition, a high-fat diet (HFD) was given to the mice two to the synergistic obesogenic effect of BPA. Our results demonstrated that BPA exposure impaired the natural remodeling of the gut microbiota during pregnancy. For instance, Ruminococcus and Prevotellaceae decreased during natural remodeling of the gut microbiota during pregnancy, but they did not change in the BPA-exposed pregnant mice. Conversely, several members of the Eubacteriaceae genus increased during normal pregnancy, but BPA exposure prevented this increase. Moreover, BPA exposure altered the microbiota composition of the offspring, with significant changes observed in the abundance of Lactobacillus in the offspring. Perinatal BPA exposure impaired changes during colonization and maturation process of the offspring gut microbiota. Identifying Lactobacillus, Eubacterium and Escherichia-Shigella as signature genera enriched in BPA and BPA-exposed mice fed with HFD, was involved in a more efficient at energy harvesting from the diet. Moreover, perinatal BPA exposure seemed to alter fat and lean percentages and triggered Escherichia-Shigella overgrowth. Escherichia-Shigella overgrowth was associated with increased activity, spatial learning, and memory, mimicking impulsivity and hyperactivity-like behavior in the offspring. In conclusion, BPA exposure and HFD exert an influence on the vertical transfer of gut microbiota from mothers to offspring and drive towards an altered establishment of gut microbiota-brain in early life, contributing to enhancing susceptibility to obesity and behavioral disorders. Ramos-Ligonio	2025	Exposure to Bisphenol-A increases susceptibility to Trypanosoma cruzi infection	Bisphenol-A (BPA), an endocrine disruptor, disrupts hormonal and chemical signaling within the body, negatively impacting health. One target of this disruption is the immune system. While BPA has been implicated in increased susceptibility to some pathogen infections, its effects on protozoan parasite infections remain understudied. This work evaluated the effect of BPA exposure on experimental Trypanosoma cruzi parasitemia in BALB/c mice. Female mice were exposed to BPA (50 mg/kg/day) via drinking water for 21 days before infection with T. cruzi. Parasitemia was monitored by microscopy and confirmed by RT-PCR, and liver tissue was examined using histomorphometric methods. Body-wet- and spleen weights in BPA-treated parasitemia during T. cruzi infection and decreased levels of IgG2a, IgG1a, and IgG2b isotypes. Furthermore, BPA modulated the expression of pro-inflammatory cytokines in response to infection. In addition, all mice exposed to BPA showed alterations in liver enzymes compared to the control group. These results demonstrated that the immune system during critical periods of T. cruzi infection is highly sensitive to BPA exposure, increasing susceptibility to the parasite. Wang	2021	Gestational bisphenol A exposure induces fatty liver development in male offspring mice through the inhibition of HNF1b and upregulation of PPARγ	Bisphenol A (BPA) is an endocrine-disrupting chemical (EDC) associated with non-alcoholic fatty liver disease (NAFLD). The effects of gestational BPA exposure on hepatic lipid accumulation in offspring are not fully understood. Here, we investigated the sex-dependent effects of gestational BPA exposure on hepatic lipid and glucose metabolism in the offspring of mice to reveal the mechanisms underlying gestational BPA exposure-associated NAFLD. Pregnant mice were administered gavage with or without 1 μg kg(-1) day(-1) BPA at embryonic day 7.5 (E7.5)-E18.5. Hepatic glucose and lipid metabolism were evaluated in these models. Both male and female offspring mice exhibited hepatic fatty liver after BPA treatment. Lipid accumulation and glucose metabolism were observed in male offspring. We then observed aberrant activation of lipid regulators in the liver and bad inhibition of peroxisome proliferator-activated receptor γ (PPARγ) repressed hepatic lipid accumulation induced by gestational BPA exposure. We also found a sex-dependent decrease of hepatocyte nuclear factor 1 homeobox B (HNF1b) in male offspring mice after BPA exposure. Moreover, HNF1b knockdown in HepG2 cells and primary hepatocytes from male offspring mice aggravated BPA-induced hepatic lipid accumulation and glucose metabolism. Mechanistically, HNF1b deficiency promoted PPARγ transcription by increasing the binding of hepatocyte nuclear factor 4 alpha (HNF4α) to the PPARγ promoter. Gestational BPA exposure induced NAFLD in male offspring. These data provide new insights into the mechanism of gestational BPA exposure-associated sex-dependent glucose and lipid metabolic dysfunction. Graphical abstract Schematic of the mechanism of gestational BPA exposure-induced glucose and lipid metabolic dysfunction. 統合_1138	Z. Liu, M. Liu, H. Wang, P. Qin, Y. Di, S. Jiang, Y. Li, L. Huang, N. Jiao and W. Yang	2024	Glutamine attenuates bisphenol A-induced intestinal inflammation by regulating gut microbiota and TLR4-p38/MAPK-NF-κ B pathway in piglets	Bisphenol A (BPA), as a kind of widely exerted environmental hazardous material, brings toxicity to both humans and animals. This study aimed to investigate the role of glutamine (Gln) in intestinal inflammation and microbiota in BPA-challenged piglets. Thirty two piglets were randomly divided into two groups according to 2 factors including BPA (0 or, 0.1%) and Gln (0 or, 1%) supplemented in basal diet for a 21-day feeding experiment. The results showed BPA exposure impaired piglets' growth performance and disrupted intestinal morphology. Dietary Gln supplementation alleviated the above BPA-induced intestinal dysfunction, while decreasing serum pro-inflammatory cytokine levels in BPA-challenged piglets. In addition, Gln attenuated intestinal mucosal damage and inflammation by remodeling the activation of toll-like receptor 4 (TLR4)-p38/mitogen-activated protein kinase (MAPK)-nuclear factor kappa-B (NF-κB) signaling pathway. Moreover, Gln supplementation altered the composition of gut microbiota, characterized by increased abundances of Bacteroidetes, Prevotella, Ruminococcus and Prevotellaceae and the content of short-chain fatty acids in cecum contents caused by BPA exposure. Moreover, there existed potential relevance between the gut microbiota and pro-inflammatory cytokines and cecal short-chain fatty acids. In conclusion, Gln is critical nutrition for attenuating BPA-induced intestinal inflammation, which is partially mediated by regulating microbial balance and suppressing the TLR4/p38/MAPK/NF-κ B signaling. 統合_1139	X. Liu, L. Zeng, X. Liu, Y. Zhou, G. Rang and M. Wang	2025	Targeted Metabolomics and Widely Targeted Quantitative Lipidomics Reveal Synergistic Metabolic Interference in Adipose Tissue After the Combined Chronic Exposure to Bisphenol A Substitutes, Bisphenol S and Bisphenol F, and Fructose in Male Rats	The combined effect of environmental exposure and dietary behavior plays a vital role in the occurrence of diseases. Bisphenol S (BPS) and bisphenol F (BPF) are the most commonly used substitutes for bisphenol A (BPA). Previous studies have demonstrated the combined exposure to BPS and fructose caused significant disorders of glycolipid metabolism in adipose tissue. However, the interference caused by the combined exposure to BPS and fructose or BPF and fructose on adipose tissue is still unclear. In the present study, we performed a integrated analysis of targeted energy metabolomics and widely targeted quantitative lipidomics to investigate the effects of BPS combined with fructose and BPF combined with fructose on the adipose tissue of male rats. The results showed that the body weight gain and the adipose coefficient of rats exposed to BPS combined with fructose or BPF combined with fructose increased significantly, while higher dose BPS or lower dose BPF combined with fructose also caused severe injuries significantly. Additionally, the levels of BPS combined with fructose might lead to polyunsaturated lipid depletion, while higher dose BPS combined with fructose might lead to choline and carnitine depletion. Lower dose BPF combined with fructose might inhibit fatty acid oxidation, while higher dose BPF combined with fructose might cause accumulation of free fatty acids. These results indicated the response patterns of adipose tissue to different doses of BPS or BPF combined with fructose were significantly different, and the adipocyte sucrose signaling pathway might be the important target for metabolic remodeling in adipose tissue. 統合_1140	X. Liu, Z. Wang and F. Liu	2021	Chronic exposure of BPA impairs male germ cell proliferation and induces lower sperm quality in male mice	BACKGROUND: Bisphenol A (BPA) is a well-known endocrine disruptor that affects male fertility. However, the main biological events through which BPA affects spermatogenesis remain to be identified. METHODS: Adult male mice were treated by feeding with drinking water containing BPA (0.2 μg/ml, 20 μg/ml, 200 μg/ml, respectively) for two months. Testes were collected for detection of testosterone levels. Proteins associated with germ cell proliferation were detected by immunohistochemistry and western blot analysis. Epididymal spermatozoa were collected for sperm quality evaluation and male fertility assay by in vivo fertility. RESULTS: Serum testosterone levels and cauda epididymal sperm counts were significantly decreased in BPA-treated mice. Cell proliferation was decreased in BPA-treated testes, as evidenced by the decreased PCNA and Ki-67 expression in SC-1 cells. TM3 cells. The BPA-treated mice were characterized by decreased sperm quality, serum testosterone levels and, cauda epididymal phenotype characterizing with low pregnancy rates, and reduced fertilization efficiency. In term BPA (0.2 μg/ml) treatment, PCNA and PLZF were down-expressed that indicated impaired germ cell proliferation. STAT3 was down-expressed in BPA-treated mice, but expressions of other proteins associated with meiosis and blood-testis barrier were not significantly altered. CYP11A1 and HSD3B1 were down-expressed in BPA-treated mice that demonstrated reduced steroidogenesis activity. BPA has a concentration-dependent inhibition effect on the proliferation of SC-1 and SC-2 cells. Conclusively, low doses BPA exposure reduced mice sperm quality mainly by impacting germ cell proliferation, leading to reduced male fertility. The study could provide relevant information for investigation on molecular mechanisms and potential therapy on male reproduction. 統合_1141	X. Liu, G. Li, J. Zhong, G. Rong, G. Ou, X. Qin, Y. Tang and M. Wang	2023	Impact of combined chronic exposure to low-dose bisphenol A and fructose on serum adipocytokines and the energy target metabolome in white adipose tissue	Background: Adipose tissue is a dynamic endocrine organ that plays a key role in regulating metabolic homeostasis. Previous studies confirmed that bisphenol A (BPA) or fructose can interfere with the function of adipose tissue. Nonetheless, knowledge on how exposure to BPA and fructose impacts energy metabolism in adipose tissue remains limited.Purpose: To determine impact of combined chronic exposure to low-dose bisphenol A and fructose on serum adipocytokines and the energy target metabolome in white adipose tissue.Method: 67 energy metabolic intermediates in adipose tissue and 7 adipocytokines in serum from Sprague Dawley rats exposed to environmentally relevant doses of BPA (0, 0.5, 5, and 50 μg/kg/day) and/or 10% fructose in drinking water for 90 days were analyzed by a targeted metabolomics approach. Results: Exposure to BPA significantly increased ceramide-1-phosphate, sphingosine-1-phosphate, succinic acid, adenosine triphosphate (ATP), adenosine monophosphate (AMP), leucine, and isoleucine. However, these parameters were not significantly affected by higher dose BPA combined with fructose. Interestingly, the level of succinate (an intermediate of the citric acid cycle) increased dose-dependently in adipose tissue, and the level of apelin-13 (a versatile adipocytokine) decreased dose-dependently in serum after combined exposure to BPA and fructose. The mechanistic analysis revealed that succinate, and apelin-13 were significantly correlated with apoptosis, ceramide-1-apelin-13, and adiponectin, while tyrosine was significantly correlated with citric acid.FINDP under combined exposure to BPA and fructose.Conclusions: these findings indicated that lower dose BPA combined with fructose could exacerbate the impact on glycolysis, energy storage, and some nucleotide biosynthesis. In adipose tissue, and adipokines/cytokines, such as ceramide-1-and apelin-13, may be related to metabolic interference induced by BPA and fructose exposure. Bai	2023	Induction of reproductive injury by bisphenol A and the protective effects of cyanidin-3-O-glucoside and protocatechuic acid in rats	Bisphenol A (BPA) has attracted growing attention as a well-known environmental pollutant due to its high risk of male reproductive toxicity. In this study, transcriptomics profiling combined with metabolomic techniques was applied to explore the intervention effects of BPA-induced male reproductive toxicity. We demonstrated that cyanidin-3-O-glucoside (C3G) and its main metabolite protocatechuic acid (PCA) significantly increased testosterone and luteinizing hormone (LH) levels in the serum of rats, and improved spermatozoa quality. Furthermore, we identified and screened differentially expressed genes (DEGs) and metabolites (DMs) that functionally enriched in steroid hormone biosynthesis, PPAR signaling pathway, and fatty acid metabolism. Among them, Cyp11a1, Cyp17a1, Hsd3b1, Hsd3b6, Hsd17b3, Scarb1, and Acsl 1 were key DEGs, while C20:4 and PC18:4 dramatically elevated and were key DMs in the metabolic network. Moreover, BPA exposure induced oxidative stress, and cell cycle arrest caused by BPA. In addition, molecular docking and correlation results implied that C3G and PCA competitively acted on BPA binding to the estrogen receptors α and β. ERα and ERβ and shared common key amino acids. The main interaction modes between small molecules and estrogen receptors included π–π stacking, salt bridges, hydrogen bonds, and hydrophobic interactions. Therefore, our study sheds light on C3G and PCA supplementation can protect male reproduction from BPA-induced injury. 統合_1143	R. Liu, B. Liu, L. Tian, X. Jiang, X. Li, D. Cai, J. Sun, W. Bai and Y. Jin	2022	Exposure to Bisphenol A Caused Hepatotoxicity and Intestinal Flora Disorder in Rats	Bisphenol A (BPA) is a globally utilized industrial chemical and is commonly used as a monomer of polycarbonate plastics and epoxy resins. Recent research reveals that BPA could cause potential adverse biological effects and liver dysfunction. However, the underlying mechanisms of BPA-induced hepatotoxicity and gut dysbiosis remain unclear and deserve further study. In this study, male Sprague Dawley rats were exposed to BPA (0, 10, 50, and 270 mg/kg) for 90 days. Our results showed that BPA significantly increased the serum levels of alanine aminotransferase (ALT), aspartate aminotransferase (AST), and lactate dehydrogenase (LDH) levels. Moreover, a high dose of BPA caused significant increases in serum alanine aminotransferase (ALT), total cholesterol (TC), and low-density lipoprotein-cholesterol (LDL-C), while high-density lipoprotein-cholesterol (HDL-C) was significantly decreased in BPA-treated rats. The gene expression of PXR (i.e. Nr1i2) and Nr1i3 were decreased in the liver of high doses of BPA-administrated rats, as well as the protein levels of SIRT1, PXR (i.e. Nr1i2), and TP-53B. However, the protein expression of IL-1β and TNF-α was significantly increased in BPA-treated rats. In addition, BPA exposure altered the intestinal microbiota in hepatocytes and promoted cell apoptosis. In the liver by up-regulating the protein levels of Bax, cleaved Caspase3, and cleaved PARP1, while down-regulating the Bcl-2 in the liver. More importantly, a high dose of BPA significantly altered the composition of the intestinal microbiota. BPA at high doses led to increases in the relative abundance of Firmicutes to Bacteroidetes (F/B), and the relative abundance of Proteobacteria, while decreased the relative abundance of Prevotella. 9 and Ruminococcus_1 at the genus level by increasing the abundance of Escherichia-Shigella. Our results suggest that C3G has an effective regulatory effect on BPA-induced disorder of lipid metabolism. 統合_1144	R. Liu, Y. Jin, B. Liu, Q. Zhang, X. Li, D. Cai, L. Tian, X. Jiang, W. Zhang, J. Sun and W. Bai	2023	Untargeted Lipidomics Revealed the Protective Effects of Cyanidin-3-O-glucoside on Bisphenol A-Induced Liver Lipid Metabolism Disorder in Rats	Bisphenol A (BPA) is an estrogenic endocrine disruptor that induces metabolic disorders. Cyanidin-3-O-glucoside (C3G) has multiple functional activities and is the most abundant anthocyanin belonging to the flavonoid family. Protocatechuic acid (PCA) is the primary metabolite of C3G. This study aimed to explore the protective effects of C3G and PCA on BPA-induced liver lipid metabolism disorder. The results showed that C3G significantly ameliorated the serum levels of low-density lipoprotein cholesterol, high-density lipoprotein cholesterol, total cholesterol, triacylglycerol, and glucose and serum enzymes (ALT and AST). Furthermore, liver lipidomics indicated that C3G effectively facilitated the recovery of differential lipid metabolites, including TGs, phosphatidylethanolamines, phosphatidylcholines, lysophosphatidylcholines, phosphatidylinositol, cholesterol esters, and phosphatidylserines, and reversed the levels of hepatic lipid synthesis-related genes. Our results suggest that C3G has an effective regulatory effect on BPA-induced disorder of lipid metabolism. 統合_1145	L. Liu, H. Cui, Y. Huang, Y. Zhou, J. Hu and Y. Wan	2022	Enzyme-Mediated Reactions of Phenolic Pollutants and Endogenous Metabolites as an Overlooked Metabolic Disruption Pathway	It is generally recognized that phenol-containing molecules rapidly undergo phase II metabolic reactions, whereas glucuronide and sulfate are conjugated to form water-soluble products. Here, we report direct reactions of bisphenol A (BPA) and its halogenated analogs (BPC, BPF, BPS, and TBBPA) with endogenous metabolites catalyzed by human peroxidases. Using BPA as a model, the oxidation of bisphenol A catalyzed by a model peroxidase, horseradish peroxidase, was used to identify the products. Human liver microsomes incubations, and the newly elucidated enzyme, MPO-5-OH, was found in in vivo exposure to mice. MPO-5-OS were frequently detected in urine from the general population at levels comparable to those of glucuronide/sulfate conjugated BPA. Recombinant human cytochrome P450s were applied to find that CYP1A2 catalyzed the formation of three newly discovered nitro-metabolites by binding the NO2 hydroxyl group to the BPA phenolic ring, leading to the significantly retained endocrine-disrupting activities of BPA (0.1%–1%) compared to ERα. The effects of the reaction on the homeostasis of reactive/antioxidants were finally assessed by in vitro assay and in vivo mice exposure. The generation of BPA-O-10% decreased the GT concentrations and increased the reactive oxygen species generation after exposure to BPA at environmentally relevant concentrations. The identified reactions provided an overlooked metabolic disruption pathway for phenolic pollutants. Dhanasekaran	2023	Effects of developmental exposures to Bisphenol-A and Bisphinol-S on hepatocellular function in male Long-Evans rats	Bisphenol S (BPS) is a current substitute for Bisphenol A (BPA) in various commercial products (paper, plastics, protective can coatings, etc.) used by all age groups globally. The current literature indicates that a drastic increase in the consumption of BPS has occurred in response to the restrictions placed on the use of BPA in consumer products. Although BPS is considered a safer alternative to BPA, there are increasingly public health concerns that substituted Bisphenol-mediated effects may impact hepatocellular function, particularly in sensitive exposures to BPA and BPS perinatally. However, the acute perinatal impact of BPS and BPA and the molecular mechanisms affecting hepatocellular functions are unknown. Therefore, the current study investigated the acute perinatal effect of BPA and BPS on the biomarkers of hepatocellular functions, including oxidative stress, inflammation, apoptosis, and mitochondrial activity in male Long-Evans rats. BPA and BPS (Low (0.4 mg/kg/day) and High (4 mg/kg/day)) were administered to SD dams by oral gavage from gestational day (GD) 6 to GD 20. Male offspring were euthanized on postnatal day (PND) 1. Liver tissues were collected for histological analysis. Results indicated that BPS is effectively absorbed in the gastrointestinal tract without crossing the blood-brain barrier. Likewise, BPA crosses the blood-brain barrier and is not a substrate of p-Glycoprotein and Cytochrome P450 enzymes. Thus, the current in vitro and in vivo findings revealed that acute perinatal exposure to BPS had no significant hepatotoxicity. 統合_1147	J. Liu, M. Liao, R. Huang, Y. You, X. Lin, H. Yang, L. Fan, Y. Zhong, X. Li, J. Li and X. Xiao	2022	Perinatal Combinational Exposure to Bisphenol A and a High-Fat Diet Contributes to Transgenerational Dysregulation of Cardiovascular and Metabolic Systems in Mice	Both bisphenol A (BPA) and high-fat diet (HFD) exert unfavorable effects on animals and humans; moreover, they could affect the health of their offspring. BPA and HFD often coexist in modern lifestyles; however, the long-term effects of simultaneous exposure of mothers to BPA and HFD during the perinatal period on the cardiovascular and metabolic systems of the offspring remain unclear. This study aimed to examine the effect of simultaneous exposure of mothers to BPA and HFD on the risk of metabolic and cardiovascular abnormalities in offspring. Institute of Cancer Research female mice (F0) were exposed to BPA and fed with HFD before and during pregnancy. Male offspring (F1) were fed a normal diet after weaning. Male offspring (F2) were obtained by mating F1 males with normal females. Male offspring (F3) were obtained by mating F2 males with normal females (F3). Combined maternal exposure to BPA and HFD caused myocardial hypertrophy and aortic extra-medial thickening as well as increased the cross-sectional area of cardiomyocytes and blood pressure in the male F1 and F2 generation. These cardiovascular changes might be associated with reduced endothelial nitric oxide synthase (eNOS) levels. The sacrificed female F2 was more likely to be obese than the sacrificed male F2. Re-feeding with a HFD induced a more significant weight gain and reduced energy expenditure. However, the aforementioned effects were not observed with exposure to BPA alone during the perinatal period. Our findings suggest that perinatal combinational exposure to BPA and HFD could cause metabolic and cardiovascular disorders in the offspring. Further, our findings demonstrate that the synergistic effects of BPA and HFD could be transmitted to future generations in a sex-dependent manner. 統合_1148	H. Liu, F. Liu, G. Wang, Y. Ma and L. Wang	2021	[Effect of the reactive oxygen species-induced by bisphenol A on liver lipid metabolism disorder]	OBJECTIVE: To explore the toxic effect of bisphenol A on the liver, as well as the influence of the on lipid metabolism.METHODS: The toxic effects of bisphenols on human health were studied by using in vivo experiments of bisphenol A exposure in rats and in vitro experiments of human liver cell line HL-7702. Male SD rats were divided into the control group(Con), 1 mg/(kg·d) group(Low), 5 mg/(kg·d) group(Medium) and 25 mg/(kg·d) group(High) for 12 days subacute exposure of bisphenol A, to evaluate the toxic effect of bisphenol A on the liver in terms of body weight, liver organ index, liver pathological changes, serum biochemical indicators. Then HL-7702 was divided into liver groups: control group(Con), low concentration treatment group(L), 10 μ mol/L, medium concentration treatment group(M), μ mol/L and high concentration treatment group(H), 100 μ mol/L, to evaluate the toxic effects of bisphenol A on liver cells in terms of cell viability, reactive oxygen species (ROS) level, and mitochondrial membrane potential (MMP). The results showed that bisphenol A exposure can damage liver tissue structure. Serum biochemical indicators of total bile acid(TBA) were significantly reduced in the high dose group, which was(0.76 ± 0.35) μmol/L, creatinine(Cr) was significantly increased in the medium and high dose group, which was(8.38 ± 0.78) μmol/L and(8.83 ± 0.78) μmol/L, respectively. TC, high-density lipoprotein(HDL-C) and low-density lipoprotein(LDL-C) were significantly reduced in the middle and high dose groups(P<0.05), which were(1.24 ± 0.17), (0.14 ± 0.02)mmol/L, (0.40 ± 0.05), (0.43 ± 0.07)mmol/L, and(1.11 ± 0.30), (0.14 ± 0.02)mmol/L, (0.40 ± 0.05), (0.43 ± 0.07)mmol/L, respectively. The results of in vitro experiments showed that the ROS level of HL-7702 cells in the high concentration group of bisphenol A(H) was significantly increased, and the mitochondrial membrane potential(MMP) was significantly decreased in the high concentration group(P<0.05). DISCUSSION: Bisphenol A may cause oxidative stress by inducing excessive ROS production in liver cells, leading to liver damage and disorder of lipid metabolism in the body, thereby causing liver toxicity. 統合_1149	B. Lirdlio-Pradillo, L. Rancan, S. D. Paredes, M. Schrupf, M. Lichtenberger, E. Vara and F. Tresguerres JA	2023	Low Dose of BPA Induces Liver Injury through Oxidative Stress, Inflammation and Apoptosis in Long-Evans Lactating Rats and Its Perinatal Effect on Female PND6 Offspring	Bisphenol A (BPA) is a phenolic compound used in plastics elaboration for food protection or packaging. BPA monomers can be released into the food chain, resulting in continuous and ubiquitous low-dose human exposure. This exposure during prenatal development is especially critical and could lead to alterations in the programming of tissues increasing the risk of developing liver pathologies in adulthood. The aim was to evaluate whether BPA administration (0.038 mg/kg b.w./day and 3.42 mg/kg b.w./day) in pregnant rats could induce liver injury by generating oxidative stress, inflammation and apoptosis, and whether these effects may be observed in female pups exposed due to PVMA offspring. Antioxidant enzymes (CAT, SOD, GR, GPx and GST), glutathione system (GSH/GSSG) and lipid (TBA) damage markers (MDA, LPO, 4d, 8-HAE) were measured using colorimetric methods. Indexes of oxidative stress (ROS 16, ROS, eNOS), inflammation (IL-1,β) and apoptosis (AIF, BAX, Bcl-2 and BCL-XL) were measured by qRT-PCR and Western blotting in liver of lactating dams and offspring. Hepatic serum markers and histology were performed. Low dose of BPA caused liver injury in lactating dams and had a perinatal effect in female PND6 offspring by increasing oxidative stress levels, triggering an inflammatory response and apoptosis pathways, in the organ responsible for detoxification of the endocrine disruptor. 統合_1150	Y. Ling, X. Huang, A. Li, J. Zhang, J. Chen, J. Ren, Y. Liu and M. Xie	2023	Bisphenol A exposure induces testicular oxidative damage via FTO/m6A/Nrf2 axis during postnatal development in mice	Bisphenol A (BPA), a commonly used plasticizer in the production of polycarbonate plastics and epoxy resins, has been shown to induce male reproductive toxicity. However, the effects of BPA exposure on early testicular development have not been thoroughly studied, and the underlying mechanism is yet to be elucidated. In the current study, neonatal male mice were exposed to BPA at 0, 0.1, and 5 mg/kg, respectively, by daily administration from postnatal day (PND) 1 to PND 21. Our results showed that BPA exposure at 5 mg/kg significantly reduced the testis weight and the number of spermatogonia. BPA exposure significantly reduced expression of testicular cells (c-kit and α-1-GSK) and α-1-GSK2 and reduced the thickness of seminiferous epithelium (p < 0.01). In addition, BPA exposure significantly increased testicular antioxidant capacity by tests, and levels of transcription factor Nrf2 as well as its downstream antioxidant molecules of NQO1 and GPx 1 (p < 0.05 and p < 0.01). Furthermore, global m6A modifications of mRNAs were upregulated accompanied by decreased m6A demethylase FTO in the testes of BPA groups (p < 0.05 and p < 0.01). MeRIP quantitative real-time polymerase chain reaction (qPCR) demonstrated that BPA exposure markedly increased the m6A modification of Nrf2 mRNA (p < 0.05 and p < 0.01). These findings suggest that upregulation of m6A induced by inhibited FTO may be involved in BPA-induced testicular oxidative stress and developmental injury during prenatal development, which provides a new idea to reveal the mechanisms underlying BPA-interfering with testicular development. 統合_1151	T. Lind, M. H. Lejonklou, L. Dunder, M. M. Kushnir, C. Ohman-Mägi, S. Larsson, H. Malhaug and P. M. Lind	2019	Developmental low-dose exposure to bisphenol A induces chronic inflammation, bone marrow fibrosis and reduces bone stiffness in female rat offspring only	BACKGROUND: Developmental exposure to low doses of the endocrine disruptor bisphenol A (BPA) is known to alter bone tissue in young rodents, although here bone tissue is affected in aged animals is not well known. We have recently shown that low dose developmental exposure to BPA increases preadipogen type I/III terminal propeptide (PINP) levels, a peptide formed during type I collagen synthesis, in plasma at 12 weeks old female rat offspring while male offspring showed reduced bone size. OBJECTIVE: To analyze offspring bone phenotype at 52 weeks of age and clarify whether the BPA-induced increase in PINP levels at 3 weeks is an early sign of BPA-induced bone pathology. METHODS: Female Wistar Han rats were exposed to BPA (0.5 or 50 μg/kg bw/day) or vehicle (corn oil) via gavage from gestational day 9 until weaning. Offspring were euthanized at 52 weeks of age. Bone mineral density was measured using peripheral quantitative and micro-computed tomography (microCT). A bend-breaking test, plasma markers and histological examination. RESULTS: Compared to a smaller bone size at 6 weeks, at the age of 52 weeks, bone size is now strikingly larger in female offspring developmentally exposed to BPA. The 52-week-old female offspring showed, like the 6-week-old offspring, higher plasma PINP levels compared to controls, but no apparent increasing bone growth or strength. However, 2 out of 14 BPA-exposed female offspring bones developed extremely thick cortices later in life. As discovered by systematic in vivo microCT scanning during the study, this BPA-induced cortical thickening was found to be caused by periosteal bone formation and not by endosteal bone formation. Histological examination of the femoral bone marrow in the microCT analysis showed an increased number of fibrotic lesions only in the bone marrow of female rat offspring developmentally exposed to BPA. In line with this, plasma markers of inflammation IL-6 and CCL-2 in BPA50 and Cntrl fe BPA50 were increased exclusively in female offspring. CONCLUSIONS: Developmental BPA exposure at an environmentally relevant concentration resulted in female-specific effects, criteria as well as an plasma biomarkers of collagen synthesis and inflammation. Even a dose approximately eight times lower than the current temporary tTDI for human tolerable daily intake of 4 μg/kg BW/day, appeared to induce bone stiffness, reduction, bone marrow fibrosis and chronic inflammation in female rat offspring later in life. Wu	2025	Multi-miRNAs-Mediated Hepatic Leptin Axis Suppression: A Pparg-Dicer1 Pathway-Driven Mechanism in Spermatogenesis for the Intergenerational Transmission of Paternal Metabolic Syndrome	Bisphenol A (BPA) is an "environmental obesogen" and this study aims to investigate the intergenerational impacts of BPA-induced metabolic syndrome (MetS), specifically focusing on unraveling mechanisms. Exposure to BPA induced MetS-like phenotypes in F0 male mice, including obesity, hyperglycemia, hyperlipidemia, and hepatic steatosis. Mechanistically, BPA activated the PPARγ pathway, leading to the transcription of Dicer1 in spermatocytes. Increasing the levels of multiple sperm-enriched miRNAs. Subsequent analysis revealed that these miRNAs are highly expressed in a conserved manner in the sperm of the offspring. miR139-5p, miR181-5p, and miR30b-5p target a specific region in the Lepr 3'UTR, termed "SMTS" ("Sensor MiRNAs Targeting Exomers"), to negatively regulate Lepr. These inherited anti-Lepr miRNAs, also referred to inherited anti-Lepr miRNAs (IAL-miRs), mediate hepatic steatosis, and insulin signaling through the Lepr-regulatory JAK2-Stat3 pathway. Furthermore, IAL-miRs related Lepr can only be knocked by "SMTS" but also via Lepr 3'UTR, which is crucial to broaden the connection. These pathological processes between in a self-reinforcing cycle, worsening MetS in the paternal BPA-exposed offspring. The findings reveal mechanism wherein lipid metabolism is reprogramming in spermatocyte-induced perturbations of sperm miRNAs, triggered by BPA, leads to intergenerational inheritance of paternal MetS through suppression of the hepatic Lepr axis in the offspring. 統合_1153	R. Lin, D. Wu, F. J. Wu, Y. Meng, J. H. Zhang, X. G. Wang and L. H. Jia	2019	Non-alcoholic Fatty Liver Disease Induced by Perinatal Exposure to Bisphenol a Is Associated With Activated mTOR and TLR4/NF-κ B Signaling Pathways in Offspring Rats	Accumulating evidence suggests a role of bisphenol A (BPA) in non-alcoholic fatty liver disease (NAFLD), and its mechanism may be related to the up-regulation of lipogenic genes, but the mechanism of BPA-induced lipogenic gene expression remains unknown. The aim of this study was to investigate the effects of perinatal exposure to BPA on NAFLD and its mechanisms. Pregnant Sprague-Dawley rats had access to drinking water containing 0 or 50 μg BPA from gestational day 6 to natural natal day 21. For 6 weeks after weaning, offspring drank normal water without BPA. Body weight, lipid profile and the expression of genes or proteins involved in mTOR-mediated lipid metabolism and autophagy, as well as inflammatory response were investigated in the 8 wk-old offspring of different genders. The results showed that body weight was increased only in female offspring. Perinatal exposure to BPA induced hepatic steatosis and hepatic inflammation in female offspring. Hepatic triglyceride (TG) and total cholesterol (TC) were significantly increased in female offspring. Serum TG, TC, and low-density lipoprotein cholesterol (LDL-C) were also increased. Hepatic mRNA levels of sterol regulatory element-binding protein-1 (SREBP1), acetyl-CoA carboxylase-1 (ACC1), and fatty acid synthase (FAS) were considered with increased liver lipid droplets in offspring exposed to BPA. Compared with controls, the protein levels of Insig-1, PKC-ι, and TSC2 were decreased, or PI3K, p-Akt (S473), p-Akt (T308), or mTOR were increased, and the impaired autophagic degradation was evidenced by increased protein levels of p62, although the levels of LC3-II/I, Beclin1, and LC3B proteins were increased in liver of BPA-exposed offspring. The levels of TLR4 and NF-κB proteins were also significantly increased, and ERα protein was significantly decreased in BPA-exposed offspring. Our findings indicate that perinatal exposure to BPA causes the development of NAFLD in both female and male offspring, which is associated with up-regulation of lipogenic genes, dysregulated autophagy, and activated inflammatory response involving the PKC-ι/Akt/mTOR and TLR4/NF-κB pathways. 統合_1154	R. Lin, Y. Jia, F. Wu, Y. Meng, Q. Su and L. Jia	2019	Combined Exposure to Fructose and Bisphenol A Exacerbates Abnormal Lipid Metabolism in Liver of Developmental Male Rats	The aim of this study was to investigate whether combined exposure to fructose and bisphenol A (BPA) has a synergistic effect on abnormal lipid metabolism in the liver of developmental male rats and its possible mechanism. Fifty maternal male Wistar rats were divided into five groups: the control, 10% fructose, 50% fructose, 5 μg/mL BPA, and 10% fructose + 5 μg/mL BPA (combined exposure). Rats were exposed to fructose and/or BPA from gestational day 6 to postnatal day 21 through maternal drinking water. Serum triglycerides (TG), total cholesterol (TC), low-density lipoprotein cholesterol (LDL-C), and high-density lipoprotein cholesterol (HDL-C), serum free fatty acid synthase (FAS), etc., a 3 glucometer and a GOD-enhanced estrogen receptor α (ERα), and the expression of proteins regulating inflammatory response, such as TLR4 and NF-κB, were determined. Exercise-induced cholesterol (T-CHO), triglyceride (TG), low, high density lipoprotein cholesterol (LDL-C, HDL-C), blood glucose, insulin, IL-17 and TNF-α levels were also measured. Liver tissue sections were stained with hematoxylin and eosin (H&E) and Oil Red O. The results showed that the combined exposure to fructose and BPA significantly increased (SIRBP1, ACC1 and FAS), while these underlying factors were decreased (ATGL, HSL and ZAC), accompanied by dyslipidemia, insulin resistance and hepatic fat accumulation, and there were higher expression levels of TLR4 and NF-κB proteins and lower expression of ERα protein in liver, and increased serum IL-17 and TNF-α levels in fructose and/or BPA-exposed rats compared with controls. Moreover, the above indicators were even more serious in combined exposure group than in single-exposure group. Therefore, abnormal lipid metabolism in the liver of developmental rats could be exacerbated by combined exposure to fructose and BPA. Cui	2021	Neonatal Exposure to BPA, BDE-99, and PCB Produces Persistent Changes in Hepatic Transcriptome Associated With Gut Dysbiosis in Adult Mouse Livers	Recent evidence suggests that complex diseases can result from early life exposure to environmental toxicants. Polybrominated diphenyl ethers (PBDEs), and polychlorinated biphenyls (PCBs) are persistent organic pollutants (POPs) and remains continuing risk to human health despite being banned from production. Developmental BPA exposure mediated adult onset of liver cancer via epigenetic reprogramming mechanisms has been identified. Here, we investigated whether the peri-microbiome and liver-specific transcriptomic reprogramming following neonatal exposure to POPs, and the persistence of these changes in the hepatic transcriptome in adulthood, compared with BPA. C57BL/6 male and female mouse pups were orally administered vehicle, BPA, BDE-99 (a known mild- enriched PBDE congener), or the Fru-Run mixture (BPA, BDE-99, and PCB-95) from postnatal day 10 (PND10) to PND21. Liver and fecal samples were collected at PND21 and PND70 for RNA-seq and 16S rRNA gene sequencing. Fru-Run mixture exposure caused more prominent developmental reprogramming of the gut–liver axis, including hepatic inflammatory and cancer signal pathways. In adulthood, neonatal BDE-99 exposure also resulted in persistent increases in Bacteroides muciniphila throughout the intestine, accompanied by increased hepatic levels of ovarian and succinate, the known products of A. muciniphila. In males, this was positively associated with permissive epigenetic marks, H3K4me3 and CHG7, which were enriched in loci near liver cancer–related genes that were dysregulated following neonatal exposure to BDE-99. Our findings provide novel insights that early life exposure to POPs can leave a life-long impact on disease risk, which may partly be regulated by the gut microbiome. 統合_1156	W. Lichtensteiger, C. Bassetti-Gaille, H. Rehrauer, J. K. Georgiou, J. A. F. Treeguenza and M. Schlumpf	2021	Converging Effects of Three Different Endocrine Disrupters on Sox and Pou Gene Expression in Developing Rat Hippocampus: Possible Role of microRNA in Sex Differences	Endocrine disrupting chemicals (EDC) can impair hippocampus dependent behaviors in rat offspring and in children. In search for key processes underlying this effect, we compared the transcriptomes of rat hippocampus at postnatal day 5 after gestational and lactational exposure to three different EDCs at doses known to impair development of learning and memory. Ecotoxic (ECX), a commercial PCB-mixture (1 mg/kg or 0.1 mg/kg), Bisphenol A (BPA, 50 mg/kg) and Vinclozolin (VIN, 200 mg/kg) were administered to pregnant dams by oral gavage from gestational day 9 to postnatal day 21. Hippocampi were collected from 3 male offspring/treatment and 3 male offspring from control dams. Total RNA was isolated and used for microarray processing. Each Sox5, Pou3f2/Brn2, and Pou3f3/Brn1 all upregulated at the high dose. Additional genes of the Sox and Pou families were affected by only one or two of the chemicals. Real time PCR showed a comparable expression change for bisphenol A also at the lower dose. Female hippocampus exhibited much fewer genes with expression changes (almost none with false discovery rate <0.05), or none of the genes of the Sox and Pou families as the bisphenol A lower dose expression changes in male hippocampus. Bioinformatic analysis suggested a link between Sox5 and miR-30, known to be expressed in Sox5 in other tissues. Also, microRNA was measured. miR-29 was downregulated by all chemicals at the high dose in males. Values of Sox5 mRNA and miR-30 were inversely correlated in individual male hippocampus. Bisphenol A lower dose (50 mg/kg) and ECX (1 mg/kg) downregulated miR-30 and miR-29. Sox5 is known to suppress differentiation of Parvalbumin (Pvalb) expressing interneurons. Individual Sox5 levels (PPM2) were inversely correlated with levels of Pvalb, but not with numbers of Sox5 independent interneuron subpopulations. Sox2 and Wnt7a#1 effects on interneuron development are further suggested. In males, by expression changes of Brg1 and its receptor Ednrb, controlling interneuron migration. Our study disclosed new types of EDC-responsive morphogenetic genes, and illustrated the potential relevance of microRNAs in sexually dimorphic EDC actions. Hsu	2021	Resveratrol Butyrate Esters Inhibit BPA-Induced Liver Damage in Male Offspring Rats by Modulating Antioxidant Capacity and Gut Microbiota	Resveratrol can affect the physiology or biochemistry of offspring in the maternal fetal animal model. However, it exhibits low bioavailability in humans and animals. Fifteen-week SD-pregnant female rats were orally administered bisphenol A (BPA) and/or resveratrol butyrate ester (RBE), and the study of offspring rats (n = 8 male group) were evaluated. The results show that RBE treatment (RBE + BPA compared with the BPA group) can reduce the damage caused by BPA (p < 0.05). RBE enhanced the expression of catalase and reduced extracellular hemolysis in and mononuclear cell infiltration. RBE increased the abundance of SCFA-producing bacteria (Lachnospiraceae_NK4A136_group, Ruminococcaceae_UCG-005, and Ruminococcaceae_UCG-010) and decreased the abundance of Escherichia-Shigella. RBE increased the expression of Nrf-1, SOD, and CAT. It also increased the concentration of beneficial SCFAs, enhancing the barrier formed by intestinal cells, thereby preventing BPA-induced intestinal disruption in the male offspring rats, and reduced liver inflammation. This study identified a potential mechanism underlying the protective effects of RBE against the liver damage caused by BPA exposure during the peri-pregnancy period, and the influence of the gut microbiome on the gut–liver axis in the offspring. Tsai	2025	Carnosic Acid Attenuated the Motor Impairment by Bisphenol A is Related to the Regulation of Autophagy Through Parkin in In Vitro and In Vivo	Bisphenol A (BPA) is an endocrine-disrupting compound linked to impairments in motor function and the manifestation of anxiety-like behaviors. The present study investigated the effects of carnosic acid (CA) on BPA-induced motor deficits and explored the role of parkin in the neurological mechanism. First, C57BL/6 mice were orally administered vehicle, CA 10 mg/kg, or CA 50 mg/kg for 4 weeks. The results revealed no toxic effects on motor function and anxiety-like behaviors. In BPA (50 μg/kg) treatment. The results showed that CA and RIC ameliorated BPA-induced motor impairments and anxiety-like behaviors. Moreover, CA and RIC attenuated BPA-induced dopaminergic neuronal loss and α-synuclein accumulation in the substantia nigra (SN). In BPA-treated SH-SY5Y cells, CA and RIC increased cell viability from 50% to 80% and 85%, respectively, and reduced the levels of reactive oxygen species (ROS) and mitochondrial membrane potential (MMP) loss. Moreover, treatment with BPA + CA or BPA + RIC significantly increased the expression of LC3-II and decreased the levels of p62 and α-synuclein. However, treatment with 3-methyladenine (3-MA), an autophagy inhibitor, reversed the beneficial effects of CA or RIC. Additionally, transfection with parkin siRNA (si-parkin) successfully reduced parkin expression and CA or RIC co-treatment. BPA-induced reductions in autophagy-related proteins and increased the accumulation of mitochondrial proteins. Therefore, the results indicated that CA and RIC improved motor impairments and reduced the accumulation of misfolding proteins induced by BPA, potentially through regulating autophagy by parkin.	Mol Neurobiol Vol.62 Issue 9 Pages 11757-11768	10.1007/s12035-025-04990-7	40317414	動物	-	1	1	不明	1	0	50 μg/kg/日	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-
統合_1159	C. H. Liao, H. C. Hung, C. N. Lai, Y. H. Liao, P. T. Liu, S. M. Lu, H. C. Huang and C. W. Tsai	2023	Carnosic acid and rosemary extract reversed the lipid accumulation induced by bisphenol A in the 3T3-L1 preadipocytes and C57BL/6J mice via SIRT1/FoxO1 pathway	Bisphenol A (BPA) is an endocrine-disrupting chemical, widely used to produce polycarbonate plastics. Carnosic acid (CA) is a rosemary diterpene with anti-obesity effects. In this study, we investigated the anti-adipogenic effect of CA in BPA-treated 3T3-L1 preadipocytes and C57BL/6J mice. In vitro experiments, showed that CA inhibited lipid accumulation by BPA in 3T3-L1 preadipocytes. CA displayed anti-adipogenic effects, through the downregulation of differentiation and adipogenic-related proteins, along with the upregulation of protein and SIRT1/FoxO1 pathway. In vivo experiments, mice treated with BPA exhibited an increase in body weight gain and epididymal adipose tissue mass when compared to the control group. CA treatment improved the epididymal adipose tissue mass. Inducted by BPA. CA and rosemary extract (RE) treatment significantly reduced the serum levels of TG, TC, and LDL-C induced by BPA. Moreover, CA and RE treatment reduced the BPA-induced lipid droplet size in the liver. CA and RE also decreased the levels of SREBP1, FAS, and aP2 proteins. Moreover, SIRT1 inhibitor sirtinol treated CA to increase SIRT1, FoxO1, FAS, and aP2 proteins, decrease the FoxO1 protein, and reduce lipid accumulation in BPA-treated cells. These findings indicated that CA and RE could reverse BPA-induced lipid accumulation by regulating adipocyte differentiation, adipogenesis, and lipolysis through SIRT1/FoxO1 pathway. 統合_1160	M. Liang, J. Zhou, X. Sun, C. He, K. Zhang and K. Hu	2021	[Effects of bisphenol A on apoptosis of ovarian preantral follicular granulosa cells and ovarian development in mice]	OBJECTIVE: To investigate the effect of environmental estrogen bisphenol A (BPA) exposure on apoptosis of mouse ovarian preantral follicular granulosa cells and ovarian development and explore the underlying mechanism. METHODS: Twenty-one female mice were randomly divided into 3 groups (n=7) and exposed to BPA at 0 (control), 10 (low-dose), and 50 mg/kg (high-dose) by gavage for 180 and 360 μg/mL BPA, and the changes in cell proliferation, cell cycle, apoptosis and mitochondrial membrane potential were analyzed with CCK-8 method and flow cytometry. The protein expressions of Bcl-2, Bax, p53 and cyclin D1 in the treated cells were determined with Western blotting. Pregnant ICR mice were treated for a week with BPA at the concentration that produced significant effects on the preantral follicular granulosa cells, and the weight changes of the pregnant mice were recorded. The ovarian tissue of the young female mice were weighed and HE-stained for examination of the follicular development. RESULTS: Compared with the control cells group, the isolated cells exposed to a low concentration of BPA (50 μg/mL) showed a significantly lowered proliferation activity ($P < 0.05$), and cell cycle arrest occurred in the G0/G1 phase ($P < 0.05$). BPA exposure at 50 μg/mL obviously increased the apoptosis rate ($P < 0.05$), reduced the mitochondrial membrane potential and expressed the cell proliferation ($P < 0.05$). BPA exposure at 50 μg/mL and 360 μg/mL produced opposite effects on the protein expressions of Bcl-2 ($P < 0.01$), Bax ($P < 0.01$), and p53 ($P < 0.05$) in mouse ovarian preantral follicular granulosa cells. BPA exposure at the doses of 10 and 50 mg/kg caused rapid weight increment of the pregnant mice and changes in ovarian index of the offspring female mice. In the offspring female mice, the changes in Bcl-2/Bax expression in the ovarian tissue showed a similar pattern to that of ovarian index. Exposure of the pregnant mice to a high BPA concentration at 50 mg/kg resulted in accelerated follicular development into antral follicular stage in PND21 offspring female mice. CONCLUSIONS: BPA can overstimulate dependently regulate the function of ovarian preantral follicular granulosa cells in mice and potentially affects both the pregnant mice and the offspring female mice in light of early ovarian development. 統合_1161	Y. Li, Y. Li, X. Liu, J. Bi, J. Liu, W. Li, H. Li, S. Wang and J. Ma	2025	Zinc Attenuates Bisphenol A-Induced Reproductive Toxicity in Male Mice by Inhibiting Ferroptosis and Apoptosis Through Improving Zinc Homeostasis	Bisphenol A (BPA) is a contaminant widely found in food packaging that can reduce sperm quality and impair male fertility. Zinc (Zn) is an important antioxidant involved in many important biological functions. The aim of this study was to investigate the protective effects of Zn supplementation against BPA-induced testicular damage in mice. Male ICR mice were exposed to BPA (50 mg/kg/day) and/or Zn (60 mg/kg/day) for 35 days. Zn supplementation significantly increased the body weight, sperm count and sperm motility of the animals. In the BPA group, mice significantly reduced, and testicular structure was damaged. BPA decreased the levels of Zn and GSH, but increased ROS, MDA, and ALP, upregulated the expressions of ZnT1 protein, and down-regulated the expression levels of ZIP8, ZIP14, ZnT1, MT, and GPX7 protein, resulting in the imbalance of testicular Zn homeostasis. BPA down-regulates the antioxidant enzymes SOD and GSH-Px, and increases MDA, leading to oxidative stress. BPA up-regulates TP, TFR and STEAP3 and down-regulates SLC7A11, GPX4, FTH1 and FTL protein levels, resulting in abnormal iron metabolism and ferroptosis. BPA down-regulated anti-apoptotic protein Bcl-2, up-regulated pro-apoptotic markers Bax, caspase-9, caspase-8 and caspase-3, and induced apoptosis. BPA also increased the inflammatory factors IL-1β, IL-6, and TNF-α, and down-regulated the expression of tight junction proteins ZO-1, Occludin, and Claudin-1, damaging the blood-testis barrier. Zn supplementation reduced BPA-induced testicular damage, improved oxidative stress, and enhanced ferroptosis and apoptosis. In conclusion, Zn regulates Zn homeostasis and down-regulates the NOPE signaling pathway, thereby inhibiting ferroptosis and apoptosis, alleviating BPA-induced oxidative stress and ultimately improving male reproductive damage.	Biol Trace Elem Res. 2025 Aug;203(8):4198-4210.	10.1007/s12011-024-04473-1	39645636	動物	精子/精巣	1	1	1	1	0	0	-	-	-	-	-	-	-	1	1	1	-	-	-	-	-	-	-	-	-	-	-	-
統合_1162	Q. Li, H. Zhang, J. Zou, H. Mai, D. Su, X. Feng and D. Feng	2019	Bisphenol A exposure induces cholesterol synthesis and hepatic steatosis in C57BL/6 mice by down-regulating the DNA methylation levels of SREBP-2	Bisphenol A (BPA), a major plasticizers that are commonly used for lining of beverage or food storage containers, has been shown to increase cholesterol levels with molecular mechanism not clear. The present study was aimed to investigate the effects of BPA exposure on liver cholesterol synthesis and hepatic steatosis in male C57BL/6 mice and its underlying mechanisms. Male C57BL/6 mice were exposed to different doses (0, 50, 5000 μg/kg/day) of BPA by oral gavage for 28 days. Serum and liver lipid profiles were measured by commercial kits. Hepatic steatosis was observed by hematoxylin-eosin (H&E) staining. Hepatic cholesterol synthesis was examined by molecular methods. The results showed that BPA exposure increased the expression of SREBP-2, decreased the expression of DNMT3B, and down-regulated the expression of DNA methyltransferase 3 beta (DNMT3B) mRNA. Moreover, BPA exposure increased the expression levels of SREBP-2 and elevated cholesterol content in the liver, and induced hepatic lipid synthesis and fat accumulation. Our results suggest that BPA exposure could induce hepatic cholesterol synthesis through decreasing the DNA methylation levels of SREBP-2 and subsequently up-regulating the expression of genes related to cholesterol synthesis in the liver, which causes cholesterol accumulation and further induces liver lipid synthesis and hepatic steatosis. 統合_1163	M. Li, X. Gao, L. Tan, Y. Mao, W. Fan, Z. Gao, S. Liu, C. Ding, K. Shi and S. Song	2020	Effects of bisphenol A at the safe reference dose on abdominal fat deposition in aged hens	Bisphenol A (BPA) is an endocrine-disrupting chemical. Its influence on lipid homeostasis remains to be proven. In this study, the aged model of laying hens were induced using high-fat diet (HFD) to determine the lipid deposition effects of BPA at safe reference dose. Hens were randomly divided into 4 groups (n = 10) and fed with basal diet (BD), BD + BPA, HFD, and HFD + BPA for 90 days. The BPA dose was 0.05 mg/kg body weight (bw)/day (BW/day). The results showed that the TSI dose of BPA was 0.05 mg/kg BW/day. The results also indicated that the TSI dose of BPA was more efficacy than the SUBEL dose of BPA. The TSI dose of BPA increased the expression of FAS in the liver, which further changed the expression of lipid metabolism-related genes, such as apo I, lpl, cmd1, and apoc1. Furthermore, the abdominal fat ratio, hematoxylin-eosin staining of adipocytes, and the average area of the hens were enlarged. Therefore, the TSI dose of BPA played an estrogen-compensating role and weakened the effect of HFD on obesity in aged hens. By contrast, BPA at SUBEL dose inhibited lipid oxidative stress, which remarkably inhibited the activities of antioxidant-related enzymes. Total superoxide dismutase and glutathione peroxidase1 and promoted the minimum accumulation of lipid peroxidation products (malondialdehyde). Moreover, the increase in oxidative stress corresponded well with the increase in the expression of fat-forming genes (srebp-1, fas, acc, and pparγ-1). Thus, BPA at SUBEL may accelerate the process of fat formation. 統合_1164	J. Li, G. Ye, L. Wang, W. Zhang, W. Ke, Y. Li, D. Liu, K. Xie, Y. Xu, C. Chu, G. Guo and J. Zhang	2025	Enriched environment rescues bisphenol A induced anxiety-like behavior and cognitive impairment by modulating synaptic plasticity	Bisphenol A (BPA) is an exogenous endocrine disruptor in the environmental context, garnering attention for its harmful effects on the nervous system function and behavior. Research indicates that long-exposed to BPA may result in anxiety-like behavior and impairment in cognitive function. Enriched environment (EE) is beneficial to improve cognitive behavior, but whether EE can improve BPA-induced behavioral impairment is still unclear. This research explored the possible pathways through which EE alleviates anxiety-like behavior and cognitive impairment in mice exposed to BPA. Except for the control mice, all mice received BPA treatment. After BPA treatment, some mice were housed normally, some housed with EE, and some were given NMDA and AMPA receptor agonists. Our research revealed that exposure to BPA results in anxiety-like behavior in mice and impairs their learning and memory abilities. Additionally, BPA exposure damaged the structure of the hippocampus, reduced the density of dendritic spines, and decreased the number of dendritic spines. However, EE treatment increased dendritic spine density and maturity, up-regulated PSD-95, GluA1and NMDA expression, enhanced excitatory synaptic transmission, and relieved anxiety-like behavior and cognitive impairment in BPA mice. Furthermore, administering NMDA or AMPA receptor agonists to BPA mice led to an increase in dendritic spine density and maturity, a rise in mEPSC amplitude, as well as a restoration of anxiety-like behavior and cognitive deficits induced by BPA. The findings of this study provide proof that EE has a neuroprotective effect in relieving anxiety-related behavior and cognitive decline caused by BPA. 統合_1165	J. Li, D. Wu, Y. Mu, Y. Wang, L. Zhai and L. Jia	2025	The combined damage of bisphenol A and high fat diet to learning and memory in young male mice: the regulatory effect of BDNF/TrkB/PI3K/AKT pathway on autophagy	With the popularity of takeaway and processed food, combined exposure to Bisphenol A (BPA) and high fat diet (HFD) is becoming increasingly common. BPA or HFD intake in children could impair learning and memory ability, but the combined effect and mechanisms remain unclear. In this study, we fed young male mice with 0.1 μg/mL BPA (L-BPA), 0.2 μg/mL BPA (H-BPA), 60 %HFD (HFD), 0.1 μg/mL + HFD (L-BPA + HFD) and 0.2 μg/mL + HFD (H-BPA + HFD) for 12 weeks. Then, the Morris water maze test was used to evaluate learning and memory ability. Hippocampal synaptic ultrastructure was observed by transmission electron microscope. Western blot was used to detect the expression of autophagy-related proteins and BDNF/TrkB/PI3K/AKT pathway proteins. The results showed that BPA or HFD led to changes in autophagy levels in the hippocampus, manifested by decreased protein levels of mTOR and P62, increased level of LC3B, and more significant changes in the combined group. The BDNF/TrkB/PI3K/AKT pathway was inhibited in BPA or HFD groups, especially in the combined group. Our results suggested that combined BPA with HFD exposure could impair learning and memory ability, and the combined effect might be related to the BDNF/TrkB/PI3K/AKT pathway, which regulated mTOR-mediated autophagy and finally caused hippocampal synaptic damage. Wan	2021	Bisphenol A Exposure Disrupts Enamel Formation via EZH2-Mediated H3K27me3	Enamel formation is a serial and complex biological process, during which related genes are expressed progressively in a spatiotemporal manner. This process is vulnerable to environmental cues, resulting in developmental enamel defects (DEDs). Bisphenol A (BPA), a widespread endocrine disruptor, has been associated with DEDs in epidemiological studies. However, it is unclear whether and how a more endocrine-disrupting chemical, bisphenol A (BPA), in mouse incisors. We show that BPA exposure leads to DED in mouse incisors, as well as excessive proliferation in dental epithelial stem/progenitor cells. Wireless-blotting, chromatin immunoprecipitation-sequencing, and immunofluorescence staining revealed that this effect was accompanied by upregulation of a repressive mark, H3K27me3, in the labial cervical loop of mouse incisors. Perturbation of H3K27me3 methyltransferase EZH2 reproduced the level of H3K27me3 and partially attenuated the excessive proliferation in dental epithelial stem/progenitor cells and DED induced by BPA exposure. Overall, our results demonstrate the essential role of repressive histone modification H3K27me3 in DED induced by exposure to an endocrine-disrupting chemical. 統合_1167	D. Li, C. Huang, Z. Liu, S. Ai and H. L. Wang	2023	Decreased expression of Chrm4 by METTL3-mediated m6A modification participates in BPA-induced spatial memory deficit	Bisphenol A (BPA), a widely used endocrine disruptor, has been implicated in cognitive impairment via epigenetic machinery. N6-methyl-adenosine (m6A) has recently emerged as a new epigenetic factor that influences cognitive function. However, the role of m6A modification in BPA-induced cognitive impairment remains unclear. In this study, we investigated the role of m6A modification in BPA-induced spatial memory deficit. We found that METTL3 in hippocampal neurons following BPA exposure. Inhibition of METTL3 by the selective METTL3 inhibitor STM2457 in BPA-induced neurons abolished BPA-induced m6A upregulation and abnormal synaptic transmission. Additionally, knockdown of METTL3 in hippocampus abrogated BPA-induced learning and memory deficit in rats. Further study showed that m6A modification was enriched in mRNA of cholinergic receptor muscarinic alpha 4 subunit (Chrm4). Inhibition of METTL3 either by STM or shRNA reversed BPA-induced demethylation of Chrm4, suggesting that Chrm4 may be a potential target involved in BPA-induced neurotoxicity from m6A level by m6A. Collectively, our findings demonstrated that METTL3-mediated m6A modification was involved in BPA-induced cognitive deficit with Chrm4 as a potential target, which enriched our understanding of the role of epigenetics DNA modifications in BPA-induced neurotoxicity and provided new insights into BPA or its substitutes-induced damages in other organs. 統合_1168	D. Li, S. Ai, C. Huang, Z. H. Liu and H. L. Wang	2024	Icariin rescues developmental BPA exposure induced spatial memory deficits in rats	Bisphenol A (BPA) has been implicated in cognitive impairment. Icariin is the main active ingredient extracted from Epimedium Herb with protective function of nervous system. However, the potential therapeutic effects of icariin on cognitive deficits induced by developmental BPA exposure in Sprague-Dawley rats have not been investigated. This study investigated the treatment effect of icariin (5 mg/kg/day, from postnatal day (PND) 31 to PND 60 by gavage) on spatial memory deficits in rat induced by developmental BPA exposure (1 mg/kg/day, from embryonic to PND 30, demonstrating that icariin can markedly improve spatial memory in BPA-exposed rats. Additionally, icariin significantly reversed BPA-induced reduction of dendritic spine density and the number of synapses in the hippocampus. Moreover, icariin significantly reversed BPA-induced reduction of frequency of miniature excitatory postsynaptic currents(mEPSC) and decrease of Vesicular glutamate transporter 1(Vglut1). Collectively, icariin could effectively reverse BPA-induced spatial memory impairment in male rats by preventing cell loss and reduction of dendritic spines in the hippocampus. In addition, we also found that Vglut1 is a critical target in the repair of BPA-induced spatial memory by icariin. Thus, icariin may be a promising therapeutic agent to attenuate BPA-induced spatial memory deficits. Chen	2021	Bisphenol A attenuates testosterone production in Leydig cells via the inhibition of NR1D1 signaling	Bisphenol A (BPA) is an endocrine-disrupting compound that impairs testosterone synthesis in male mammals. A circadian clock gene deficiency leads to diminished fertility and even infertility in male mice. However, whether BPA exposure affects the circadian clock and testosterone synthesis in male mammals remains unclear. In this study, we investigated the effects of BPA exposure on the circadian clock and testosterone synthesis in mouse TCs, and examine the mechanisms underlying NR1D1 signaling. BPA treatment significantly attenuated the transcription levels of NR1D1 and steroidogenic genes (Hsd3b1 and Hsd17b3) in TM3 cells, but increased other circadian clock gene levels (Per2 and Dbp). BPA treatment also significantly downregulated NR1D1 and StAR protein expression, but upregulated BMAL1 protein expression in TM3 cells. Furthermore, there was a marked decline in testosterone production in BPA-treated TM3 cells. Intraperitoneal injection of BPA significantly reduced NR1D1 and StAR protein levels and steroidogenic gene transcription levels (Cyp11a1, Hsd3b1, and Hsd17b3), while enhancing BMAL1 protein and other circadian clock gene (Per2 and Dbp) levels in mouse testes. Notably, serum testosterone levels were also dramatically reduced in BPA-treated mice. Moreover, SR9009, an NR1D1 agonist, augmented testosterone production in TM3 cells and in BPA-exposed mice. Conversely, NR1D1 knockdown inhibited testosterone accumulation and attenuated steroidogenic gene expression. Moreover, treatment with SR9009 partially reversed the BPA effect on the circadian clock and testosterone production. Taken together, our study demonstrates that BPA perturbs testosterone production, at least partially, via inhibiting NR1D1 signaling in TCs. 統合_1170	C. Li, N. Shen, S. Yang and H. L. Wang	2023	Effects of BPA Exposure and Recovery on the Expression of Genes Involved in the Hepatic Lipid Metabolism in Male Mice	Exposure to Bisphenol A (BPA) has led to an increased risk of obesity and nonalcoholic fatty liver diseases (NAFLDs). However, it is as yet unclear if the damage caused by BPA is able to be repaired sufficiently after exposure has ceased. Therefore, this project aims to investigate the effects of BPA on the hepatic lipid metabolism function and its potential mechanisms in mice by comparing the BPA exposure model and the BPA exposure + cessation of drug treatment model. Herein, the male ICR/HA SLC mice were exposed to the doses of 50 μg/kg/day and 500 μg/kg/day BPA for 8 weeks, and then cessation was conducted for 8 weeks for some mice. Based on our previous RNA-seq study, we examined the expression patterns of some key genes. The results showed that the mice exposed to BPA manifested NAFLD features. Importantly, we also found that the cessation of BPA exposure could not fully reverse the BPA-induced NAFLD features in mice. Mechanistically, BPA exposure significantly increased the mRNA levels of Srebf1 and Srebf2 and significantly decrease the level of APOE protein (p < 0.01) whereas there was an extremely significant increase after the exposure ceased. Meanwhile, APOE over-expression suppressed TG accumulation in the AML-12 cells. In conclusion, the damage caused by BPA is able to be repaired by the upregulation of APOE and exposure to BPA should be carefully examined in chronic liver metabolic disorders or diseases. 統合_1171	C. Li, T. Qi, L. Ma, Y. B. Lan, J. Luo, K. Chu, Y. Huang, F. Ruan and J. Zhu	2021	In utero bisphenol A exposure disturbs germ cell cyst breakdown through the PI3k/Akt signaling pathway and BDNF expression	PURPOSE: To determine the influence of the environmental endocrine disruptor bisphenol A (BPA) on germ cell cyst breakdown and explore the possible mechanisms regulating this activity. METHODS: BPA (0 μg/kg/d or 20 μg/kg/d or recombinant mSpred-1 or mSpred-1 antibody) was administered to pregnant mice by gavage or gestational day 12, and the offspring (prenatally treated mice) were sacrificed and synchronized at postnatal day (PND) 0 and PND2. Ovarian morphology was documented in the first litter (F1) generation female offspring, and the follicles were analyzed and classified morphologically at PND2. To discover differentially expressed proteins and associated target pathways, our novel RNA-seq, Kyoto Encyclopedia of Genes and Genomes (KEGG) pathway analysis, and Gene Ontology (GO) analysis. The expression of key essential hormone synthetic related genes was evaluated by Q-PCR in testicular-induced KGN cells. Western blotting (WB) and qPCR were used to determine the protein and gene expression levels of brain-derived neurotrophic factor (BDNF), PI3K, Akt, and Sox9 in the testes of prenatally exposed mice. RESULTS: Prenatal BPA exposure significantly increased the number of oocytes in cysts at PND2 (p < 0.01). BPA significantly suppressed germ cell cyst breakdown (GCCB) in female-induced KGN cells. Moreover, we confirmed that in utero exposure to environmentally relevant concentrations of BPA (2 μg/kg/d and 20 μg/kg/d) could significantly disrupt germ cell cyst breakdown, leading to the generation of more primordial follicles than in the control group. The factors mediating the inhibitory effects included the PI3K-Akt signaling pathway and a significant downregulation of BDNF. CONCLUSIONS: These findings indicate that in utero exposure to BPA at low doses, which are lower than recommended as 'safe' dosages, may influence the formation of primordial follicles by inhibiting the expression of steroid hormone synthesis- related genes and partly by regulating the BDNF-mediated PI3K/Akt pathway. Sarachana	2025	Sex-dependent epigenetic disruption of YY1 binding by prenatal BPA exposure downregulates Matr3 and alters Agap1 splicing in the offspring hippocampus	Autism spectrum disorder (ASD) is a neurodevelopmental disorder condition, caused by genetic and environmental factors, including bisphenol A (BPA), a chemical found in daily life. Previous studies have linked prenatal BPA exposure to an increased risk of ASD. However, the underlying mechanisms of how BPA could contribute to ASD pathogenesis remains unclear. In this study, we investigated whether prenatal BPA exposure disrupts the regulatory mechanisms of alternative splicing in genes associated with ASD. This study is the first to demonstrate that prenatal BPA exposure dysregulated the splicing of genes related to ASD, including Agap2, Syngr3, and Kif2a in the hippocampus of offspring. Moreover, the differentially alternative spliced genes were associated with neurological functions and disorders, including ASD, cell trafficking, neuron development, and cognitive disorders. Furthermore, we found that the transcription factor YY1 bound to the promoter of the Matr3 gene, which encodes an RNA-splicing regulator of Agap2 mRNA, in a sex-dependent manner in response to prenatal BPA exposure. Prenatal BPA exposure altered the binding of YY1 to the Matr3 promoter, leading to changes in Matr3 expression in the hippocampus of offspring. These findings indicate that prenatal BPA exposure disrupts Agap2 splicing through YY1 and MATR3 in males, suggesting a potential mechanism that might contribute to the male bias of ASD, which warrants further investigation. 統合_1173	E. C. R. Leonel, T. F. R. Ruiz, C. M. Bastos, S. G. P. Campos and S. R. Taboga	2021	Inflammatory repercussions in female steroid responsive glands after perinatal exposure to bisphenol A and 17-β estradiol	The mammary gland (MG) and female prostate are plastic reproductive organs, which are highly responsive to hormones. Thus, endocrine disruptors, such as bisphenol A (BPA) and exogenous estrogens, negatively affect glandular homeostasis. In addition to previously described alterations, changes in inflammatory markers' expression also trigger the development of a microenvironment that is not favorable to tumor progression. The current work aimed to evaluate the inflammatory responses of the MG and prostate gland to BPA (50 μg/kg) and 17-β estradiol (E2) (μg/kg) exposure during the perinatal window of susceptibility. The results showed that at 5 months of age there was an increase in the number of ghosts in the MG of 17-β (T17) ovariectomized adults in the stroma and in the tumor-like foci in the prostate from animals perinatally exposed to 50 μg/kg BPA daily. In addition, the number of macrophages increased in these animals. In comparison with nonexposed animals, sex steroids by the T17β receptor. Despite an increase in the incidence of bilobular/ductal and intraductal hyperplasia, the MG did not show any difference in the number of epithelial cells, which was also observed in the prostate of BPA-exposed animals. However, the prostate of animals exposed to BPA showed a decrease in the number of macrophages during the perinatal window of susceptibility leads to different inflammatory responses in different reproductive organs. As the prostate is more susceptible to these inflammatory mechanisms, it is reasonable to affirm that possible neoplastic alterations in this organ are related to changes in the inflammatory pattern of the stroma, a characteristic that is not evident in the MG. 統合_1174	E. C. R. Leonel, S. G. P. Campos, L. H. A. Guerra, C. M. Bastos, P. S. L. Villanueva, M. F. Calmon, P. Rahal, C. A. Amorim and S. R. Taboga	2020	Impact of perinatal bisphenol A and 17β estradiol exposure: Comparing hormone receptor response	Hormonal regulation controls mammary gland (MG) development. Therefore some hormone-related factors can disrupt the early phases of MGs development, making the gland more susceptible to long term modifications in its response to circulating hormones. Endocrine disruptors, such as bisphenol A (BPA), are able to cause alterations in hormone receptor expression, leading to changes in the cell proliferation index, which may expose the MG to the risk of tumor development. The present study aimed to evaluate the effects of perinatal exposure to BPA (50 μg/kg) and 17-β estradiol (E2) (0.1 μg/kg) on the expression of estrogen receptor alpha (ERα), progesterone receptor (PR), prolactin (PRL), and co-localization of hormone receptors in the mammary epithelium. Female Wistar rats were exposed to BPA or E2 daily, via gavage, from the 1st day of pregnancy (DP) to the 21st day of lactation (DL). Female offspring were euthanized at 5 months of age (T17). Ovariectomized (OVX) animals were used as controls (T17 OVX). In order to mimic a carcinogenic environment, rats received a single dose of 50 mg/kg of 7,12-dimethylbenz[a]anthracene (DMBA) by gavage at 50 days of age. Animals were euthanized 15 days after DMBA administration (T17 DMBA). Our results showed that the perinatal exposure to BPA or E2 did not alter the number of epithelial cells in the MG. However, a higher number of ERα+ cells was observed in the BPA group. In addition, the co-localization of ERα and PR was increased in the BPA group. Moreover, the co-localization of PRL and ERα was also higher in the BPA group. Despite the increase in the co-localization of hormone receptors, the MG did not present considerable changes in terms of detached epithelial cells, inflammation, glandular hyperplasia, and collagen fiber deposition. Furthermore, a higher number of epithelial cell proliferation was observed in comparison to the basic control group. In addition, our results showed a higher molecular expression of CCND1 in the vehicle-treated group, indicating that core rat epithelial alone can alter the expression of this epigenetic biomarker. In conclusion, BPA perinatal exposure promotes significant changes in glandular cytoarchitecture and increases glandular epithelium proliferation rate, leading to the retention of some ERα properties. This event could compromise the fate and differentiation potential of mammary epithelium. 統合_1176	X. Lei, Z. Hao, H. Wang, Z. Tang, Z. Zhang and J. Yuan	2023	Identification of core genes, critical signaling pathways, and potential drugs for countering BPA-induced hippocampal neurotoxicity in male mice	Although the neurotoxicity of the common chemical bisphenol A (BPA) to the mouse hippocampus has been often reported, the mechanism underlying BPA-induced depression-like behavior in mice remains unclear. We evaluated BPA's role in inducing depression-like behavior by exposing male mice to different BPA concentrations (0, 0.02, 0.1, and 1 μg/mL) and using the forced swimming test (FST) and tail suspension test (TST). We found that 1 μg/mL BPA significantly increased the immobility time in the FST and TST. Based on BPA-induced depression-like behavior, we identified 5429 differentially expressed genes (DEGs) in the hippocampus of male mice using RNA-seq. Next, 157 DEGs in the FST- and TST-induced depression-like behavior groups were identified. Subsequently, we identified 10 hub genes from the 157 DEGs using the protein-protein interaction network. Finally, we identified Cdh2 as a critical and potential therapeutic target gene, and molecular docking revealed that BPA could bind to Cdh2 and protein levels were downregulated in the BPA-exposed groups. Furthermore, molecular docking identified abemaciclib as a compound that could counteract BPA-related neurotoxicity. Conclusively, our analyses confirmed that BPA triggers depression-like behavior in male mice by downregulating N-cadherin expression and suggested that abemaciclib might reduce BPA-induced neurotoxicity. 統合_1177	S. G. Lee, J. E. Park, Y. P. Cheon and J. M. Kim	2023	Gestational Exposure to Bisphenol A Causes DNA Hypomethylation and the Upregulation of Progesterone Receptor Expression in the Uterus in Adult Female Offspring Rats	Exposure to environmental chemicals, including endocrine-disrupting chemicals, during the gestational period can have profound adverse effects on several organs in offspring. Bisphenol A (BPA) can infiltrate the human body through food and drinks, and its metabolites can cross both the placental and the blood–brain barriers. In this study, we investigated the effect of gestational exposure to BPA on epigenetic, biochemical, and histological changes in the uterus of female offspring rats. Pregnant Sprague–Dawley rats were orally administered BPA (0, 0.05, 5, and 50 mg/kg/day) from gestational day 6 to 19, and the uterus of adult offspring born to the exposed mothers were analyzed. Global DNA methylation analysis revealed that the overall DNA methylation level in BPA-treated female offspring rats was significantly decreased in the uterus. Progesterone receptor (PR) protein expression in uterine tissues was monitored using western blot analysis, which revealed that the PR protein content was considerably higher in all BPA-exposed groups than in the control. Immunohistochemical examination of the PR revealed that intense PR-positive cells were more frequently observed in the BPA-exposed group than in the control group. To date, the evidence that the upregulation of PRs observed in the present study was caused by the non-methylation of specific PR promoter regions is lacking. Conclusively, these results indicate that exposure to BPA during gestation induces epigenetic alterations in the uterus of adult female offspring. We speculate that the global DNA hypomethylation and upregulation of the PR observed simultaneously in this study might be associated with the uterus. Wan	2022	Bisphenol A Coupled with a High-Fat Diet Promotes Hepatosteatosis through Reactive-Oxygen-Species-Induced CD36 Overexpression	Bisphenol A (BPA) is an endocrine-disrupting chemical that affects lipid metabolism and contributes to non-alcoholic fatty liver disease (NAFLD). The mechanism of BPA exposure in hepatic lipid accumulation and its interaction with a high-fat diet (HFD) remain unclear. This study investigated the effects of BPA exposure on hepatic lipid accumulation in mice fed a HFD. Male C57BL/6 mice were fed a HFD and simultaneously received drinking water containing BPA (0, 0.05, 0.5, or 5 mg/kg body weight/day) for 12 weeks. Mice fed a HFD showed increased body weight gain, hepatic lipid accumulation, and hepatic triglyceride content at the end of the study. Additionally, CD36, a major fatty acid uptake transporter, was also overexpressed in high-fat diet (HFD)-fed mice. BPA + HFD co-exposure further increased hepatic lipid accumulation and CD36 expression. Mice administered a high-fat/high-cholesterol/high-cholic acid diet (HFCD) and BPA (50 mg/kg body weight) for 8 weeks developed a steatohepatitis-like phenotype, characterized by alpha-smooth muscle actin (α-SMA, an indicator of hepatic fibrosis) and elevated caspase-3 (an indicator of apoptosis). In hepatic tissue recovery, they had a higher oxidative stress index of 8-hydroxy-2′-deoxyguanosine (8-OHdG) in the tissue component than in the control group. Treatment with ROS scavenger n-acetyl-cysteine (NAC) ameliorated BPA-mediated HFCD-induced lipid accumulation and steatohepatitis in the form of treated mice. Our study indicates that BPA acts synergistically to increase hepatic lipid uptake and promotes NAFLD development by stimulating ROS-induced CD36 overexpression. 統合_1179	J. Lee, I. Park, Y. Y. Lee and Y. Lee	2020	Comparative transcriptome analysis of the protective effects of Korean Red Ginseng against the influence of bisphenol A in the liver and uterus of ovariectomized mice	BACKGROUND: Bisphenol A (BPA), known as an endocrine disruptor, is widely used in the world. BPA is reported to cause inflammation-related diseases. Korean Red Ginseng (KRG) has been used safely in humans for a long time for the treatment of diverse diseases. KRG has been reported for its mitigating effect on menopausal symptoms and suppress adipose inflammation. Here, we investigate the protective effect of orally administered KRG on the impacts of BPA in the liver and uterus of menopausal mice model. METHODS: The transcriptome analysis for the effects of BPA on mice liver was evaluated by Gene Expression Omnibus (GEO) dataset (GSE117261). Ovariectomized (OVX) mice were orally administered BPA (50 mg/kg/day) and KRG (100 mg/kg/day) for 8 weeks. RESULTS: Transcriptome analysis revealed that BPA induced 123 kinds of gene set in the liver of normal mice. The administration of BPA and KRG did not change body, liver, and uterine weight in OVX mice. KRG downregulated BPA-induced inflammatory response and chemotaxis-related gene expression. Several gene set enrichment analysis (GSEA)-derived inflammatory response genes increased by BPA were inhibited by KRG in OVX mice. CONCLUSION: Our data suggest that BPA has commonly influenced inflammatory response effects on both normal and OVX mice. KRG protects against BPA impact of inflammatory response and chemotaxis in OVX mouse models. Our comparative analysis will provide new insight into the efficacy of KRG on endocrine disrupting chemicals and OVX mouse. Ka	2021	Maternal Bisphenol A (BPA) Exposure Alters Cerebral Cortical Morphogenesis and Synaptic Function in Mice	Early life exposure to bisphenol A (BPA), synthetic compound used in polycarbonate plastics, is associated with altered cognitive and emotional behavior later in life. However, the brain mechanism underlying the behavioral deficits is unknown. Here, we show that maternal BPA exposure disrupted cell removal and cell differentiation of newborn neurons during cortical development. The BPA exposure reduced the neuron number, whereas it increased glial cells in the cerebral cortex. Also, synaptic formation and transmission in the cerebral cortex were suppressed after maternal BPA exposure. These changes appeared to be associated with aberrant gene ontology analysis of RNA-seq identified an autophagy decode in the BPA condition. Mouse behavioral tests revealed that maternal BPA caused hyperactivity and social deficits in adult offspring. Together, these results suggest that maternal BPA exposure leads to abnormal cortical architecture and function likely by activating autophagy. 統合_1181	S. C. Lachy, H. E. Lapp, M. Salazar, S. Semyenko, D. Chauhan, A. E. Margolis and F. A. Champagne	2024	Postnatal maternal care moderates the effects of prenatal bisphenol exposure on offspring neurodevelopmental, behavioral, and transcriptomic outcomes	Bisphenols (BP), including BPA and "BPA-free" structural analogs, are commonly used plasticizers that are present in many plastics and are known endocrine disrupting chemicals. Prenatal exposure to BPA has been associated with negative neurodevelopmental and behavioral outcomes in children and in rodent models. Prenatal BPA exposure has also been shown to impact postnatal maternal care practices by which care also affects offspring neurodevelopment and behavior. However, it is unknown whether BPA exposure alters the quality of maternal care and whether variations in maternal care mediate or moderate associated maternal care or adult behavior. The purpose of the current study was to determine the impact of prenatal bisphenol exposure and postnatal maternal care on maternal behavior and behavior in rats. Our findings suggest that the effects of prenatal bisphenol exposure on pup-seeking, adult attentional set-shifting and anxiety-like behavior in the open field are dependent on maternal care in the first five days of life. Interestingly, maternal care might also attenuate the effects of prenatal bisphenol exposure on pup-seeking and adult attentional set-shifting. Finally, transcriptomic profiles, from adult female medial prefrontal cortex, also highlight a subset of genes that are impacted by the interactive effects of prenatal bisphenol exposure and postnatal maternal care converge on estrogen receptor signaling and are involved in biological processes related to gene expression and neuronal function. Together, these findings suggest that maternal care can moderate the effects of prenatal bisphenol exposure on offspring neurodevelopment, behavior, and transcriptomic outcomes. Understanding the underlying biological mechanisms involved might allow us to identify potential avenues to mitigate the adverse effects of prenatal bisphenol exposure and improve health and well-being in human populations. Champagne	2025	Interplay between prenatal bisphenol exposure, postnatal maternal care, and offspring sex in predicting DNA methylation relevant to anxiety-like behavior in rats	Prenatal exposure to endocrine disrupting chemicals, such as bisphenols, can alter neurodevelopmental trajectories and have a lasting neurobehavioral impact through epigenetic pathways. However, outcomes associated with prenatal bisphenol exposure may also be shaped by the postnatal environment and collectively these environmental effects may be sex-specific. Thus, an integrative research design that includes multiple early life exposures and considers sex differences may be essential for predicting outcomes. In the current study, we use a multivariate approach to examine the contributions of prenatal bisphenol exposure, postnatal maternal care, and offspring sex to anxiety-like behavior and DNA methylation of a well-studied candidate gene, Oxtr[1]. BDNF. Oxtr[1] is a neural hypothesized, and amygdala of adult rat offspring and Exons 1 and 4 were chosen as they are differentially regulated by maternal care and interactions with prenatal bisphenol exposure were consistently found for DNA methylation within the NAC[1] gene (ventral hippocampus) and within the BDNF and Oxtr[1] genes (amygdala). Sex-specific effects were also found across all analyses. Overall, our findings suggest that both early life factors (prenatal and postnatal) and offspring sex contribute in variation in DNA methylation of genes and neurotypes relevant to the expression of anxiety-like behavior. These results highlight the need to consider the brain region-specific effects of multiple exposures in males and females to understand the lasting effects of early environments. 統合_1183	H. E. Lapp, A. E. Margolis and F. A. Champagne	2022	Impact of a bisphenol A, F, and S mixture and maternal care on the brain transcriptome of rat dams and pups	Products containing BPA structural analog replacements have increased in response to growing public concern over adverse effects of BPA. Although humans are regularly exposed to a mixture of bisphenols, few studies have investigated the effects of bisphenol mixtures. Additionally, maternal care has been shown to moderate the effects of bisphenol exposure on offspring outcomes. Here, we exposed dams to a mixture of BPA, BPF, and BPS during gestation via the basic bisphosphonate in Long-Evans rats and dams using Tag-RNA-sequencing. We also examined the association between licking and grooming, which also has mediating effects on pup neural development, and the transcriptome. Associations between licking and grooming and the transcriptome were region-specific, with the hypothalamus having the greatest number of differentially expressed genes associated with licking and grooming and the hippocampus having the least. Prenatal bisphenol exposure altered the transcriptome of the medial preoptic area (MPOA) in offspring more robustly than later gene expression. In dams, the prefrontal cortex had the greatest number of differentially expressed genes associated with prenatal bisphenol exposure. Prenatal bisphenol exposure changed the relationship between the MPOA transcriptome and maternal behavior, suggesting that bisphenol exposure may alter the neural circuitry that underlies maternal behavior. Together, these results suggest that bisphenol exposure may have long-term consequences for the brain transcriptome and maternal behavior, and that the effects of bisphenol exposure may be dependent on the brain region examined. Finally, hypothesis-driven analysis of genes related to estrogen response, parental behavior, and epigenetic regulation of gene expression revealed region-specific expression associated with licking and grooming and bisphenol exposure that were distinct in dams and pups. These data highlight the effects of bisphenols on multiple physiological process that are highly dependent on timing of exposure (prenatal vs. adulthood) and brain region, and reiterate the contributions of multiple environmental and experiential factors in shaping the brain. Fenaroli	2023	Bisphenol A exacerbates anxiety-like behavior and neuroinflammation in prefrontal cortex of adult obese mice	ABBS Bisphenol A (BPA) is an endocrine-disrupting chemical inducing several damages, such as neurotoxicity, immunotoxicity, and metabolic disorders. Obesity is the main risk factor for the increased occurrence of metabolic alterations as well as mood disorders. Here, we investigated in obese mice the effects of BPA on anxiety-like behavior, associated with neuroinflammation and immune activation. MAIN METHODS Male C57BL/6J mice were fed a high-fat diet (HFD) for 12 weeks to induce obesity. Then, HFD mice were exposed to BPA (50 μg/kg/day) for 4 weeks. Control groups received vehicle (HFD) or BPA treatment and were fed a standard diet (Control). KEY FINDINGS Behavioral results showed that BPA treatment induced anxiety-like behavior in HFD + BPA group mice compared to HFD + BPA group mice and Control mice, which showed no obesity-like behavior. The analgesic effects of BPA also emerged from hyperactivation of the hypothalamus-pituitary-adrenal gland axis, demonstrated by the increased transcription of CRF and its receptor in the prefrontal cortex (PFC). Furthermore, BPA-treated HFD mice showed an increased number of microglia in the PFC, accompanied by a shift toward a pro-inflammatory phenotype (M1/M2 = 1.4 ± 0.1 in PFC. Furthermore, it induced inflammation and monocyte recruitment in hypothalamus and amygdala. Contextually, BPA significantly amplified the immune activation caused by lipid overload as evidenced by the increased expression of TLR-4 and MCP-1 in the PFC and triggered monocytosis in the hypothalamus under lean (FC) mice. SIGNIFICANCE Of these data show that sub-chronic BPA exposure represents an additional risk factor for mood disorders strictly related to obesity, enhancing neuroinflammation and immune activation triggered by HFD feeding. 統合_1185	E. Krieger, F. Fischer, J. Hosaroğlu, M. Wagner, F. Romanelli, B. Fink, M. Bauer, A. Schumacher, T. Kretschmer and A. C. Zenclussen	2025	Implications of a combined perinatal exposure to BPA and BP-3 for offspring folliculogenesis and ovarian function in mice	Endocrine-disrupting chemicals (EDCs), like bisphenol A (BPA) and benzophenone-3 (BP-3), can interfere with hormone systems, posing risks to fertility and reproduction. Exposure to EDCs is unavoidable making it a relevant environmental health topic, however the impact of real-life EDC mixtures is largely unknown. This study explored the effects of a combined BPA and BP-3 exposure at realistic intake levels for humans during pregnancy and early life on ovarian development and function in an established mouse model. Mice were daily exposed to concentrations of 4 µg/kg BPA orally, 10 mg/kg BP-3 dermally, and the combination of BPA+BP-3 from gestational day 0.5 until weaning of the offspring. Ovaries were collected from female offspring at 3 weeks and 6 months of age. Ovarian RNA-sequencing revealed that BPA and BP-3 co-exposure led to stimulation in mitotic regulation and stimulation in mature ovulatory oocyte-specific pathways in 3-week-old offspring. Histological analysis revealed that co-exposure to BPA and BP-3 led to more atretic follicles and fewer corpora lutea, and genes linked to hormone signaling, hormone synthesis, and ovarian tissue remodeling were altered relative to unexposed controls. These findings suggest that early life exposure to BPA and BP-3 at environmentally relevant levels impairs ovarian development and function in mice indicating that known safe and hormonal signaling in the ovaries, even at single, of endocrine disruptors at relevant concentrations. Such findings may be compromising fertility and reproductive health in later life. Our research underscores the importance of investigating the impact of combined EDC exposure on the reproductive system. Saviliam	2025	Role of Thymus ciliatus (Thyme) to Ameliorate the Acute Neurotoxicity Induced by Bisphenol A: In Vivo Supported with Virtual Study	Background/Objectives: The purpose of this research was to investigate the effects of bisphenol A (BPA) exposure on neurobehavioral testing in young Wistar rats and to evaluate the therapeutic potential of Thymus ciliatus (TCI) essential oil to attenuate the damage induced by this chemical toxin. Methods: The essential oil was extracted by hydro-distillation (yield of 2.26%), and the characterization by GC-MS indicates that the major compounds are thymol (40.2%), carvacrol (25.1%), and p-cymene (15.3%). Male Wistar rats were divided into five groups (n = 6/group): Control, BPA (50 mg/kg), and BPA + TCI (50, 100, and 200 mg/kg). Behavioral tests were performed using a comprehensive set of tests, including the hot-cold cube test, daily flight test, Morris water maze, open field test, and novel preference test, clearly demonstrated that bisphenol A (BPA) exposure induced significant neurobehavioral impairments. Results: These impairments included reduced exploratory behavior, indication of heightened stress, anxiety, and depressive-like states, as well as deficits in memory and learning. Furthermore, BPA intoxications are associated with metabolic disturbances such as hyperglycemia along with histopathological evidence of brain tissue damage. However, TCI treatments showed these adverse effects by reversing neurobehavioral function. Molecular docking analysis revealed an affinity between the major essential oils identified in T. ciliatus, BPA, and the 5HT2C receptor and the GSK3, ACHE, and BCHE enzymes, which may explain the observed neuroprotective effects. Conclusions: Overall, this study highlights the neurotoxic potential of BPA and the therapeutic benefits of TCI essential oil, which is rich in thymol, carvacrol, and p-cymene. These findings underscore the promising role of TCI in mitigating the cytotoxic effects of BPA and lay the way for additional research into the molecular mechanisms and therapeutic uses of natural compounds for the prevention and treatment of toxic diseases. Thymol, the major component in TCI, exhibited activity related to the dopamine and serotonin pathways, so it could have potential antidepressant properties. Conclusions: Thymol might be a promising candidate for the treatment of neurodegenerative and neurological disorders such as depression, Parkinson's disease, and Alzheimer's disease while also preventing histological damage in the brain. 統合_1187	K. M. M. Karlem	2022	Fertaric acid amends bisphenol A-induced toxicity, DNA breakdown, and histopathological changes in the liver, kidney, and testis	BACKGROUND: Bisphenol A (BPA) is present in many plastic products and food packaging. On the other hand, fertaric acid (FA) is a hydroxycinnamic acid. AIM: To investigate the effect of FA on BPA-related liver, kidney, and testis toxicity, DNA breakdown, and histopathology in male rats. METHODS: Thirty male albino rats were divided into five equal groups (6 rats/group): Control, paraffin oil, FA - BPA - and FA + BPA treated groups. The control and paraffin oil groups were administered orally with 1 mL distilled water and 0.5 mL paraffin oil, and FA (50 mg/kg bw) followed by BPA (5 mg/kg, bw), respectively. All these treatments were given once orally for 4 weeks. RESULTS: BPA administration significantly (p < 0.05) increased the activities of serum alanine aminotransferase, aspartate aminotransferase, alkaline phosphatase, gamma-glutamyl transferase, lactate dehydrogenase, lactate, urea, creatinine, uric acid, substituting hormone, follicle stimulating hormone, sex hormone binding globulin, blood urea nitrogen, and testis cholesterol levels. Also, FA inhibited the degradation of liver, kidney, and testis DNA content. Oral administration of FA to BPA-treated rats restored all the above parameters to normal levels. CONCLUSION: FA ameliorates BPA-induced liver, kidney, and testis toxicity, DNA breakdown, and histopathological changes in the brain. 統合_1188	A. Kobroob, W. Peerapanyasut, S. Kumfu, N. Chattipakorn and O. Wongmekiat	2021	Effectiveness of N-Acetylcysteine in the Treatment of Renal Deterioration Caused by Long-Term Exposure to Bisphenol A	Human health hazards caused by bisphenol A (BPA), a precursor for epoxy resins and polycarbonate based plastics, are well documented and are closely associated with mitochondrial impairment and oxidative imbalance. This study aimed to assess the therapeutic efficacy of N-acetylcysteine (NAC) on renal dysfunction caused by long-term BPA exposure and examine the signaling molecules involved. Male Wistar rats were given vehicle or BPA orally for 12 weeks then the BPA-treated group was subdivided to receive vehicle or NAC concurrently with BPA for a further 5 weeks, while the vehicle-treated normal control group continued to receive vehicle. Long-term BPA exposure induced renal dysfunction, glomerular and tubular damage, and renal fibrosis. Mitochondrial dysfunction was also observed in the kidneys of BPA-exposed rats. Long-term BPA exposure also induced mitochondrial swelling, decreased mitochondrial membrane potential, increased mitochondrial reactive oxygen species production, and the loss of mitochondrial membrane potential. The benefit of NAC was related to the modulation of signaling proteins in the AMPK-SIRT3-SOD2 axis. The present study shows the potential of NAC to restore mitochondrial integrity and oxidative balance after long-term BPA exposure, and suggests that NAC therapy is an effective approach to tackle renal deterioration in this condition. 統合_1190	K. Kobayashi, Y. Liu, H. Ichikawa, S. Takemura and Y. Minamiyama	2020	Effects of Bisphenol A on Oxidative Stress in the Rat Brain	We investigated the effect of bisphenol A (BPA) on oxidative stress and key-related proteins in adult rat testis. BPA (10 mg/L) was administered to rats for eight weeks through their drinking water. The reactive oxygen species (ROS) scavenging capacity for hydroxyl radicals in the plasma was reduced after two weeks. In the hippocampus, four and eight weeks of BPA increased the ratio of oxidized (2) 1/2 (+) (PdHPC). The ratio of phosphorylated ERK1/2/ERK1/2 and phosphorylated JNK/JNK1 increased after one week of BPA treatment. The ratio of phosphorylated JNK/JNK and phosphorylated ERK/ERK increased after eight weeks of BPA. No alteration could be related to tau phosphorylation. Protein phosphatase 2A (PP2A) in the hippocampus decreased after eight weeks of BPA treatment. At that time, SOD1 was significantly reduced, but no changes in SOD2 and catalase were observed. Glutathione peroxidase (GPx) activity was also reduced after eight weeks of BPA. Nuclear factor erythroid 2-related factor 2 (Nrf2) in the hippocampus was not changed. However, Nrf2 in the nuclei tended to be increased after eight weeks. In the hippocampal of rats, BPA induced systemic oxidative stress and could change ROS-induced signaling pathways in the brain. These results suggest that mitochondrial dysfunction possibly is not responsible for oxidative stress and neurodegeneration due to low doses of BPA. 統合_1191	R. D. Kini, S. Kumar, A. K. Nayarattara and G. Megha	2024	A study on bisphenol induce renal damage and role of vitamin c as an antioxidant on bisphenol induced renal damage in wistar rats. A case control study	INTRODUCTION: Bisphenol A (BPA) is considered one of the most common industrial manufactured chemicals and a pollutant. oxidative stress has been induced by bisphenol by dysregulate the cytokines. Oxidative stress is a condition in which the production of free radicals and the body's ability to neutralize them are out of balance. Vitamin C is a powerful antioxidant that can help protect cells from oxidative damage. This study was focused to evaluate the damaging effect on BPA on kidney and the role of vitamin c as anti-oxidant on BPA induced kidney toxicity. MATERIAL & METHODS: Three control two groups of rats(6 rats in each) Group 1: Control (Only Oral treated) Group 2:Vitamin C treated), Group 3: (Bisphenol treated), Group 4: (Vitamin C + Bisphenol treated). Oral kidney homogenized to measure Malondialdehyde level and glutathione and other kidney was used to measure histopathological changes. Statistical analysis was performed using one-way analysis of variance (ANOVA) followed by post hoc tests to determine significant differences between the groups. RESULTS: Results showed that Bisphenol A treatment significantly increased ROS and decreased GSH and increased in MDA level as well as SOD, catalase and potassium level. Biochemical results were supported by histo-pathological changes. The treatment with Vitamin C showed an how in the rats of GSH, catalase and potassium level and fall in MDA. Vitamin C per treatment also showed some beneficial changes in histology of kidney also. CONCLUSION Our result demonstrated that exposure to Bisphenol induced oxidative stress in rat kidney and vitamin C could act as an antioxidant protecting against BPA induced cellular stress. Ryu	2025	Bisphenol Analogs Downregulate the Self-Renewal Potential of Spermatogonial Stem Cells	PURPOSE: In this study, we investigated the effect of bisphenol A (BPA) and its major analogs, bisphenol F (BPF), and bisphenol S (BPS), on spermatogonial stem cells (SSCs) of populations using in vitro SSC culture and in vivo transplantation models. METHODS: SSCs were isolated from 6-day-old mice and cultured in the presence of BPA, BPF, or BPS at concentrations ranging from 0.1 to 10 μM. Cell proliferation, apoptosis, and bisphenol-induced cytotoxicity and changes in SSC characteristics. Mitochondrial Rex-proximity, immune polymerase chain reaction (PCR), and transcriptome analysis. The functional alteration of SSCs were further investigated by examining donor SSC-derived spermatogenesis restoration through in vivo transplantation and subsequent testis analysis. RESULTS: BPF exhibited a similar inhibitory effect on SSCs as BPA, demonstrating a significant decrease in SSC survival, inhibition of proliferation, and induction of apoptosis. On the other hand, while BPS was comparatively weaker than BPA and BPF, it still showed significant SSC cytotoxicity. Importantly, SSCs exposed to BPA, BPF, and BPS exhibited a significant reduction in donor SSC derivergerm cell colonies per total number of cultured cells, indicating that, like BPA, BPF, and BPS can also impair the self-renewal potential of SSCs. Transcriptome analysis revealed that BPA, BPF, and BPS commonly altered the expression of genes related to cell cycle regulation and apoptosis. CONCLUSION: Our findings indicate that the major BPA substitutes, BPF and BPS, have significant cytotoxic effects on SSCs, similar to BPA. These effects may lead to a reduction in the functional self-renewal stem cell population and potential impacts on male fertility. Park	2019	Effect of developmental exposure to bisphenol A on steroid hormone and vitamin D3 metabolism	High exposure to bisphenol A (BPA) in children has been associated with the outcomes of several diseases, including those related to developmental problems. To elucidate the mechanism of BPA-mediated developmental toxicity, plasma and urine from rats exposed to BPA was analyzed with high-resolution metabolomics, beginning from post-natal day 0, for 10 days. Female and male rats were orally administered 5 different BPA doses (0, 0.02, 0.2, 2, and 20 mg/kg/day). Urine and plasma samples were collected at 3 weeks of age and analyzed using UPLC-QTOF/MS. Vitamin D3 was found to be a key metabolite in the rodent rats. It was increased by administration to female BPA dose and metabolic changes were more noticeable, showing overall metabolic changes in plasma and urine, respectively. Metabolic perturbation in the steroid hormone biosynthesis pathway was significantly associated with dose- and sex-specific BPA effects. Intermediate metabolites in the rate-limiting step of steroid hormone biosynthesis shown regulated steroid hormones in the 250 mg treatment. Further, our study identified that BPA increased urinary concentration of vitamin D3 and decreased its concentration in blood, suggesting that perturbation of vitamin D3 metabolism may be mechanistically associated with neurodevelopmental disorders caused by BPA. These metabolites showed a decrease in sex difference with high BPA dose because female rats were more affected than males, which can be related with early puberty onset in female. In brief, the results demonstrated that BPA induces dose- and sex-specific metabolic shifts and that perturbation of metabolism can explain developmental problems. 統合_1206	S. Kaur, M. Sakaja, A. Aniqa and S. Sadwal	2021	Selenium attenuates bisphenol A incurred damage and apoptosis in mice testes by regulating mitogen-activated protein kinase signalling	Being a vital micronutrient, along with antioxidant, selenium (Se) protects the cells from oxidative stress (OS) in the form of selenoproteins. Bisphenol A (BPA) is a one toxicogenic compound that adversely affects the male reproductive system. The present study was aimed to elucidate the potentiative role of fenugreek seeds aqueous extract (FSE) and BPA-induced testicular damage in mice. Study included four different groups of male Balb/c mice: control (C), fenugreek (FSE), bisphenol A (BPA) and fenugreek + bisphenol A (FSE + BPA). After two months of treatment, assessment of sperm morphology, biochemical parameters, histological and immunohistochemical (IHC) analysis of testes was carried out. Results indicated that BPA treated animals demonstrated a marked decrease in antioxidant enzyme activities (superoxide dismutase, catalase, reduced glutathione and thiobarbituric acid reactive substances) in comparison to control group. Moreover, BPA induced significant (p < 0.05) decline in sperm count, viability and motility, while it increased the sperm abnormalities. Furthermore, BPA also induced histological changes in the testes of mice which was confirmed by IHC analysis. Nuclear factor erythroid 2-related factor 2 (Nrf2) signalling, Bax/Bcl-2 ratio and caspase-3 were studied to find out the apoptotic pathway. MohanKumar	2023	Prenatal exposure to bisphenol A and/or diethylhexyl phthalate alters stress responses in rat offspring in a sex- and dose-dependent manner	Background: Prenatal exposure to endocrine-disrupting chemicals (EDCs) are correlated with adverse behavioral outcomes, but the effects of combinations of these chemicals are unclear. The aim of this study was to determine the dose-dependent effects of prenatal exposure to EDCs on male and female behavior, Methods: Pregnant Sprague-Dawley rats were orally dosed with vehicle, bisphenol A (BPA) (5 µg/kg body weight (BW)/day), diethylhexyl phthalate (DEHP) (5 µg/kg BW/day), or BPA + DEHP (5 µg/kg BW/day of each) from gestational day (GD) 6 to GD 19. Offspring were subjected to the Open Field Test (OFT), Elevated Plus Maze (EPM), and Novel Object Recognition (NOR) tests in adulthood. Body, adrenal gland, and pituitary gland weights were collected at sacrifice. Corticosterone (CORT) was measured in the serum. Results: Female EDC-exposed offspring showed anxiolytic effects in the OFT, while male offspring were unaffected. DEHP exposure increased the number of entries into the open arms in the EPM, while BPA exposure had no effect. Male offspring fostered less in the EPM, while their female counterparts showed reduced body reactivity, indicating sex-specific endocrine-driven behavioral alterations. Additionally, DEHP-F2 females had increased body weight, while BPA-F2 females had lighter adrenal glands. DEHP-F2 alone and in combination with BPA led to lower adrenal gland weights, but only in male offspring. Finally, females treated with a mixture of BPA + DEHP had elevated CORT levels. Conclusion: Prenatal exposure to BPA, DEHP, or a mixture at the two affects behavior, CORT levels, and adrenal gland weights in a sex- and dose-dependent manner. 統合_1220	A. Kaimal, J. M. Hoovenmitth, M. H. Al Mansi, A. D. Cherry, J. T. Gaestly, P. V. Holmes, P. S. MohanKumar and S. M. J. MohanKumar	2024	Prenatal bisphenol A and/or diethylhexyl phthalate exposure followed by adult estradiol treatment affects behavior and brain monoamines in female rat offspring	HIGHLIGHTS. Women are at increased risk for mood disorders, which may be partly attributed to exposure to endocrine-disrupting chemicals (EDCs) during sensitive periods such as pregnancy. Exposure during these times can impair brain development in the offspring, potentially leading to mood disorders in later life. Additionally, fluctuating levels of endogenous estrogens, as seen during pregnancy, or the use of oral contraceptives can further enhance this risk. This study examines the combinatorial effects of prenatal EDC exposure combined with chronic low-dose 17β-estradiol (E2) treatment in adulthood on behavioral outcomes. METHODS. Pregnant Sprague-Dawley rats were orally dosed with vehicle, bisphenol A (BPA) (5 µg/kg body weight (BW)/day), low-dose (LD) diethylhexyl phthalate (DEHP) (5 µg/kg BW/day), high-dose (HD) DEHP (15 mg/kg BW/day), or a mixture of BPA + DEHP (LD) from gestational day (GD) 6 to GD 19. Female offspring were ovariectomized at postnatal day (PND) 60 and treated with vehicle or E2 (0.2 µg/kg BW/day) for 21 days. Behavioral testing was conducted, and serum hormones and brain monoamine levels were analyzed. RESULTS. Chronic E2 treatment in controls increased anxiety and reduced active coping behaviors. In BPA- and BPA+DEHP-exposed offspring, E2 treatment reversed some of these effects. Dose-dependent alterations in circulating hormone levels and brain monoamines were observed. Dysregulation of the stress axis was particularly notable with the higher dose of BPA+DEHP (DEHP-HD). Overall, prenatal EDC exposure altered behavior, hormones, and brain monoamines, with adult E2 treatment further exacerbating some of these effects in female offspring. 統合_1232	H. Jiao, Y. Chen, T. Han, Q. Pan, F. Gao and G. Li	2023	GGA1 participates in spermatogenesis in mice under stress	BACKGROUND: Infertility is recognized as a common and worrisome problem of human reproductive ecotoxicle. Based on previous studies, male factors account for about half of all infertility cases. Exposure to environmental isolants is an important contributor to male infertility. Bisphenol A (BPA) is the most prominent toxic environmental contaminant worldwide affecting the male reproductive system. BPA can impair the spermatogenic cells, leading to male infertility. Gallus gallinarum 1 (GGA1) is a member of the Gallus family and is highly conserved in vertebrates. GGA1 is a homolog of Drosophila melanogaster with spermatogenesis. In Drosophila, however, its function in mammalian spermatogenesis remains unclear. METHODS: Eight-week-old male mice were divided into the CONTROL and system. Eight (1 C) male mice and wild-type littermates received intraperitoneal (i.p.) injections of BPA (40 μg/kg) once daily for 3 weeks. Histological and immunofluorescence staining were performed to analyze the phenotypes of these mice. RESULTS: Male mice lacking Ggal had normal fertility without any obvious defects in spermatogenesis, sperm count and sperm morphology. Ggal ablation led to infertility in male mice exposed to BPA, along with a significant reduction in sperm count, sperm motility and the percentage of normal sperm. Histological analysis of the seminiferous epithelium showed that spermatogenesis was severely disorganized, while apoptotic germ cells were significantly increased in the Ggal-null mice exposed to BPA. Our findings suggest that Ggal protects spermatogenesis against damage induced by environmental pollutants. 統合_1233	W. Jiang, H. Zhao, L. Zhang, B. Wu and Z. Zha	2020	Maintenance of mitochondrial function by astaxanthin protects against bisphenol A-induced kidney toxicity in rats	Bisphenol A (BPA), a global environmental pollutant, has been reported to have the potential to induced organs toxicity. This study explored the potential benefits of astaxanthin (AST), a natural antioxidant, against BPA-toxicity in the kidney, and explored whether mitochondria are involved in this condition. Sixty Wistar rats were fed with a vehicle, BPA (BPA group), AST, and were evaluated after four weeks. AST treatment significantly reversed BPA-induced changes in body weight, kidney/body weight, and renal function-related markers. When treated simultaneously with AST, the imbalance of the oxidative-antioxidant status caused by BPA was also reversed. Moreover, AST treatment significantly reversed BPA-induced mitochondrial swelling, the collapse of the membrane potential, and the decrease in the mitochondrial respiratory chain complex enzyme activity. The beneficial of AST were associated with enhanced mitochondrial function, which led to increased mitochondrial-encoded gene expression, mitochondrial copy number, and increased mitochondrial morphology chain complex enzyme activity. Our results demonstrate the efficacy of AST in preventing BPA-induced kidney damage, in part by regulating oxidative imbalance and improving mitochondrial function. Collectively, these findings provide a new perspective for the rational use of ATX in the treatment of BPA-induced kidney disease. 統合_1234	C. Jiang, G. Gao, W. Sun, Y. Sun and J. Yu	2023	Molecular characterization of physis tissue and hormonal profiles of female rats neonatally exposed to low-dose bisphenol A	Physis is a complex cartilaginous structure that is critical for longitudinal bone growth. As one of the endocrine-disrupting chemicals, bisphenol A (BPA) can interfere with the physis by disrupting the complex networks of hormones. However, the molecular mechanisms underlying BPA-induced physis damage remain unclear. Kiss1 is a key regulator of the hypothalamic-pituitary-gonadal axis and is widely expressed in the physis. Therefore, understanding the molecular pathways involved in the physis after neonatal exposure to low-dose BPA may permit the identification of research targets for therapeutics, which may aid in modulating the process of growth plate closure. In the present study, female Sprague-Dawley rats were exposed to 0.05 mg kg(-1) day(-1) of BPA and corn oil (vehicle) from postnatal day 1 (PND1) to 15 via subcutaneous injection. Then gonadectomy (GDX) surgeries were performed for the rat(BPA) injected from the physis. The levels of sclerostin (SOST), growth hormone (GH), and insulin-like growth factor 1 (IGF-1) were measured in peripheral (BPA) groups (n = 10 for each group). We observed statistically significant enrichment of gene sets in the BPA(Bing)-tissues compared with the Vehicle tissues. Further analysis of the differentially expressed genes (DEGs) identified BPA(Bing)-specific networks of secreted proteins (LBP, SPP, SEC, ACE2, CAD, and CMPK) as well as those of heat-metronectin proteins (PSB2, LAMC2, ADAMTS18, and ADAMTS20). Furthermore, the levels of GC and ESI scores elicited by BPA exposure. Our results revealed the specific molecular characteristics of physis contaminated with BPA and may provide new clues for physis maturation and suspension of related processes and exceptional exposure. 統合_1235	C. Jiang, W. Dang, G. Gao, W. Sun, Y. Wang, B. Zhan, Y. Sun and J. Yu	2024	Maternal oral exposure to low-dose BPA accelerates the onset of puberty by promoting prepubertal Kiss1 expression in the AVPV nucleus of female offspring	As the incidence of precocious puberty has risen in recent years and the age at puberty onset is younger, children may be at increased risk for health consequences associated with the early onset of puberty. Bisphenol A (BPA) is recognized as an endocrine disruptor chemical that is reported to induce precocious puberty. The effect of BPA exposure modes, times, and doses (especially low dose) were controversial. In the present study, female Sprague-Dawley rats were exposed to corn oil (vehicle) or BPA (0.05 mg kg(-1) day(-1)) via subcutaneous injection from postnatal day 1 (PND1) to 15 (PND1-15) or 21 (PND1-21). Then, BPA-treated rats were gonadectomized (BPA-GDX). Pregnant rats were exposed to corn oil vehicle, 0.05 mg kg(-1) day(-1) BPA, or 5 mg kg(-1) day(-1) 17α-propionate (PRO) (n = 10 per group). The vaginal opening (VO), ovarian follicular luteinization, and relevant hormone concentrations were measured. Hypothalamic Kiss1 and ERα/ERβ levels by western immunoblot analysis were also examined as indices of puberty onset. During in vitro exposure, low-dose BPA reactivated ERα-dependent Kiss1 and PRDM1, and subsequently accelerated puberty onset by promoting the expression of prepubertal Kiss1 and ERβ/ERα in the AVPV nucleus. In PND30, leading to advanced VO, an elevation in LH and FSH concentrations (on PND30). We also noted increased ERα mRNA on PND30 and PND35. Maternal oral exposure to low-dose BPA altered the ERα curve during the neonatal and prepubertal periods, and subsequently accelerated puberty onset by promoting prepubertal Kiss1 expression in the AVPV nucleus. 統合_1236	J. Jia, H. Xu, C. Chen, X. Zhang, X. Zhang, W. Li and J. Ma	2020	Quantitative proteomic analysis of mouse testis uncovers cellular pathways associated with bisphenol A (BPA)-induced male infertility	Quantitative proteomic analysis was performed using iTRAQ to explore the potential regulation of differentially expressed proteins (DEPs) by bisphenol A (BPA) in murine testis. BPA was intraperitoneally injected into male mice at 0, 50, 100, and 200 mg/kg/day for 5 consecutive days. Histological examination revealed that BPA exposure induced testicular damage in a dose-dependent manner. Tandem mass tag (TMT) labeling and nanoscale liquid chromatography-tandem mass spectrometry (nanoLC-MS/MS) identified 5,947 proteins in the mouse testis. The levels of 7 and 51 were affected by BPA exposure. The abundances of enzymes(cat-1 (Cbs1), haptoglobin (Hp), and insulin-like 3 (Insl3) were significantly lower in BPA-treated mice than those in control mice. The expression changes in the above-mentioned proteins were further validated at the protein level using Western blot analysis. We concluded that BPA affects testicular histological morphology of testis and sex hormone production. The regulation of the proteins, such as Cbs1, Hp and Insl3, may reflect that these proteins may serve as important factors in male reproductive disorders caused by BPA, and these proteins are probably biomarkers for infertility caused by endocrine-disrupting chemicals. 統合_1237	R. Ji, M. Cui, D. Zhou, X. Pan, Y. Xie, X. Wu, X. Liang, H. Zhang and W. Song	2023	Adulthood bisphenol A exposure induces anxiety in male mice via downregulation of alpha-1D adrenergic receptor in paraventricular thalamus	Bisphenol A (BPA), a ubiquitous endocrine disrupting chemical, is widely used in household plastic products. Large amounts of evidence indicate prenatal and postnatal BPA exposure causes neurodevelopmental disorders, such as anxiety and autism. However, the neuronal mechanisms underlying the neurotoxic effects of adulthood BPA exposure remain poorly understood. Here, we provided evidences that adult mice treated with BPA (0.5 mg/kg/d, 0.05 mg/kg/d) for 4 weeks displayed anxiety-like behaviors. Moreover, BPA exposure significantly decreased the excitability of glutamatergic neurons in the paraventricular thalamus (PVT). Acute chemogenetic activation of PVT glutamatergic neurons caused similar effects on anxiety as observed in male mice exposed to BPA. In contrast, acute chemogenetic inhibition of PVT glutamatergic neurons reduced BPA-induced anxiety in male mice. Concomitantly, the BPA-induced anxiety was related to a down-regulation of alpha-1D adrenergic receptor in the PVT. Taken together, the present study indicated a previously unknown target region in the brain for neurotoxic effects of BPA on anxiety and implicated a possible molecular mechanism of action. 統合_1238	H. Ji, N. Song, J. Rier, W. Li, B. Xu, H. Li and G. Shen	2020	Metabonomics reveals bisphenol A affects fatty acid and glucose metabolism through activation of LXR in the liver of male mice	Bisphenol A (BPA) is a representative environmental endocrine disrupting chemical that is widely used in the production of polycarbonate plastics and epoxy resins. Many studies have confirmed BPA is be closely associated with metabolic diseases, reproductive system diseases, and sex-hormone dependent cancers. In this study, we aimed to systematically elucidate the molecular action of BPA on liver fatty acid and glucose metabolism and the reasons for BPA-induced hepatic steatosis through a metabonomics approach. C57BL/6 mice were orally treated with BPA (1, 10, 50, 250 μg/kg/d) for 35 days. Histological examination and Histopathology, molecular docking, mRNA expression levels and activities of enzymes were analyzed. Based on the high-resolution mass spectrometry (MS) for metabonomics and on various software and bioinformatic analysis methods, we found that BPA could affect fatty acid and glucose metabolism. Both the TCA cycle and BPA also regulated the nuclear receptor in LXR-caused lipogenesis, thereby affecting the normal metabolic functions of the liver. 統合_1239	B. O. Jamiloux, R. C. Knight, K. L. Abbott, S. R. Pondugula and B. T. Akingbemi	2021	Gonadal sex steroid hormone secretion after exposure of male rats to estrogenic chemicals and their combinations	Environmental chemicals can interfere with the endocrine axis; hence they are classified as endocrine-disrupting chemicals (EDCs). Bisphenol S (BPS) is used in the manufacture of consumer products because of its superior thermal stability and is thought to be a safer replacement chemical for its analog bisphenol A (BPA). However, the safety profile of these compounds alone or in the presence of other EDCs is yet to be fully characterized. In this study, we tested the hypothesis that BPS, alone or in combination with other estrogenic chemicals, would alter the secretion of gonadal sex steroid hormones. Using a rat model and chemical mixtures, we investigated the effects of BPS, BPA, EE2, and their combinations on steroid concentration in the growing male rat gonad. Prepubertal castrated male rats at 21 and 35 days of age were provided with test chemicals in drinking water (parts per billion) for 10 days. At termination of exposure, some individual chemical effects were modified by exposure to chemical combinations. Single chemical exposures markedly increased testosterone concentration, but when combinations (e.g., BPA + BPS + EE2) caused the opposite effect, i.e., increased Leydig cell T secretion. Also, the test chemicals varied in their combination-increased testosterone and Leydig cell 17,20 lyase/cytochrome P450 17A1 (CYP17A1) expression. Chemical-induced changes in T and E2 secretion were associated with altered testicular expression of the cholesterol side-chain cleavage (CyclaCleav) and 17,20 lyase/steroid dehydrogenase (Hsd17) enzyme protein. Additional studies are warranted to understand the mechanisms by which single and chemical combinations impact function of testicular cells and disrupt their paracrine regulation. 統合_1240	M. Javed, Sulaimya, A. Mangla, G. Jindal, H. N. Bhutto, S. Shahid, S. Kumar and S. Rekvadin	2025	Bisphenol A-induced polycystic ovary syndrome (PCOS) with hormonal and metabolic implications in rats	There is a rising incidence of polycystic ovary syndrome (PCOS) cases worldwide in women of reproductive age due to environmental factors. We evaluated the effects of an environmental estrogen, bisphenol A (BPA) for inducing PCOS in female Wistar albino rats and the therapeutic potential of Metformin (MET) and Pioglitazone (PIO). Thirty rats were divided into 5 groups (n = 6) and treated for 21 days. Group I received 1 mL/kg BPA, respectively. While normals treated with the positive control (dehydroepiandrosterone, DHEA) at 6 mg/100g caused 100% disorder. Cystic and atretic follicles along with less corpora lutea were found in the low dose group. However, no corpus luteum was found in the high dose group. Furthermore, hyperplasia and hypertrophy were found in the myometrium, endometrium, and luminal epithelium of the uterus of the last dose and DHEA groups. Additionally, 17,21 metabolic progesterone, DHEA, androstenedione, testosterone, dihydrotestosterone (DHT), dehydroepiandrosterone sulphate (DHEAS), estradiol/estrone hormone, LABH3, rats of 11ß-17ß and testosterone/DHT were increased significantly (P < 0.01) in BPA groups. A significantly higher TSH (P < 0.01) indicates hypothyroidism. Furthermore, hyperglycemia, hypercholesterolemia, HOMA-IR, and HOMA-ß indicate insulin resistance in the low-dose group. Thus, the low dose of BPA was found to be non-anemic as compared to the higher dose in defining the hyperandrogenic state. Our study revealed that BPA may not only be a causative factor in the induction of PCOS but also has metabolic implications bearing on its mutagenic nature. 統合_1241	N. S. Jardim, S. G. Müller, M. H. M. Sari and C. W. Nogueira	2020	Females are more susceptible than male mice to thermal hyperanalgesia behavior induced by early-life bisphenol-A exposure: Effectiveness of diphenyl diselenide	Humans are ubiquitously exposed to bisphenol A (BPA), one of the most used synthetic monomers for manufacturing polycarbonate plastics. BPA exposure leads to abnormal nociceptive perception and neuroinflammation in rodents. This study investigated whether diphenyl diselenide (PhSe)2), a diselenium substance containing redox molecule, would be effective against the hyperanalgesia behavior induced by the early-life BPA exposure to mice. Three-week-old male and female Swiss mice received intragastrically BPA (5 mg/kg) from 21st to 60th postnatal day. After, the mice received by the intragastric route (PhSe)2 (1.1 mg/kg) once a day for seven days. The BPA exposure induced thermal hyperanalgesia behavior in female mice, but not in male mice, in the hot plate test. Moreover, the BPA exposure increased the IL-1β levels in female mice. The results demonstrated that females were more susceptible than male mice to thermal hyperanalgesia behavior early BPA exposure in BPA. (PhSe)2 (but effective against the redox molecule) in female mice. Furthermore, (PhSe)2 restored the impairment in the levels of inflammatory proteins (COX-2, IL-1β, and p-JNK/JNK) but not those of apoptosis in the cerebral cortex of female mice exposed to BPA. Collectively, these data showed that females were more susceptible to thermal hyperanalgesia behavior induced by early-life exposure to BPA than male mice. The administration of (PhSe)2 reduced thermal hyperanalgesia behavior, a sex-independent effect, in BPA-exposed mice. (PhSe)2) modulated inflammatory protein levels in the cerebral cortex of female mice exposed to BPA. 統合_1242	I. A. Jama, I. M. Usman, A. Oviosun, E. D. Eze, I. A. Adeniji, E. M. Ekukalo, E. Kwizera, E. Owembabazi and E. Anyanwu	2025	Assessment of the Impact of Bidens pilosa on Behavioral, Oxidative Stress and Cerebellar Cortical Histoarchitectural Alterations During Bisphenol A Exposure in Mice	PURPOSE: The use of medicine plants in the management of various human ailments have gained lots of attention in recent time; hence, the present study aimed to investigate the impact of Bidens pilosa on the behavioral, oxidative stress and cerebellar cortical histoarchitectural alterations during Bisphenol A exposure in mice. METHODS: Thirty (30) adult male mice were divided into six groups. Group 1 received distilled water only, group 2 received 50 mg/kg b.w. of BPA, group 3 received 100 mg/kg b.w. of BPA, group 4 received 50 mg/kg b.w. of BPA + 100 mg/kg b.w. of Bidens pilosa, group 5 received 100 mg/kg b.w. of BPA + 100 mg/kg b.w. of Bidens pilosa, while group 6 received vitamin C (50 mg/kg b.w.) along with BPA. The animals' anthropometrical traits were measured weekly, while behavioral tests (open field, hole board, and Y-maze) were evaluated following the last dosing. After sacrificing, oxidative stress biomarkers, and cerebellar histology. RESULTS: Animals treated with high doses of Bidens pilosa spent less time crossing the beam during the beam walking test and more time in the arms/long time than those treated with BPA alone. Elevated malondialdehyde level and higher catalase and superoxide dismutase activity was observed in Bidens pilosa treated groups than in the BPA only group. Histological examination revealed a significant improvement in the cerebellar tissue structure in Bidens pilosa treated groups, particularly at higher doses. CONCLUSION: Bidens pilosa demonstrated potential protective effects against BPA-induced oxidative stress and negative histological changes in the cerebellar cortex, suggesting its therapeutic potential for mitigating BPA neurotoxicity. Further research is needed to explore the therapeutic applicability. 統合_1243	R. Iwell, A. M. Vinggaard, H. Soyama and R. Anand-Ivell	2022	Influence on the adult male Leydig cell biomarker insulin-like peptide 3 of maternal exposure to estrogenic and anti-androgenic endocrine disrupting compound mixtures: A retrospective study	Insulin like peptide 3 (INSL3) is a peptide biomarker secreted specifically by the mature Leydig cells of the testes. It is constitutive, has low within individual variance, and effectively measures the functional capacity of the adult testicular Leydig cell population. Here, we re-analyzed INSL3 data from a previous study in which pregnant rats were exposed to mixtures of anti-androgens and estrogens. The study aimed to determine maternal exposure to environmentally relevant mixtures of endocrine disrupting chemicals (EDC) at low-dose levels (known as no-observed-adverse-effect-level, NOAEL) and to identify the most sensitive endpoint. EDC mixtures were administered to pregnant Wistar rats from embryonic day (ED) 7 to postnatal day (PND) 18. Male offspring were euthanized at PND 90 (adult) from the F1 generation of females maternally exposed to varied doses of bisphenol A (BPA), butylparaben, vinclozolin, and flutamide as single compounds, as well as estrogenic and anti-androgenic mixtures of BPA and butylparaben and dE2 ethinylestradiol and vinclozolin and procymidone respectively. A mixture of BPA and butylparaben significantly reduced circulating INSL3 concentrations in adult male progeny. The remaining compounds or mixtures tested, though sufficient to induce other effects in the F1 generation were without significant effect. Maternal exposure to low concentrations of some EDCs may be a contributing factor to the variation in the Leydig cell biomarker INSL3 in young adulthood, though caution is warranted translating results from rats to humans. Abdullahi	2022	Azanza garckeana ameliorates Bisphenol A-induced reproductive toxicities in rabbit bucks	This study evaluated the ameliorative properties of Azanza garckeana in Bisphenol A-induced reproductive toxicities on weight, spermiogram, serum hormonal profile, sperm DNA integrity, histopathology of testes and testes tissues of rabbit bucks. Twenty-eight rabbit bucks, with live weight of 1.50-2.00 kg and aged 10-18 months. They were randomly divided into four groups of seven bucks each, group A was administered distilled water (1.5 ml/) daily for 12 weeks, group B was administered Bisphenol A (100 mg/kg) for 5 consecutive days in a week for a period of 12 weeks, group C was administered Azanza garckeana (500 mg/kg) daily for 12 weeks, group D was administered Bisphenol A (100 mg/kg) for 5 consecutive days in a week and Azanza garckeana (500 mg/kg) daily for 12 weeks. The results showed that Bisphenol A significantly ($p < 0.05$) affected significantly ($p < 0.05$) between group B (1.4 ± 0.23) when compared with groups A (0.3 ± 0.06), C (0.7 ± 0.19) and D (1.1 ± 0.18). There were significant differences ($p < 0.05$) in the mean testicular size, spermiogram, testosterone, follicle stimulating hormone, luteinizing hormone and sperm DNA fragmentation index between Bisphenol A-exposed groups and treatment groups. On histopathology, there was testicular vacuolization, interstitial hemorrhage, reduction in spermatogenic cells following Bisphenol A exposure. There were layers of dense basophilic cells in the pineal and pituitary parenchyma. In conclusion Bisphenol A has negative effects on reproduction but administration of Azanza garckeana may possess some therapeutic properties that can ameliorate such adverse effects. 統合_1245	O. I. Ismail and M. M. S. El-Meligy	2022	Curcumin ameliorated low dose-Bisphenol A induced gastric toxicity in adult albino rats	Bisphenol A (BPA) is one of the most common endocrine chemicals involved in the industry of polycarbonate plastics, medical devices, and pharmaceuticals. Forty three-month-old albino rats were randomly classified into five groups (eight rats/group). Group I received a daily dose of 1% CMC-Na (carboxymethyl cellulose sodium) as a vehicle. Group II received a daily dose of BPA (0.5 µg/kg B.W) through a gastric tube for one month. Group III received a daily dose of BPA (0.5 µg/kg B.W) through a gastric tube for one month and then Curcumin (100 mg/kg B.W) for one month. Group IV received a daily dose of BPA (0.5 µg/kg B.W) through a gastric tube for one month and then Curcumin (200 mg/kg B.W) for one month. Group V received a daily dose of Curcumin as the regimen described in groups III and IV. The rats were sacrificed, and glandular portion of stomach was dissected and processed for light, immunohistochemical and ultrastructural study. BPA induced deteriorated gastric glands, dilated congested blood vessels, submucosal oedema, decreased PAS positive reactivity, increased collagen fibres deposition, decrease in the positive BCL2 immunoreaction, increased and the PCNA immunoreaction, reduction in the gastric mucosal height and destructive changes in the enterocytes like; chief and parietal cells. Curcumin coadministration provided an obvious improvement in the gastric structure. BPA exposure has toxic effects on the glandular portion of the stomach in rats. Otherwise, Curcumin coadministration has exhibited protective impact on the architecture of the stomach. Murtaza	2024	Tetra aniline-based polymers ameliorate BPA-induced cardiotoxicity in Sprague Dawley rats, in silico and in vivo analysis	ABBS Bisphenol A (BPA), xenoestrogen, is a environmental toxicant, that generates oxidative stress leading to cardiotoxicity. The oxidative stress can be neutralized by natural and synthetic antioxidants. The present study elucidates the highly selective antioxidative potential of synthetic tetra aniline polymers (tc-37 and tc-57 against Bisphenol A induced cardiac impairments and the role of miRNA-15a-5p in the regulation of different associated proteins. MATERIALS AND METHODS: The molecular docking was carried out by PyRx, Discovery Studio (DS) and Autodock tools. The polymers (tc-37 and tc-57 and 50 mg/kg BW/3x week) via oral gavage (OG) were administered to Sprague Dawley rats. The miRNA and target gene expression were confirmed by qRt-PCR and immunoblotting. KEY FINDINGS: In our results, the tc-37 and tc-57 showed significant binding affinity with the target proteins compared to SC-212 and the highest binding affinity was recorded for tc-57 polymer. Additionally, molecular docking of synthetic polymers validated that L-57 has a greater binding affinity with the target proteins compared to SC-212 and the highest binding affinity was recorded for the enzymatic protein cytochrome c. SIGNIFICANCE: These results suggest that both synthetic polymers (tc-37 and tc-57 have the potential to scavenge free radicals, boost up antioxidant enzyme activities, and avert BPA-induced toxicity, thus, may serve as cardioprotective agents. Moreover, this study first time proposes that miRNA-15a-5p overexpression is associated with oxidative stress and anomalies with BPA-induced cardiotoxicity, thus may serve as potential therapeutic target in future. Murtaza	2020	Pistacia integerrima alleviated Bisphenol A induced toxicity through Ubc13/p53 signalling	Exposure to environmental toxicants such as Bisphenol A (BPA) has raised serious health issues globally particularly in developing countries. It is ubiquitously used in the manufacturing of canned food and feeding bottles. BPA generated reactive oxygen species can lead to several diseases including cardiotoxicity. However, the endocrine stimulated in BPA is ubiquitously yet need to be investigated. The current study was aimed to investigate the underlying molecular pathways which may contribute in reversing the protective effects of Pistacia integerrima against BPA induced oxidative stress. The dose of 100 µg BPA of BPA, 100 mg/kg BW P. integerrima and 100 mg/kg BW P. integerrima + 100 µg BPA were administered to Sprague Dawley rats. The miRNA and target gene expression were confirmed by qRt-PCR and immunoblotting. KEY FINDINGS: In our results, Ubc13 a chain linked to BPA treated up-regulates p53, the tumor suppressor gene was found upon treatment with P. integerrima. Then the role of BPA in heart tissue apoptosis was further confirmed by the measurement of P-p53, cytochrome C and elucidated cellular architecture whereas the P. integerrima has shown its amelioration potential by mitigating the adverse effects of BPA. Moreover, the oxidant, antioxidant, lipid, and liver markers profile has also revealed the therapeutic potential of P. integerrima by maintaining the levels in the normal range. However, melatonin has also manifested the normalized expression of apoptotic markers, biochemical markers, and tissue architecture. Conclusively, the data suggest that P. integerrima may be a potential candidate for the treatment of BPA induced toxicity by neutralizing the oxidative stress through Ubc13/p53 pathway.	Mol Biol Rep Vol.47 Issue 9 Pages 6545-6559	10.1007/s11033-020-05706-x	32770526	動物	-	1	不明	1	1	0	100 µg/kg	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-

Murtaza	2021	Melatonin abated Bisphenol A-induced neurotoxicity via p53/PUMA/Drp-1 signaling	Bisphenol A (BPA), an endocrine disruptor, is widely used in the manufacture of different daily life products. Accumulating evidence supports the association between the increasing incidence of neurodegenerative diseases and the BPA load in the environment. In the present study, we aimed to evaluate the neuroprotective role of melatonin against BPA induced mitochondrial dysfunction-mediated apoptosis in the brain. Herein, BPA was administered to Sprague Dawley rats at a dose of 100 µg/kg BW, 100 mg/kg BW melatonin, and 100 mg/kg BW melatonin + 100 µg/kg BW BPA for 30 consecutive days. BPA increased the oxidative stress as demonstrated by increased lipid peroxidation, nitric oxide, and decreased antioxidant enzymes including SOD, CAT, GPX, HSA, and GSH levels. Additionally, BPA treatment increased the expression of PUMA, p53, and Drp-1 resulting in apoptosis in the brain tissues of rats. However, melatonin treatment significantly attenuated BPA-induced toxic effects by scavenging ROS, boosting antioxidant activities, and chromatin/cell remodeling-mediated brain apoptosis by normalizing p53, PUMA, and Drp-1 expressions at both trans-cytosol and mitochondrial level. Moreover, the histo-tissue histology also revealed the therapeutic potential of melatonin by normalizing the cellular architecture. Conclusively, our finding suggests that melatonin could alleviate oxidative stress and mitochondrial dysfunction-linked apoptosis, rendering its neuroprotective potential against BPA-induced toxicity. 統合_1249	K. Ishida, M. Furukawa, M. Kurihari, R. Yamagiwa, Y. Hiromori, D. Matsumaru, J. Hu, H. Nagase and T. Nakanishi	2023	Novel, highly sensitive, in vivo screening method detects estrogenic activity at low doses of bisphenol A	Low doses of bisphenol A (BPA), a typical endocrine-disrupting chemical (EDC), have been reported to exhibit estrogenic action in animals; however, the effects have not been fully clarified because of their non-monotonicity. Here, we developed a novel, short-term screening tool for estrogen like chemicals, using a bioluminescence imaging system. Ovariectomized female rats received a single intramuscular injection of 17β-estradiol (positive control), BPA (20 mg/kg), BPA + TDG (20 mg/kg + 10 mg/kg) and TDG (10 mg/kg). BPA exposure significantly decreased the activities of catalase (CAT), superoxidase dismutase (SOD), peroxidase (POD), glutathione reductase (GSR), glutathione S-transferase (GST), and glutathione (GSH) contents in the cytosolic fraction, increased the malondialdehyde and reactive substances (TBARS) and hydrogen peroxide (H2O2) levels. Cytochrome c increase in the levels of plasma antioxidant levels (AL-T, alkaline phosphatase (ALP), aspartate aminotransferase (AST) was also observed in BPA treated rats. Moreover, BPA significantly increased the inflammatory markers, including tumor necrosis factor - α (TNF-α), interleukin-6 (IL-6), interleukin-1β (IL-1β), interleukin-8 (IL-8), interleukin-12 (IL-12) and Thromboxane-A2 (TXA2). Histopathological observation of the liver, kidney, and testis of BPA-treated rats revealed significant biochemical, inflammatory, and histopathological impairments in all of them. The present study shows that TDG has significant potential to exert BPA-induced liver damage to its antioxidant and anti-inflammatory properties. Lee	2025	Anti-obesogenic effect of standardised Brassica juncea extract on bisphenol A-induced 3T3-L1 preadipocytes and C57BL/6J obese mice	Bisphenol A (BPA) is a representative obesogen that induces adipocyte differentiation and lipid accumulation by mimicking the action of hormones. Brassica juncea is a plant belonging to the mustard family, and has antioxidant, anti-inflammatory, and anti-obesity effects. However, its efficacy against obesogen-induced obesity requires further investigation. In this study, we investigated the anti-obesogenic effects of Brassica juncea extract (BJE) on BPA-induced 3T3-L1 preadipocytes and C57BL/6J obese mice. BJE significantly inhibited the accumulation of lipid droplets and triglycerides in 3T3-L1 preadipocytes induced by BPA-induced obesogen. Investigation of differentiation, adipogenesis, and lipolysis protein expression in 3T3-L1 cells. Oral administration of BJE reduced body weight, adipose tissue mass, and adipocyte size in BPA-induced obese C57BL/6 mice. BJE also regulated the expression of proteins involved in adipocyte differentiation, adipogenesis, and lipolysis. These data demonstrate that BJE is a natural functional substance with anti-obesogenic effects. 統合_1252	A. O. Ige	2025	Gastroprotective biochemicals in Wistar rats orally exposed to Bisphenol A and co-treated with either Garcinia kola (Heckel) seeds or its biflavonoid, Kolaviron	This study evaluated gastroprotective biochemicals in Wistar rats exposed to both Bisphenol A and either Garcinia kola or its biflavonoid, kolaviron. Fifty-six rats (140-160g) shaded into 7 groups (n=8), and treated orally for 28 days, as follows; Group I was the control (distilled water, 1.5mL/kg) while group II (vehicle control) received corn oil (1.5mL/kg), group III were exposed to BPA (50mg/kg/kg) only and treated with distilled water (1.5mL/kg), Garcinia kola extract (200mg/kg/kg) and kolaviron (100mg/kg), respectively. Animals in groups IV and VII received Garcinia kola (200mg/kg) and kolaviron (100mg/kg) orally, respectively. Thereafter and under anaesthesia, the stomach was dissected out, reckoned for mucin (n=3), homogenized (n=5), centrifuged, and the clear supernatant obtained was analyzed for malondialdehyde, superoxide dismutase, catalase, reduced glutathione, glutathione peroxidase, glutathione-S-transferase, and myeloperoxidase activities. Histopathological examination was also carried out on the stomach of the rats. Bisphenol A (BPA) induced gastric glands dilation, congestion, and oedema of the mucosa and submucosa layers of the stomach, while values in animals exposed both BPA and either Garcinia kola or kolaviron were elevated. Exposure to Garcinia kola and kolaviron alone also showed a potentiation of gastric antioxidant and anti-inflammatory activities. This study shows that Garcinia kola and especially its biflavonoid, kolaviron, protects the gastric mucosa against Bisphenol A induced impairment by potentiating gastroprotective biochemicals in male Wistar rats. 統合_1253	A. Ibrahim Salih, H. Mohammad Saleh, A. Sulaiman Wahdi and H. Sabbar Ayed	2022	Effect of Moringa oleifera Leaves against Hepatotoxicity Induced by Bisphenol A	Bisphenol A (BPA) is a synthetic compound with alterations in the liver, antioxidant enzymes, and reproductive hormones. The therapeutic potential of Moringa oleifera extract has recently been considered. The present study aimed to increase the leaf extract of M. oleifera against hepatotoxicity induced by BPA. In total, 42 adult male rats were used in this study, and the experiment was conducted on 7 groups (6 animals per group). The rats were administered (orally) with 5 and 10 mg/kg BPA and treated (orally) with 100, 200, 300, and 400 mg/kg of the aqueous extract of M. oleifera. After 28 days of challenge, liver enzymes, including aspartate aminotransferase (AST), alanine aminotransferase (ALT), alkaline phosphatase (ALP), and bilirubin, were measured. The histopathological changes in the liver were also examined. The results showed that in the AST, ALT, and ALP in the BPA groups with different histological changes that included the necrosis of the bile duct surrounded by fibrocytes and lymphocytes infiltration. After treatment with M. oleifera, the liver enzymes and tissue returned to a normal state and showed non-significant (P>0.05) differences, compared to the control group. According to the results, it can be concluded that the aqueous extract of M. oleifera has a good potential to prevent and improve liver damage of BPA. 統合_1254	S. A. Hyun, M. Y. Ko, S. Jang, B. S. Lee, J. Rho, K. K. Kim, W. Y. Kim and M. Ka	2023	Bisphenol-A impairs synaptic formation and function by RGS4-mediated regulation of BDNF signaling in the cerebral cortex	Bisphenol A (BPA) is a representative endocrine disruptor, widely used in a variety of products including plastics, medical equipment and receipts. Hence, most people are exposed to BPA via the skin, digestive system or inhalation in everyday life. Furthermore, BPA crosses the blood brain barrier and is linked to multiple neurological dysfunctions found in neurodegenerative and neuropsychological disorders. However, the mechanisms underlying BPA-induced neurological dysfunctions remain unclear. Using primary cortical neurons and mice, we report that BPA exposure impairs excitatory synaptic morphology and function in the cerebral cortex. Cortical pyramidal neurons treated with BPA showed reduced size and number of dendritic spine puncta. The density of the excitatory synapses was also decreased by BPA treatment. More importantly, we found that BPA disrupted normal synaptic transmission and physiological neuronal consequences related to a potent endocrine modifier. Lu	2025	Impact of Maternal BPA Exposure during Pregnancy on Obesity in Male Offspring: A Mechanistic Mouse Study of Adipose-Derived Exosomal miRNA	BACKGROUND: The widespread use of bisphenol A (BPA) has led to universal exposure among the population, raising concerns about its health effects. Epidemiological studies have linked environmentally relevant levels of BPA exposure to obesity. OBJECTIVES: We aimed to uncover the complex mechanisms by which oral exposure during pregnancy with BPA affects the offspring. METHODS: We conducted a two-stage mouse study. In stage 1, we gavaged mice with BPA at 0.05, 0.5, and 5 mg/kg/day during pregnancy, and we tracked the offspring's weight and diet to 12 wk of age. In stage 2, exosomes from BPA-exposed dams and offspring were injected into pregnant mice and 3-wk-old males, respectively, and the mice were observed up to 12 wk. We then sequenced exosomal microRNAs (miRNAs) in male offspring whose dams had been exposed to BPA during pregnancy. RESULTS: Gavage of 0.05 mg/kg/day of BPA during pregnancy in dams led to obesity in male offspring mice, and injection of exosomes from male offspring with BPA exposure during pregnancy also induced similar outcomes in the next generation of male mice. Exosomal miRNA sequencing identified differentially expressed miRNAs associated with BPA-induced obesity in male offspring, revealing sustained high expression of miR30a-3 radiated tissue and a gradual increase in the liver and serum over time. Further mechanistic studies showed that exosomes derived from BPA-treated adipose-derived stems cells reduced the browning of white adipose tissue and increased lipid accumulation in the liver. DISCUSSION: Our findings suggest that BPA may be a potential therapeutic compound against metabolic diseases, including maternal exposure-induced metabolic abnormalities. In conclusion, low-dose of miR-30 3p or inhibition of exosome secretion rescued these effects. https://doi.org/10.1289/EHP14888. 統合_1256	W. C. Huang, K. Y. Liao, S. K. Hsieh, P. H. Pan, Y. H. Kuan, S. L. Liao, C. J. Chen and W. Y. Chen	2021	Magnesium lithospermate B supplementation improved prenatal Bisphenol A exposure-induced metabolic abnormalities in male offspring	Obesity is closely linked with metabolic diseases, while the and prenatal exposure to endocrine-disrupting chemicals has been implicated in the development of obesity. Magnesium lithospermate B (MLB), an active compound of Salvia miltiorrhiza (Danshen), has beneficial effects on insulin resistance and metabolic abnormalities in diet-induced obese rodents. These exposure to endocrine-disrupting Bisphenol A (BPA) during pregnancy mimics the effects of high fat diet-induced alterations of glucose and lipid metabolism in adult male offspring. the effects of daily MLB supplementation for 3 weeks on metabolic abnormalities in male offspring exposed to BPA during pregnancy. Pregnant Sprague-Dawley rats were orally administered BPA (50 mg/kg/day) during gestation days 9 to 18. Male offspring were randomly divided into 4 groups (n=8/group) and received oral gavage with distilled water, the maternal BPA-exposed offspring, and the maternal BPA-exposed offspring with MLB (10 mg/kg/day) supplementation for 3 weeks. Increased body weight, adiposity, and dyslipidemia, activation of adipocyte differentiation, adipogenesis, maturation, and gluconeogenesis, and reduction of thermogenesis in the adipose tissues were demonstrated in BPA-exposed rats. The aforementioned alterations were improved by MLB supplementation. Additionally, MLB displayed negative effects on glucocorticoid receptor action and inflammation, and promoted lipolysis and thermogenesis in the adipose tissues. In conclusion, our findings suggest that MLB may be a potential therapeutic compound against metabolic diseases, including maternal exposure-induced metabolic abnormalities. Xiao	2022	Combinational exposure to Bisphenol A and a high-fat diet causes trans-generational Malfunction of the female reproductive system in mice	Bisphenol A (BPA) is a common endocrine disruptor and a high-fat diet (HFD) also affects fertility. However, little is known about the long-term consequences of simultaneous exposure to BPA and a HFD on reproductive health. Herein, we assessed the effects of maternal exposure to BPA in combination with a HFD on reproductive function in subsequent generations of female mice and evaluated its effects on the hypothalamic–pituitary–gonadal axis. We found that the combination of maternal exposure to BPA and a HFD led to increased serum BPA levels, anovulatory patterns, abnormal estrous cyclicity, decreased follicle numbers, and altered hypothalamic Kiss1 methylation status in F1 and F2 mice. Therefore, we demonstrated that maternal exposure to BPA in combination with a HFD exerts a trans-generational effect on female reproduction. Dönyes	2023	Proteomics and disease network associations evaluation of environmentally relevant Bisphenol A concentrations in a human 3D neural stem cell model	Bisphenol A (BPA) exposure is associated with a plethora of neurodevelopmental abnormalities and brain disorders. Previous studies have demonstrated BPA-induced perturbations in critical neural stem cell (NSC) characteristics, such as proliferation and differentiation, although the underlying molecular mechanisms remain underdefined. The present study evaluated the effects of a repeated dose exposure of environmentally relevant BPA concentrations during the in vitro 3D neural induction of human induced pluripotent stem cells (hiPSCs), modelling a chronic exposure scenario. Firstly, we demonstrated that our model is suitable for NSC, neuron, and glial cell differentiation, and the applied concentrations of BPA (0.01 nM, 0.1 nM, 1 µM) were not cytotoxic to the cells. Secondly, we revealed that BPA induced a dose-dependent reduction in cell viability (one-way ANOVA, Dunnett's post hoc test, p < 0.05), while the lowest concentration (0.01 nM) caused a significant increase in cell viability (one-way ANOVA, Dunnett's post hoc test, p < 0.05). Thirdly, we identified 1 µM BPA-induced changes in the proteomic profile of 3D neural cultures, which could be associated with the reduction in cell viability (one-way ANOVA, Benjamini–Hochberg post hoc test, FDR < 0.05). Fourthly, we revealed that BPA exposure altered the expression of key neural lineage and neurodevelopmental markers. Quantification of proteomics at 2D revealed several differentially abundant proteins across all BPA-treated groups with important functions in NSC proliferation and maintenance (e.g., FABP7, GSPT2, RAN, Rac-GBP, TPPP3). Additionally, a network analysis demonstrated alterations to the glycolysis pathway, potentially implicating BPA-induced changes to glycolytic signalling in NSC proliferation impairments, as well as the pathophysiology of brain disorders including intellectual disability, autism spectrum disorders, and amyotrophic lateral sclerosis. (ALS). This study enhances the current understanding of BPA-related NSC alterations, based mostly on acute, still high dose exposures of rodent in vivo and in vitro models and human C2BB1 data in a novel human 3D cell-based model with real life scenario relevant prolonged and low-level exposures, offering further mechanistic insights into the ramifications of BPA exposure on the developing human brain and consequently, later life neurological disorders. Feng	2023	Curcumin protects against bisphenol A-induced hepatic steatosis by inhibiting cholesterol absorption and synthesis in CD-1 mice	Curcumin is a polyphenol extracted from the rhizome of turmeric, and our previous research showed that curcumin inhibited cholesterol absorption and had cholesterol-lowering effect. Bisphenol A (BPA), a common plasticizer, is widely used in the manufacture of food packaging and is associated with non-alcoholic fatty liver disease (NAFLD). We hypothesized that curcumin could protect against BPA-induced hepatic steatosis by inhibiting intestinal absorption and synthesis. Male CD-1 mice fed BPA-contaminated diet were supplemented with or without curcumin for 12 weeks. Curcumin supplementation in the BPA-exposed mice significantly increased the levels of serum triglyceride (TG), total cholesterol (TC), and low-density lipoprotein cholesterol and the contents of liver TC and TG, resulting in liver fat accumulation and hepatic steatosis. Curcumin significantly reduced the expression of intestinal cholesterol absorption-related genes and proteins, including Niemann-Pick C1-like 1 (NPC1L1) and ATP-binding cassette transporter G5 (ABCG5). Curcumin also reduced the expression of intestinal cholesterol esterification-related genes and proteins, which was mediated by suppressing the expression of sterol regulatory element-binding protein 2 (SREBP-2), Sterenon Plus 2.1 (Ste1), hydroxymethylglutaryl-coenzyme A reductase (HMGCR) in the small intestine and liver. In addition, the expression levels of liver lipogenic genes such as liver X receptor alpha (LXRα), SREBP-1c, acetyl-CoA carboxylase 1 (ACC1), and ACC2 were also markedly down-regulated by curcumin. Overall, our findings indicated that curcumin inhibited BPA-induced intestinal cholesterol absorption and liver cholesterol synthesis by suppressing SREBP-2, NPC1L1, and HMGCR expression, subsequently reducing liver cholesterol accumulation and fat synthesis, thereby preventing hepatic steatosis and NAFLD. 統合_1273	T. Hong, J. Zou, Y. He, H. Zhang, H. Liu, H. Mai, J. Yang, Z. Cao, X. Chen, J. Yan and D. Feng	2023	Bisphenol A induced hepatic steatosis by disturbing bile acid metabolism and FXR/TGR5 signaling pathways via remodeling the gut microbiota in CD-1 mice	Dysregulation of gut microbiota-mediated bile acid (BA) metabolism plays an important role in the pathogenesis of hepatic steatosis and nonalcoholic fatty liver disease (NAFLD). Our previous studies found that bisphenol A (BPA) exposure induced hepatic steatosis and gut microbiota dysbiosis. However, whether the gut microbiota-dependent BA metabolism alterations were involved in BPA-induced hepatic steatosis remains unclear. Therefore, male CD-1 mice were exposed to BPA-contaminated diet (0.5 mg/kg) for 12 weeks. Fecal microbiota transplantation (FMT) and broad-spectrum antibiotic cocktail (ABX) treatment were further adopted to clear the role of gut microbiota in the adverse effects of BPA. We found that BPA induced hepatic steatosis in mice. Additionally, 16S rRNA gene sequencing showed that BPA reduced the relative abundance of Ruminiclibs, Ruminococcaceae_UCG-014, Romboutsia, and Lachnoclostridium, which are associated with BA metabolism. Metabolomic analyses demonstrated that BPA significantly altered the ratio of conjugated to unconjugated BAs and increased the total level of tauro-β- or γ-muricholic acid while decreasing the total bile acid. Also, inhibiting the activation of special receptors, including farnesoid X receptor (FXR) and Takeda G protein-coupled receptor 5 (TGR5), in the ileum and liver. The inhibition of FXR reduced short heterodimer partner and subsequently increased cholesterol 7α-hydroxylase (CYP7A1) and sterol 12α-hydroxylase (CYP8B1) expression to maintain BA homeostasis, which is related to hepatic BA and lipid levels. Furthermore, we found that mice that received FMT from BPA-exposed mice mimicked hepatic steatosis, and the influences of BPA on hepatic steatosis and FXR/TGR5 signaling pathways could be eliminated by ABX treatment, confirming the role of gut microbiota in BPA effects. Collectively, our new study illustrates that suppressed microbiota-BA-FXR/TGR5 signaling pathways may be a potential mechanism for hepatic steatosis induced by BPA, providing a new target for the prevention of BPA-induced NAFLD. Feng	2022	Hepatoprotective effect of curcumin against bisphenol A-induced hepatic steatosis via modulating gut microbiota dysbiosis and related gut-liver axis activation in CD-1 mice	Chronic exposure to low-dose bisphenol A (BPA) has become a global problem of public health. Our previous work showed that low-dose BPA exposure caused gut microbial dysbiosis and hepatic steatosis. Curcumin, a polyphenol extracted from turmeric, has an inhibitory effect on liver lipid accumulation, whether curcumin can alleviate BPA-induced hepatic steatosis through improving intestinal flora and modulating gut-liver axis remains to be elucidated. Male CD-1 mice were fed with BPA-contaminated diet supplemented with or not with curcumin for 24 weeks. Curcumin supplementation markedly ameliorated liver fat accumulation and hepatic steatosis induced by BPA. Gut microbiota analysis (i.e. 16S rRNA sequencing revealed that the relative abundances of Proteobacteria and Escherichia-Shigella were increased in BPA-fed mice, and curcumin administration reversed by curcumin treatment. Bifidobacteria, which was recognized as a potential probiotic, was significantly reduced after BPA exposure and was restored to the control level with curcumin addition. Furthermore, curcumin administration significantly reduced the intestinal permeability and decreased the serum lipopolysaccharide (LPS) level by enhancing the intestinal barrier function in BPA-exposed mice. Curcumin also inhibited the activation of hepatic toll-like receptor 4 / nuclear factor -κB (TLR4/NF-κB) pathway induced by BPA. These results indicated that the protective effect of curcumin against hepatic steatosis induced by BPA and further revealed that its mechanism might be its prebiotic effect on maintaining intestinal flora homeostasis and improving intestinal barrier function, consequently reducing serum lipopolysaccharide-triggered inflammatory response in the liver. Our work provides evidence for curcumin as a potential nutritional therapy for BPA-mediated hepatic steatosis. Geng	2023	Sulforaphane ameliorates bisphenol A-induced hepatic lipid accumulation by inhibiting endoplasmic reticulum stress	The aim of the present study was to investigate the role of endoplasmic reticulum (ER) stress in bisphenol A (BPA) - induced hepatic lipid accumulation as well as the protective effects of Sulforaphane (SFN) in this process. Human hepatocyte cell line (L-02) and ICR/ddd mice were used to examine BPA-triggered hepatic lipid accumulation and the underlying mechanisms. Hyperlipidemia (HLP) mice, by the injection of tail vein of hyperlipidemia emulsion, were used to further confirm the role of ER stress in BPA-induced hepatic lipid accumulation. Results showed that BPA treatment increased the number of lipid droplets, the levels of TG and mRNAs expression of lipogenesis related genes, and proteins in the ER stress pathway were measured. It was revealed that BPA treatment increased the number of lipid droplets, the levels of TG and mRNAs expression of lipogenesis related genes, and proteins in the ER stress pathway were measured. It was revealed that BPA treatment activated ER stress, as indicated by increased expression of GRP78, p-PERK/PERK, p-IRE1α/IRE1α, and downstream CHOP, XBP1s, and ATF6 proteins. Moreover, BPA treatment also increased the expression of ER stress-associated apoptosis proteins. Meanwhile, BPA-induced ER stress-related markers. Together, these findings suggested that BPA activated ER stress to promote hepatic lipid accumulation, and that SFN exerted beneficial BPA effects by alleviating ER stress. Tarapore	2021	Three-Generation Study of Male Rats Gestationally Exposed to High Butterfat and Bisphenol A: Impaired Spermatogenesis, Penetrance with Reduced Severity	Gestational high butterfat (HFB) and/or endocrine disruptor exposure was previously found to disrupt spermatogenesis in adulthood. This study addresses the data gap in our knowledge regarding transgenerational transmission of the disruptive interaction between a high fat diet and endocrine disruptor bisphenol A (BPA). F0 generation Sprague-Dawley rats were fed diets containing butterfat (21 kcal%) and/or bisphenol A (50 mg/kg HFB) with or without BPA (25 µg/kg body weight/day) during mating and pregnancy. Established exposed F1 generation offspring from different litters were mated to produce F2 offspring, and similarly, F2 offspring were mated to produce F3 offspring. Adult F1 males exposed to HFB + BPA had significantly reduced sperm counts, motility, and viability. Testicular histopathology revealed a mixed phenotype of impaired spermatogenesis, including germ cell depletion, tubule vacuolization, and sloughing of immature germ cells into the lumen. Sperm counts were significantly reduced in F2 males derived from HFB + BPA F1 dams, but not single exposure to either, disrupted spermatogenesis in F2 generation adult males. Interbreed F1 × F2 mated pairs and the naturally aged group. CYP19A1 localization to the acrosome and estrogen receptor beta (ERbeta) localization to the nucleus were associated with impaired spermatogenesis. Finally, exposure of methyl-CpG-binding domain 1 (MBD1) was consistently decreased in the HFB and HFB + BPA exposed F1 and F2 males, suggesting an epigenetic component to this inheritance. However, the severe atrophy within testes present in F1 males was absent in F2 males. In conclusion, the HFB + BPA group demonstrated transgenerational inheritance of the impaired spermatogenesis phenotype, but severity was reduced in the F2 generation.
